YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Table of Contents

	About the Documentation	cxlv
	Documentation and Release Notes	cxlv
	Using the Examples in This Manual	cxlv
	Merging a Full Example	cxlvi
	Merging a Snippet	cxlvi
	Documentation Conventions	cxlvii
	Documentation Feedback	cxlix
	Requesting Technical Support	cxlix
	Self-Help Online Tools and Resources	cxlix
	Opening a Case with JTAC	cl
Guide 1	Application Layer Gateways Feature Guide for Security Devices	
Part 1	Overview	
Chapter 1	Introduction to ALGs	3
	ALG Overview	3
	Understanding Custom ALG Services	4
	Understanding IPv6 ALG Support for ICMP	5
	ICMP Error Messages	6
	ICMP ALG Functionality	6
Part 2	Configuring Data ALGs	
Chapter 2	Data ALG Types	11
	Understanding Data ALG Types	11
Chapter 3	Configuring the DNS ALG	13
	DNS ALG Overview	13
	Understanding the IPv6 DNS ALG for Routing, NAT, and NAT-PT	14
	IPv6 DNS ALG Traffic in NAT mode	14
	IPv6 DNS ALG Traffic in NAT-PT mode	15
	Example: Configuring the DNS ALG	16
	Understanding DNS and DDNS Doctoring	19
	Disabling DNS and DDNS Doctoring	23
Chapter 4	Configuring the FTP ALG	25
	FTP ALG Overview	25
	Understanding FTP Commands	26
	PORT Command	26
	PASV Command	26

	Extended FTP Commands	26
	EPRT Command	26
	EPSV mode	27
	Example: Configuring the FTP ALG	28
	Understanding the IPv6 FTP ALG for Routing	31
	FTP ALG Support for IPv6	31
	EPRT mode	31
	EPSV mode	32
Chapter 5	Configuring the IKE and ESP ALG	33
	Understanding the ALG for IKE and ESP	33
	Understanding IKE and ESP ALG Operation	34
	Example: Configuring the IKE and ESP ALG	35
	Example: Enabling the IKE and ESP ALG and Setting Timeouts	41
Chapter 6	Configuring the PPTP ALG	45
	Understanding the PPTP ALG	45
	Understanding IPv6 Support for the PPTP ALG	45
	Example: Configuring the PPTP ALG	46
Chapter 7	Configuring the RPC ALG	61
	Understanding RPC ALGs	61
	Understanding Sun RPC ALGs	62
	Enabling Sun RPC ALGs (CLI Procedure)	63
	Enabling Sun RPC ALGs (J-Web Procedure)	63
	Customizing Sun RPC Applications (CLI Procedure)	64
	Understanding Sun RPC Services	64
	Understanding Microsoft RPC ALGs	67
	Configuring the Microsoft RPC ALG	68
	Configuring the MS-RPC ALG with a Predefined Microsoft Application	68
	Configuring the MS-RPC ALG with a Wildcard UUID	69
	Configuring the MS-RPC ALG with a Specific UUID	69
	Enabling Microsoft RPC ALGs (CLI Procedure)	70
	Enabling Microsoft RPC ALGs (J-Web Procedure)	70
	Verifying the Microsoft RPC ALG Tables	71
	Understanding Microsoft RPC Services	71
	Customizing Microsoft RPC Applications (CLI Procedure)	73
Chapter 8	Configuring the RSH ALG	75
	Understanding the RSH ALG	75
	Example: Configuring the RSH ALG	75
Chapter 9	Configuring the RTSP ALG	89
	Understanding the RTSP ALG	89
	Overview	89
	RTSP Modes	90
	Standard Mode	90
	Interleave Mode	90
	Understanding IPv6 Support for RTSP ALG	91

	Understanding RTSP ALG Messages	91
	RTSP Messages Format	91
	RTSP Methods	92
	RTSP Status Code	92
	RTSP Header	93
	Understanding RTSP ALG Conversation and NAT	93
	Example: Configuring the RTSP ALG	96
Chapter 10	Configuring the SQLNET ALG	103
	Understanding the SQLNET ALG	103
	Example: Configuring the SQLNET ALG	104
Chapter 11	Configuring the TALK ALG	117
	Understanding the TALK ALG	117
	Example: Configuring the TALK ALG	117
Chapter 12	Configuring the TFTP ALG	131
	Understanding the TFTP ALG	131
	Overview	131
	TFTP Packets	131
	TFTP Session	132
	Understanding TFTP ALG Conversation	132
	Understanding IPv6 Support for the TFTP ALG	133
	Example: Configuring the TFTP ALG	134
Part 3	Configuring VoIP ALGs	
Chapter 13	VoIP ALG Types	141
	Understanding VoIP ALG Types	141
Chapter 14	Configuring VoIP Rewrite Rules	143
	Understanding VoIP DSCP Rewrite Rules	143
	Example: Configuring VoIP DSCP Rewrite Rules	144
Chapter 15	Configuring the H.323 ALG	145
	Understanding H.323 ALG	145
	Understanding the Avaya H.323 ALG	147
	Avaya H.323 ALG-Specific Features	147
	Call Flow Details in the Avaya H.323 ALG	148
	H.323 ALG Configuration Overview	149
	Example: Passing H.323 ALG Traffic to a Gatekeeper in the Private Zone	149
	Example: Passing H.323 ALG Traffic to a Gatekeeper in the External Zone	154
	Example: Using NAT with the H.323 ALG to Enable Incoming Calls	160
	Example: Using NAT with the H.323 ALG to Enable Outgoing Calls	168
	Understanding H.323 ALG Endpoint Registration Timeouts	174
	Example: Setting H.323 ALG Endpoint Registration Timeouts	175
	Understanding H.323 ALG Media Source Port Ranges	176
	Example: Setting H.323 ALG Media Source Port Ranges	176
	Understanding H.323 ALG DoS Attack Protection	177
	Example: Configuring H.323 ALG DoS Attack Protection	178
	Understanding H.323 ALG Unknown Message Types	179

	Example: Allowing Unknown H.323 ALG Message Types	179
Chapter 16	Configuring the MGCP ALG	183
	Understanding the MGCP ALG	183
	MGCP Security	184
	Entities in MGCP	184
	Endpoint	185
	Connection	185
	Call	185
	Call Agent	185
	Commands	186
	Response Codes	188
	MGCP ALG Configuration Overview	189
	Example: Configuring Media Gateways in Subscriber Homes Using MGCP	
	ALGs	189
	Example: Configuring Three-Zone ISP-Hosted Service Using MGCP ALG and	
	NAT	196
	Understanding MGCP ALG Call Duration and Timeouts	208
	Example: Setting MGCP ALG Call Duration	209
	Example: Setting MGCP ALG Inactive Media Timeout	210
	Example: Setting MGCP ALG Transaction Timeout	211
	Understanding MGCP ALG DoS Attack Protection	212
	Example: Configuring MGCP ALG DoS Attack Protection	213
	Understanding MGCP ALG Unknown Message Types	214
	Example: Allowing Unknown MGCP ALG Message Types	214
Chapter 17	Configuring the SCCP ALG	217
	Understanding SCCP ALGs	217
	SCCP Security	218
	SCCP Components	219
	SCCP Client	219
	Call Manager	219
	Cluster	219
	SCCP Transactions	220
	Client Initialization	220
	Client Registration	220
	Call Setup	220
	Media Setup	220
	SCCP Version	221
	SCCP Control Messages and RTP Flow	221
	SCCP Messages	221
	SCCP ALG Configuration Overview	223
	Example: Configuring the SCCP ALG Call Manager or TFTP Server in the Private	
	Zone	223
	Understanding SCCP ALG Inactive Media Timeouts	233
	Example: Setting SCCP ALG Inactive Media Timeouts	233
	Understanding SCCP ALG Unknown Message Types	234
	Example: Allowing Unknown SCCP ALG Message Types	235
	Understanding SCCP ALG DoS Attack Protection	236

	Example: Configuring SCCP ALG DoS Attack Protection	236
	Verifying SCCP ALG Configurations	237
	Verifying SCCP ALG	237
	Verifying SCCP ALG Calls	238
	Verifying SCCP ALG Call Details	238
	Verifying SCCP ALG Counters	239
Chapter 18	Configuring the SIP ALG	241
	Understanding the SIP ALG	241
	SIP ALG Operation	242
	SDP Session Descriptions	244
	Pinhole Creation	244
	Understanding IPv6 Support for SIP ALG	247
	Understanding SIP ALG Request Methods	247
	SIP ALG Configuration Overview	248
	Understanding SIP ALG Call Duration and Timeouts	249
	Example: Setting SIP ALG Call Duration and Timeouts	250
	Understanding SIP ALG DoS Attack Protection	251
	Example: Configuring SIP ALG DoS Attack Protection	252
	Understanding SIP ALG Unknown Message Types	253
	Example: Allowing Unknown SIP ALG Message Types	254
	Understanding SIP ALG Hold Resources	255
	Retaining SIP ALG Hold Resources (CLI Procedure)	255
	Retaining SIP ALG Hold Resources (J-Web Procedure)	256
	Understanding the SIP ALG and NAT	256
	Outgoing Calls	257
	Incoming Calls	258
	Forwarded Calls	258
	Call Termination	258
	Call Re-INVITE Messages	258
	Call Session Timers	259
	Call Cancellation	259
	Forking	259
	SIP Messages	259
	SIP Headers	259
	SIP Body	261
	SIP NAT Scenario	262
	Classes of SIP Responses	263
	NAT Mode in Pure IPv6 Mode (NAT66) for SIP IPv6 ALG	264
	NAT-PT	264
	NAT64	265
	STUN and SIP ALG	265
	Understanding Incoming SIP ALG Call Support Using the SIP Registrar and NAT	266
	Example: Configuring Interface Source NAT for Incoming SIP Calls	267
	Decreasing Network Complexity by Configuring a Source NAT Pool for Incoming SIP Calls	273
	Example: Configuring Static NAT for Incoming SIP Calls	281

Example: Configuring the SIP Proxy in the Private Zone and NAT in the Public Zone	288
Example: Configuring a Three-Zone SIP ALG and NAT Scenario	294
Verifying SIP ALG Configurations	302
Verifying SIP ALG	302
Verifying SIP ALG Calls	302
Verifying SIP ALG Call Details	302
Verifying SIP ALG Counters	303
Verifying the Rate of SIP ALG Messages	304

Part 4

Chapter 19

Configuration Statements and Operational Commands

Configuration Statements	309
Applications Configuration Statement Hierarchy	311
[edit security alg] Hierarchy Level	312
[edit security nat] Hierarchy Level	316
[edit security policies] Hierarchy Level	320
[edit security zones] Hierarchy Level	324
[edit security traceoptions] Hierarchy Level	325
address (Security Destination NAT)	326
alg	327
alg (Applications)	332
alg-manager	333
allow-dns-reply	333
application (Security Policies)	334
application-protocol (Applications)	335
application-screen (Security H323)	336
application-screen (Security MGCP)	337
application-screen (Security SCCP)	338
application-screen (Security SIP)	339
banner (Access FTP HTTP Telnet Authentication)	340
call-flood	340
c-timeout	341
deny (Security SIP)	342
destination-address (Security Destination NAT)	343
destination-address (Security Policies)	344
destination-address (Security Source NAT)	345
destination-address (Security Static NAT)	345
destination-nat	346
destination-port (Applications)	347
dns	351
dns (System Services)	352
dscp-rewrite	353
endpoint-registration-timeout	354
family inet (Interfaces)	355
ftp (Access)	357
ftp (Security ALG)	358
gatekeeper	359
h323	360

unknown-message (Security MGCP ALG)	411
unknown-message (Security SCCP ALG)	412
unknown-message (Security SIP ALG)	413

Chapter 20	Operational Commands	415
	clear security alg h323 counters	416
	clear security alg ike-esp-nat	417
	clear security alg sccp calls	418
	clear security alg sccp counters	419
	clear security alg sip calls	420
	clear security alg sip counters	421
	clear security flow session application	422
	show chassis cluster data-plane statistics	424
	show chassis cluster statistics	426
	show security alg h323 counters	430
	show security alg ike-esp-nat summary	432
	show security alg msrpc	433
	show security alg sccp calls	435
	show security alg sccp counters	437
	show security alg sip calls	439
	show security alg sip counters	441
	show security alg sip rate	445
	show security alg status	447
	show security flow gate	449
	show security flow session	453
	show security flow session application	459
	show security flow session resource-manager	463
	show security idp policy-templates	467
	show security resource-manager group active	468
	show security resource-manager resource active	471
	show security resource-manager summary	474
	show security zones	475
	show security zones type	478
Guide 2	AppSecure Services Feature Guide for Security Devices	
Chapter 21	Overview	483
	Understanding AppSecure Services	483
Chapter 22	Understanding Application Identification	485
	Understanding Application Identification Techniques	485
	Junos OS Next-Generation Application Identification	485
	Application Signature Mapping	486
	Application Identification Match Sequence	486
	Understanding the Junos OS Application Identification Database	488

Chapter 23	Installing Application Signature Package	489
	Understanding the Junos OS Application Package Installation	489
	Upgrading to Next-Generation Application Identification	490
	Installing and Verifying Licenses for an Application Signature Package	491
	Downloading and Installing the Junos OS Application Signature Package	
	Manually	492
	Downloading and Installing the Junos OS Application Signature Package As Part	
	of the IDP Security Package	496
	Example: Scheduling the Application Signature Package Updates	499
	Scheduling the Application Signature Package Updates As Part of the IDP	
	Security Package	501
	Example: Downloading and Installing the Application Identification Package in	
	Chassis Cluster Mode	503
	Verifying the Junos OS Application Identification Extracted Application	
	Package	506
	Uninstalling the Junos OS Application Identification Application Package	507
	Disabling and Reenabling Junos OS Application Identification	508
Chapter 24	Configuring Application Groups	509
	Customizing Application Groups for Junos OS Application Identification	509
	Enabling Application Groups in Junos OS Application Identification	510
	Example: Configuring a Custom Application Group for Junos OS Application	
	Identification for Simplified Management	510
Chapter 25	Configuring Application System Cache	515
	Understanding the Application System Cache	515
	Deactivating Application System Cache Information for Application Identification	
	(CLI Procedure)	515
	Verifying Application System Cache Statistics	516
Chapter 26	Controlling Application Identification Performance	519
	Onbox Application Identification Statistics	519
	Understanding Jumbo Frames Support for Junos OS Application Identification	
	Services	520
	Improving the Application Traffic Throughput	520
Chapter 27	Configuring Encrypted Files Using SSL Proxy	523
	SSL Proxy Overview	523
	Supported Ciphers in Proxy Mode	525
	Server Authentication	526
	Trusted CA List	527
	Root CA	527
	Client Authentication	528
	Whitelists	528
	Dynamic Resolution of Domain Names	528
	Session Resumption	528
	Session Renegotiation	528
	SSL Proxy Logs	529
	Leveraging Dynamic Application Identification	530
	Logical Systems Support	530

	Limitations	531
	Application Firewall, IDP, and Application Tracking with SSL Proxy Overview . . .	531
	Working with the Certificate Revocation Lists for SSL Proxy	532
	Disabling CRL Verification	533
	Allowing Sessions When CRL Information Is Not Available	533
	Allowing Sessions When CRL Status Is Unknown	533
	Configuring SSL Proxy	534
	SSL Proxy Configuration Overview	535
	Configuring a Root CA Certificate	535
	Configuring a CA Profile Group	537
	Configuring a Trusted CA Profile	538
	Importing a Root CA Certificate into a Browser	539
	Applying an SSL Proxy Profile to a Security Policy	540
	Creating a Whitelist of Exempted Destinations	541
	Configuring SSL Proxy Logging	542
	Configuring Ciphers	542
	Exporting Certificates to a Specified Location	543
	Ignoring Server Authentication	543
	Enabling Debugging and Tracing for SSL Proxy	544
Chapter 28	Configuring Application Firewall	547
	Application Firewall Overview	547
	Understanding Application Firewall Rule Sets	548
	Configuring an Application Firewall Within a Security Policy	549
	Application Group Support for Application Firewall	549
	Redirecting Users	550
	Session Logging for Application Firewalls	551
	Application Firewall Support in Chassis Cluster	551
	Example: Configuring Application Firewall Rule Sets Within a Security Policy . .	552
	Example: Configuring an Application Group for Application Firewall	556
	Example: Configuring Application Firewall When SSL Proxy Is Enabled	560
Chapter 29	Configuring Application Tracking	565
	Understanding AppTrack	565
	Example: Configuring AppTrack	566
	Example: Configuring AppTrack When SSL Proxy Is Enabled	572
	Disabling AppTrack	573
Chapter 30	Configuring Application QoS	575
	Understanding Application QoS (AppQoS)	575
	Unique Forwarding Classes and Queue Assignments	576
	Application-Aware DSCP Code-Point and Loss Priority Settings	576
	Rate Limiters and Profiles	578
	Rate-Limiter Assignment	579
	Rate-Limiter Action	581
	AppQoS Security Policy Configuration	581
	Example: Configuring AppQoS	581

Chapter 31	Configuration Statements	589
	Class-of-Service Configuration Statement Hierarchy	591
	Security Configuration Statement Hierarchy	595
	Services Configuration Statement Hierarchy	596
	System Configuration Statement Hierarchy	603
	[edit security address-book] Hierarchy Level	634
	[edit security application-firewall] Hierarchy Level	635
	[edit security application-tracking] Hierarchy Level	636
	[edit security log] Hierarchy Level	636
	[edit security pki] Hierarchy Level	637
	[edit security policies] Hierarchy Level	638
	[edit security zones] Hierarchy Level	642
	actions (Services SSL Proxy)	645
	actions (Services SSL Initiation)	646
	appfw-profile (System)	647
	appfw-rule	648
	appfw-rule-set	649
	application-firewall	650
	application-firewall (Application Services)	651
	application-identification	652
	application-group (Services)	653
	application-services (Security Policies)	654
	application-system-cache	655
	application-system-cache-timeout (Services)	655
	application-tracking	656
	application-tracking (Security Zones)	656
	application-traffic-control	657
	application-traffic-control (Application Services)	658
	block-message (Application Firewall)	659
	custom-ciphers	661
	default-rule	662
	disable (Application Tracking)	663
	download (Services)	664
	dynamic-application	665
	dynamic-application-group	665
	enable-flow-tracing (Services)	666
	enable-performance-mode	666
	enable-session-cache	667
	file (Services)	667
	files (Services)	668
	file (System Logging)	669
	first-update	671
	first-update-interval	672

Guide 3

Attack Detection and Prevention Feature Guide for Security Devices

Part 5

Overview

Chapter 33

Introduction to Attack Detection and Prevention	813
Attack Detection and Prevention Overview	813
Understanding IPv6 Support for Screens	814
IPv6 Extension Header Checking and Filtering	814
Maximum Number of Extension Headers	815
Bad Option Extension Headers	816
ICMPv6 Checking and Filtering	816
IPv6 Packet Header Checking and Filtering	817
Understanding Screens Options on SRX Series Devices	818

	Understanding Screen Options on the SRX5000 Module Port Concentrator . . .	821
	Statistics-Based Screens	822
	Differences Between IOC1 and IOC2	822
	Signature-Based Screens	826
	Example: Configuring Multiple Screening Options	827
	Understanding Central Point Architecture Enhancements for Screens	832
Part 6	Configuring Screen Options to Protect Against Denial-of-Service Attacks	
Chapter 34	Understanding DoS Attacks	837
	DoS Attack Overview	837
Chapter 35	Protecting Against Firewall DoS Attacks	839
	Firewall DoS Attacks Overview	839
	Understanding Firewall Filters on the SRX5000 Module Port Concentrator . . .	839
	Understanding Session Table Flood Attacks	840
	Understanding Source-Based Session Limits	841
	Example: Setting Source-Based Session Limits	842
	Understanding Destination-Based Session Limits	844
	Example: Setting Destination-Based Session Limits	845
	Understanding SYN-ACK-ACK Proxy Flood Attacks	847
	Protecting Your Network Against a SYN-ACK-ACK Proxy Flood Attack	848
Chapter 36	Protecting Against Network DoS Attacks	851
	Network DoS Attacks Overview	851
	Understanding SYN Flood Attacks	852
	SYN Flood Protection	853
	SYN Flood Options	854
	Protecting Your Network Against SYN Flood Attacks by Enabling SYN Flood Protection	855
	Example: Enabling SYN Flood Protection for Webservers in the DMZ	857
	Understanding Whitelists for SYN Flood Screens	863
	Example: Configuring Whitelists for SYN Flood Screens	864
	Understanding SYN Cookie Protection	865
	SYN Cookie Options	867
	Detecting and Protecting Your Network Against SYN Flood Attacks by Enabling SYN Cookie Protection	868
	Understanding ICMP Flood Attacks	871
	Protecting Your Network Against ICMP Flood Attacks by Enabling ICMP Flood Protection	872
	Understanding UDP Flood Attacks	874
	Protecting Your Network Against UDP Flood Attacks by Enabling UDP Flood Protection	875
	Understanding Land Attacks	877
	Protecting Your Network Against Land Attacks by Enabling Land Attack	878
	Understanding Screen IPv6 Tunneling Control	880
	Example: Improving Tunnel Traffic Security with IP Tunneling Screen Options	883

Chapter 37	Protecting Against OS-Specific DoS Attacks	891
	OS-Specific DoS Attacks Overview	891
	Understanding Ping of Death Attacks	891
	Example: Protecting Against a Ping of Death Attack	892
	Understanding Teardrop Attacks	893
	Example: Protecting Against a Teardrop Attack	895
	Understanding WinNuke Attacks	895
	Example: Protecting Against a WinNuke Attack	897
Part 7	Configuring Reconnaissance Deterrence for Security Devices	
Chapter 38	Protecting Against IP Sweep and Port Options	901
	Reconnaissance Deterrence Overview	901
	Understanding IP Address Sweeps	901
	Example: Blocking IP Address Sweeps	902
	Understanding TCP Port Scanning	904
	Enhancing Traffic Management by Blocking Port Scans	905
	Understanding UDP Port Scanning	908
	Understanding Network Reconnaissance Using IP Options	908
	Uses for IP Packet Header Options	909
	Screen Options for Detecting IP Options Used for Reconnaissance	911
	Example: Detecting Packets That Use IP Screen Options for Reconnaissance	911
Chapter 39	Protecting Against System Probes and Flag Set	915
	Understanding Operating System Probes	915
	Understanding Domain Name System Resolve	915
	Understanding TCP Headers with SYN and FIN Flags Set	916
	Example: Blocking Packets with SYN and FIN Flags Set	917
	Understanding TCP Headers With FIN Flag Set and Without ACK Flag Set	918
	Example: Blocking Packets With FIN Flag Set and Without ACK Flag Set	919
	Understanding TCP Header with No Flags Set	921
	Example: Blocking Packets with No Flags Set	922
Chapter 40	Protecting Against Attacker Evasion Techniques	925
	Understanding Attacker Evasion Techniques	925
	Understanding FIN Scans	926
	Thwarting a FIN Scan	926
	Understanding TCP SYN Checking	926
	Setting TCP SYN Checking	928
	Setting Strict SYN Checking	929
	Understanding IP Spoofing	929
	Example: Blocking IP Spoofing	929
	Understanding IP Spoofing in Layer 2 Transparent Mode	931
	Configuring IP Spoofing in Layer 2 Transparent Mode	932
	Understanding IP Source Route Options	933
	Example: Blocking Packets with Either a Loose or a Strict Source Route Option Set	935
	Example: Detecting Packets with Either a Loose or a Strict Source Route Option Set	936

Part 8	Configuring Suspicious Packet Attributes for Security Devices
Chapter 41	Protecting Against ICMP and SYN Fragment Attacks 941
	Suspicious Packet Attributes Overview 941
	Understanding ICMP Fragment Protection 941
	Example: Blocking Fragmented ICMP Packets 942
	Understanding Large ICMP Packet Protection 943
	Example: Blocking Large ICMP Packets 944
	Understanding SYN Fragment Protection 944
	Example: Dropping IP Packets Containing SYN Fragments 945
Chapter 42	Protecting Against IP Attacks 947
	Understanding Bad IP Option Protection 947
	Example: Blocking IP Packets with Incorrectly Formatted Options 948
	Understanding Unknown Protocol Protection 949
	Example: Dropping Packets Using an Unknown Protocol 950
	Understanding IP Packet Fragment Protection 950
	Example: Dropping Fragmented IP Packets 951
Part 9	Configuration Statements and Operational Commands
Chapter 43	Configuration Statements 955
	Security Configuration Statement Hierarchy 956
	[edit security screen] Hierarchy Level 957
	attack-threshold 960
	bad-inner-header 961
	description (Security Screen) 961
	destination-ip-based 962
	destination-threshold 963
	fin-no-ack 963
	flood (Security ICMP) 964
	flood (Security UDP) 965
	gre 966
	icmp (Security Screen) 967
	ids-option 968
	ipip 971
	ip (Security Screen) 972
	ip-sweep 975
	ip-in-udp 976
	land 976
	large 977
	limit-session 977
	no-syn-check 978
	no-syn-check-in-tunnel 978
	ping-death 979
	port-scan 980
	screen (Security) 981
	screen (Security Zones) 984
	source-ip-based 984
	source-threshold 985

	strict-syn-check	985
	syn-ack-ack-proxy	986
	syn-check-required	986
	syn-fin	987
	syn-flood	988
	syn-flood-protection-mode	989
	syn-frag	989
	tcp (Security Screen)	990
	tcp-no-flag	991
	tcp-sweep	992
	timeout (Security Screen)	993
	traceoptions (Security Screen)	994
	trap	995
	tunnel (Security Screen)	996
	udp (Security Screen)	997
	udp-sweep	998
	white-list	999
	winnuke	1000
Chapter 44	Operational Commands	1001
	clear security screen statistics	1002
	clear security screen statistics interface	1003
	clear security screen statistics zone	1005
	show security screen ids-option	1007
	show security screen statistics	1012
	show security screen status	1020
Guide 4	Building Blocks Feature Guide for Security Devices	
Part 10	Overview	
Chapter 45	Introduction to Security Building Blocks	1025
	Understanding Security Building Blocks for Security Devices	1025
Part 11	Configuring Security Zones and Interfaces	
Chapter 46	Configuring Security Zones	1029
	Security Zones and Interfaces Overview	1029
	Understanding Security Zone Interfaces	1030
	Understanding Functional Zones	1030
	Understanding Security Zones	1030
	Example: Creating Security Zones	1031
Chapter 47	Managing Inbound Traffic for Security Zones	1035
	Understanding How to Control Inbound Traffic Based on Traffic Types	1035
	Example: Controlling Inbound Traffic Based on Traffic Types	1036
	Understanding How to Control Inbound Traffic Based on Protocols	1038
	Example: Controlling Inbound Traffic Based on Protocols	1039
	Supported System Services for Host Inbound Traffic	1041

Chapter 48	Identifying Duplicate Sessions by Configuring TCP-Reset Parameters . .	1045
	Understanding How to Identify Duplicate Sessions Using the TCP-Reset Parameter	1045
	Example: Configuring the TCP-Reset Parameter	1045
Part 12	Configuring Address Books and Address Sets	
Chapter 49	Configuring Address, Address Books, and Address Sets	1049
	Understanding Address Books	1049
	Predefined Addresses	1049
	Network Prefixes in Address Books	1050
	Wildcard Addresses in Address Books	1050
	DNS Names in Address Books	1050
	Understanding Address Sets	1051
	Understanding Global Address Books	1051
	Configuring Addresses and Address Sets	1052
	Addresses and Address Sets	1052
	Address Books and Security Zones	1053
	Address Books and Security Policies	1053
	Addresses Available for Security Policies	1054
	Applying Policies to Address Sets	1054
	Address Books and NAT	1055
	Example: Configuring Address Books and Address Sets	1056
	Limitations of Addresses and Address Sets in a Security Policy	1061
Part 13	Configuring Security Policies	
Chapter 50	Enforcing Transit Traffic Rules by Configuring Security Policies	1065
	Security Policies Overview	1065
	Understanding Security Policy Rules	1067
	Understanding Wildcard Addresses	1070
	Understanding Security Policy Elements	1071
	Understanding Security Policies for Self Traffic	1072
	Security Policies Configuration Overview	1073
	Configuring Policies Using the Firewall Wizard	1074
	Example: Configuring a Security Policy to Permit or Deny All Traffic	1074
	Example: Configuring a Security Policy to Permit or Deny Selected Traffic	1078
	Example: Configuring a Security Policy to Permit or Deny Wildcard Address Traffic	1082
	Example: Configuring a Security Policy to Redirect Traffic Logs to an External System Log Server	1085
Chapter 51	Configuring Negated Addresses	1089
	Understanding Negated Address Support	1089
	Example: Configuring Negated Addresses	1090
Chapter 52	Configuring Global Security Policy	1095
	Global Policy Overview	1095
	Example: Configuring a Global Policy with No Zone Restrictions	1097
	Example: Configuring a Global Policy with Multiple Zones	1099

Chapter 53	Managing Security Policy Activation By Configuring Schedulers	1103
	Security Policy Schedulers Overview	1103
	Example: Configuring Schedulers for a Daily Schedule Excluding One Day	1104
Chapter 54	Configuring User Role Firewall Security Policies	1107
	Understanding User Role Firewalls	1107
	User Role Retrieval and the Policy Lookup Process	1108
	Understanding the User Identification Table	1110
	Local Authentication Table	1111
	UAC Authentication Table	1113
	Firewall Authentication Table	1114
	Policy Provisioning With Users and Roles	1115
	Obtaining Username and Role Information Through Firewall Authentication . .	1116
	Configuring a User Role Firewall For Captive Portal Redirection	1117
	Example: Configuring a User Role Firewall on an SRX Series Device	1118
	Configuring Resource Policies Using UAC	1125
Chapter 55	Setting Security Policy Reorder	1129
	Understanding Security Policy Ordering	1129
	Example: Reordering the Policies	1131
Chapter 56	Monitoring and Troubleshooting Security Policies	1133
	Matching Security Policies	1133
	Tracking Policy Hit Counts	1135
	Best Practices for Defining Policies on High-End SRX Series Devices	1135
	Checking Memory Status	1137
	Synchronizing a Security Policy on SRX Series Devices	1139
	Verifying Scheduled Policies	1139
	Verifying Shadow Policies	1140
	Verifying All Shadow Policies	1141
	Verifying a Policy Shadows One or More Policies	1141
	Verifying a Policy Is Shadowed by One or More Policies	1141
	Monitoring Policy Statistics	1142
	Troubleshooting Security Policies	1143
	Checking a Security Policy Commit Failure	1143
	Verifying a Security Policy Commit	1143
	Debugging Policy Lookup	1144
Chapter 57	Handling Security Policy Violations	1145
	Understanding Searching and Sorting Audit Logs	1145
	Understanding Packet Flow Alarms and Auditing	1146
	Example: Generating a Security Alarm in Response to Policy Violations	1147
Part 14	Configuring Security Policy Applications	
Chapter 58	Configuring Applications and Application Sets	1151
	Security Policy Applications Overview	1151
	Policy Application Sets Overview	1152
	Example: Configuring Applications and Application Sets	1152

Chapter 59	Configuring Custom Policy Applications	1155
	Understanding Custom Policy Applications	1155
	Custom Application Mappings	1155
	Example: Adding and Modifying Custom Policy Applications	1156
	Example: Configuring Custom Policy Application Term Options	1157
Chapter 60	Setting Policy Application Timeout	1161
	Understanding Policy Application Timeout Configuration and Lookup	1161
	Understanding Policy Application Timeouts Contingencies	1162
	Example: Setting a Policy Application Timeout	1162
Chapter 61	Understanding Predefined Policy Applications	1165
	Understanding Internet-Related Predefined Policy Applications	1165
	Understanding Microsoft Predefined Policy Applications	1167
	Understanding Dynamic Routing Protocols in Predefined Policy Applications	1168
	Understanding Streaming Video Predefined Policy Applications	1168
	Understanding Sun RPC Predefined Policy Applications	1169
	Understanding Security and Tunnel Predefined Policy Applications	1170
	Understanding IP-Related Predefined Policy Applications	1171
	Understanding Instant Messaging Predefined Policy Applications	1171
	Understanding Management Predefined Policy Applications	1172
	Understanding Mail Predefined Policy Applications	1173
	Understanding UNIX Predefined Policy Applications	1174
	Understanding Miscellaneous Predefined Policy Applications	1174
	Understanding the ICMP Predefined Policy Application	1175
	Example: Defining a Custom ICMP Application	1179
	Default Behavior of ICMP Unreachable Errors	1181
Part 15	Configuration Statements and Operational Commands	
Chapter 62	Configuration Statements	1185
	Applications Configuration Statement Hierarchy	1188
	Security Configuration Statement Hierarchy	1189
	[edit security address-book] Hierarchy Level	1190
	[edit security policies] Hierarchy Level	1191
	[edit security user-identification] Hierarchy Level	1195
	[edit security zones] Hierarchy Level	1195
	address (Security Address Book)	1198
	address-book	1199
	address-set	1200

Guide 5 Class of Service Feature Guide for Security Devices

Part 16

Chapter 64

Overview

Introduction to Class of Service	1381
Understanding Class of Service	1381
Benefits of CoS	1382
CoS Across the Network	1383
Junos OS CoS Components	1383
CoS Components Packet Flow	1385
CoS Process on Incoming Packets	1386
CoS Process on Outgoing Packets	1386
CoS Device Configuration Overview	1387
Understanding CoS Default Settings	1387

Part 17	Configuring Class of Service Components	
Chapter 65	Assigning Service Levels with Classifiers	1391
	Classification Overview	1391
	Behavior Aggregate Classifiers	1392
	Multifield Classifiers	1392
	Default IP Precedence Classifier	1393
	Understanding Packet Loss Priorities	1394
	Default Behavior Aggregate Classification	1394
	Sample Behavior Aggregate Classification	1396
	Example: Configuring Behavior Aggregate Classifiers	1397
Chapter 66	Controlling Network Access with Traffic Policing	1407
	Simple Filters and Policers Overview	1407
	Two-Rate Three-Color Policer Overview	1408
	Example: Configuring a Two-Rate Three-Color Policer	1409
	Guidelines for Configuring Simple Filters	1414
	Statement Hierarchy for Configuring Simple Filters	1414
	Simple Filter Protocol Families	1415
	Simple Filter Names	1415
	Simple Filter Terms	1415
	Simple Filter Match Conditions	1416
	Simple Filter Terminating Actions	1417
	Simple Filter Nonterminating Actions	1417
	Example: Configuring and Applying a Firewall Filter for a Multifield Classifier	1417
Chapter 67	Controlling Output Queues with Forwarding Classes	1425
	Forwarding Classes Overview	1425
	Forwarding Class Queue Assignments	1426
	Forwarding Policy Options	1427
	Example: Configuring Forwarding Classes	1427
	Example: Assigning Forwarding Classes to Output Queues	1432
	Example: Assigning a Forwarding Class to an Interface	1434
	Understanding the SPC High-Priority Queue	1435
	Example: Configuring the SPC High-Priority Queue	1435
Chapter 68	Altering Outgoing Packets Headers with Rewrite Rules	1439
	Rewrite Rules Overview	1439
	Rewriting Frame Relay Headers	1439
	Assigning the Default Frame Relay Rewrite Rule to an Interface	1440
	Defining a Custom Frame Relay Rewrite Rule	1440
	Example: Configuring and Applying Rewrite Rules	1441
Chapter 69	Defining Output Queue Properties with Schedulers	1445
	Schedulers Overview	1445
	Transmit Rate	1446
	Delay Buffer Size	1447
	Scheduling Priority	1448

	Shaping Rate	1449
	Default Scheduler Settings	1450
	Transmission Scheduling Overview	1451
	Excess Bandwidth Sharing and Minimum Logical Interface Shaping	1452
	Excess Bandwidth Sharing Proportional Rates	1453
	Calculated Weights Mapped to Hardware Weights	1454
	Weight Allocation with Only Shaping Rates or Unshaped Logical Interfaces	1455
	Shared Bandwidth Among Logical Interfaces	1456
	Example: Configuring Class-of-Service Schedulers	1457
	Scheduler Buffer Size Overview	1461
	Maximum Delay Buffer Sizes Available to Channelized T1/E1 Interfaces	1462
	Maximum Delay Buffer Size for vSRX Interfaces	1463
	Delay Buffer Size Allocation Methods	1463
	Delay Buffer Sizes for Queues	1464
	Example: Configuring a Large Delay Buffer on a Channelized T1 Interface	1465
	Configuring Large Delay Buffers in CoS	1468
	Example: Configuring and Applying Scheduler Maps	1472
Chapter 70	Removing Delays with Strict-Priority Queues	1477
	Strict-Priority Queue Overview	1477
	Understanding Strict-Priority Queues	1478
	Example: Configuring Priority Scheduling	1478
	Example: Configuring Strict-Priority Queuing	1480
Chapter 71	Controlling Congestion with Drop Profiles	1491
	RED Drop Profiles Overview	1491
	Default Drop Profiles	1492
	RED Drop Profiles and Congestion Control	1492
	Configuring RED Drop Profiles	1494
	Example: Configuring RED Drop Profiles	1495
Chapter 72	Controlling Congestion with Adaptive Shapers	1499
	Adaptive Shaping Overview	1499
	Assigning the Default Frame Relay Loss Priority Map to an Interface	1500
	Defining a Custom Frame Relay Loss Priority Map	1500
	Example: Configuring and Applying an Adaptive Shaper	1501
Chapter 73	Limiting Traffic Using Virtual Channels	1503
	Virtual Channels Overview	1503
	Understanding Virtual Channels	1504
	Example: Configuring Virtual Channels	1505
Chapter 74	Enabling Queuing for Tunnel Interfaces	1511
	CoS Queuing for Tunnels Overview	1511
	Benefits of CoS Queuing for Tunnel Interfaces	1511
	How CoS Queuing Works	1512
	Limitations on CoS Shapers for Tunnel Interfaces	1513
	Understanding the ToS Value of a Tunnel Packet	1513
	Example: Configuring CoS Queuing for GRE or IP-IP Tunnels	1514
	Copying Outer IP Header DSCP and ECN to Inner IP Header	1518

Chapter 75	Naming Components with Code-Point Aliases	1521
	Code-Point Aliases Overview	1521
	Default CoS Values and Aliases	1522
	Example: Defining Code-Point Aliases for Bits	1525
Part 18	Configuring Class of Service Scheduler Hierarchy	
Chapter 76	Controlling Traffic by Configuring Scheduler Hierarchy	1529
	Understanding Hierarchical Schedulers	1529
	Understanding Internal Scheduler Nodes	1532
	SRX1400, SRX3400, and SRX3600 Device Hardware Capabilities and Limitations	1533
	Example: Configuring a Four-Level Scheduler Hierarchy	1535
	Example: Controlling Remaining Traffic	1547
Part 19	Configuring Class of Service for IPv6	
Chapter 77	Configuring Class of Service for IPv6 Traffic	1555
	CoS Functions for IPv6 Traffic Overview	1555
	Understanding CoS with DSCP IPv6 BA Classifier	1557
	Example: Configuring CoS with DSCP IPv6 BA Classifiers	1559
	Understanding DSCP IPv6 Rewrite Rules	1562
	Example: Configuring CoS with DSCP IPv6 Rewrite Rules	1562
Part 20	Configuring Class of Service for I/O Cards	
Chapter 78	Configuring Class of Service for I/O Cards	1569
	PIR-Only and CIR Mode Overview	1569
	PIR-only Mode	1569
	CIR Mode	1570
	Understanding Priority Propagation	1571
	Understanding IOC Hardware Properties	1572
	Understanding IOC Map Queues	1574
	WRED on the IOC Overview	1575
	Shapers at the Logical Interface Level (Level 3)	1576
	Shapers at the Interface Set Level (Level 2)	1577
	Shapers at the Port Level (Level 1)	1578
	MDRR on the IOC Overview	1579
	CoS Support on the SRX5000 Module Port Concentrator Overview	1581
	Example: Configuring CoS on High-End SRX Series Devices with an MPC	1582

Guide 6 Flow-Based and Packet-Based Processing Feature Guide for Security Devices

Part 22	Overview	
Chapter 81	Introduction to Processing on Security Devices	1641
	Juniper Networks Devices Processing Overview	1641
	Understanding Flow-Based Processing	1642
	Zones and Policies	1643
	Flows and Sessions	1643
	Understanding Packet-Based Processing	1643
	Configuring Packet-Based Processing	1644
	Stateless Firewall Filters	1644
	Class-of-Service Features	1644

Screens	1645
Understanding SRX Series Services Gateways Central Point Architecture	1645
Load Distribution in Combo Mode	1646
Sharing Processing Power and Memory in Combo Mode	1646
Understanding Enhancements to Central Point Architecture for the SRX5000	
Line	1647
SRX5000 Line Devices Processing Overview	1648
Understanding First-Packet Processing	1649
Understanding Fast-Path Processing	1650
Understanding the Data Path for Unicast Sessions	1651
Session Lookup and Packet-Match Criteria	1651
Understanding Session Creation: First-Packet Processing	1651
Understanding Fast-Path Processing	1654
Understanding Services Processing Units	1657
Understanding Scheduler Characteristics	1657
Understanding Network Processor Bundling	1657
Network Processor Bundling Limitations	1657
SRX3000 Line and SRX1400 Devices Processing Overview	1658
Components Involved in Setting Up a Session	1659
Understanding the Data Path for Unicast Sessions	1659
Session Lookup and Packet Match Criteria	1660
Understanding Session Creation: First Packet Processing	1660
Understanding Fast-Path Processing	1662
SRX210 Services Gateway Processing Overview	1662
Understanding Flow Processing and Session Management	1662
Understanding First-Packet Processing	1663
Understanding Session Creation	1663
Understanding Fast-Path Processing	1663

Part 23

Chapter 82

Configuring Flow-Based Sessions

Configuring Security Flow Sessions	1667
Understanding Session Characteristics for SRX Series Services Gateways	1667
Understanding Aggressive Session Aging	1668
Example: Controlling Session Termination for SRX Series Services Gateways ..	1668
Understanding TCP Session Checks per Policy	1670
Example: Disabling TCP Packet Security Checks for SRX Series Services	
Gateways	1671
Example: Setting the Maximum Segment Size for All TCP Sessions for SRX	
Series Services Gateways	1672
Example: Configuring TCP Packet Security Checks Per Policy	1674
Configuring the Timeout Value for Multicast Flow Sessions	1675
Clearing Sessions for SRX Series Services Gateways	1677
Terminating Sessions for SRX Series Services Gateways	1677
Terminating a Specific Session for SRX Series Services Gateways	1677
Using Filters to Specify the Sessions to Be Terminated for SRX Series	
Services Gateways	1677

Part 24	Improving Flow-Based Performance	
Chapter 83	Expanding Session Capacity by Device	1681
	Expanding Session Capacity by Device	1681
	Expanding Session Capacity on an SRX3400 or SRX3600 Device	1682
	Reverting to Default Session Capacity on an SRX5800 Device	1682
	Verifying the Current Session Capacity	1682
Chapter 84	Managing Sessions and Flow Distribution	1685
	Understanding Load Distribution in High-End SRX Series Devices	1685
	Hash-Based Forwarding on the SRX5K-MPC, SRX5K-MPC3-40G10G (IOC3), and the SRX5K-MPC3-100G10G (IOC3)	1685
	Understanding Load Distribution on SRX5000 Line Devices Using the Packet-Ordering Function	1687
	Disabling Packet-Ordering Mode on SRX5000 Line Devices	1688
Chapter 85	Reducing Long Packet-Processing Latency by Express Path	1691
	Understanding Session Cache	1691
	Overview	1691
	Selective Session Cache Installation	1693
	IPsec VPN Session Affinity Enhancement Using Session Cache	1694
	Fragmentation Packet Ordering Using NP Session Cache	1694
	Express Path Overview	1695
	Understanding Express Path Functionality	1695
	Understanding Express Path Support on SRX Series Devices	1696
	Express Path Support on NP-IOC Card	1697
	Express Path Support on SRX5K Modular Port Concentrator	1698
	Express Path Support on SRX5K-MPC3-100G10G (IOC3) and SRX5K-MPC3-40G10G (IOC3)	1699
	Understanding Express Path Features	1701
	Wing Statistics Counter	1701
	Cross-Network Traffic	1702
	LAG Support in Express Path Mode	1703
	End-to-End Debugging	1704
	Per-Session Statistics CLI	1705
	Disabling TCP Packet Security Checks	1706
	Express Path Limitations	1706
	Understanding the Express Path Solution	1707
	Enabling and Disabling Express Path	1708
	Example: Enabling Express Path in Security Policies	1710
	Example: Configuring an NPC on SRX3000 Line Devices or SRX1400 Devices to Support Express Path	1712
	Example: Configuring an IOC on SRX5000 Line Devices to Support Express Path	1713
	Example: Configuring an NP-IOC on SRX3000 Line Devices or SRX1400 Devices to Support Express Path	1715
	Example: Configuring an SRX5K-MPC on an SRX5000 Line Device to Support Express Path	1716
	Example: Configuring SRX5K-MPC3-100G10G (IOC3) and SRX5K-MPC3-40G10G (IOC3) on an SRX5000 Line Device to Support Express Path	1719

	Example: Configuring Low Latency	1721
Part 25	Managing Flow-Based Processing for IPv6	
Chapter 86	Enabling IPv6 Flow-Based Processing	1727
	IPv6 Advanced Flow	1727
	Understanding Sessions for IPv6 Flows	1728
	Understanding IPv6 Flow Processing on High-End SRX Series Devices	1729
	Enabling Flow-Based Processing for IPv6 Traffic	1732
	Using Filters to Display IPv6 Session and Flow Information for SRX Series Services Gateways	1733
Chapter 87	Managing IPv6 Packets	1739
	The IPv6 Packet Header and SRX Series Overview	1739
	About the IPv6 Basic Packet Header	1740
	Understanding IPv6 Packet Header Extensions	1741
	About IPv6 Packet Header Verification Performed by the Flow Module for SRX Series Devices	1743
	Understanding Path MTU Messages for IPv6 Packets	1743
	Understanding How SRX Series Devices Handle Packet Fragmentation for IPv6 Flows	1745
	Understanding How SRX Series Devices Handle ICMPv6 Packets	1745
Chapter 88	Configuring IPv6 Dual-Stack	1747
	Understanding IPv6 Dual-Stack Lite	1747
	Example: Configuring IPv6 Dual-Stack Lite	1750
Part 26	Monitoring Flow-Based Sessions	
Chapter 89	Monitoring Security Flow Sessions	1755
	Monitoring Security Flow Sessions Overview	1755
	Understanding How to Obtain Session Information for SRX Series Services Gateways	1756
	Displaying Global Session Parameters for All SRX Series Services Gateways	1758
	Displaying a Summary of Sessions for SRX Series Services Gateways	1759
	Displaying Session and Flow Information About Sessions for SRX Series Services Gateways	1759
	Displaying Session and Flow Information About a Specific Session for SRX Series Services Gateways	1760
	Using Filters to Display Session and Flow Information for SRX Series Services Gateways	1761
	Information Provided in Session Log Entries for SRX Series Services Gateways	1761
Chapter 90	Monitoring X2 Traffic By Configuring Mirror Filters	1767
	Understanding X2 Traffic Monitoring	1767
	X2 Traffic Monitoring Overview	1767
	Limitations of X2 Traffic Monitoring	1769
	X2 Traffic Terminology	1769
	Example: Configuring Mirror Filters for X2 Traffic Monitoring	1770

Part 27	Configuring Packet-Based Forwarding	
Chapter 91	Configuring Selective Stateless Packet-Based Services	1777
	Understanding Packet-Based Processing	1777
	Understanding Selective Stateless Packet-Based Services	1778
	Selective Stateless Packet-Based Services Configuration Overview	1780
	Example: Configuring Selective Stateless Packet-Based Services for End-to-End Packet-Based Forwarding	1782
	Example: Configuring Selective Stateless Packet-Based Services for Packet-Based to Flow-Based Forwarding	1792
Part 28	Configuration Statements and Operational Commands	
Chapter 92	Configuration Statements	1803
	Chassis Configuration Statement Hierarchy	1805
	Security Configuration Statement Hierarchy	1808
	[edit security flow] Hierarchy Level	1809
	[edit security forwarding-process] Hierarchy Level	1810
	aging	1811
	all-tcp	1812

Guide 7 General Packet Radio Service Feature Guide for Security Devices

Part 29	Overview
Chapter 94	Introduction to General Packet Radio Service 2189
	GPRS Overview 2189
	Gp and Gn Interfaces 2190
	Gi Interface 2190
	Operational Modes 2191
	GTP In-Service Software Upgrade 2192
Part 30	Configuring GPRS Tunnel Protocol v1
Chapter 95	Configuring Policy-Based GTP 2195
	Understanding Policy-Based GTP 2195
	Example: Enabling GTP Inspection in Policies 2196
Chapter 96	Configuring GTP Inspection Objects 2201
	Understanding GTP Inspection Objects 2201
	Example: Creating a GTP Inspection Object 2201
	Understanding GTP-U Inspection 2202
Chapter 97	Configuring GTP Message Filtering 2205
	Understanding GTP Message Filtering 2205
	Understanding GTP Message-Length Filtering 2205
	Example: Setting the GTP Message Lengths 2206
	Understanding GTP Message-Type Filtering 2207
	Supported GTP Message Types 2207
	Example: Permitting and Denying GTP Message Types 2210
	Understanding GTP Message-Rate Limiting 2211
	Understanding GTP Control Message Path Rate Limiting 2211
	Example: Limiting the Message Rate and Path Rate for GTP Control Messages 2212
	Example: Enabling GTP Sequence Number Validation 2216
	Understanding GTP IP Fragmentation 2217

Chapter 98	Configuring GTP Information Elements	2219
	Understanding GTP Information Elements	2219
	Understanding GTP APN Filtering	2220
	Example: Setting a GTP APN and a Selection Mode	2221
	Understanding IMSI Prefix Filtering of GTP Packets	2222
	Example: Setting a Combined IMSI Prefix and APN Filter	2223
	Understanding R6, R7, R8, and R9 Information Elements Removal	2224
	Supported R6 Information Elements	2224
	Example: Removing R6 Information Elements from GTP Messages	2228
	Supported R7 Information Elements	2229
	Example: Removing R7 Information Elements from GTP Messages	2230
	Supported R8 Information Elements	2231
	Example: Removing R8 Information Elements from GTP Messages	2231
	Supported R9 Information Elements	2232
	Example: Removing R9 Information Elements from GTP Messages	2233
	Understanding GTPv1 Information Element Removal	2234
	Example: Removing GTPv1 Information Elements Using IE Number	2234
Chapter 99	Configuring NAT for GTP	2237
	Understanding NAT for GTP	2237
	Example: Configuring GTP Inspection in NAT	2238
	Understanding Network Address Translation-Protocol Translation	2242
	Enhancing Traffic Engineering by Configuring NAT-PT Between an IPv4 and an IPv6 Endpoint with SCTP Multihoming	2243
Chapter 100	Configuring GGSN	2251
	Understanding GGSN Redirection	2251
	GGSN Pooling Scenarios Overview	2251
	Understanding GGSN Pooling for Scenario 1	2251
	Install Request Information to Remote SPU	2252
	Workarounds for Scenario 1	2253
	Understanding GGSN Pooling for Scenario 2	2253
	Install Tunnel Information to Remote SPU	2254
	Example: Configuring a GGSN Custom Policy	2255
	Example: Configuring Custom Applications	2258
Part 31	Configuring GPRS Tunnel Protocol v2	
Chapter 101	Configuring GTPv2	2263
	Understanding GTPv2	2263
	Understanding Policy-Based GTPv2	2265
	Example: Enabling GTPv2 Inspection in Policies	2265
	Understanding GTP Path Restart	2268
	Example: Restarting a GTPv2 Path	2269
	Understanding GTPv2 Tunnel Cleanup	2270
	Example: Setting the Timeout Value for GTPv2 Tunnels	2271
	Understanding GTPv2 Traffic Logging	2272
	Example: Enabling GTPv2 Traffic Logging	2273

Chapter 102	Configuring GTPv2 Message Filtering	2275
	Understanding GTPv2 Message Filtering	2275
	Supported GTPv2 Message Types	2275
	Example: Permitting and Denying GTPv2 Message Types	2279
	Understanding GTPv2 Message-Length Filtering	2280
	Example: Setting GTPv2 Message Lengths	2280
	Understanding GTPv2 Message-Type Filtering	2281
	Understanding GTPv2 Message-Rate Limiting	2282
	Example: Limiting the GTPv2 Message Rate	2283
Chapter 103	GTPv2 Information Elements Overview	2285
	Understanding GTPv2 Information Elements	2285
	Understanding GTPv2 IMSI Prefix and APN Filtering	2285
	Example: Setting a Combined GTPv2 IMSI Prefix and APN Filter	2287
Part 32	Configuring Stream Control Transmission Protocol	
Chapter 104	Configuring SCTP	2291
	Understanding Stream Control Transmission Protocol	2291
	SCTP Features Overview	2295
	Understanding SCTP Behavior in Chassis Cluster	2296
	Understanding SCTP Multihoming	2297
	Understanding SCTP Multichunk Inspection	2298
	SCTP Packet Structure Overview	2298
	SCTP Configuration Overview	2300
	Example: Configuring a GPRS SCTP Profile for Policy-Based Inspection to Reduce Security Risks	2301
	Example: Configuring a Security Policy to Permit or Deny SCTP Traffic	2303
Part 33	Configuration Statements and Operational Commands	
Chapter 105	Configuration Statements	2311
	Security Configuration Statement Hierarchy	2312
	[edit security gprs] Hierarchy Level	2313
	action (APN GTP)	2318
	alarm-threshold (Security GPRS)	2319
	apn	2320
	association-timeout	2321
	create-req	2321
	delete-req	2322
	drop (Security GTP)	2323
	drop (Security SCTP)	2328
	drop-threshold (Security GPRS)	2330
	echo-req	2331
	enable (GPRS GTP)	2331
	end-user-address-validated (GTP)	2332
	forward	2332
	gprs	2333
	gprs-gtp-profile	2336
	gprs-sctp-profile	2337

traceoptions (Security GTP)	2371
traceoptions (Security SCTP)	2373
u-tunnel-validated (GTP)	2374
version (Security GTP)	2375
Chapter 106	
Operational Commands	2377
clear gtp tunnels	2378
clear security gprs gtp counters	2379
clear security gprs sctp association	2381
clear security gprs sctp counters	2383
show gtp tunnels	2384
show security gprs gtp counters	2386
show security gprs gtp counters path-rate-limit	2393
show security gprs gtp gsn statistics	2394
show security gprs sctp association	2395
show security gprs sctp counters	2397

Guide 8 Interfaces Feature Guide for Security Devices

Part 34

Overview

Chapter 107

Introduction to Interfaces 2407

Understanding Interfaces 2407

Network Interfaces 2408

Services Interfaces 2408

Special Interfaces 2411

Interface Naming Conventions 2411

Understanding the Data Link Layer 2413

Physical Addressing 2414

Network Topology 2414

Error Notification 2414

Frame Sequencing 2414

Flow Control 2414

Data Link Sublayers 2414

MAC Addressing 2415

Monitoring Interfaces 2415

GRE Keepalive Time Overview 2417

Configuring GRE Keepalive Time 2417

Configuring Keepalive Time and Hold time for a GRE Tunnel Interface ... 2417

Display GRE Keepalive Time Configuration 2418

Display Keepalive Time Information on a GRE Tunnel Interface 2418

Chapter 108

Configuring Interface Logical Properties 2421

Understanding Interface Logical Properties 2421

Understanding Protocol Families 2422

Common Protocol Suites 2422

Other Protocol Suites 2422

Understanding IPv4 Addressing 2423

IPv4 Classful Addressing 2423

IPv4 Dotted Decimal Notation 2424

IPv4 Subnetting 2424

IPv4 Variable-Length Subnet Masks 2425

Understanding IPv6 Address Space, Addressing, Address Format, and Address

Types 2425

Understanding IP Version 6 (IPv6) 2425

Understanding IPv6 Address Types and How Junos OS for SRX Series

Services Gateway Uses Them 2426

IPv6 Address Scope 2427

IPv6 Address Structure 2427

Understanding IPv6 Address Space, Addressing, and Address Types ... 2428

	Understanding IPv6 Address Format	2428
	Limitations	2429
	Configuring the inet6 IPv6 Protocol Family	2429
	Enabling Flow-Based Processing for IPv6 Traffic	2430
	Configuring Flow Aggregation to Use Version 9 Flow Templates	2431
	Configuring the Traffic to Be Sampled	2432
	Configuring the Version 9 Template Properties	2432
	Restrictions	2433
	Fields Included in Each Template Type	2435
	inet Sampling Behavior	2436
	Verification	2436
	Examples: Configuring Version 9 Flow Templates	2437
	Understanding IPv6 Support on ADSL, G.SHDSL, and VDSL2 Interfaces	2440
	Example: Configuring the IPv6 Address on an ADSL Interface	2440
	Understanding MAC Limiting on Layer 3 Routing Interfaces	2443
	Overview	2443
	Limitations	2445
Chapter 109	Understanding Interface Physical Properties	2447
	Understanding Interface Physical Properties	2447
	Understanding Bit Error Rate Testing	2448
	Understanding Interface Clocking	2449
	Data Stream Clocking	2450
	Explicit Clocking Signal Transmission	2450
	Understanding Frame Check Sequences	2450
	Cyclic Redundancy Checks and Checksums	2450
	Two-Dimensional Parity	2451
	MTU Default and Maximum Values	2451
	Understanding Jumbo Frames Support for Ethernet Interfaces	2453
Chapter 110	Configuring VLAN Tagging	2455
	Understanding Virtual LANs	2455
	VLAN IDs and Ethernet Interface Types Supported on the SRX Series	
	Devices	2457
	Configuring VLAN Tagging	2457
	Configuring Single-Tag Framing	2458
	Configuring Dual Tagging	2458
	Configuring Mixed Tagging	2458
	Configuring Mixed Tagging Support for Untagged Packets	2459
Part 35	Configuring DS1 and DS3 Interfaces	
Chapter 111	Configuring DS1 Interfaces	2463
	Understanding T1 and E1 Interfaces	2463
	T1 Overview	2463
	E1 Overview	2464
	T1 and E1 Signals	2464
	Encoding	2464
	AMI Encoding	2464
	B8ZS and HDB3 Encoding	2464

	T1 and E1 Framing	2465
	ESF Framing for T1	2465
	T1 and E1 Loopback Signals	2465
	Example: Configuring a T1 Interface	2466
	Example: Deleting a T1 Interface	2468
Chapter 112	Configuring DS3 Interfaces	2471
	Understanding T3 and E3 Interfaces	2471
	Multiplexing DS1 Signals	2471
	DS2 Bit Stuffing	2472
	DS3 Framing	2472
	M13 Asynchronous Framing	2472
	C-Bit Parity Framing	2474
	Example: Configuring a T3 Interface	2476
	Example: Deleting a T3 Interface	2478
Chapter 113	Configuring 1-Port Clear Channel DS3/E3 GPIM	2481
	Understanding the 1-Port Clear Channel DS3/E3 GPIM	2481
	Supported Features	2481
	Interface Naming	2482
	Physical Interface Settings	2482
	Logical Interface Settings	2482
	Example: Configuring the 1-Port Clear-Channel DS3/E3 GPIM for M23 Mapping Mode	2484
	Example: Configuring the 1-Port Clear-Channel DS3/E3 GPIM for DS3 Port Mode	2485
	Example: Configuring the 1-Port Clear Channel DS3/E3 GPIM for E3 Port Mode	2486
Part 36	Configuring DSL Interfaces	
Chapter 114	Configuring ADSL Interfaces	2491
	ADSL Interface Overview	2491
	ADSL Systems	2492
	ADSL2 and ADSL2+	2493
	ATM CoS Support	2493
	ADSL and SHDSL Interfaces Configuration Overview	2494
	Example: Configuring ATM-over-SHDSL Network Interfaces	2498
	Example: Configuring MLPPP-over-ADSL Interfaces	2504
	Example: Configuring the DHCP Client on ADSL Interface	2505
	Example: Configuring CHAP on DSL Interfaces	2509
	Example: Configuring ATM-over-ADSL Network Interfaces	2517
Chapter 115	Configuring G.SHDSL Interfaces	2525
	SHDSL Interface Overview	2525
	G.SHDSL Mini-PIM Overview	2526
	Operating Modes and Line Rates of the G.SHDSL Mini-PIM	2527
	G.SHDSL Mini-PIM Configuration Overview	2528
	Example: Configuring the G.SHDSL Interface	2530
	Example: Configuring the G.SHDSL Interface on SRX Series Devices	2537

	Example: Configuring the G.SHDSL Interface in EFM Mode	2547
Chapter 116	Configuring VDSL2 Interfaces	2557
	VDSL2 Interface Technology Overview	2557
	VDSL2 Network Deployment Topology	2558
	VDSL2 Interface Support on SRX Series Devices	2559
	VDSL2 Interface Compatibility with ADSL Interfaces	2560
	VDSL2 Interfaces Supported Profiles	2562
	VDSL2 Interfaces Supported Features	2562
	Example: Configuring VDSL2 Interfaces in ADSL Mode (Basic)	2563
	Example: Configuring VDSL2 Interfaces in ADSL Mode (Detail)	2568
	Example: Configuring VDSL2 Interfaces (Basic)	2594
	Example: Configuring VDSL2 Interfaces (Detail)	2601
Part 37	Configuring Ethernet Interfaces	
Chapter 117	Performing Initial Configuration on Ethernet Interfaces	2629
	Understanding Ethernet Interfaces	2629
	Ethernet Access Control and Transmission	2630
	Collisions and Detection	2630
	Collision Detection	2630
	Backoff Algorithm	2630
	Collision Domains and LAN Segments	2631
	Repeaters	2631
	Bridges and Switches	2631
	Broadcast Domains	2632
	Ethernet Frames	2632
	Understanding Static ARP Entries on Ethernet Interfaces	2633
	Understanding Promiscuous Mode on Ethernet Interface	2633
	Understanding Promiscuous Mode on the SRX5K-MPC	2634
	Example: Creating an Ethernet Interface	2634
	Example: Deleting an Ethernet Interface	2635
	Example: Configuring Static ARP Entries on Ethernet Interfaces	2636
	Enabling and Disabling Promiscuous Mode on Ethernet Interfaces (CLI Procedure)	2639
	Example: Configuring Promiscuous Mode on the SRX5K-MPC	2640
Chapter 118	Configuring Aggregated Ethernet Interfaces	2645
	Understanding Aggregated Ethernet Interfaces	2645
	LAGs	2646
	LACP	2646
	Aggregated Ethernet Interfaces Configuration Overview	2647
	Understanding the Aggregated Ethernet Interfaces Device Count	2648
	Example: Configuring the Number of Aggregated Ethernet Interfaces on a Device	2649
	Understanding Physical Interfaces for Aggregated Ethernet Interfaces	2650
	Example: Associating Physical Interfaces with Aggregated Ethernet Interfaces	2650
	Understanding Aggregated Ethernet Interface Link Speed	2651
	Example: Configuring Aggregated Ethernet Link Speed	2652

	Understanding Minimum Links for Aggregated Ethernet Interfaces	2653
	Example: Configuring Aggregated Ethernet Minimum Links	2653
	Understanding Aggregated Ethernet Interface Removal	2654
	Example: Deleting Aggregated Ethernet Interfaces	2654
	Example: Deleting Aggregated Ethernet Interface Contents	2655
	Verifying Aggregated Ethernet Interfaces	2656
	Verifying Aggregated Ethernet Interfaces (terse)	2656
	Verifying Aggregated Ethernet Interfaces (extensive)	2657
	Understanding VLAN Tagging for Aggregated Ethernet Interfaces	2658
	Understanding Promiscuous Mode for Aggregated Ethernet Interfaces	2658
Chapter 119	Configuring Link Aggregation Control Protocol	2659
	Understanding LACP on Standalone Devices	2659
	Example: Configuring LACP on Standalone Devices	2660
	Verifying LACP on Standalone Devices	2661
	Verifying LACP Statistics	2661
	Verifying LACP Aggregated Ethernet Interfaces	2662
	Understanding LACP on Chassis Clusters	2663
	Chassis Cluster Redundant Ethernet Interface Link Aggregation Groups	2663
	Minimum Links	2664
	Sub-LAGs	2664
	Supporting Hitless Failover	2664
	Managing Link Aggregation Control PDUs	2665
	Example: Configuring LACP on Chassis Clusters	2665
	Verifying LACP on Redundant Ethernet Interfaces	2667
	LAG and LACP Support on the SRX5000 Module Port Concentrator	2668
Chapter 120	Configuring Gigabit Ethernet Physical Interface Modules	2671
	Understanding the 1-Port Gigabit Ethernet SFP Mini-PIM	2671
	Supported Features	2671
	Interface Names and Settings	2672
	Available Link Speeds and Modes	2672
	Link Settings	2673
	Example: Configuring the 1-Port Gigabit Ethernet SFP Mini-PIM Interface	2673
	Understanding the 2-Port 10-Gigabit Ethernet XPIM	2679
	Supported Features	2680
	Interface Names and Settings	2680
	Copper and Fiber Operating Modes	2681
	Link Speeds	2681
	Link Settings	2681
	Example: Configuring the 2-Port 10-Gigabit Ethernet XPIM Interface	2682
	Understanding the 8-Port Gigabit Ethernet SFP XPIM	2686
	Supported Features	2686
	Interface Names and Settings	2687
	Example: Configuring 8-Port Gigabit Ethernet SFP XPIMs	2688
Chapter 121	Configuring Ethernet OAM Link Fault Management	2703
	Understanding Ethernet OAM Link Fault Management for SRX Series Services Gateways	2703
	Example: Configuring Ethernet OAM Link Fault Management	2705

Chapter 122	Configuring Power over Ethernet	2711
	Understanding Power over Ethernet	2711
	SRX Series Services Gateway PoE Specifications	2711
	PoE Classes and Power Ratings	2713
	PoE Options	2713
	Example: Configuring PoE on All Interfaces	2714
	Example: Configuring PoE on an Individual Interface	2716
	Example: Disabling a PoE Interface	2719
 Part 38	 Configuring Interface Encapsulation	
Chapter 123	Interface Encapsulation Overview	2723
	Understanding Physical Encapsulation on an Interface	2723
	Understanding Frame Relay Encapsulation on an Interface	2724
	Virtual Circuits	2724
	Switched and Permanent Virtual Circuits	2724
	Data-Link Connection Identifiers	2725
	Congestion Control and Discard Eligibility	2725
	Understanding Point-to-Point Protocol	2725
	Link Control Protocol	2726
	PPP Authentication	2726
	Network Control Protocols	2727
	Magic Numbers	2727
	CSU/DSU Devices	2728
	Understanding High-Level Data Link Control	2728
	HDLC Stations	2728
	HDLC Operational Modes	2729
 Chapter 124	 Configuring Point-to-Point Protocol over Ethernet	 2731
	Understanding Point-to-Point Protocol over Ethernet	2731
	PPPoE Discovery Stage	2732
	PPPoE Session Stage	2733
	Understanding PPPoE Interfaces	2734
	Example: Configuring PPPoE Interfaces	2735
	Understanding PPPoE Ethernet Interfaces	2741
	Example: Configuring PPPoE Encapsulation on an Ethernet Interface	2741
	Understanding PPPoE ATM-over-ADSL and ATM-over-SHDSL Interfaces	2742
	Example: Configuring PPPoE Encapsulation on an ATM-over-ADSL Interface	2743
	Understanding CHAP Authentication on a PPPoE Interface	2745
	Example: Configuring CHAP Authentication on a PPPoE Interface	2745
	Verifying Credit-Flow Control	2747
	Verifying PPPoE Interfaces	2748
	Verifying R2CP Interfaces	2748
	Displaying Statistics for PPPoE	2749
	Setting Tracing Options for PPPoE	2750

Chapter 125	Configuring PPPoE-Based Radio-to-Router Protocol	2753
	PPPoE-Based Radio-to-Router Protocols Overview	2753
	Understanding the PPPoE-Based Radio-to-Router Protocol	2754
	Configuring PPPoE-Based Radio-to-Router Protocols	2756
	Example: Configuring the PPPoE-Based Radio-to-Router Protocol	2756
	Credit Flow Control for PPPoE	2759
	PPPoE Credit-Based Flow Control Configuration	2759
Chapter 126	Configuring R2CP Radio-to-Router Protocol	2761
	R2CP Radio-to-Router Protocol Overview	2761
	Configuring the R2CP Radio-to-Router Protocol	2762
Part 39	Configuring Link Services and Special Interfaces	
Chapter 127	Configuring Link Services Interfaces	2769
	Link Services Interfaces Overview	2769
	Services Available on a Link Services Interface	2770
	Link Services Exceptions	2770
	Configuring Multiclass MLPPP	2771
	Queuing with LFI	2772
	Queuing on Q2s of Constituent Links	2772
	Compressed Real-Time Transport Protocol Overview	2773
	Configuring Fragmentation by Forwarding Class	2773
	Configuring Link-Layer Overhead	2775
	Link Services Configuration Overview	2775
	Verifying the Link Services Interface	2776
	Verifying Link Services Interface Statistics	2776
	Verifying Link Services CoS Configuration	2779
	Troubleshooting the Link Services Interface	2781
	Determine Which CoS Components Are Applied to the Constituent Links	2781
	Determine What Causes Jitter and Latency on the Multilink Bundle	2782
	Determine If LFI and Load Balancing Are Working Correctly	2783
	Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device	2789
Chapter 128	Configuring Link Fragmentation and Interleaving	2791
	Understanding Link Fragmentation and Interleaving Configuration	2791
	Example: Configuring Link Fragmentation and Interleaving	2792
Chapter 129	Configuring Class-of-Service on Link Services Interfaces	2795
	Understanding How to Define Classifiers and Forwarding Classes	2795
	Example: Defining Classifiers and Forwarding Classes	2796
	Understanding How to Define and Apply Scheduler Maps	2799
	Example: Configuring Scheduler Maps	2800
	Understanding Interface Shaping Rates	2803
	Example: Configuring Interface Shaping Rates	2804

Chapter 130	Achieving Greater Bandwidth, Load Balancing, and Redundancy with Multilink Bundles	2807
	Understanding MLPPP Bundles and Link Fragmentation and Interleaving (LFI) on Serial Links	2807
	Example: Configuring an MLPPP Bundle	2808
Chapter 131	Configuring Multilink Frame Relay	2813
	Understanding Multilink Frame Relay FRF.15	2813
	Example: Configuring Multilink Frame Relay FRF.15	2813
	Understanding Multilink Frame Relay FRF.16	2816
	Example: Configuring Multilink Frame Relay FRF.16	2817
Chapter 132	Configuring Compressed Real-Time Transport Protocol	2821
	Understanding Compressed Real-Time Transport Protocol	2821
	Example: Configuring the Compressed Real-Time Transport Protocol	2821
Chapter 133	Configuring Link Services Queuing Interface	2825
	Understanding the Internal Interface LSQ-0/0/0 Configuration	2825
	Example: Upgrading from ls-0/0/0 to lsq-0/0/0 for Multilink Services	2825
Chapter 134	Understanding Special Interfaces	2829
	Understanding Management Interfaces	2829
	Understanding the Discard Interface	2830
	Understanding the Loopback Interface	2830
	Configuring a Loopback Interface	2831
Part 40	Configuring Modem Interfaces	
Chapter 135	Configuring 3G Wireless Modems for WAN Connections	2835
	3G Wireless Modem Overview	2835
	3G Wireless Modem Configuration Overview	2836
	Understanding the Dialer Interface	2837
	Dialer Interface Configuration Rules	2838
	Dialer Interface Authentication Support for GSM HSDPA 3G Wireless Modems	2838
	Dialer Interface Functions	2839
	Dialer Interface Operating Parameters	2839
	Example: Configuring the Dialer Interface	2840
	Understanding the 3G Wireless Modem Physical Interface	2845
	Example: Configuring the 3G Wireless Modem Interface	2845
	Understanding the GSM Profile	2846
	Example: Configuring the GSM Profile	2847
Chapter 136	Configuring CDMA EV-DO Modem Cards	2849
	Understanding Account Activation for CDMA EV-DO Modem Cards	2849
	Obtaining Electronic Serial Number (ESN)	2849
	Account Activation Modes	2850
	Activating the CDMA EV-DO Modem Card with IOTA Provisioning	2851
	Activating the CDMA EV-DO Modem Card with OTASP Provisioning	2851
	Activating the CDMA EV-DO Modem Card Manually	2852
	Unlocking the GSM 3G Wireless Modem	2854

Chapter 137	Configuring USB Modems for Dial Backup	2857
	USB Modem Interface Overview	2857
	USB Modem Interfaces	2858
	Dialer Interface Rules	2858
	How the Device Initializes USB Modems	2859
	USB Modem Configuration Overview	2860
	Example: Configuring a USB Modem Interface	2862
	Example: Configuring Dialer Interfaces and Backup Methods for USB Modem	
	Dial Backup	2864
	Example: Configuring a Dialer Interface for USB Modem Dial-In	2870
	Example: Configuring PAP on Dialer Interfaces	2872
	Example: Configuring CHAP on Dialer Interfaces	2873
Chapter 138	Configuring DOCSIS Mini-PIM Interfaces	2875
	DOCSIS Mini-PIM Interface Overview	2875
	Software Features Supported on DOCSIS Mini-PIMs	2876
	Example: Configuring the DOCSIS Mini-PIM Interfaces	2877
Chapter 139	Configuring Serial Interfaces	2883
	Serial Interfaces Overview	2883
	Serial Transmissions	2884
	Signal Polarity	2885
	Serial Clocking Modes	2885
	Serial Interface Transmit Clock Inversion	2886
	DTE Clock Rate Reduction	2886
	Serial Line Protocols	2886
	EIA-530	2886
	RS-232	2887
	RS-422/449	2887
	V.35	2888
	X.21	2888
	Example: Configuring a Serial Interface	2889
	Example: Deleting a Serial Interface	2891
	Understanding the 8-Port Synchronous Serial GPIM	2892
	Supported Features	2892
	Example: Configuring an 8-Port Synchronous Serial GPIM in Back-to-Back	
	SRX650 Services Gateways	2894
Part 41	Configuration Statements and Operational Commands	
Chapter 140	Configuration Statements	2913
	Chassis Configuration Statement Hierarchy	2916
	Class-of-Service Configuration Statement Hierarchy	2919
	Interfaces Configuration Statement Hierarchy	2923
	PoE Configuration Statement Hierarchy	2938

Guide 9	Layer 2 Bridging and Transparent Mode for Security Devices
----------------	-------------------------------------------------------------------

Part 42	Overview
Chapter 142	Introduction to Layer 2 Bridging and Switching
	Layer 2 Bridging and Switching Overview

Part 43	Configuring Layer 2 Bridging and Transparent Mode	
Chapter 143	Configuring Bridging and Transparent Mode	3163
	Layer 2 Bridging and Transparent Mode Overview	3163
	Layer 2 Bridging Exceptions on SRX Series Devices	3164
	Layer 2 Transparent Mode on the SRX5000 Line Module Port Concentrator	3165
	Understanding VLANs	3166
	Example: Configuring VLANs	3167
	Enhanced Layer 2 CLI Configuration Statement and Command Changes	3168
Chapter 144	Configuring Interfaces	3171
	Understanding Transparent Mode Conditions	3171
	Understanding Layer 2 Interfaces	3172
	Example: Configuring Layer 2 Logical Interfaces	3173
	Understanding VLAN Retagging	3174
	Example: Configuring VLAN Retagging for Layer 2 Transparent Mode	3174
	Understanding Integrated Routing and Bridging Interfaces	3175
	Example: Configuring an IRB Interface	3177
	Understanding Mixed Mode (Layer 2 and Layer 3)	3178
	Example: Improving Security Services by Configuring an SRX Series Device Using Mixed Mode (Layer 2 and Layer 3)	3181
Chapter 145	Configuring Security Zones and Security Policies	3189
	Understanding Layer 2 Security Zones	3189
	Example: Configuring Layer 2 Security Zones	3190
	Understanding Security Policies in Transparent Mode	3191
	Example: Configuring Security Policies in Transparent Mode	3192
	Understanding Firewall User Authentication in Transparent Mode	3194
Chapter 146	Configuring Layer 2 Forwarding Tables	3195
	Understanding Layer 2 Forwarding Tables	3195
	Example: Configuring the Default Learning for Unknown MAC Addresses	3197
Chapter 147	Configuring Layer 2 Transparent Mode Chassis Clusters	3199
	Understanding Layer 2 Transparent Mode Chassis Clusters	3199
	Example: Configuring Redundant Ethernet Interfaces for Layer 2 Transparent Mode Chassis Clusters	3201
Chapter 148	Configuring IP Spoofing in Layer 2 Transparent Mode	3203
	Understanding IP Spoofing in Layer 2 Transparent Mode	3203
	Configuring IP Spoofing in Layer 2 Transparent Mode	3204
Chapter 149	Configuring Class of Service in Transparent Mode	3207
	Class of Service Functions in Transparent Mode Overview	3207
	Understanding BA Traffic Classification on Transparent Mode Devices	3208
	Example: Configuring BA Classifiers on Transparent Mode Devices	3209
	Understanding Rewrite of Packet Headers on Transparent Mode Devices	3211
	Example: Configuring Rewrite Rules on Transparent Mode Devices	3212

Chapter 150	Configuring IPv6 Flows	3215
	Understanding IPv6 Flows in Transparent Mode	3215
	Enabling Flow-Based Processing for IPv6 Traffic	3216
	Example: Configuring Transparent Mode for IPv6 Flows	3218
Chapter 151	Configuring Secure Wire	3223
	Understanding Secure Wire	3223
	Example: Simplifying SRX Series Device Deployment with Secure Wire over Access Mode Interfaces	3225
	Example: Simplifying SRX Series Device Deployment with Secure Wire over Trunk Mode Interfaces	3228
	Example: Simplifying SRX Series Device Deployment with Secure Wire over Aggregated Interface Member Links	3232
	Example: Simplifying Chassis Cluster Deployment with Secure Wire over Redundant Ethernet Interfaces	3236
	Example: Simplifying Chassis Cluster Deployment with Secure Wire over Aggregated Redundant Ethernet Interfaces	3240
Part 44	Configuring Ethernet Ports for Switching	
Chapter 152	Configuring Switching Modes	3251
	Understanding Switching Modes	3251
	Ethernet Ports Switching Overview	3252
	Supported Devices and Ports	3252
	Integrated Bridging and Routing	3253
	Link Layer Discovery Protocol and LLDP-Media Endpoint Discovery	3253
	Types of Switch Ports	3255
	uPIM in a Daisy Chain	3255
	Q-in-Q VLAN Tagging	3256
	Example: Configuring Switching Modes	3258
	Verifying Switching Mode Configuration	3259
Chapter 153	Configuring VLANs	3261
	Understanding VLANs	3261
	Example: Configuring VLANs	3263
	Example: Configuring a Guest VLAN	3264
Chapter 154	Configuring GARP VLAN Registration Protocol	3267
	Understanding GARP VLAN Registration Protocol	3267
	Example: Configuring GARP VLAN Registration Protocol	3268
Chapter 155	Configuring Spanning Tree Protocol	3271
	Understanding the Spanning Tree Protocol	3271
	Configuring the Spanning Tree Protocol	3274
Chapter 156	Configuring Link Aggregation Control Protocol	3277
	Understanding Link Aggregation Control Protocol	3277
	Link Aggregation Benefits	3277
	Link Aggregation Configuration Guidelines	3278
	Example: Configuring Link Aggregation Control Protocol	3280

Chapter 157	Configuring 802.1X Port-Based Network Authentication	3283
	Understanding 802.1X Port-Based Network Authentication	3283
	Dynamic VLAN Assignment	3284
	MAC RADIUS Authentication	3285
	Static MAC Bypass	3285
	Guest VLAN	3285
	RADIUS Server Failure Fallback	3286
	VoIP VLAN Support	3288
	RADIUS Accounting	3288
	Server Reject VLAN	3288
	Example: Configuring 802.1x Authentication	3288
	Example: Specifying RADIUS Server Connections on the Device	3290
	Example: Configuring 802.1x Interface Settings	3292
Chapter 158	Configuring Port Security	3295
	Port Security Overview	3295
	Understanding MAC Limiting	3295
	Example: Configuring MAC Limiting	3296
Chapter 159	Configuring IGMP Snooping	3299
	Understanding IGMP Snooping	3299
	How IGMP Snooping Works	3299
	How Hosts Join and Leave Multicast Groups	3300
	Example: Configuring IGMP Snooping	3301
Chapter 160	Configuring Ethernet OAM Connectivity Fault Management	3303
	Understanding Ethernet OAM Connectivity Fault Management	3303
	Example: Configuring Ethernet OAM Connectivity Fault Management	3304
	Creating the Maintenance Domain	3315
	Creating a Maintenance Association	3316
	Configuring a Maintenance Association End Point	3316
	Configuring the Maintenance Domain MIP Half Function	3317
	Configuring the Continuity Check Protocol	3318
	Configuring the Link Trace Protocol	3319
Chapter 161	Configuring Ethernet OAM Link Fault Management	3321
	Understanding Ethernet OAM Link Fault Management for SRX Series Services Gateways	3321
	Example: Configuring Ethernet OAM Link Fault Management	3323
Part 45	Configuration Statements and Operational Commands	
Chapter 162	Configuration Statements	3331
	[edit security forwarding-options] Hierarchy Level	3332
	Access Configuration Statement Hierarchy	3333
	Class-of-Service Configuration Statement Hierarchy	3341
	Interfaces Configuration Statement Hierarchy	3345
	VLANS Configuration Statement Hierarchy	3361
	authentication-order (Access Profile)	3366
	code-points (CoS)	3367

Guide 10 Logical Systems Feature Guide for Security Devices

Part 46

Overview

Chapter 164

Introduction to Logical Systems 3527

Understanding Logical Systems for SRX Series Services Gateways 3527

Understanding the Fundamentals and Constraints of Logical Systems 3530

Understanding Licenses for Logical Systems on SRX Series Devices 3531

Understanding the Interconnect Logical System and Logical Tunnel
Interfaces 3532

Understanding Flow in Logical Systems for SRX Series Devices 3533

Understanding Junos OS SRX Series Services Gateways Architecture . . . 3535

Session Creation for Devices Running Logical Systems 3536

Understanding Flow on Logical Systems 3536

Understanding Packet Classification 3536

Handling Pass-Through Traffic for Logical Systems 3537

Pass-Through Traffic Within a Logical System 3537

Pass-Through Traffic Between Logical Systems 3537

Handling Self-Traffic 3538

Self-Initiated Traffic 3538

Traffic Terminated on a Logical System 3539

Understanding Session and Gate Limitation Control 3540

Understanding Sessions 3540

About Configuring Sessions 3540

Chapter 165

Understanding Master Logical Systems 3543

Understanding the Master Logical System and the Master Administrator

Role 3543

SRX Series Logical System Master Administrator Configuration Tasks

Overview 3544

Chapter 166	Understanding User Logical Systems	3547
	User Logical System Configuration Overview	3547
	Understanding User Logical Systems and the User Logical System Administrator Role	3549
	Example: Configuring User Logical Systems	3550
Part 47	Getting Started for Master Administrators	
Chapter 167	Configuring Device for Master Logical Systems	3563
	Example: Configuring a Root Password for the Device (Master Administrators Only)	3563
	Example: Creating User Logical Systems, Their Administrators, Their Users, and an Interconnect Logical System (Master Administrators Only)	3564
Part 48	Configuring Security Features	
Chapter 168	Configuring Master Logical System Security Profiles	3575
	Understanding Logical System Security Profiles (Master Administrators Only)	3575
	Logical Systems Security Profiles	3576
	How the System Assesses Resources Assignment and Use Across Logical Systems	3576
	Cases: Assessments of Reserved Resources Assigned Through Security Profiles	3578
	Example: Configuring Logical Systems Security Profiles (Master Administrators Only)	3580
Chapter 169	Configuring Master Logical System Security Features	3589
	Understanding Logical System Firewall Authentication	3589
	Example: Configuring Access Profiles (Master Administrators Only)	3591
	Example: Configuring Security Features for the Master Logical System	3593
	IDP in Logical Systems Overview	3598
	IDP Policies	3599
	IDP Installation and Licensing for Logical Systems	3599
	Understanding IDP Features in Logical Systems	3600
	Rulebases	3600
	Protocol Decoders	3600
	SSL Inspection	3601
	Inline Tap Mode	3601
	Multi-Detectors	3601
	Logging and Monitoring	3601
	Example: Configuring an IDP Policy for the Master Logical System	3603
	Understanding Logical System Application Identification Services	3608
	Understanding Logical System Application Firewall Services	3609
	Example: Configuring Application Firewall Services for a Master Logical System	3610
	Understanding Logical System Application Tracking Services	3614
	Understanding Route-Based VPN Tunnels in Logical Systems	3615
	Example: Configuring IKE and IPsec SAs for a VPN Tunnel (Master Administrators Only)	3616

Chapter 170	Configuring User Logical System Security Features	3621
	Understanding Logical System Zones	3621
	Example: Configuring Zones for a User Logical System	3623
	Understanding Logical System Screen Options	3626
	Example: Configuring Screen Options for a User Logical System	3626
	Understanding Logical System Security Policies	3628
	Security Policies in Logical Systems	3628
	Application Timeouts	3629
	Security Policy Allocation	3629
	Example: Configuring Security Policies in a User Logical System	3630
	Understanding Logical System Firewall Authentication	3633
	Example: Configuring Firewall Authentication for a User Logical System	3635
	IDP in Logical Systems Overview	3639
	IDP Policies	3639
	IDP Installation and Licensing for Logical Systems	3640
	Understanding IDP Features in Logical Systems	3640
	Rulebases	3640
	Protocol Decoders	3641
	SSL Inspection	3641
	Inline Tap Mode	3641
	Multi-Detectors	3641
	Logging and Monitoring	3642
	Example: Configuring an IDP Policy for a User Logical System	3643
	Example: Enabling IDP in a User Logical System Security Policy	3645
	Understanding Logical System Application Identification Services	3648
	Example: Configuring Application Firewall Services for a User Logical System	3648
	Understanding Logical System Application Tracking Services	3652
	Example: Configuring AppTrack for a User Logical System	3653
	Understanding Route-Based VPN Tunnels in Logical Systems	3655
	Example: Configuring a Route-Based VPN Tunnel in a User Logical System	3657
Part 49	Configuring Routing and Interfaces Features	
Chapter 171	Configuring Master Logical System Routing and Interfaces	3663
	Understanding Logical System Interfaces and Routing Instances	3663
	Example: Configuring Interfaces, Routing Instances, and Static Routes for the Master and Interconnect Logical Systems and Logical Tunnel Interfaces for the User Logical Systems (Master Administrators Only)	3664
	Example: Configuring OSPF Routing Protocol for the Master Logical System	3672
Chapter 172	Configuring User Logical System Routing, Interfaces, and NAT Features	3677
	Understanding Logical System Network Address Translation	3677
	Example: Configuring Network Address Translation for a User Logical System	3678
	Understanding Logical System Interfaces and Routing Instances	3681
	Example: Configuring Interfaces and Routing Instances for a User Logical System	3682

	Example: Configuring OSPF Routing Protocol for a User Logical System	3684
Part 50	Configuring Logical Systems in Chassis Cluster	
Chapter 173	Configuring Logical Systems When Device is in Chassis Cluster Mode . . .	3691
	Understanding Logical Systems in the Context of Chassis Cluster	3691
	Example: Configuring Logical Systems in an Active/Passive Chassis Cluster (Master Administrators Only)	3692
	Example: Configuring Logical Systems in an Active/Passive Chassis Cluster (IPv6) (Master Administrators Only)	3725
Part 51	Configuring IPv6 for Logical Systems	
Chapter 174	Configuring IPv6 Addresses for Logical Systems	3761
	IPv6 Addresses in Logical Systems Overview	3761
	Understanding IPv6 Dual-Stack Lite in Logical Systems	3762
	Example: Configuring IPv6 for the Master, Interconnect, and User Logical Systems (Master Administrators Only)	3763
	Example: Configuring IPv6 Zones for a User Logical System	3771
	Example: Configuring IPv6 Security Policies for a User Logical System	3774
	Example: Configuring IPv6 Dual-Stack Lite for a User Logical System	3778
Part 52	Configuring System Resources Allocation	
Chapter 175	System Resources Allocation (Master Administrators Only)	3783
	Understanding CPU Allocation and Control	3783
	CPU Control	3784
	Reserved CPU Utilization Quota for Logical Systems	3784
	CPU Control Target	3785
	Shared CPU Resources and CPU Quotas	3785
	CPU Utilization Scenario 1	3786
	CPU Utilization Scenario 2	3786
	CPU Utilization Scenario 3	3786
	Monitoring CPU Utilization	3787
	Example: Configuring CPU Utilization (Master Administrators Only)	3787
	Example: Deleting an SRX Series Services Gateway Logical System (Master Administrators Only)	3790
Part 53	Troubleshooting	
Chapter 176	Troubleshooting Logical Systems (Master Administrators Only)	3797
	Understanding Security Logs and Logical Systems	3797
	Understanding Data Path Debugging for Logical Systems	3798
	Performing Tracing for Logical Systems (Master Administrators Only)	3799
	Troubleshooting DNS Name Resolution in Logical System Security Policies (Master Administrators Only)	3803

Part 54

Chapter 177

Configuration Statements and Operational Commands

Configuration Statements 3807

Chassis Configuration Statement Hierarchy	3809
Logical-Systems Configuration Statement Hierarchy	3812
Security Configuration Statement Hierarchy	3814
System Configuration Statement Hierarchy	3815

Guide 11 MPLS Feature Guide for Security Devices

Part 55	Overview
Chapter 179	Introduction to MPLS 4061
	MPLS Overview 4061
	Label Switching 4062
	Label-Switched Paths 4062
	Label-Switching Routers 4063
	Labels 4064
	Label Operations 4064
	Penultimate Hop Popping 4065
	LSP Establishment 4065
	Static LSPs 4065
	Dynamic LSPs 4065
	MPLS Configuration Overview 4066
	Example: Deleting Security Services 4066
	Example: Enabling MPLS 4068
Part 56	Configuring Traffic Engineering
Chapter 180	Configuring MPLS Traffic Engineering and Signaling Protocols 4073
	MPLS Traffic Engineering and Signaling Protocols Overview 4073
	Understanding the LDP Signaling Protocol 4074
	Example: Configuring LDP-Signaled LSPs 4075
	Understanding the RSVP Signaling Protocol 4079
	RSVP Fundamentals 4080
	Bandwidth Reservation Requirement 4080
	Explicit Route Objects 4080
	Constrained Shortest Path First 4081
	Link Coloring 4082
	Example: Configuring RSVP-Signaled LSPs 4083
	Understanding Point-to-Multipoint LSPs 4086
	Point-to-Multipoint LSP Configuration Overview 4088
	Example: Configuring an RSVP-Signaled Point-to-Multipoint LSP 4088
Part 57	Configuring MPLS VPNs
Chapter 181	Introduction to MPLS VPNs 4109
	MPLS VPN Overview 4109
	MPLS VPN Topology 4109
	MPLS VPN Routing 4111

	VRF Instances	4111
	Route Distinguishers	4111
	Configuring a BGP Session for MPLS VPNs (CLI Procedure)	4112
	Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)	4113
	Configuring Routing Options for MPLS VPNs (CLI Procedure)	4113
	Configuring a Routing Instance for MPLS VPNs (CLI Procedure)	4114
Chapter 182	Configuring MPLS Layer 2 VPNs	4117
	Understanding MPLS Layer 2 VPNs	4117
	MPLS Layer 2 VPN Configuration Overview	4117
	Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)	4119
	Configuring Interfaces for Layer 2 VPNs (CLI Procedure)	4120
	Verifying an MPLS Layer 2 VPN Configuration	4121
Chapter 183	Configuring MPLS Layer 2 Circuit VPNs	4123
	Understanding MPLS Layer 2 Circuits	4123
	MPLS Layer 2 Circuit Configuration Overview	4124
	Configuring an MPLS Layer 2 Circuit (CLI Procedure)	4125
	Verifying an MPLS Layer 2 Circuit Configuration	4125
	Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)	4126
Chapter 184	Configuring MPLS Layer 3 VPNs	4127
	Understanding MPLS Layer 3 VPNs	4127
	MPLS Layer 3 VPN Configuration Overview	4128
	Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure)	4129
	Verifying an MPLS Layer 3 VPN Configuration	4130
Part 58	Configuring CLNS VPNs	
Chapter 185	Introduction to CLNS	4133
	CLNS Overview	4133
	CLNS Configuration Overview	4133
Chapter 186	Configuring ES-IS for CLNS	4137
	Understanding ES-IS for CLNS	4137
	Example: Configuring ES-IS for CLNS	4138
Chapter 187	Configuring IS-IS for CLNS	4141
	Understanding IS-IS for CLNS	4141
	Example: Configuring IS-IS for CLNS	4141
Chapter 188	Configuring Static Routes for CLNS	4145
	Understanding Static Routes for CLNS	4145
	Example: Configuring Static Routes for CLNS	4145
Chapter 189	Configuring BGP for CLNS	4149
	Understanding BGP for CLNS VPNs	4149
	Example: Configuring BGP for CLNS VPNs	4150
	Example: Configuring a VPN Routing Instance for CLNS	4152
	Verifying a CLNS VPN Configuration	4153

Part 59	Configuring VPLS	
Chapter 190	Introduction to VPLS	4159
	VPLS Overview	4159
	Sample VPLS Topology	4160
	VPLS on PE Routers	4161
	Using an Ethernet Switch as the VPLS CE Device	4163
	VPLS Exceptions on SRX Series Devices	4163
	VPLS Configuration Overview	4164
Chapter 191	Configuring Interfaces	4167
	Understanding VPLS Interfaces	4167
	Interface Name	4167
	Encapsulation Type	4167
	Flexible VLAN Tagging	4168
	VLAN Rewrite	4168
	Example: Configuring Routing Interfaces on the VPLS PE Router	4169
	Example: Configuring the Interface to the VPLS CE Device	4170
	VPLS Filters and Policers Overview	4171
	Example: Configuring VPLS Filters	4171
	Example: Configuring VPLS Policers	4173
Chapter 192	Configuring Routing Instances	4177
	Understanding VPLS Routing Instances	4177
	BGP Signaling	4178
	VPLS Routing Table	4178
	Trace Options	4179
	Example: Configuring the VPLS Routing Instance	4180
	Example: Configuring Automatic Site Identifiers for VPLS	4182
Chapter 193	Configuring Routing and Signaling Protocols	4185
	Example: Configuring OSPF on the VPLS PE Router	4185
	Example: Configuring RSVP on the VPLS PE Router	4186
	Example: Configuring MPLS on the VPLS PE Router	4187
	Example: Configuring LDP on the VPLS PE Router	4189
	Example: Configuring VPLS over GRE with IPsec VPNs	4190
	Example: Configuring VPLS with BGP Signaling	4207
	Example: Configuring BGP on the VPLS PE Router	4220
	Example: Configuring Routing Options on the VPLS PE Router	4221
Chapter 194	Configuring Encapsulation	4223
	Understanding VPLS VLAN Encapsulation	4223
	Understanding VPLS VLAN Encapsulation on a Logical Interface	4224
	Example: Configuring VPLS VLAN Encapsulation	4224
	Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces	4227
	Example: Configuring Extended VLAN VPLS Encapsulation	4228

Part 60	Configuration Statements and Operational Commands	
Chapter 195	Configuration Statements	4235
	Accounting-Options Configuration Statement Hierarchy	4235
	Firewall Configuration Statement Hierarchy	4237
	Forwarding-Options Configuration Statement Hierarchy	4247
	Interfaces Configuration Statement Hierarchy	4259
	Policy-Options Configuration Statement Hierarchy	4275
	[edit security address-book] Hierarchy Level	4276
	[edit security forwarding-options] Hierarchy Level	4277
	[edit security ike] Hierarchy Level	4277
	[edit security ipsec] Hierarchy Level	4279
	[edit security policies] Hierarchy Level	4281
	condition (Policy Options)	4285
	family (Security Forwarding Options)	4286
	flow-server (Forwarding Options)	4287
	forwarding-options (Security)	4289
	fragment	4290
	hash-key (Forwarding Options)	4291
	iso (Security Forwarding Options)	4292
	mpls (Security Forwarding Options)	4293
	multicast-scope	4294
	policer (Firewall)	4295
	simple-filter (Firewall)	4297
	template (Flow Monitoring)	4299
	traceoptions (Security Flow)	4300

Guide 12 Multicast Feature Guide for Security Devices

Part 61	Overview	
Chapter 197	Introduction to Multicast	4339
	Multicast Overview	4339
	Comparing Multicast to Unicast	4340
	IP Multicast Uses	4341
	IP Multicast Terminology	4342
	Reverse-Path Forwarding for Loop Prevention	4343
	Shortest-Path Tree for Loop Prevention	4343
	Administrative Scoping for Loop Prevention	4344
	Multicast Leaf and Branch Terminology	4344
	IP Multicast Addressing	4344

	Multicast Addresses	4345
	Layer 2 Frames and IPv4 Multicast Addresses	4345
	Multicast Interface Lists	4347
	Multicast Routing Protocols	4348
	T Series Router Multicast Performance	4351
	Understanding Layer 3 Multicast Functionality on the SRX5K-MPC	4351
	Supported IP Multicast Protocol Standards	4352
Part 62	Managing Group Membership	
Chapter 198	Configuring IGMP	4357
	Understanding Group Membership Protocols	4357
	Understanding IGMP	4358
	Configuring IGMP	4360
	Enabling IGMP	4361
	Modifying the IGMP Host-Query Message Interval	4362
	Modifying the IGMP Query Response Interval	4363
	Specifying Immediate-Leave Host Removal for IGMP	4364
	Filtering Unwanted IGMP Reports at the IGMP Interface Level	4365
	Accepting IGMP Messages from Remote Subnetworks	4366
	Modifying the IGMP Last-Member Query Interval	4367
	Modifying the IGMP Robustness Variable	4367
	Limiting the Maximum IGMP Message Rate	4369
	Changing the IGMP Version	4369
	Enabling IGMP Static Group Membership	4370
	Recording IGMP Join and Leave Events	4376
	Limiting the Number of IGMP Multicast Group Joins on Logical Interfaces	4377
	Tracing IGMP Protocol Traffic	4379
	Disabling IGMP	4380
	IGMP and Nonstop Active Routing	4380
Chapter 199	Examples: Configuring MLD	4383
	Understanding MLD	4383
	Configuring MLD	4386
	Enabling MLD	4387
	Modifying the MLD Version	4388
	Modifying the MLD Host-Query Message Interval	4388
	Modifying the MLD Query Response Interval	4389
	Modifying the MLD Last-Member Query Interval	4390
	Specifying Immediate-Leave Host Removal for MLD	4391
	Filtering Unwanted MLD Reports at the MLD Interface Level	4392
	Example: Modifying the MLD Robustness Variable	4393
	Limiting the Maximum MLD Message Rate	4395
	Enabling MLD Static Group Membership	4395
	Example: Recording MLD Join and Leave Events	4402
	Configuring the Number of MLD Multicast Group Joins on Logical Interfaces	4404
	Disabling MLD	4405

Part 63	Configuring Protocol Independent Multicast	
Chapter 200	Understanding PIM	4409
	PIM Overview	4409
	Basic PIM Network Components	4411
Chapter 201	Configuring PIM Basics	4413
	Configuring Basic PIM Settings	4413
	PIM Configuration Statements	4413
	Changing the PIM Version	4416
	Modifying the PIM Hello Interval	4416
	Preserving Multicast Performance by Disabling Response to the ping Utility	4417
	PIM on Aggregated Interfaces	4418
	Configuring PIM Trace Options	4418
	Disabling PIM	4420
	Disabling the PIM Protocol	4421
	Disabling PIM on an Interface	4421
	Disabling PIM for a Family	4422
	Disabling PIM for a Rendezvous Point	4422
	Configuring a Designated Router for PIM	4423
	Configuring Interface Priority for PIM Designated Router Selection	4423
	Configuring PIM Designated Router Election on Point-to-Point Links	4424
Chapter 202	Routing Content to Densely Clustered Receivers with PIM Dense Mode	4427
	Configuring PIM Dense Mode	4427
	Understanding PIM Dense Mode	4427
	Configuring PIM Dense Mode Properties	4429
	Configuring PIM Sparse-Dense Mode	4430
	Understanding PIM Sparse-Dense Mode	4430
	Mixing PIM Sparse and Dense Modes	4430
	Configuring PIM Sparse-Dense Mode Properties	4431
Chapter 203	Routing Content to Larger, Sparser Groups with PIM Sparse Mode	4433
	Examples: Configuring PIM Sparse Mode	4433
	Understanding PIM Sparse Mode	4433
	Rendezvous Point	4435
	RP Mapping Options	4436
	Designated Router	4436
	Tunnel Services PICs and Multicast	4436
	Enabling PIM Sparse Mode	4438
	Configuring PIM Join Load Balancing	4439

Modifying the Join State Timeout	4442
Example: Enabling Join Suppression	4442
Example: Configuring PIM Sparse Mode over an IPsec VPN	4447
Example: Configuring Multicast for Virtual Routers with IPv6 Interfaces	4451
Configuring Static RP	4455
Understanding Static RP	4455
Configuring Local PIM RPs	4456
Configuring the Static PIM RP Address on the Non-RP Routing Device	4457
Example: Configuring Anycast RP	4459
Understanding RP Mapping with Anycast RP	4459
Example: Configuring Multiple RPs in a Domain with Anycast RP	4460
Example: Configuring PIM Anycast With or Without MSDP	4462
Configuring a PIM Anycast RP Router Using Only PIM	4466
Configuring PIM Bootstrap Router	4467
Understanding the PIM Bootstrap Router	4467
Configuring PIM Bootstrap Properties for IPv4	4467
Configuring PIM Bootstrap Properties for IPv4 or IPv6	4469
Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain	4470
Example: Configuring PIM BSR Filters	4471
Configuring PIM Auto-RP	4471
Understanding PIM Auto-RP	4471
Configuring PIM Auto-RP	4472
Configuring Embedded RP	4476
Understanding Embedded RP for IPv6 Multicast	4476
Configuring PIM Embedded RP for IPv6	4478
Configuring PIM Filtering	4479
Understanding Multicast Message Filters	4479
Filtering MAC Addresses	4480
Filtering RP and DR Register Messages	4480
Filtering MSDP SA Messages	4481
Configuring Interface-Level PIM Neighbor Policies	4481
Filtering Outgoing PIM Join Messages	4482
Filtering Incoming PIM Join Messages	4483
Configuring Register Message Filters on a PIM RP and DR	4484
Examples: Configuring PIM RPT and SPT Cutover	4486
Understanding Multicast Rendezvous Points, Shared Trees, and Rendezvous-Point Trees	4487
Building an RPT Between the RP and Receivers	4488
PIM Sparse Mode Source Registration	4489
Multicast Shortest-Path Tree	4491
SPT Cutover	4492
SPT Cutover Control	4495
Example: Configuring the PIM Assert Timeout	4495
Example: Configuring the PIM SPT Threshold Policy	4497

Chapter 204	Receiving Content Directly from the Source with SSM	4503
	Example: Configuring Source-Specific Multicast	4503
	Understanding PIM Source-Specific Mode	4503
	PIM SSM	4504
	Source-Specific Multicast Groups Overview	4506
	Example: Configuring Source-Specific Multicast Groups with Any-Source Override	4507
	Example: Configuring an SSM-Only Domain	4510
	Example: Configuring PIM SSM on a Network	4511
	Example: Configuring SSM Mapping	4512
	Example: Configuring SSM Maps for Different Groups to Different Sources	4515
	Multiple SSM Maps and Groups for Interfaces	4515
	Example: Configuring Multiple SSM Maps Per Interface	4515
Chapter 205	Minimizing Routing State Information with Bidirectional PIM	4519
	Example: Configuring Bidirectional PIM	4519
	Understanding Bidirectional PIM	4519
	Designated Forwarder Election	4521
	Bidirectional PIM Modes	4522
	Bidirectional Rendezvous Points	4522
	PIM Bootstrap and Auto-RP Support	4523
	IGMP and MLD Support	4523
	Bidirectional PIM and Graceful Restart	4523
	Junos OS Enhancements to Bidirectional PIM	4524
	Limitations of Bidirectional PIM	4524
	Example: Configuring Bidirectional PIM	4525
Chapter 206	Rapidly Detecting Communication Failures with PIM and the BFD Protocol	4539
	Configuring PIM and the Bidirectional Forwarding Detection (BFD) Protocol	4539
	Understanding Bidirectional Forwarding Detection Authentication for PIM	4539
	BFD Authentication Algorithms	4540
	Security Authentication Keychains	4540
	Strict Versus Loose Authentication	4541
	Configuring BFD for PIM	4541
	Configuring BFD Authentication for PIM	4542
	Configuring BFD Authentication Parameters	4543
	Viewing Authentication Information for BFD Sessions	4544
Chapter 207	Configuring PIM Options	4547
	Example: Configuring Nonstop Active Routing for PIM	4547
	Understanding Nonstop Active Routing for PIM	4547
	Example: Configuring Nonstop Active Routing with PIM	4548
	Configuring PIM Sparse Mode Graceful Restart	4558
	Configuring PIM-to-IGMP and PIM-to-MLD Message Translation	4560
	Understanding PIM-to-IGMP and PIM-to-MLD Message Translation	4560
	Configuring PIM-to-IGMP Message Translation	4561
	Configuring PIM-to-MLD Message Translation	4562

Part 64	Configuring Multicast Routing Protocols	
Chapter 208	Improving Multicast Reliability with PGM	4567
	Configuring PGM	4567
	Understanding Pragmatic General Multicast	4567
	PGM Architecture and PGM Routers	4568
	PGM-Enabled Source	4569
	PGM-Enabled Receivers	4569
	PGM-Enabled Routers	4570
	PGM Configuration Guidelines	4571
Chapter 209	Connecting Routing Domains Using MSDP	4573
	Examples: Configuring MSDP	4573
	Configuring MSDP	4573
	Example: Configuring MSDP in a Routing Instance	4574
	Configuring the Interface to Accept Traffic from a Remote Source	4582
	Example: Configuring MSDP with Active Source Limits and Mesh Groups	4582
	Tracing MSDP Protocol Traffic	4588
	Disabling MSDP	4589
Chapter 210	Handling Session Announcements with SAP	4591
	Configuring the Session Announcement Protocol	4591
Chapter 211	Facilitating Multicast Delivery Across Unicast-Only Networks with AMT	4593
	Example: Configuring Automatic IP Multicast Without Explicit Tunnels	4593
	Understanding AMT	4593
	AMT Applications	4594
	AMT Operation	4596
	Configuring the AMT Protocol	4597
	Configuring Default IGMP Parameters for AMT Interfaces	4599
	Example: Configuring the AMT Protocol	4601
Chapter 212	Routing Content to Densely Clustered Receivers with DVMRP	4607
	Examples: Configuring DVMRP	4607
	Understanding DVMRP	4607
	Configuring DVMRP	4608
	Example: Configuring DVMRP	4608
	Example: Configuring DVMRP to Announce Unicast Routes	4612
	Tracing DVMRP Protocol Traffic	4615
Part 65	Configuring Multicast VPNs	
Chapter 213	Configuring PIM Join Load Balancing	4619
	PIM Join Load Balancing on Multipath MVPN Routes Overview	4619
Chapter 214	Configuring Next-Generation Multicast VPNs	4623
	Example: Configuring PIM Join Load Balancing on Next-Generation Multicast VPN	4623

Part 66	Configuring General Multicast Routing Options	
Chapter 215	Preventing Routing Loops with Reverse Path Forwarding	4635
	Examples: Configuring Reverse Path Forwarding	4635
	Understanding Multicast Reverse Path Forwarding	4635
	RPF Table	4636
	Multicast RPF Configuration Guidelines	4637
	Example: Configuring a Dedicated PIM RPF Routing Table	4637
	Example: Configuring RPF Policies	4641
	Example: Configuring PIM RPF Selection	4643
Chapter 216	Enabling Multicast Between Layer 2 and Layer 3 Devices Using Snooping	4649
	Example: Configuring IGMP Snooping	4649
	Understanding Multicast Snooping	4649
	Understanding IGMP Snooping	4650
	IGMP Snooping Interfaces and Forwarding	4651
	IGMP Snooping and Proxies	4651
	Multicast-Router Interfaces and IGMP Snooping Proxy Mode	4652
	Host-Side Interfaces and IGMP Snooping Proxy Mode	4653
	IGMP Snooping and Bridge Domains	4653
	Configuring IGMP Snooping	4653
	Configuring VLAN-Specific IGMP Snooping Parameters	4654
	Example: Configuring IGMP Snooping	4655
	Configuring IGMP Snooping Trace Operations	4661
	Example: Configuring Multicast Snooping	4663
	Understanding Multicast Snooping	4663
	Understanding Multicast Snooping and VPLS Root Protection	4664
	Configuring Multicast Snooping	4664
	Example: Configuring Multicast Snooping	4665
	Enabling Bulk Updates for Multicast Snooping	4670
	Enabling Multicast Snooping for Multichassis Link Aggregation Group Interfaces	4671
Chapter 217	Configuring Multicast Routing Options	4673
	Examples: Configuring Bandwidth Management	4673
	Understanding Bandwidth Management for Multicast	4673
	Bandwidth Management and PIM Graceful Restart	4674
	Bandwidth Management and Source Redundancy	4674
	Logical Systems and Bandwidth Oversubscription	4674
	Example: Defining Interface Bandwidth Maximums	4675
	Example: Configuring Multicast with Subscriber VLANs	4678
	Configuring Multicast Routing over IP Demux Interfaces	4691
	Classifying Packets by Egress Interface	4692
	Examples: Configuring the Multicast Forwarding Cache	4694
	Understanding the Multicast Forwarding Cache	4694
	Example: Configuring the Multicast Forwarding Cache	4694
	Example: Configuring a Multicast Flow Map	4697

Example: Configuring Ingress PE Redundancy	4701
Understanding Ingress PE Redundancy	4701
Example: Configuring Ingress PE Redundancy	4701

Part 67

Chapter 218

Configuration Statements and Operational Commands

Configuration Statements	4709
accept-remote-source	4716
accounting (Protocols IGMP)	4716
accounting (Protocols IGMP AMT Interface)	4717
accounting (Protocols IGMP Interface)	4717
accounting (Protocols MLD)	4718
accounting (Protocols MLD Interface)	4718
active-source-limit	4719
address (Anycast RPs)	4720
address (Bidirectional Rendezvous Points)	4721
address (Local RPs)	4722
address (Static RPs)	4723
algorithm	4724
amt (IGMP)	4725
amt (Protocols)	4726

Guide 13

Network Address Translation Feature Guide for Security Devices

Chapter 220	Overview	5165
	Introduction to NAT	5165
	Understanding NAT Rule Sets and Rules	5166
	NAT Rule Sets	5166
	NAT Rules	5167
	Rule Processing	5167
	NAT Rule Capacity	5168
Chapter 221	Configuring General NAT Options	5171
	Configuring NAT Using the NAT Wizard	5171
	Example: Configuring NAT for Multiple ISPs	5171
	Configuring Proxy ARP (CLI Procedure)	5183
	Verifying NAT Configuration	5184
	Monitoring Incoming Table Information	5185
	Monitoring Interface NAT Port Information	5186
Chapter 222	Configuring Source NAT	5189
	Understanding Source NAT	5189
	Source NAT Configuration Overview	5190
	Example: Configuring Source NAT for Egress Interface Translation	5191
	Example: Configuring Source NAT for Single Address Translation	5195

	Example: Configuring Source and Destination NAT Translations	5199
	Understanding Central Point Architecture Enhancements for NAT	5207
	Understanding Reverse NAT Enhancements for Central Point Architecture . . .	5207
	Understanding Source NAT Rules	5208
	Example: Configuring Source NAT with Multiple Rules	5209
	Disabling Port Randomization for Source NAT (CLI Procedure)	5215
	Monitoring Source NAT Information	5216
Chapter 223	Configuring Source NAT Pools	5223
	Understanding Source NAT Pools	5223
	Understanding Source NAT Pool Capacities	5225
	Understanding Persistent Addresses	5226
	Example: Configuring Capacity for Source NAT Pools with PAT	5226
	Understanding Source NAT Pools with Address Pooling	5228
	Understanding Source NAT Pools with Address Shifting	5229
	Example: Configuring Source NAT with Address Shifting	5229
	Understanding Source NAT Pools with PAT	5234
	Example: Configuring Source NAT for Multiple Addresses with PAT	5235
	Understanding Source NAT Pools Without PAT	5240
	Example: Configuring a Single IP Address in a Source NAT Pool Without PAT . .	5241
	Example: Configuring Source NAT for Multiple Addresses Without PAT	5245
	Understanding Source NAT Pools with Shared Address	5249
Chapter 224	Configuring Destination NAT	5251
	Understanding Destination NAT	5251
	Understanding Destination NAT Address Pools	5252
	Understanding Destination NAT Rules	5253
	Destination NAT Configuration Overview	5254
	Example: Improving Security by Configuring Destination NAT for Single Address Translation	5254
	Example: Configuring Destination NAT for IP Address and Port Translation . .	5262
	Example: Configuring Destination NAT for Subnet Translation	5267
	Monitoring Destination NAT Information	5272
Chapter 225	Configuring Static NAT	5275
	Understanding Static NAT	5275
	Understanding Static NAT Rules	5276
	Static NAT Configuration Overview	5277
	Example: Configuring Static NAT for Single Address Translation	5277
	Example: Configuring Static NAT for Subnet Translation	5281
	Example: Configuring Static NAT for Port Mapping	5286
	Monitoring Static NAT Information	5293
Chapter 226	Configuring Persistent NAT and NAT64	5297
	Understanding Persistent NAT and NAT64	5297
	Understanding Session Traversal Utilities for NAT (STUN) Protocol	5299

	Understanding NAT64 IPv6 Prefix to IPv4 Address-Persistent Translation . . .	5300
	Persistent NAT and NAT64 Configuration Overview	5302
	Example: Configuring Address-Persistent NAT64 Pools	5303
	Example: Supporting Network Configuration By Configuring Persistent NAT with Interface NAT	5305
	Example: Configuring Persistent NAT with Source NAT Address Pool (CLI) . . .	5310
	Example: Configuring Address-Dependent Filtering for IPv6 Clients	5312
	Example: Configuring Endpoint-Independent Filtering for IPv6 Clients	5315
	Example: Setting Maximum Persistent NAT Bindings	5318
Chapter 227	Configuring NAT Hairpinning	5321
	Persistent NAT Hairpinning Overview	5321
	Example: Configuring Persistent NAT Hairpinning with Source NAT Pool with Address Shifting	5322
Chapter 228	Configuring NAT for Multicast Flows	5327
	Understanding NAT for Multicast Flows	5327
	Example: Configuring NAT for Multicast Flows	5328
Chapter 229	Configuring IPv6 NAT	5337
	IPv6 NAT Overview	5337
	Source NAT Translations Supported by IPv6 NAT	5337
	Destination NAT Mappings Supported by IPv6 NAT	5338
	Static NAT Mappings Supported by IPv6 NAT	5338
	IPv6 NAT PT Overview	5339
	IPv6 NAT-PT Communication Overview	5340
	Example: Configuring an IPv4-Initiated Connection to an IPv6 Node Using Default Destination Address Prefix Static Mapping	5341
	Example: Configuring an IPv4-Initiated Connection to an IPv6 Node Using Static Destination Address One-to-One Mapping	5344
	Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Default Destination Address Prefix Static Mapping	5348
	Example: Configuring an IPv6-Initiated Connection to an IPv4 Node Using Static Destination Address One-to-One Mapping	5352
Chapter 230	Configuring IPv6 Dual-Stack	5357
	Understanding IPv6 Dual-Stack Lite	5357
	Example: Configuring IPv6 Dual-Stack Lite	5360
Chapter 231	Configuration Statements	5363
	Security Configuration Statement Hierarchy	5365
	[edit security nat] Hierarchy Level	5367
	address (Security ARP Proxy)	5370
	address (Security Destination NAT)	5371
	address (Security NDP Proxy)	5371
	address-mapping	5372
	address-persistent (Security Source NAT)	5372
	address-persistent (Security Source NAT Pool)	5373

Guide 14 Authentication and Integrated User Firewalls Feature Guide for Security Devices

Part 68	Overview
Chapter 233	Introduction to User Authentication 5499
	Understanding User Authentication for Security Devices 5499
	Understanding the Three-Tiered User Firewall Features 5499
Part 69	Configuring Firewall User Authentication
Chapter 234	Understanding Firewall Authentication 5505
	Firewall User Authentication Overview 5505
	Obtaining Username and Role Information Through Firewall Authentication . . 5506
Chapter 235	Configuring Pass-Through Authentication 5509
	Understanding Pass-Through Authentication 5509
	Example: Configuring Pass-Through Authentication 5511
	Example: Configuring HTTPS Traffic to Trigger Pass-Through Authentication . . 5517
Chapter 236	Configuring Web Authentication 5525
	Understanding Web Authentication 5525
	Example: Configuring Web Authentication 5527
	Example: Configuring HTTPS Traffic to Trigger Web Authentication 5534
Chapter 237	Configuring External Authentication Servers 5539
	Understanding External Authentication Servers 5539
	Understanding SecurID User Authentication 5540
	Example: Configuring RADIUS and LDAP User Authentication 5540
	Example: Configuring SecurID User Authentication 5545
	Example: Deleting the SecurID Node Secret File 5548
Chapter 238	Configuring Client Groups 5551
	Understanding Client Groups for Firewall Authentication 5551
	Example: Configuring the Access Profile 5551
	Example: Configuring Local Users for Client Groups 5552
Chapter 239	Customizing the Firewall Authentication Banner 5555
	Understanding Firewall Authentication Banner Customization 5555
	Example: Customizing a Firewall Authentication Banner 5555

Part 70	Configuring Infranet Authentication	
Chapter 240	Configuring UAC in a Junos OS Environment	5561
	Understanding UAC in a Junos OS Environment	5561
	Enabling UAC in a Junos OS Environment (CLI Procedure)	5563
Chapter 241	Establishing Communications Between Devices	5565
	Understanding Communications Between the Junos OS Enforcer and the IC Series UAC Appliance	5565
	Understanding Communications Between Junos OS Enforcer and a Cluster of IC Series UAC Appliances	5566
	Configuring Communications Between the Junos OS Enforcer and the IC Series UAC Appliance (CLI Procedure)	5566
Chapter 242	Configuring Policy Enforcement	5569
	Understanding Junos OS Enforcer Policy Enforcement	5569
	Configuring Junos OS Enforcer Failover Options (CLI Procedure)	5570
	Testing Junos OS Enforcer Policy Access Decisions Using Test-Only Mode (CLI Procedure)	5571
	Verifying Junos OS Enforcer Policy Enforcement	5572
	Displaying IC Series UAC Appliance Authentication Table Entries from the Junos OS Enforcer	5572
	Displaying IC Series UAC Appliance Resource Access Policies from the Junos OS Enforcer	5572
Chapter 243	Classifying Traffic with User Roles	5573
	Understanding Unified Access Control	5573
	Acquiring User Role Information from an Active Directory Authentication Server	5573
Chapter 244	Configuring Endpoint Security	5591
	Understanding Endpoint Security Using the Infranet Agent with the Junos OS Enforcer	5591
	Configuring Endpoint Security Using the Infranet Agent with the Junos OS Enforcer	5592
Chapter 245	Configuring IPsec	5593
	Understanding Junos OS Enforcer Implementations Using IPsec	5593
	Example: Configuring the Device as a Junos OS Enforcer Using IPsec (CLI)	5594
Chapter 246	Configuring Captive Portal	5603
	Understanding the Captive Portal on the Junos OS Enforcer	5603
	Understanding Captive Portal Configuration on the Junos OS Enforcer	5605
	Understanding the Captive Portal Redirect URL Options	5605
	Example: Creating a Captive Portal Policy on the Junos OS Enforcer	5606
	Example: Configuring a Redirect URL for Captive Portal	5609

Part 71	Configuring Integrated User Firewall	
Chapter 247	Understanding Integrated User Firewalls	5613
	Overview of Integrated User Firewall	5613
	Integrated User Firewall and Authentication Sources	5613
	Benefits of Integrated User Firewall	5614
	How the Integrated User Firewall Works	5614
	Deployment Scenario for User Firewall Integration with Windows Active Directory	5615
	Limitations	5615
	Understanding Active Directory Authentication Tables	5616
	Active Directory Authentication as an Authentication Source	5616
	Active Directory Authentication Tables	5617
	State Information for Active Directory Authentication Table Entries	5618
	Active Directory Authentication Table Management	5619
	Timeout Interval for Table Entries	5620
	LDAP Functionality in Integrated User Firewall	5621
	Role of LDAP in Integrated User Firewall	5622
	LDAP Server Configuration and Base Distinguished Name	5622
	LDAP's Authentication Method	5622
	LDAP Server's Username, Password, and Server Address	5622
	Caching and Calculation of User-to-Group Mappings	5623
	Updating Group Information in the Authentication Entry Table	5623
	LDAP Server Status and Statistics	5623
	Active Directory Autodiscovery	5623
	Example: Configuring Integrated User Firewall	5624
Chapter 248	Managing Event Logs	5633
	Understanding How the WMIC Reads the Event Log on the Domain Controller	5633
	Controller	5633
	Windows Management Instrumentation Client	5633
	WMIC Reads the Event Log on the Domain Controller	5634
	Specifying IP Filters to Limit IP-to-User Mapping	5634
	Event Log Verification and Statistics	5634
	Using Firewall Authentication as an Alternative to WMIC	5635
	WMIC Limitations	5635
	Firewall Authentication as a Backup Method for IP Address-to-User Mappings	5635
	Understanding Integrated User Firewall Domain PC Probing	5636
	Overview of Domain PC Probing	5636
	Probing Domain PCs for User Information	5636
	Probe Response	5637
	Probe Configuration	5638
	Probe Rate and Statistics	5638
Part 72	Configuration Statements and Operational Commands	
Chapter 249	Configuration Statements	5643

Guide 15 UTM Feature Guide for Security Devices

Part 73	Overview
Chapter 251	Understanding Unified Threat Management 5879
	Unified Threat Management Overview 5879
	Understanding UTM Custom Objects 5881
Chapter 252	Managing UTM Licensing 5883
	Understanding UTM Licensing 5883
	Updating UTM Licenses (CLI Procedure) 5884
Chapter 253	Configuring WELF Logging 5885
	Understanding WELF Logging for UTM Features 5885
	Example: Configuring WELF Logging for UTM Features 5886
Chapter 254	Configuring UTM for Chassis Cluster 5889
	Understanding UTM Support for Active/Active Chassis Cluster 5889
	Understanding Chassis Cluster Support for UTM Modules 5891
Part 74	Configuring Antispam Filtering
Chapter 255	Understanding Antispam Filtering 5897
	Antispam Filtering Overview 5897
	Handling Spam Messages 5897
	Blocking Detected Spam 5897
	Tagging Detected Spam 5898

Chapter 256	Configuring Server-Based Antispam Filtering	5899
	Understanding Server-Based Antispam Filtering	5899
	Server-Based Antispam Filtering Configuration Overview	5900
	Example: Configuring Server-Based Antispam Filtering	5901
Chapter 257	Configuring Local List Antispam Filtering	5909
	Understanding Local List Antispam Filtering	5909
	Local List Antispam Filtering Configuration Overview	5910
	Example: Configuring Local List Antispam Filtering	5910
Part 75	Configuring Express Antivirus Protection and Pattern Updates	
Chapter 258	Configuring Express Antivirus Protection	5921
	Express Antivirus Protection Overview	5921
	Express Antivirus Packet-Based Scanning Versus File-Based Scanning	5921
	Express Antivirus Expanded MIME Decoding Support	5922
	Express Antivirus Scan Result Handling	5922
	Express Antivirus Intelligent Prescreening	5922
	Express Antivirus Limitations	5922
	Express Antivirus Configuration Overview	5923
	Example: Configuring Express Antivirus Custom Objects	5924
	Configuring Express Antivirus Custom Objects (J-Web Procedure)	5926
	Example: Configuring Express Antivirus Feature Profiles	5929
	Configuring Express Antivirus Feature Profiles (J-Web Procedure)	5934
	Example: Configuring Express Antivirus UTM Policies	5936
	Configuring Express Antivirus UTM Policies (J-Web Procedure)	5937
	Example: Attaching Express Antivirus UTM Policies to Security Policies	5938
	Attaching Express Antivirus UTM Policies to Security Policies (J-Web Procedure)	5939
Chapter 259	Configuring Express Antivirus Pattern Updates	5941
	Understanding Express Antivirus Scanner Pattern Updates	5941
	Example: Automatically Updating Express Antivirus Patterns	5942
	Example: Automatically Updating Express Antivirus Patterns (J-Web)	5943
	Manually Updating, Reloading, and Deleting Express Antivirus Patterns (CLI Procedure)	5943
Part 76	Configuring Full Antivirus Protection and Pattern Updates	
Chapter 260	Configuring Full Antivirus Protection	5947
	Full Antivirus Protection Overview	5947
	Full Antivirus Configuration Overview	5948
	Full Antivirus Pattern Update Configuration Overview	5949
	Example: Configuring Full Antivirus Custom Objects	5950
	Configuring Full Antivirus Custom Objects (J-Web Procedure)	5953
	Example: Configuring Full Antivirus Feature Profiles	5955
	Configuring Full Antivirus Feature Profiles (J-Web Procedure)	5961
	Example: Configuring Full Antivirus UTM Policies	5964
	Configuring Full Antivirus UTM Policies (J-Web Procedure)	5965
	Example: Attaching Full Antivirus UTM Policies to Security Policies	5966

	Attaching Full Antivirus UTM Policies to Security Policies (J-Web Procedure) . . .	5967
Chapter 261	Configuring Full Antivirus Pattern Updates	5969
	Understanding Full Antivirus Pattern Updates	5969
	Example: Configuring the Full Antivirus Pattern Update Server	5970
	Example: Automatically Updating Full Antivirus Patterns (J-Web)	5971
	Example: Automatically Updating Full Antivirus Patterns	5972
	Manually Updating, Reloading, and Deleting Full Antivirus Patterns (CLI Procedure)	5973
Chapter 262	Configuring File Scanning	5975
	Understanding the Full Antivirus Internal Scan Engine	5975
	Understanding Full Antivirus Scan Mode Support	5976
	Configuring Full Antivirus File Extension Scanning (CLI Procedure)	5977
	Example: Configuring Full Antivirus File Extension Scanning	5977
	Understanding Full Antivirus Scan Level Settings	5978
	Example: Configuring Full Antivirus Scan Settings at Different Levels	5979
	Understanding Full Antivirus Intelligent Prescreening	5981
	Example: Configuring Full Antivirus Intelligent Prescreening	5981
	Understanding Full Antivirus Content Size Limits	5982
	Configuring Full Antivirus Content Size Limits (CLI Procedure)	5983
	Understanding Full Antivirus Decompression Layer Limits	5983
	Configuring Full Antivirus Decompression Layer Limits (CLI Procedure)	5984
	Understanding Full Antivirus Scanning Timeouts	5984
	Configuring Full Antivirus Scanning Timeouts (CLI Procedure)	5984
	Understanding Full Antivirus Scan Session Throttling	5985
	Configuring Full Antivirus Scan Session Throttling (CLI Procedure)	5985
Chapter 263	Configuring Scan Results and Fallback Options	5987
	Understanding Full Antivirus Scan Result Handling	5987
	Monitoring Antivirus Scan Engine Status	5987
	Monitoring Antivirus Session Status	5988
	Monitoring Antivirus Scan Results	5989
	Understanding Antivirus Scanning Fallback Options	5991
	Example: Configuring Antivirus Scanning Fallback Options	5992
Chapter 264	Configuring Application Protocol Scanning	5995
	Understanding Full Antivirus Application Protocol Scanning	5995
	Understanding HTTP Scanning	5996
	Enabling HTTP Scanning (CLI Procedure)	5997
	Understanding FTP Antivirus Scanning	5997
	Enabling FTP Antivirus Scanning (CLI Procedure)	5998
	Understanding SMTP Antivirus Scanning	5998
	Understanding SMTP Antivirus Mail Message Replacement	5999
	Understanding SMTP Antivirus Sender Notification	5999
	Understanding SMTP Antivirus Subject Tagging	6000
	Enabling SMTP Antivirus Scanning (CLI Procedure)	6000
	Understanding POP3 Antivirus Scanning	6000
	Understanding POP3 Antivirus Mail Message Replacement	6001
	Understanding POP3 Antivirus Sender Notification	6001

	Understanding POP3 Antivirus Subject Tagging	6001
	Enabling POP3 Antivirus Scanning (CLI Procedure)	6002
	Understanding IMAP Antivirus Scanning	6002
	Understanding IMAP Antivirus Mail Message Replacement	6002
	Understanding IMAP Antivirus Sender Notification	6003
	Understanding IMAP Antivirus Subject Tagging	6003
	Understanding IMAP Antivirus Scanning Limitations	6003
	Enabling IMAP Antivirus Scanning (CLI Procedure)	6004
Chapter 265	Configuring Whitelists	6005
	Understanding MIME Whitelists	6005
	Example: Configuring MIME Whitelists to Bypass Antivirus Scanning	6006
	Understanding URL Whitelists	6006
	Configuring URL Whitelists to Bypass Antivirus Scanning (CLI Procedure) . . .	6007
Chapter 266	Configuring HTTP Trickling	6009
	Understanding HTTP Trickling	6009
	Configuring HTTP Trickling to Prevent Timeouts During Antivirus Scanning (CLI Procedure)	6009
Chapter 267	Configuring Notifications	6011
	Understanding Protocol-Only Virus-Detected Notifications	6011
	Configuring Protocol-Only Virus-Detected Notifications (CLI Procedure)	6011
	Understanding E-Mail Virus-Detected Notifications	6012
	Configuring E-Mail Virus-Detected Notifications (CLI Procedure)	6012
	Understanding Custom Message Virus-Detected Notifications	6013
	Configuring Custom Message Virus-Detected Notifications (CLI Procedure) . .	6013
Part 77	Configuring and Managing Sophos Antivirus Protection	
Chapter 268	Configuring Sophos Antivirus Protection	6017
	Sophos Antivirus Protection Overview	6017
	Sophos Antivirus Features	6018
	Understanding Sophos Antivirus Data File Update	6018
	Comparison of Sophos Antivirus to Kaspersky Antivirus	6019
	Sophos Antivirus Configuration Overview	6020
	Example: Configuring Sophos Antivirus Custom Objects	6020
	Example: Configuring Sophos Antivirus Feature Profile	6024
	Example: Configuring Sophos Antivirus UTM Policies	6030
	Example: Configuring Sophos Antivirus Firewall Security Policies	6031
	Managing Sophos Antivirus Data Files	6033
Part 78	Configuring and Monitoring Content Filtering	
Chapter 269	Configuring Content Filtering	6037
	Content Filtering Overview	6037
	Understanding Content Filtering Protocol Support	6038
	HTTP Support	6038
	FTP Support	6039

	E-Mail Support	6039
	Specifying Content Filtering Protocols (CLI Procedure)	6039
	Content Filtering Configuration Overview	6040
	Example: Configuring Content Filtering Custom Objects	6041
	Example: Configuring Content Filtering Feature Profiles	6043
	Example: Configuring Content Filtering UTM Policies	6047
	Example: Attaching Content Filtering UTM Policies to Security Policies	6048
	Monitoring Content Filtering Configurations	6050
Part 79	Configuring Web Filtering	
Chapter 270	Configuring Web Filtering	6055
	Web Filtering Overview	6056
	Enhanced Web Filtering Overview	6057
	Understanding Enhanced Web Filtering Process	6058
	Functional Requirements for Enhanced Web Filtering	6059
	Example: Configuring Enhanced Web Filtering	6063
	Understanding the Quarantine Action for Enhanced Web Filtering	6071
	Example: Configuring Site Reputation Action for Enhanced Web Filtering	6072
	Understanding Integrated Web Filtering	6078
	Integrated Web Filtering Process	6078
	Integrated Web Filtering Cache	6079
	Integrated Web Filtering Profiles	6079
	Profile Matching Precedence	6080
	Example: Configuring Integrated Web Filtering	6080
	Understanding Local Web Filtering	6089
	User-Defined URL Categories	6089
	Local Web Filtering Process	6089
	Local Web Filtering Profiles	6090
	Profile Matching Precedence	6090
	Example: Configuring Local Web Filtering	6091
	Understanding Redirect Web Filtering	6097
	Example: Enhancing Security by Configuring Redirect Web Filtering Using Custom Objects	6098
	Displaying Global SurfControl URL categories	6106
	Monitoring Web Filtering Configurations	6106
Part 80	Configuration Statements and Operational Commands	
Chapter 271	Configuration Statements	6111
	Security Configuration Statement Hierarchy	6116
	SMTP Configuration Statement Hierarchy	6117
	[edit security policies] Hierarchy Level	6118
	[edit security utm] Hierarchy Level	6122
	action (Security UTM Web Filtering)	6130
	address-blacklist	6130
	address-whitelist	6131
	admin-email	6131
	administrator-email (Security Fallback Block)	6132

administrator-email (Security Virus Detection)	6132
allow-email (Security Fallback Block)	6133
allow-email (Security Virus Detection)	6133
application (Security Policies)	6134
application-proxy (Security UTM)	6135
anti-spam (Security Feature Profile)	6136
anti-spam (Security UTM Policy)	6136
anti-virus (Security Feature Profile)	6137
anti-virus (Security UTM Policy)	6141
block-command	6141
block-content-type	6142
block-extension	6142
block-message (Security UTM)	6143
block-mime	6143
cache	6144
category (Security Logging)	6145
category (Security Web Filtering)	6146
content-filtering (Security Feature Profile)	6152
content-filtering (Security UTM Policy)	6153
content-size	6154
content-size (Security Antivirus Sophos Engine)	6155
content-size-limit	6156
corrupt-file	6156
custom-block-message	6157
custom-message (Security Content Filtering)	6157
custom-message (Security Email Notify)	6158
custom-message (Security Fallback Block)	6158
custom-message (Security Fallback Non-Block)	6159
custom-message (Security Virus Detection)	6159
custom-message-subject (Security Email Notify)	6160
custom-message-subject (Security Fallback Block)	6160
custom-message-subject (Security Fallback Non-Block)	6161
custom-message-subject (Security Virus Detection)	6161
custom-objects	6162
custom-tag-string	6163
custom-url-category	6164
decompress-layer	6165
decompress-layer-limit	6165
default (Security Antivirus)	6166
default (Security Antivirus Sophos Engine)	6166
default (Security UTM)	6167
default (Security Web Filtering)	6168
display-host (Security Fallback Block)	6169
display-host (Security Virus Detection)	6169
download-profile (Security Antivirus FTP)	6170
download-profile (Security Content Filtering FTP)	6170
email-notify	6171
engine-not-ready	6171
engine-not-ready (Security Antivirus Sophos Engine)	6172

exception (Security Antivirus Mime Whitelist)	6172
exception (Security Content Filtering)	6173
fallback-block (Security Antivirus)	6173
fallback-non-block (Security Antivirus)	6174
fallback-options (Security Antivirus Juniper Express Engine)	6175
fallback-options (Security Antivirus Kaspersky Lab Engine)	6176
fallback-options (Security Antivirus Sophos Engine)	6177
fallback-settings (Security Web Filtering)	6178
fallback-settings (Security Web Filtering Juniper Local)	6178
fallback-settings (Security Web Filtering Websense Redirect)	6179
feature-profile	6180

Guide 16 VPN Feature Guide for Security Devices

Part 81

Chapter 273

Overview

Introduction to IPsec VPNs	6337
IPsec VPN Overview	6337
IPsec VPN Topologies	6338
Comparison of Policy-Based VPNs and Route-Based VPNs	6338
Security Associations	6339
IPsec Key Management	6340
Manual Key	6340
AutoKey IKE	6341
Diffie-Hellman Exchange	6341
IPsec Security Protocols	6342
AH Protocol	6342
ESP Protocol	6343
IPsec Tunnel Negotiation	6343
Understanding IKE and IPsec Packet Processing	6344
Packet Processing in Tunnel Mode	6345
IKE Packet Processing	6346
IPsec Packet Processing	6349
Understanding Phase 1 of IKE Tunnel Negotiation	6351
Main Mode	6352
Aggressive Mode	6353
Understanding Phase 2 of IKE Tunnel Negotiation	6353
Proxy IDs	6354
Perfect Forward Secrecy	6354

	Replay Protection	6354
	IPsec VPN with Autokey IKE Configuration Overview	6355
	IPsec VPN with Manual Keys Configuration Overview	6356
	Recommended Configuration Options for Site-to-Site VPN with Static IP Addresses	6356
	Recommended Configuration Options for Site-to-Site or Dialup VPNs with Dynamic IP Addresses	6357
	Configuring Remote IKE IDs for Site-to-Site VPNs	6358
	Configuring IPsec VPN Using the VPN Wizard	6359
	Understanding Suite B Cryptographic Suites	6360
Chapter 274	Understanding VPN Tunnel Management	6363
	Understanding Distributed VPNs in SRX Series Services Gateways	6363
	Understanding VPN Support for Inserting Services Processing Cards	6364
Part 82	Configuring Route-Based IPsec VPNs	
Chapter 275	Configuring Route-Based VPNs	6369
	Understanding Route-Based IPsec VPNs	6369
	Example: Configuring a Route-Based VPN	6370
Chapter 276	Configuring Hub-and-Spoke VPNs	6389
	Understanding Hub-and-Spoke VPNs	6389
	Example: Configuring a Hub-and-Spoke VPN	6390
Chapter 277	Configuring VPNs for IKEv2	6423
	Understanding Internet Key Exchange Version 2	6423
	Understanding IKEv2 Configuration Payload	6424
	Example: Configuring a Route-Based VPN for IKEv2	6426
	Understanding Pico Cell Provisioning	6442
	Example: Configuring the SRX Series for Pico Cell Provisioning with IKEv2 Configuration Payload	6445
Chapter 278	Configuring Secure Tunnel Interface in a Virtual Router	6471
	Understanding Virtual Router Support for Route-Based VPNs	6471
	Understanding Virtual Router Limitations	6472
	Example: Configuring an st0 Interface in a Virtual Router	6472
Chapter 279	Configuring Dual Stack Tunnels over an External Interface	6477
	Understanding VPN Tunnel Modes	6477
	Understanding Dual-Stack Tunnels over an External Interface	6479
	Example: Configuring Dual-Stack Tunnels over an External Interface	6480
Chapter 280	Configuring Traffic Selectors in Route-Based VPNs	6491
	Understanding Traffic Selectors in Route-Based VPNs	6491
	Traffic Selector Configuration	6491
	Traffic Selector Flexible Matches	6492
	Multiple Tunnels for Traffic Selector Configuration	6493
	Limitations	6494
	Example: Configuring Traffic Selectors in a Route-Based VPN	6494
	Understanding Auto Route Insertion	6508

	Understanding Traffic Selectors and Overlapping IP Addresses	6509
	Overlapping IP Addresses in Different VPNs Bound to the Same st0	
	Interface	6509
	Overlapping IP Addresses in the Same VPN Bound to the Same st0	
	Interface	6510
	Overlapping IP Addresses in Different VPNs Bound to Different st0	
	Interfaces	6510
Part 83	Configuring Policy-Based IPsec VPNs	
Chapter 281	Configuring Policy-Based VPNs	6517
	Understanding Policy-Based IPsec VPNs	6517
	Example: Configuring a Policy-Based VPN	6518
Part 84	Configuring VPNs with NAT-T	
Chapter 282	Configuring Route-Based and Policy-Based VPNs with NAT-T	6539
	Understanding NAT-T	6539
	Example: Configuring a Route-Based VPN with Only the Responder Behind a	
	NAT Device	6540
	Example: Configuring a Policy-Based VPN with Both an Initiator and a Responder	
	Behind a NAT Device	6568
	Example: Configuring NAT-T with Dynamic Endpoint VPN	6594
Part 85	Configuring IPsec VPN Tunnels with Chassis Clusters	
Chapter 283	Configuring IPsec VPN Tunnels with Chassis Clusters	6615
	Understanding Dual Active-Backup IPsec VPN Chassis Clusters	6615
	Understanding Loopback Interface for a High Availability VPN	6616
	Example: Configuring Redundancy Groups for Loopback Interfaces	6617
Part 86	Configuring IPv6 IPsec VPNs	
Chapter 284	Configuring IPv6 IPsec VPNs	6627
	VPN Feature Support for IPv6 Addresses	6627
	Understanding IPv6 IKE and IPsec Packet Processing	6631
	IPv6 IKE Packet Processing	6631
	IPv6 IPsec Packet Processing	6632
	AH Protocol in IPv6	6633
	ESP Protocol in IPv6	6633
	IPv4 Options and IPv6 Extension Headers with AH and ESP	6634
	Integrity Check Value (ICV) Calculation in IPv6	6634
	Header Construction in Tunnel Modes	6635
	IPv6 IPsec Configuration Overview	6637
	Example: Configuring an IPv6 IPsec Manual VPN	6637

Part 87	Configuring Public Key Infrastructure	
Chapter 285	Managing Digital Certificates with PKI	6643
	Understanding Certificates and PKI	6643
	Certificate Signatures and Verification	6643
	Public Key Infrastructure	6644
	PKI Management and Implementation	6646
	Internet Key Exchange	6647
	Cryptographic Key Handling Overview	6648
	Digital Certificates Configuration Overview	6648
	Enabling Digital Certificates Online: Configuration Overview	6649
	Manually Generating Digital Certificates: Configuration Overview	6649
Chapter 286	Configuring Digital Certificate Validation	6651
	Understanding Digital Certificate Validation	6651
	Policy Validation	6651
	Policy OIDs Configured on SRX Series Devices	6652
	No Policy OIDs Configured on SRX Series Devices	6652
	Path Length Validation	6653
	Key Usage	6654
	EE Certificates	6654
	CA Certificates	6654
	Issuer and Subject Distinguished Name Validation	6655
	Example: Improving Digital Certificate Validation by Configuring Policy OIDs on an SRX Series Device	6656
Chapter 287	Generating a Public-Private Key Pair	6661
	Understanding Public Key Cryptography	6661
	Example: Generating a Public-Private Key Pair	6662
Chapter 288	Configuring Certificate Authority Profiles	6663
	Understanding Certificate Authority Profiles	6663
	Example: Configuring a CA Profile	6663
Chapter 289	Configuring CA and Local Certificates	6665
	Understanding Online CA Certificate Enrollment	6665
	Understanding Local Certificate Requests	6665
	Enrolling a CA Certificate Online Using SCEP	6666
	Example: Enrolling a Local Certificate Online Using SCEP	6667
	Example: Using SCEP to Automatically Renew a Local Certificate	6669
	Example: Manually Generating a CSR for the Local Certificate and Sending it to the CA Server	6670
	Understanding Certificate Loading	6671
	Example: Loading CA and Local Certificates Manually	6672
	Deleting Certificates (CLI Procedure)	6673
	Example: Configuring PKI	6674

Chapter 290	Managing Certificate Revocation 6703
	Understanding Online Certificate Status Protocol 6703
	Understanding Certificate Revocation Lists 6704
	Comparison of Online Certificate Status Protocol and Certificate Revocation List 6705
	Improving Security by Configuring OCSP for Certificate Revocation Status . . . 6706
	Example: Manually Loading a CRL onto the Device 6721
	Example: Configuring a Certificate Authority Profile with CRL Locations 6722
	Example: Verifying Certificate Validity 6723
	Deleting a Loaded CRL (CLI Procedure) 6725
Chapter 291	Generating Self-Signed Certificates 6727
	Understanding Self-Signed Certificates 6727
	Generating Self-Signed Certificates 6727
	Automatically Generating Self-Signed Certificates 6728
	Manually Generating Self-Signed Certificates 6728
	Example: Manually Generating Self-Signed Certificates 6728
	Using Automatically Generated Self-Signed Certificates (CLI Procedure) 6729
Chapter 292	Configuring a Device for Certificate Chains 6731
	Understanding Certificate Chains 6731
	Multilevel Hierarchy for Certificate Authentication 6731
	Dynamic CRL Download and Checking 6733
	Example: Configuring a Device for Peer Certificate Chain Validation 6734
Part 88	Configuring AutoVPN
Chapter 293	Configuring AutoVPN on Hub-and-Spoke Devices 6745
	Understanding AutoVPN 6745
	Secure Tunnel Modes 6745
	Authentication 6746
	Configuration and Management 6746
	Understanding AutoVPN Limitations 6747
	Understanding Spoke Authentication in AutoVPN Deployments 6748
	Group IKE ID Configuration on the Hub 6748
	Excluding a Spoke Connection 6750
	AutoVPN Configuration Overview 6750
	Example: Configuring Basic AutoVPN with iBGP 6751
	Example: Configuring Basic AutoVPN with OSPF 6776
	Example: Configuring AutoVPN with iBGP and ECMP 6800
	Example: Configuring AutoVPN with iBGP and Active-Backup Tunnels 6825
Chapter 294	Configuring Auto Discovery VPNs 6853
	Understanding Auto Discovery VPN 6853
	ADVPN Protocol 6853
	Establishing a Shortcut 6854
	Shortcut Initiator and Responder Roles 6855
	Shortcut Attributes 6855
	Shortcut Termination 6856

	ADVPN Configuration Limitations	6857
	Understanding Traffic Routing with Shortcut Tunnels	6858
	Example: Improving Network Resource Utilization with Auto Discovery VPN Dynamic Tunnels	6860
	Enabling OSPF to Update Routes Quickly After ADVPN Shortcut Tunnels Are Established	6898
Chapter 295	Configuring AutoVPN and Traffic Selectors	6901
	Understanding AutoVPN with Traffic Selectors	6901
	Example: Forwarding Traffic Through an AutoVPN Tunnel with Traffic Selectors	6902
	Example: Ensuring VPN Tunnel Availability with AutoVPN and Traffic Selectors	6918
Part 89	Monitoring and Improving VPN Traffic Performance	
Chapter 296	Configuring VPN Monitoring Features	6943
	Understanding VPN Alarms and Auditing	6943
	Example: Setting an Audible Alert as Notification of a Security Alarm	6945
	Example: Generating Security Alarms in Response to Potential Violations	6946
	Understanding VPN Monitoring and DPD	6948
	Understanding Dead Peer Detection	6949
	Understanding VPN Monitoring	6951
	Understanding Global SPI and VPN Monitoring Features	6951
	Example: Configuring Global SPI and VPN Monitoring Features	6952
	Understanding Tunnel Events	6952
Chapter 297	Improving IPsec VPN Traffic Performance	6955
	Understanding VPN Session Affinity	6955
	Enabling VPN Session Affinity	6957
	Accelerating the IPsec VPN Traffic Performance	6958
Part 90	Troubleshooting	
Chapter 298	Tunnel Events	6963
	Tunnel Events	6963

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

Documentation Conventions

[Table 1](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

[Table 2](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
<i>Italic text like this</i>	<ul style="list-style-type: none">Introduces or emphasizes important new terms.Identifies guide names.Identifies RFC and Internet draft titles.	<ul style="list-style-type: none">A policy <i>term</i> is a named structure that defines match conditions and actions.<i>Junos OS CLI User Guide</i>RFC 1997, <i>BGP Communities Attribute</i>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none">To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level.The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (<i>string1</i> <i>string2</i> <i>string3</i>)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [<i>community-ids</i>]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none">In the Logical Interfaces box, select All Interfaces.To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page of the Juniper Networks TechLibrary site at <http://www.juniper.net/techpubs/index.html>, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at <http://www.juniper.net/techpubs/feedback/>.
- E-mail—Send your comments to techpubs-comments@juniper.net. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <http://kb.juniper.net/InfoCenter/>

- Join and participate in the Juniper Networks Community Forum:
<http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

Application Layer Gateways Feature Guide for Security Devices

PART 1

Overview

- [Introduction to ALGs on page 3](#)

CHAPTER 1

Introduction to ALGs

- [ALG Overview on page 3](#)
- [Understanding Custom ALG Services on page 4](#)
- [Understanding IPv6 ALG Support for ICMP on page 5](#)

ALG Overview

An Application Layer Gateway (ALG) is a software component that is designed to manage specific protocols such as Session Initiation Protocol (SIP) or FTP on Juniper Networks devices running Junos OS. The ALG module is responsible for Application-Layer aware packet processing.

ALG functionality can be triggered either by a service or application configured in the security policy:

- A service is an object that identifies an application protocol using Layer 4 information (such as standard and accepted TCP and UDP port numbers) for an application service (such as Telnet, FTP, SMTP, and HTTP).
- An application specifies the Layer 7 application that maps to a Layer 4 service.

A predefined service already has a mapping to a Layer 7 application. However, for custom services, you must link the service to an application explicitly, especially if you want the policy to apply an ALG.

ALGs for packets destined to well-known ports are triggered by service type. The ALG intercepts and analyzes the specified traffic, allocates resources, and defines dynamic policies to permit the traffic to pass securely through the device:

1. When a packet arrives at the device, the flow module forwards the packet according to the security rule set in the policy.
2. If a policy is found to permit the packet, the associated service type or application type is assigned and a session is created for this type of traffic.
3. If a session is found for the packet, no policy rule match is needed. The ALG module is triggered if that particular service or application type requires the supported ALG processing.

The ALG also inspects the packet for embedded IP address and port information in the packet payload, and performs Network Address Translation (NAT) processing if necessary. The ALG also opens a gate for the IP address and port number to permit data exchange for the session. The control session and data session can be coupled to have the same timeout value, or they can be independent.

ALGs are supported on chassis clusters.

The ALG message buffer optimization is enhanced to reduce high memory consumption. A message buffer is allocated only when the packet is ready to process. The buffer is freed after the packet completes ALG handling, including modifying the payload, performing NAT, opening a pinhole for a new connection between a client and a server, and transferring data between a client and a server located on opposite sides of a Juniper Networks device.

The maximum size of the jbuf is 9 Kb. If the message buffer size is more than 9 Kb, the entire message cannot be transferred to the ALG packet handler. This causes subsequent packets in the session to bypass ALG handling, resulting in a transaction failure.

Understanding Custom ALG Services

By default, ALGs are bound to predefined services. For example, the FTP ALG is bound to junos-ftp, the RTSP ALG is bound to junos-rtsp, and so on.

A predefined service already has a mapping to a Layer 7 application. However, for custom services, you must link the service to an application explicitly, especially if you want the policy to apply an ALG.

When you apply predefined services to your policy, traffic matching the service will be sent to its corresponding ALG for further processing. However, under some circumstances, the customer needs to define custom services in order to achieve the following:

- Utilize the ALG handler to process special traffic, with customer-specified protocols, destination ports and so on.
- Permit traffic but bypass ALG processing, when traffic matches predefined services that bind with ALG.
- Add more applications to the current ALG's application set.

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

The three usages of custom services are illustrated below, considering MSRPC ALG as an example:

- **Utilize the ALG handler to process special traffic:**

```
[edit]
user@host# set applications application customer-msrpc application-protocol ms-rpc
user@host# set applications application customer-msrpc protocol tcp
user@host# set applications application customer-msrpc destination-port 6000
```

Traffic with TCP destination port 6000 will be sent to MSRPC ALG for further processing.

- **Permit traffic but bypass ALG processing:**

```
[edit]
user@host# set applications application customer-ignore application-protocol ignore
user@host# set applications application customer-ignore protocol tcp
user@host# set applications application customer-ignore destination-port 135
```

MSRPC ALG will be ignored by traffic with TCP destination port 135.

- **Add more applications to the current ALG's application set**—To add applications such as MSRPC or SUNRPC services, which are not predefined on SRX Series devices:

```
[edit]
user@host# set applications application customer-msrpc term t1 protocol tcp
user@host# set applications application customer-msrpc term t1 uuid
e3514235-4b06-11d1-ab04-00c04fc2dcd2
```

MSRPC data traffic with TCP, uuid e3514235-4b06-11d1-ab04-00c04fc2dcd2, will be permitted, when custom-msrpc is applied to the policy along with other predefined junos-ms-rpc** applications.

Understanding IPv6 ALG Support for ICMP

The Internet Control Message Protocol (ICMP) Application Layer Gateway (ALG) is one of the ALG's that handle ICMP traffic.

IPv6 nodes use the ICMPv6 protocol to report errors encountered in processing packets and to perform other Internet-layer functions such as diagnostics. ICMPv6 is an integral part of IPv6 and must be fully implemented by every IPv6 node; therefore the ALG layer is always enabled for ICMPv6.

ICMP Error Messages

ICMPv6 messages are grouped into two classes:

- ICMPv6 error messages
 - Destination unreachable
 - Packet too big
 - Time exceeded
 - Parameter problem
- ICMPv6 informational (or ping) messages
 - Echo request
 - Echo reply

The ICMP ALG monitors all these messages, and then does the following :

- Closes the session
- Modifies the payload

The ICMP ALG closes a session if it meets the following conditions:

- Receives echo reply message.
- Receives a destination unreachable error message and has not received any replies yet.

NOTE: The ICMP ALG checks if the session has received any replies from destination node. If it has received any reply, the destination should be reachable and the ICMP error message is not credible, therefore it does not close the session. This is to avoid hackers from sniffing the TCP/UDP packet and forging an ICMP destination unreachable packet to kill the session.

ICMP ALG Functionality

ICMP ALG behaves differently in various modes.

ICMP ALG functionality in NAT mode:

1. Close the session.
2. Modify the identifier, the sequence number or both of the echo request.
3. Resume the original identifier and sequence number for the echo reply.
4. NAT translates the embedded IPv6 packet for the ICMPv6 error message.

ICMP ALG functionality in NAT-PT support mode:

1. Close the session.
2. Translate the ICMPv4 ping message to the ICMPv6 ping message.
3. Translate the ICMPv6 ping message to the ICMPv4 ping message.
4. Translate the ICMPv4 error message to the ICMPv6 error message and translate its embedded IPv4 packet to an IPv6 packet.
5. Translate the ICMPv6 error message to the ICMPv4 error message and translate its embedded IPv6 packet to an IPv4 packet .

Data ALG Types

- [Understanding Data ALG Types on page 11](#)

Understanding Data ALG Types

Junos OS supports the following data ALGs:

- DNS—Provides an ALG for the Domain Name System. The DNS ALG monitors DNS query and reply packets and closes session if the DNS flag indicates the packet is a reply message.
- DDNS—Dynamic DNS (DDNS) is an addition to the DNS standard. DDNS updates a DNS server with new or changed records for IP addresses without the need for human intervention. Unlike DNS that only works with static IP addresses, DDNS is also designed to support dynamic IP addresses, such as those assigned by a DHCP server. DDNS is a good option for home networks, which often receive dynamic public IP addresses from their Internet provider that occasionally changes.
- FTP—Provides an ALG for the File Transfer Protocol (FTP).The FTP ALG monitors PORT, PASV, and 227 commands. It performs NAT on the IP, port, or both in the message and gate opening on the device as necessary.
- IKE and ESP ALG—Monitors IKE traffic between the client and the server and permits only one IKE Phase 2 message exchange between any given client/server pair, not just one exchange between any client and any server.

Internet Key Exchange (IKE) and Encapsulating Security Payload (ESP) traffic is exchanged between the clients and the server. However, if the clients do not support NAT-Traversal (NAT-T) and if the device assigns the same NAT-generated IP address to two or more clients, the device will be unable to distinguish and route return traffic properly.

NOTE: If the user wants to support both NAT-T-capable and non-NAT-T-capable clients, then some additional configurations are required. If there are NAT-T capable clients, the user must enable the source NAT address persistence.

- TFTP—Provides an ALG for the Trivial File Transfer Protocol (TFTP). The TFTP ALG processes TFTP packets that initiate the request and opens a gate to allow return packets from the reverse direction to the port that sends the request.
- PPTP—Provides an ALG for the Point-to-Point Tunneling Protocol (PPTP). The PPTP is a Layer 2 protocol that tunnels PPP data across TCP/IP networks. The PPTP client is freely available on Windows systems and it is also popularly applied on Linux systems, and is widely deployed for building Virtual Private Networks (VPNs).
- MSRPC—Provides an ALG for the Microsoft Remote Procedure Call.
- SUNRPC—Provides an ALG for the SUN Remote Procedure Call.
- RSH—Provides an ALG for the Remote Shell (RSH). The RSH ALG handles TCP packets destined for port 514 and processes the RSH port command. The RSH ALG performs NAT on the port in the port command and opens gates as necessary.
- SQL—Provides an ALG for the Structured Query Language (SQL). The SQLNET ALG processes SQL TNS response frame from the server side. It parses the packet and looks for the (HOST=ipaddress), (PORT=port) pattern and performs NAT and gate opening on the client side for the TCP data channel.
- TALK—Provides an ALG for the TALK Protocol. The TALK protocol uses UDP port 517 and port 518 for control channel connections. The talk program consists of a server and a client. The server handles client notifications and helps to establish talk sessions. There are two types of talk servers: `ntalk` and `talkd`. The TALK ALG processes packets of both `ntalk` and `talkd` formats. It also performs NAT and gate opening as necessary.
- RTSP—Provides an ALG for the Real Time Streaming Protocol (RTSP). RTSP is a standard protocol for streaming media applications. It controls the delivery of data with real-time properties such as audio and video.

For information about enabling and configuring each of these ALGs through J-Web, select the **Configure>Security>ALG** page in the J-Web user interface and click **Help**.

DNS ALG Overview

The DNS Application Layer Gateway (ALG) service provides an application-level gateway for use with DNS clients. The DNS ALG service allows a client to access multiple DNS servers in different networks and provides routing to and from those servers. It also supports flexible address translation of the DNS query and response packets. These functions allow the DNS client to query many different domains from a single DNS server instance on the client side of the network.

The DNS server listens through UDP port 53 for incoming queries from DNS resolvers. A resolver communicates with DNS servers by sending DNS queries and handling DNS responses.

NOTE: The default port for DNS ALG is port 53.

The DNS ALG performs the following functions:

- Monitors DNS query and reply packets and closes the session when the DNS reply is received
- Performs DNS doctoring
- Performs the IPv4 and IPv6 address transformations
- Modifies the DNS payload in NAT mode

Dynamic DNS (DDNS) support is now available in addition to the DNS standard. The Domain Name System (DNS) was originally designed to support queries of a static configured database and the data was expected to change.

The main difference between DNS and DDNS is in the message format of the header section and the update message.

DDNS messages are processed differently when compared to DNS messages. Message parsing is rewritten for DDNS. DDNS does NAT and NAT-PT in the query part of the message and DNS does NAT and NAT-PT in the response part of the message.

NOTE: The DNS ALG supports all the new formats and new functionality.

Understanding the IPv6 DNS ALG for Routing, NAT, and NAT-PT

Domain Name System (DNS) is the part of the ALG that handles DNS traffic, monitors DNS query and reply packets, and closes the session if the DNS flag indicates the packet is a reply message.

The DNS ALG supports IPv4 in route mode for Junos OS Release 10.0 and earlier releases. In Junos OS Release 10.4, this feature implements IPv6 support on the DNS ALG for routing, Network Address Translation (NAT), and Network Address Translation-Protocol Translation (NAT-PT).

When the DNS ALG receives a DNS query from the DNS client, a security check is done on the DNS packet. When the DNS ALG receives a DNS reply from the DNS server, a similar security check is done, and then the session for the DNS traffic closes.

IPv6 DNS ALG Traffic in NAT mode

IPv6 NAT provides address translation between IPv4 and IPv6 addressed network devices. It also provides address translation between IPv6 hosts. NAT between IPv6 hosts is done in a similar manner and for similar purposes as IPv4 NAT.

When the DNS traffic works in NAT mode, the DNS ALG translates the public address in a DNS reply to a private address when the DNS client is on private network, and similarly translates a private address to a public address when the DNS client is on a public network.

In Junos OS Release 10.4 IPv6 NAT supports:

- Source NAT translations
- Destination NAT mappings
- Static NAT mappings

NOTE: The IPv6 DNS ALG NAT supports only static NAT mapping.

IPv6 DNS ALG Traffic in NAT-PT mode

IPv6 NAT-PT provides address allocation and protocol translation between IPv4 and IPv6 addressed network devices. The translation process is based on the Stateless IP/ICMP Translation (SIIT) method; however, the state and the context of each communication is retained during the session lifetime. IPv6 NAT-PT supports Internet Control Message Protocol (ICMP), Transmission Control Protocol (TCP), and User Datagram Protocol (UDP) packets.

IPv6 NAT-PT supports the following types of NAT-PT:

- Traditional NAT-PT
- Bidirectional NAT-PT

A DNS-based mechanism dynamically maps IPv6 addresses to IPv4-only servers. NAT-PT uses the DNS ALG to transparently do the translations.

For example, a company using an internal IPv6 network needs to be able to communicate with external IPv4 servers that do not have IPv6 addresses.

To support the dynamic address binding, a DNS should be used for name resolution. The IPv4 host looks up the name of the IPv6 node in its local configured IPv4 DNS server, which then passes the query to the IPv6 DNS server through an SRX Series device using NAT-PT.

When DNS traffic works in NAT-PT mode, the DNS ALG translates the IP address in a DNS reply packet between the IPv4 address and the IPv6 address when the DNS client is in an IPv6 network and the server is in an IPv4 network, and vice versa.

NOTE: In NAT-PT mode, only IPV4 to IPV6 addresses translation is supported in the DNS ALG. To support NAT-PT mode in a DNS ALG, the NAT module should support NAT-PT.

When the DNS ALG receives a DNS query from the DNS client, the DNS ALG performs the following security and sanity checks on the DNS packets:

- Enforces the maximum DNS message length (the default is 512 bytes and the maximum length is 8KB)
- Enforces a domain-name length of 255 bytes and a label length of 63 bytes
- Verifies the integrity of the domain-name referred to by the pointer if compression pointers are encountered in the DNS message
- Checks to see if a compression pointer loop exists

Similar sanity checks are done when the DNS ALG receives a DNS reply from the DNS Server, after which the session for this DNS traffic gets closed.

Example: Configuring the DNS ALG

This example shows how to configure the DNS ALG to pass through DNS traffic with a static NAT pool on Juniper Networks devices.

- [Requirements on page 16](#)
- [Overview on page 16](#)
- [Configuration on page 16](#)
- [Verification on page 18](#)

Requirements

Before you begin:

- Configure static NAT pool for all IP address.
- Understand the concepts behind ALG for DNS. See “[DNS ALG Overview](#)” on page 13.

Overview

In this example, the ALG for DNS is configured to monitor and allow DNS traffic to be exchanged between the clients and the server located on opposite sides of a Juniper Networks device.

This example shows how to configure a static NAT pool and rule set, and associate the DNS ALG to a policy.

Configuration

- [Configuring a NAT Static Pool and Rule Set on page 16](#)
- [Configuring and Printing the DNS Trace on page 18](#)

Configuring a NAT Static Pool and Rule Set

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat static rule-set rs1 from zone untrust
set security nat static rule-set rs1 rule r1 match destination-address 1.1.1.1/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 2.2.2.2/32
set security policies from-zone untrust to-zone trust policy u2t match source-address
any
set security policies from-zone untrust to-zone trust policy u2t match destination-address
any
set security policies from-zone untrust to-zone trust policy u2t match application
junos-dns-udp
```

```
set security policies from-zone untrust to-zone trust policy u2t then permit
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a static NAT pool:

1. Create a NAT static rule set.

```
[edit ]
user@host# set security nat static rule-set rs1 from zone untrust
user@host# set security nat static rule-set rs1 rule r1 match destination-address
1.1.1.1/32
user@host# set security nat static rule-set rs1 rule r1 then static-nat prefix 2.2.2.2/32
```

2. Associate the NAT Traversal (NAT-T) application using a policy.

```
[edit]
user@host# set security policies from-zone untrust to-zone trust policy u2t match
source-address any
user@host# set security policies from-zone untrust to-zone trust policy u2t match
destination-address any
user@host# set security policies from-zone untrust to-zone trust policy u2t match
application junos-dns-udp
user@host# set security policies from-zone untrust to-zone trust policy u2t then
permit
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show security nat
static {
  rule-set rs1 {
    from zone untrust;
    rule r1 {
      match {
        destination-address 1.1.1.1/32;
      }
      then {
        static-nat {
          prefix {
            2.2.2.2/32;
          }
        }
      }
    }
  }
}

[edit]
user@host# show security policies
from-zone untrust to-zone trust {
  policy u2t {
    match {
```

```
        source-address any;
        destination-address any;
        application [ junos-dns-udp];
    }
    then {
        permit;
    }
}
}
default-policy {
    permit-all;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring and Printing the DNS Trace

- Purpose** Print the DNS trace file.
- Action** From configuration mode, enter the following command.
- ```
set security alg traceoptions file alglog
set security alg traceoptions file size 1g
set security alg traceoptions level verbose
set security alg dns traceoptions flag all
```

### Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying DNS ALG Custom Applications on page 18](#)
- [Verifying DNS ALG on page 18](#)

---

### Verifying DNS ALG Custom Applications

- Purpose** Verify that the custom applications to support the DNS ALG are enabled.
- Action** From operational mode, enter the **show security policies** command.
- ```
user@host> show security policies

Default policy: permit-all
From zone: untrust, To zone: trust
Policy: u2t, State: enabled, Index: 6, Scope Policy: 0, Sequence number: 1
Source addresses: any
Destination addresses: any
Applications: junos-dns-udp
Action: permit
```
- Meaning** The sample output shows that the custom applications to support the DNS ALG is enabled.

Verifying DNS ALG

- Purpose** Verify that DNS ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
```

```
DNS      : Enabled
FTP      : Enabled
H323     : Enabled
```

Meaning The output shows the DNS ALG status as follows:

- Enabled—Shows the DNS ALG is enabled.
- Disabled—Shows the DNS ALG is disabled.

Related Documentation

- [DNS ALG Overview on page 13](#)

Understanding DNS and DDNS Doctoring

Junos OS for SRX Series devices provides Domain Name System (DNS) support. The DNS ALG monitors DNS query and reply packets and closes the session if the DNS flag indicates that the packet is a reply message. To configure the DNS ALG, use the **edit security alg dns** statement at the **[edit security alg]** hierarchy level.

DNS provides name-to-address mapping within a routing class, whereas Network Address Translation (NAT) attempts to provide transparent routing between hosts in disparate address realms of the same routing class. As a result, NAT can cause some DNS problems the DNG ALG must handle through a process called DNS doctoring.

The same doctoring feature applies to the dynamic domain name system (DDNS). For DDNS in NAT mode, you also can do the IP translation in the DDNS update.

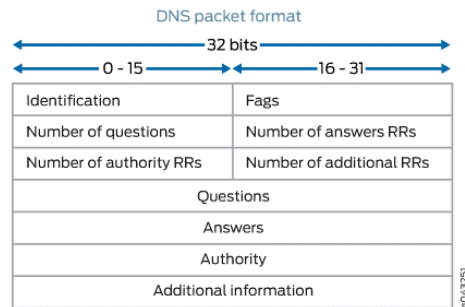

To resolve the problems introduced by NAT, DNS and DDNS ALG functionality has been extended to support static NAT, allowing the problems to be resolved through DNS doctoring.

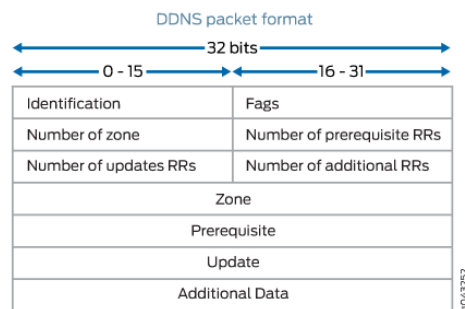

NOTE: The DNS ALG must be enabled on the devices to perform DNS doctoring. With the DNS ALG enabled on SRX3400, SRX3600, SRX5600, and SRX5800 devices, DNS doctoring is enabled by default.

The restoring and doctoring process is performed in two parts:

- **Packet sanity check**

For the DNS packet, the DNS ALG check fields are questions, answers, authority, and additional information. The DNS ALG drops the packet if the number of questions is more than 1, the domain name is more than 255 bytes, or the label length is more than 63 bytes.

For the DDNS packet, the DNS ALG check fields are zone, prerequisite, update, and additional data. The DNS ALG drops the packet if the number of zones is more than 1, the domain name is more than 255 bytes, or the label length is more than 63 bytes.

For both DNS and DDNS, the DNS ALG drops the packet that does not comply with the standards.

- NAT

Figure 1 shows how DNS translates a private address to a public address.

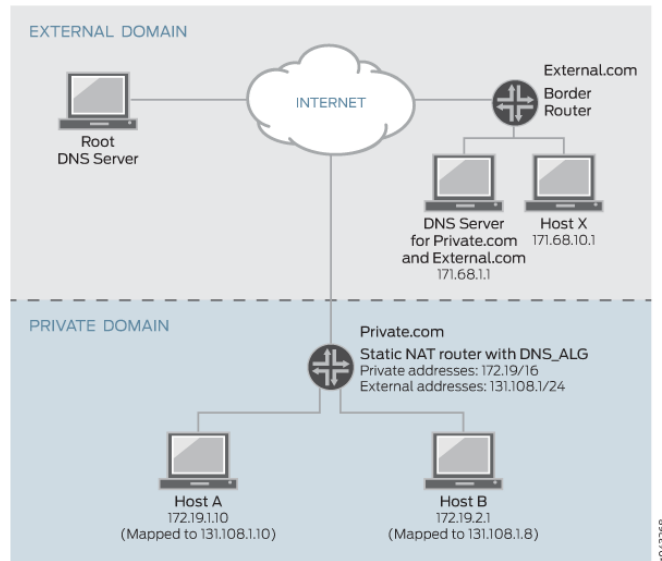

Figure 1: DNS Address Translation (Private to Public)

When host X in external.com wants to resolve host A's address through DNS and if the DNS ALG does not support NAT, it takes a private address such as 172.19.1.10, which is invalid to host X. The private address is translated to public address 131.108.1.10 through the DNS ALG.

Figure 2 shows how DNS translates a public address to a private address.

Figure 2: DNS Address Translation (Public to Private)

When host A in private.com wants to resolve host B's address through DNS and if the DNS ALG does not support NAT, it takes a public address from the DNS server in external.com, such as 131.108.1.8. If Host A sends traffic to host B with public address 131.108.1.8, which is invalid to host B in the private domain. Hence, the public address in the DNS query A-record is translated to private address 172.19.2.1 through the DNS ALG.

NOTE: The DNS ALG can translate the first 32 A-records in a single DNS reply. A-records after the first 32 records are not handled. Also note that the DNS ALG supports only IPv4 addresses and does not support VPN tunnels.

Disabling DNS and DDNS Doctoring

The DNS and DDNS doctoring feature is enabled by default. You can disable DNS and DDNS doctoring with the CLI.

To disable DNS and DDNS doctoring:

1. Disable all the doctoring features by specifying the **none** configuration option.

This command disables all the doctoring features.

```
user@host# set security alg dns doctoring none
```

2. Disable the NAT feature and retain the sanity-check feature by specifying the **sanity-check** configuration option.

This option disables the NAT feature and retains the sanity-check feature.

```
user@host# set security alg dns doctoring sanity-check
```

3. If you are finished configuring the device, commit the configuration.
4. From configuration mode in the CLI, enter the **show security alg dns doctoring** command to verify the configuration.

CHAPTER 4

Configuring the FTP ALG

- [FTP ALG Overview on page 25](#)
- [Understanding FTP Commands on page 26](#)
- [Example: Configuring the FTP ALG on page 28](#)
- [Understanding the IPv6 FTP ALG for Routing on page 31](#)

FTP ALG Overview

The File Transfer Protocol (FTP) is a widely and commonly used method of exchanging files over IP networks. In addition to the main control connection, data connections are also made for any data transfer between the client and the server; and the host, port, and direction are negotiated through the control channel.

For active mode FTP, the Junos OS stateful firewall service scans the client-to-server application data for the PORT command, which provides the IP address and port number to which the server connects. For passive-mode FTP, the Junos OS stateful firewall service scans the client-to-server application data for the PASV command and then scans the server-to-client responses for the 227 response, which contains the IP address and port number to which the client connects.

FTP represents the addresses and port numbers in ASCII. As a result, when addresses and ports are rewritten, the TCP sequence number might be changed, and thereafter the NAT service needs to maintain this delta in SEQ and ACK numbers by performing sequence NAT on all subsequent packets.

The FTP ALG supports the following:

- Automatically allocates data ports and firewall permissions for dynamic data connection
- Monitors the control connection in both active and passive modes
- Rewrites the control packets with the appropriate NAT address and port information
- Network Address Translation, Protocol Translation (NAT-PT)
- Transport Layer Security (TLS) as the security mechanism

Related Documentation

- [Example: Configuring the FTP ALG on page 28](#)

Understanding FTP Commands

The FTP ALG monitors commands and responses on the FTP control channel for syntactical correctness and opens corresponding pinholes to permit data channel connections to be established. In Junos OS Release 10.4, the FTP ALG supported IPv4 routing and NAT mode, and IPv6 routing mode only. In Junos OS Release 11.2 and later releases, the FTP ALG also supports IPv6 NAT and NAT-PT modes.

PORT Command

The PORT command is used in active FTP mode. The PORT command specifies the address and the port number to which a server should connect. When you use this command, the argument is a concatenation of a 32-bit Internet host address and a 16-bit TCP port address. The address information is broken into 8-bit fields, and the value of each field is transmitted as a decimal number (in character string representation). The fields are separated by commas.

The following is a sample PORT command, where h1 is the highest order 8-bit of the Internet host address:

```
PORT h1,h2,h3,h4,p1,p2
```

PASV Command

The PASV command requests a server to listen on a data port that is not the default data port of the server and to wait for a connection, rather than initiating another connection. The response to the PASV command includes the host and port address the server is listening on.

Extended FTP Commands

Extended FTP commands provide a method by which FTP can communicate the data connection endpoint information for network protocols other than IPv4. Extended FTP commands are specified in RFC 2428. In RFC 2428, the extended FTP commands EPRT and EPSV, replace the FTP commands PORT and PASV, respectively.

EPRT Command

The EPRT command allows for the specification of an extended address for the data connection. The extended address must consist of the network protocol as well as the network and transport addresses.

The format of EPRT is:

EPRT <space><d><net-prt><d><net-addr><d><tcp-port><d>

Parameter	Description
net-prt	An address family number defined by IANA.
net-addr	A protocol-specific string of the network address.
tcp-port	A TCP port number on which the host is listening for data connection.
Delimiter	The delimiter character must be one of the ASCII characters in range 33 to 126 inclusive. The character " " (ASCII 124) is recommended.

The following command shows how to specify the server to use an IPv4 address to open a data connection to host 132.235.1.2 on TCP port 6275:

```
EPRT |1|132.235.1.2|6275|
```

The following command shows how to specify the server to use an IPv6 network protocol and a network address to open a TCP data connection on port 5282:

```
EPRT |2|1080::8:800:200C:417A|5282|
```

In this mode, FTP ALG focuses only on the EPRT command; it extracts the IPv6 address and port from the EPRT command and opens the pinhole.

EPSV mode

The EPSV command requests that a server listen on a data port and wait for a connection. The response to this command includes only the TCP port number of the listening connection.

An example response string is as follows:

```
Entering Extended Passive Mode (|||6446|)
```

NOTE: The response code for entering passive mode using an extended address must be 229. You should extract the TCP port in 229 payloads and use it to open the pinhole.

Example: Configuring the FTP ALG

This example shows how to configure the NAT-PT for FTP ALG.

- [Requirements on page 28](#)
- [Overview on page 28](#)
- [Configuration on page 28](#)
- [Verification on page 30](#)

Requirements

Before you begin:

- Configure proxy ARP for all IP addresses in the source NAT pool.
- Understand the concepts behind ALG for FTP. See [“FTP ALG Overview” on page 25](#).

Overview

In this example, the ALG for FTP is configured to monitor and allow FTP traffic to be exchanged between the clients and the server located on opposite sides of a Juniper Networks device.

This example shows how to configure the NAT-PT for FTP ALG.

Configuration

Configuring a NAT Source Pool, NAT Static Pool and Rule Set

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat static rule-set rs1 from zone untrust
set security nat source rule-set rs-source to zone trust
set security nat source rule-set rs-source rule src-nat match source-address 3333::130/128
set security nat source rule-set rs-source rule src-nat match destination-address 40.0.0.211/32
set security nat source rule-set rs-source rule src-nat then source-nat interface
set security nat static rule-set rs2 from zone untrust
set security nat static rule-set rs2 rule r2 match destination-address 4444::141/128
set security nat static rule-set rs2 rule r2 then static-nat prefix 40.0.0.211/32
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT pool:

1. Create a source NAT, static NAT, and interface NAT rule set.

[edit]

```

user@host# set security nat source rule-set rs-source from zone untrust
user@host# set security nat source rule-set rs-source to zone trust
user@host# set security nat source rule-set rs-source rule src-nat match
source-address 3333::130/128
user@host# set security nat source rule-set rs-source rule src-nat match
destination-address 40.0.0.211/32
user@host# set security nat source rule-set rs-source rule src-nat then source-nat
interface
user@host# set security nat static rule-set rs2 from zone untrust
user@host# set security nat static rule-set rs2 rule r2 match destination-address
4444::141/128
user@host# set security nat static rule-set rs2 rule r2 then static-nat prefix
40.0.0.211/32

```

2. Associate the NAT-PT application using a policy.

```

[edit]
user@host# set security policies from-zone trust to-zone untrust policy ftp-basic
match source-address any
user@host# set security policies from-zone trust to-zone untrust policy ftp-basic
match destination-address any
user@host# set security policies from-zone trust to-zone untrust policy ftp-basic
match application junos-ftp
user@host# set security policies from-zone trust to-zone untrust policy ftp-basic
then permit

```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@host# show security nat
static {
  rule-set rs2 {
    from zone untrust;
    rule r2 {
      match {
        destination-address 4444::141/128;
      }
      then {
        static-nat {
          prefix {
            40.0.0.211/32
          }
        }
      }
    }
  }
}

```

```

[edit]
user@host# show security policies
from-zone untrust to-zone trust {
  policy ftp-basic {
    match {
      source-address any;
      destination-address any;
    }
  }
}

```

```

        application [ junos-ping junos-mgcp junos-ftp junos-rsh junos-h323 ];
    }
    then {
        permit;
    }
}
}
default-policy {
    permit-all;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring FTP ALG Security Extension

Purpose Set the security alg ftp extension

Action From configuration mode, enter the following command.
set security alg ftp ftps-extension

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the NAT Source Pool, NAT Static Pool Rule Set on page 30](#)
- [Verifying FTP ALGs on page 30](#)

Verifying the NAT Source Pool, NAT Static Pool Rule Set

Purpose Verify that the NAT source pool and rule set used to support the FTP ALG are working properly.

Action From operational mode, enter the **show configuration security nat** command.

Verifying FTP ALGs

Purpose Verify that FTP ALG is enabled.

Action From the operational mode, enter the **show security alg status** command.

```

user@host> show security alg status
FTP      : Enabled

```

Meaning The output shows the FTP ALG status as follows:

- Enabled—Shows the FTP ALG is enabled.
- Disabled—Shows the FTP ALG is disabled.

NOTE: The FTP ALG is enabled by default.

Related Documentation

- [FTP ALG Overview on page 25](#)

Understanding the IPv6 FTP ALG for Routing

File Transfer Protocol (FTP) is the part of the ALG that handles FTP traffic. The PORT/PASV requests and corresponding 200/227 responses in FTP are used to announce the TCP port, which the host listens to for the FTP data connection.

EPRT/EPSV/229 commands are used for these requests and responses. FTP ALG supports EPRT/EPSV/229 already, but only for IPv4 addresses.

In Junos OS Release 10.4, EPRT/EPSV/229 commands have been updated to support both IPv4 and IPv6 addresses.

FTP ALG uses preallocated objcache to store its session cookies. When both IPv4 and IPv6 addresses are supported on FTP ALG, the session cookie structure will enlarge by 256 bits (32 bytes) to store IPv6 address.

FTP ALG Support for IPv6

The FTP ALG monitors commands and responses on the FTP control channel for syntactical correctness and opens corresponding pinholes to permit data channel connections to be established. In Junos OS Release 10.4, the FTP ALG supported IPv4 routing, IPv6 routing, and NAT mode only. In Junos OS Release 11.2 and later releases, the FTP ALG also supports IPv6 NAT and NAT-PT modes.

EPRT mode

The EPRT command allows for the specification of an extended address for the data connection. The extended address must consist of the network protocol as well as the network and transport addresses.

The format of EPRT is:

```
EPRT<space><d><net-prt><d><net-addr><d><tcp-port><d>
```

- <net-prt>: An address family number defined by IANA
- <net-addr>: A protocol specific string of the network address
- <tcp-port>: A TCP port number

The following are sample EPRT commands for IPv6:

```
EPRT |2|1080::8:800:200C:417A|5282|
```

In this mode, FTP ALG focuses only on the EPRT command; it extracts the IPv6 address and port from the EPRT command and opens the pinhole.

EPSV mode

The EPSV command requests that a server be listening on a data port and waiting for a connection. The response to this command includes only the TCP port number of the listening connection.

An example response string is follows:

Entering Extended Passive Mode (|||6446|)

NOTE: The response code for entering passive mode using an extended address must be 229. You should extract the TCP port in 229 payloads and use it to open the pinhole.

CHAPTER 5

Configuring the IKE and ESP ALG

- [Understanding the ALG for IKE and ESP on page 33](#)
- [Understanding IKE and ESP ALG Operation on page 34](#)
- [Example: Configuring the IKE and ESP ALG on page 35](#)
- [Example: Enabling the IKE and ESP ALG and Setting Timeouts on page 41](#)

Understanding the ALG for IKE and ESP

An SRX Series device can be used solely as a Network Address Translation (NAT) device when placed between VPN clients on the private side of the NAT gateway and the virtual private network (VPN) gateways on the public side.

Internet Key Exchange (IKE) and Encapsulating Security Payload (ESP) traffic is exchanged between the clients and the server. However, if the clients do not support NAT-Traversal (NAT-T) and if the device assigns the same NAT-generated IP address to two or more clients, the device will be unable to distinguish and route return traffic properly.

NOTE: If the user wants to support both NAT-T-capable and non-NAT-T-capable clients, then some additional configurations are required. If there are NAT-T capable clients, the user must enable the source NAT address persistence.

The ALG for IKE and ESP monitors IKE traffic between the client and the server and permits only one IKE Phase 2 message exchange between any given client/server pair, not just one exchange between any client and any server.

ALG for IKE and ESP traffic has been created and NAT has been enhanced to implement the following:

- To enable the SRX Series devices to pass IKE and ESP traffic with a source NAT pool
- To allow the device to be configured to return the same NAT-generated IP address for the same IP address without NAT ("address-persistent NAT"). As a result, the device is able to associate a client's outgoing IKE traffic with its return traffic from the server, especially when the IKE session times out and needs to be reestablished.

- The resulting ESP traffic between the client and the server is also allowed, especially in the direction from the server to the client.
- The return ESP traffic matches the following:
 - The server IP address as source IP
 - The client IP address as destination IP

NOTE: In SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices, IKE negotiations involving NAT traversal do not work if the IKE peer is behind a NAT device that will change the source IP address of the IKE packets during the negotiation. For example, if the NAT device is configured with DIP, it changes the source IP because the IKE protocol switches the UDP port from 500 to 4500.

**Related
Documentation**

- [Example: Configuring the IKE and ESP ALG on page 35](#)

Understanding IKE and ESP ALG Operation

Application Layer Gateway (ALG) for Internet Key Exchange (IKE) and Encapsulating Security Payload (ESP) traffic has the following behavior:

- An IKE and ESP ALG monitors IKE traffic between the client and the server, and it permits only one IKE Phase 2 message exchange between the client and the server at any given time.
- For a Phase 2 message:
 - If a Phase 2 message exchange between the client and server does not happen, the IKE ALG gates are opened for the relevant ESP traffic from the client to the server and from the server to the client.
 - If both IKE ALG gates are not opened successfully, or if the Phase 2 message exchange already took place, then the Phase 2 message is dropped.
- When ESP traffic hits the IKE ALG gates, sessions are created to capture subsequent ESP traffic, and to perform the proper NATing (that is, the source IP address translation from the client to the server traffic and the destination IP address translation from the server to the client traffic).
- When the ESP traffic does not hit either one or both of the gates, then the gates naturally time out.
- Once the IKE ALG gates are collapsed or timed out, another IKE Phase 2 message exchange is permitted.
- IKE NAT-T traffic on floating port 4500 is processed in an IKE ALG. To support a mixture of NAT-T-capable and non-capable clients, you need to enable source NAT address persistent.

Example: Configuring the IKE and ESP ALG

This example shows how to configure the IKE and ESP ALG to pass through IKE and ESP traffic with a source NAT pool on Juniper Networks devices.

- [Requirements on page 35](#)
- [Overview on page 35](#)
- [Configuration on page 35](#)
- [Verification on page 40](#)

Requirements

Before you begin:

- Configure proxy ARP for all IP addresses in the source NAT pool.
- Understand the concepts behind IKE and ESP ALG. See [“Understanding IKE and ESP ALG Operation” on page 34](#).

Overview

In this example, the ALG for IKE and ESP is configured to monitor and allow IKE and ESP traffic to be exchanged between the clients and the server located on opposite sides of a Juniper Networks device.

This example shows how to configure a source NAT pool and rule set, configure a custom application to support the IKE and ESP ALG, and associate this ALG to a policy.

If you want to support a mixture of NAT-traversal (NAT-T) capable clients and noncapable clients, you must enable persistent source NAT translation (so that once a particular source NAT is associated with a given IP address, subsequent source NAT translations use the same IP address). You also must configure a custom IKE NAT traversal application to support the encapsulation of IKE and ESP in UDP port 4500. This configuration enables IKE and ESP to pass through the NAT-enabled device.

Configuration

- [Configuring a NAT Source Pool and Rule Set on page 36](#)
- [Configuring a Custom Application and Associating it to a Policy on page 37](#)
- [Configuring IKE and ESP ALG Support for Both NAT-T Capable and Noncapable Clients on page 38](#)

Configuring a NAT Source Pool and Rule Set

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
set security zones security-zone green address-book address sa1 1.1.1.0/24
set security zones security-zone red address-book address da1 2.2.2.0/24
set security nat source rule-set rs1 from zone green
set security nat source rule-set rs1 to zone red
set security nat source rule-set rs1 rule r1 match source-address 1.1.1.0/24
set security nat source rule-set rs1 rule r1 match destination-address 2.2.2.0/24
set security nat source rule-set rs1 rule r1 then source-nat pool pool1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT pool:

1. Create a NAT source pool.

```
[edit ]
user@host# set security nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
```

2. Configure security zone address book entries.

```
[edit]
user@host# set security zones security-zone green address-book address sa1
1.1.1.0/24
user@host# set security zones security-zone red address-book address da1 2.2.2.0/24
```

3. Create a NAT source rule set.

```
[edit security nat source rule-set rs1]
user@host# set from zone green
user@host# set to zone red
user@host# set rule r1 match source-address 1.1.1.0/24
user@host# set rule r1 match destination-address 2.2.2.0/24
user@host# set rule r1 then source-nat pool pool1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show security nat
source {
  pool pool1 {
    address {
      10.10.10.1/32 to 10.10.10.10/32;
    }
  }
}
rule-set rs1 {
  from zone green;
```

```

to zone red;
rule r1 {
  match {
    source-address 1.1.1.0/24;
    destination-address 2.2.2.0/24;
  }
  then {
    source-nat {
      pool {
        pool1;
      }
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Custom Application and Associating it to a Policy

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set applications application custom-ike-alg source-port 500 destination-port 500 protocol
  udp application-protocol ike-esp-nat
set security policies from-zone green to-zone red policy pol1 match destination-address
  da1
set security policies from-zone green to-zone red policy pol1 match application
  custom-ike-alg
set security policies from-zone green to-zone red policy pol1 then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a custom application and associate it to a policy:

1. Configure a custom application.

```

[edit]
user@host# set applications application custom-ike-alg source-port 500
  destination-port 500 protocol udp application-protocol ike-esp-nat

```

2. Associate the custom application to a policy.

```

[edit security policies from-zone green to-zone red policy pol1]
user@host# set match source-address sa1
user@host# set match destination-address da1
user@host# set match application custom-ike-alg
user@host# set then permit

```

Results From configuration mode, confirm your configuration by entering the **show applications** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show applications
application custom-ike-alg {
  application-protocol ike-esp-nat;
  protocol udp;
  source-port 500;
  destination-port 500;
}

[edit]
user@host# show security zones
security-zone Trust {
  host-inbound-traffic {
    system-services {
      all;
    }
    protocols {
      all;
    }
  }
  interfaces {
    ge-0/0/1.0;
  }
}
security-zone green {
  address-book {
    address sa1 1.1.1.0/24;
  }
}
security-zone red {
  address-book {
    address da1 2.2.2.0/24;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring IKE and ESP ALG Support for Both NAT-T Capable and Noncapable Clients

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source address-persistent
set applications application custom-ike-natt protocol udp source-port 4500
  destination-port 4500
set security policies from-zone green to-zone red policy pol1 match source-address sa1
set security policies from-zone green to-zone red policy pol1 match destination-address
  da1
```

```

set security policies from-zone green to-zone red policy pol1 match application
custom-ike-natt
set security policies from-zone green to-zone red policy pol1 then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure IKE and ESP ALG support for both NAT-T capable and noncapable clients:

1. Globally enable persistent source NAT translation.

```

[edit]
user@host# set security nat source address-persistent

```

2. Configure the IKE NAT-T application.

```

[edit]
user@host# set applications application custom-ike-natt protocol udp source-port
4500 destination-port 4500

```

3. Associate the NAT-T application using a policy.

```

[edit security policies from-zone green to-zone red policy pol1]
user@host# set match source-address sa1
user@host# set match destination-address da1
user@host# set match application custom-ike-natt
user@host# set then permit

```

Results From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security nat
source {
    address-persistent;
}

[edit]
user@host# show security policies
from-zone green to-zone red {
    policy pol1 {
        match {
            source-address sa1;
            destination-address da1;
            application [ custom-ike-alg custom-ike-natt ];
        }
        then {
            permit;
        }
    }
}
default-policy {
    permit-all;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying IKE and ESP ALG Custom Applications on page 40](#)
- [Verifying the Security Policies of ALG on page 40](#)

Verifying IKE and ESP ALG Custom Applications

Purpose Verify that the custom applications to support the IKE and ESP ALG are enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
```

```
ALG Status :
DNS       : Enabled
FTP       : Enabled
H323      : Enabled
MGCP      : Enabled
MSRPC     : Enabled
PPTP      : Enabled
RSH       : Disabled
RTSP      : Enabled
SCCP      : Enabled
SIP       : Enabled
SQL       : Enabled
SUNRPC    : Enabled
TALK      : Enabled
TFTP      : Enabled
IKE-ESP   : Enabled
```

Meaning The output shows the ALG status as follows:

- Enabled—Shows the ALG is enabled.
- Disabled—Shows the ALG is disabled.

Verifying the Security Policies of ALG

Purpose Verify that the application custom IKE ALG and application custom IKE NATT are set.

Action From operational mode, enter the **show security policies** command.

```
user@host> show security policies
```

```
Default policy: permit-all
From zone: green, To zone: red
Policy: pol1, State: enabled, Index: 7, Scope Policy: 0, Sequence number: 1
Source addresses: sa1
Destination addresses: da1
Applications: custom-ike-alg, custom-ike-natt
Action: permit
```

Meaning The sample output shows that custom IKE ALG and custom IKE NATT applications are set.

- Related Documentation**
- [ALG Overview on page 3](#)
 - [Understanding the ALG for IKE and ESP on page 33](#)
 - [Example: Enabling the IKE and ESP ALG and Setting Timeouts on page 41](#)

Example: Enabling the IKE and ESP ALG and Setting Timeouts

This example shows how to enable the IKE and ESP ALG and set the timeout values to allow time for the ALG to process ALG state information, ESP gates, and ESP sessions.

- [Requirements on page 41](#)
- [Overview on page 41](#)
- [Configuration on page 41](#)
- [Verification on page 42](#)

Requirements

Understand the concepts behind ALG for IKE and ESP. See “[Understanding IKE and ESP ALG Operation](#)” on page 34.

Overview

The IKE and ESP ALG processes all traffic specified in any policy to which the ALG is attached. In this example, you configure the **set security alg ike-esp-nat enable** statement so the current default IPsec pass-through behavior is disabled for all IPsec pass-through traffic, regardless of policy.

You then set the timeout values to allow time for the IKE and ESP ALG to process ALG state information, ESP gates, and ESP sessions. In this example, you set the timeout of ALG state information. The timeout range is 180 through 86400 seconds. The default timeout is 14400 seconds. You then set the timeout of the ESP gates created after an IKE Phase 2 exchange has completed. The timeout range is 2 through 30 seconds. The default timeout is 5 seconds. Finally, you set the idle timeout of the ESP sessions created from the IPsec gates. If no traffic hits the session, it is aged out after this period of time. The timeout range is 60 through 2400 seconds. The default timeout is 1800 seconds.

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security alg ike-esp-nat enable
set security alg ike-esp-nat esp-gate-timeout 20
set security alg ike-esp-nat esp-session-timeout 2400
set security alg ike-esp-nat state-timeout 360
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable the IKE and ESP ALG and set the timeout values:

1. Enable the IKE and ESP ALG.

```
[edit]  
user@host# set security alg ike-esp-nat enable
```
2. Set the timeout for the ALG state information.

```
[edit security alg ike-esp-nat]  
user@host# set state-timeout 360
```
3. Set the timeout for the ESP gates created after an IKE Phase 2 exchange has completed.

```
[edit security alg ike-esp-nat]  
user@host# set esp-gate-timeout 20
```
4. Set the idle timeout for the ESP sessions created from the IPsec gates.

```
[edit security alg ike-esp-nat]  
user@host# set esp-session-timeout 2400
```

Results From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]  
user@host# show security alg  
ike-esp-nat {  
  enable;  
  state-timeout 360;  
  esp-gate-timeout 20;  
  esp-session-timeout 2400;  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the ALG for IKE and ESP and Timeout Settings on page 42](#)

Verifying the ALG for IKE and ESP and Timeout Settings

Purpose Verify that the ALG for IKE and ESP is enabled and the timeout settings for this feature are correct.

Action From operational mode, enter the **show security alg ike-esp-nat** command.

Configuring the PPTP ALG

- [Understanding the PPTP ALG on page 45](#)
- [Understanding IPv6 Support for the PPTP ALG on page 45](#)
- [Example: Configuring the PPTP ALG on page 46](#)

Understanding the PPTP ALG

The Point-to-Point Tunneling Protocol (PPTP) ALG is used for tunneling Point-to-Point Protocol (PPP) packets over an IP network. The PPTP ALG is often used to implement a client/server architecture, a PPTP network server, and a PPTP access concentrator.

The PPTP ALG processes PPTP packets, performs Network Address Translation (NAT), open pinholes for new data connections between a client and a server, and transfers data between a client and a server located on opposite sides of a Juniper Networks device.

Related Documentation

- [Example: Configuring the PPTP ALG on page 46](#)

Understanding IPv6 Support for the PPTP ALG

IPv6 is supported on the PPTP ALG.

The PPTP ALG supports IPv6 data packets. The PPTP ALG uses TCP port 1723 to connect and disconnect a client and a server.

To support IPv6, the PPTP ALG parses both IPv4 and IPv6 PPTP packets, performs NAT, and then opens a pinhole for the data tunnel. The flow module supports IPv6 to parse the GRE packet and use the GRE call ID as fake port information to search the session table and gate table.

The PPTP ALG with IPv6 support does not support NAT-PT and NAT64, because PPP packets are compressed with Microsoft Point-to-Point Encryption (MPPE) protocol after the tunnel is set up; therefore translation of the IP header in the PPP package cannot be handled.

NOTE: The PPTP ALG can support NAT64 in a specific scenario in which translation of the IP header in the PPP package is not required—that is, if the PPTP client works in dual-stack mode in the IPv6 network and server in the IPv4 network.

- The PPTP ALG with IPv6 support has the following limitation:
 - Because PPP packets are compressed with Microsoft Point-to-Point Encryption (MPPE) protocol after the tunnel is set up, translation of the IP header in the PPP package cannot be handled; therefore, to make sure PPTP connection works well, the PPTP client must be able to work in dual stack mode. So that an IPv6 PPTP client can accept an IPv4 address for PPP tunnel interface, by which it can communicate with the IPv4 PPTP server without IP address translation for PPP packets.

Documentation**

- [Understanding the PPTP ALG on page 45](#)

Example: Configuring the PPTP ALG

The PPTP ALG processes PPTP packets, performs NAT, and open pinholes for new data connections between a client and a server.

This example shows how to configure the PPTP ALG in route or NAT mode. The configuration allows PPTP traffic to pass through a device, transferring data between a client and a server located on opposite sides of a Juniper Networks device.

- [Requirements on page 46](#)
- [Overview on page 47](#)
- [Configuration on page 48](#)
- [Verification on page 56](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device
- Two PCs (client and server)

Before you begin:

- Understand the concepts behind ALGs. See [“ALG Overview” on page 3](#).
- Understand the basics of PPTP ALG. See [“Understanding the PPTP ALG” on page 45](#).

Overview

In this example, first you configure network interfaces on the device, create security zones and assign interfaces to the zones, and configure a policy to allow PPTP traffic to go through an SRX Series device.

Then you create a static NAT rule set `rs1` with a rule `r1` to match with the destination address `30.5.2.120/32`, and you create a static NAT prefix with address `10.5.1.120/32`.

Next you create a source NAT pool `src-p1` with a source rule set `src-rs1` to translate packets from zone `trust` to zone `untrust`. For matching packets, the source address is translated to an IP address in the `src-p1` pool.

Then you create a destination NAT pool `des-p1` with a destination rule set `des-rs1` to translate packets from zone `trust` to destination address `30.5.1.120/32`. For matching packets, the destination address is translated to an IP address in the `des-p1` pool. Finally, you configure PPTP ALG trace options.

Topology

Figure 3 shows the PPTP ALG topology.

Figure 3: PPTP ALG Topology

Configuration

To configure the PPTP ALG, perform these tasks:

- [Configuring a Route Mode on page 49](#)
- [Configuring a Static NAT Rule Set on page 51](#)
- [Configuring a Source NAT Pool and Rule Set on page 52](#)
- [Configuring a Destination NAT Pool and Rule Set on page 54](#)
- [Configuring PPTP ALG trace options on page 55](#)

Configuring a Route Mode

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/1 unit 0 family inet address 20.20.20.1/8
set interfaces fe-0/0/2 unit 0 family inet address 10.10.10.1/8
set security zones security-zone trust interfaces ge-0/0/1 host-inbound-traffic system-services
all
set security zones security-zone trust interfaces ge-0/0/1 host-inbound-traffic protocols all
set security zones security-zone untrust interfaces fe-0/0/2 host-inbound-traffic system-services
all
set security zones security-zone untrust interfaces fe-0/0/2 host-inbound-traffic protocols all
set security policies from-zone trust to-zone untrust policy ptp match source-address any
set security policies from-zone trust to-zone untrust policy ptp match destination-address any
set security policies from-zone trust to-zone untrust policy ptp match application junos-pttp
set security policies from-zone trust to-zone untrust policy ptp then permit
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure route mode:

1. Configure interfaces.

```
[edit interfaces]
user@host#set ge-0/0/1 unit 0 family inet address 20.20.20.1/8
user@host#set fe-0/0/2 unit 0 family inet address 10.10.10.1/8
```
2. Configure zones and assign interfaces to the zones.

```
[edit security zones security-zone trust]
user@host#set interfaces ge-0/0/1 host-inbound-traffic system-services all
user@host#set interfaces ge-0/0/1 host-inbound-traffic protocols all
[edit security zones security-zone untrust]
user@host#set interfaces fe-0/0/2 host-inbound-traffic system-services all
user@host#set interfaces fe-0/0/2 host-inbound-traffic protocols all
```
3. Configure a PPTP policy that allows PPTP traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone untrust to-zone trust]
user@host#set policy ptp match source-address any
user@host#set policy ptp match destination-address any
user@host#set policy ptp match application junos-pttp
user@host#set policy ptp then permit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show interfaces
...
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 20.20.20.1/8;
      }
    }
  }
  fe-0/0/2 {
    unit 0 {
      family inet {
        address 10.10.10.1/8;
      }
    }
  }
...

[edit]
user@host# show security zones
security-zone trust {
  ....
  interfaces {
    ge-0/0/1 {
      host-inbound-traffic {
        system-services {
          all;
        }
        protocols {
          all;
        }
      }
    }
  }
}
...
security-zone untrust {
  interfaces {
    fe-0/0/2 {
      host-inbound-traffic {
        system-services {
          all;
        }
        protocols {
          all;
        }
      }
    }
  }
}
```

```

    }
  }
}

[edit]
user@host# show security policies
from-zone trust to-zone untrust {
  policy pptp {
    match {
      source-address any;
      destination-address any;
      application junos-pptp;
    }
    then {
      permit;
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Static NAT Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat static rule-set rs1 from zone trust
set security nat static rule-set rs1 rule r1 match destination-address 30.5.2.120/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 10.5.1.120/32

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure a static NAT rule set:

1. Create a static NAT rule set.

```

[edit security nat static rule-set rs1]
user@host# set from zone trust

```
2. Define the rule to match with the destination address.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 match destination-address 30.5.2.120/32

```
3. Define the static NAT prefix for the device.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 then static-nat prefix 10.5.1.120/32

```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security nat
static {
  rule-set rs1 {
    from zone trust;
    rule r1 {
      match {
        destination-address 30.5.2.120/32;
      }
      then {
        static-nat {
          prefix {
            10.5.1.120/32;
          }
        }
      }
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Source NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat source pool src-p1 address 30.5.1.120/32
set security nat source rule-set src-rs1 from zone trust
set security nat source rule-set src-rs1 to zone untrust
set security nat source rule-set src-rs1 rule src-r1 match source-address 20.5.1.120/32
set security nat source rule-set src-rs1 rule src-r1 match destination-address 10.5.2.120/32
set security nat source rule-set src-rs1 rule src-r1 then source-nat pool src-p1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure a source NAT pool and rule set:

1. Create a source NAT pool.

```

[edit security nat source]
user@host# set pool src-p1 address 30.5.1.120/32

```
2. Create a source NAT rule set.

```

[edit security nat source ]
user@host# set rule-set src-rs1 from zone trust
user@host# set rule-set src-rs1 to zone untrust

```
3. Configure a rule that matches packets and translates the source address to an address in the source pool.

```

[edit security nat source]

```

```
user@host# set rule-set src-rs1 rule src-r1 match source-address 20.5.1.120/32
```

4. Configure a rule that matches packets and translates the destination address to an address in the source pool.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule src-r1 match destination-address 10.5.2.120/32
```

5. Configure a source NAT pool in the rule.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule src-r1 then source-nat pool src-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
  pool src-p1 {
    address {
      30.5.1.120/32;
    }
  }
  rule-set src-rs1 {
    from zone trust;
    to zone untrust;
    rule src-r1 {
      match {
        source-address 20.5.1.120/32;
        destination-address 10.5.2.120/32;
      }
      then {
        source-nat {
          pool {
            src-p1;
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Destination NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat destination pool des-p1 address 10.5.1.120/32
set security nat destination rule-set des-rs1 from zone trust
set security nat destination rule-set des-rs1 rule des-r1 match source-address 20.5.1.120/32
set security nat destination rule-set des-rs1 rule des-r1 match destination-address 30.5.1.120/32
set security nat destination rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure a destination NAT pool and rule set:

1. Create a destination NAT pool.

```
[edit security nat destination]
user@host# set pool des-p1 address 10.5.1.120/32
```
2. Create a destination NAT rule set.

```
[edit security nat destination]
user@host# set rule-set des-rs1 from zone trust
```
3. Configure a rule that matches packets and translates the source address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match source-address 20.5.1.120/32
```
4. Configure a rule that matches packets and translates the destination address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match destination-address 30.5.1.120/32
```
5. Configure a source NAT pool in the rule.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
destination {
  pool des-p1 {
    address {
      10.5.1.120/32;
    }
  }
}
```

```

}
rule-set des-rs1 {
  from zone trust;
  rule des-r1 {
    match {
      source-address 20.5.1.120/32;
      destination-address 30.5.1.120/32;
    }
    then {
      destination-nat {
        pool {
          des-p1;
        }
      }
    }
  }
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring PPTP ALG trace options

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security alg pptp traceoptions flag all
set security alg traceoptions file trace
set security alg traceoptions file size 1g
set security alg traceoptions level verbose

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the [CLI User Guide](#).

To configure PPTP ALG trace options:

1. Enable PPTP ALG trace options.

```
[edit security alg]
user@host#set pptp traceoptions flag all
```
2. Configure a filename to receive output from the tracing operation.

```
[edit security alg]
user@host#set traceoptions file trace
```
3. Specify the maximum trace file size.

```
[edit security alg]
user@host#set traceoptions file size 1g
```
4. Specify the level of tracing output.

```
[edit security alg]
```

```
user@host#set traceoptions level verbose
```

Results From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security alg
traceoptions {
  file trace size 1g;
  level verbose;
}
pptp traceoptions flag all;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the PPTP ALG Control Session on page 57](#)
- [Verifying the PPTP ALG Flow Gate Information on page 57](#)
- [Verifying PPTP ALG on page 58](#)
- [Verifying the PPTP Resource Manager Group on page 58](#)
- [Verifying the PPTP Resource Information on page 58](#)

Verifying the PPTP ALG Control Session

Purpose Verify that the PPTP control session is created and all the PPTP control and data sessions are created.

Action From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
  SSession ID: 57, Policy name: pptp, Timeout: 1787
Resource information : PPTP ALG, 1, 0
In: 20.20.20.32/3905 --> 10.10.10.32/1723;tcp, If: ge-0/0/1.0 Pkts: 6, Bytes: 584
Out: 10.10.10.32/1723 --> 20.20.20.32/3905;tcp, If: fe-0/0/2.0 Pkts: 4, Bytes:
352

Session ID: 58, Policy name: pptp, Timeout: 1799
In: 20.20.20.32/0 --> 10.10.10.32/256;gre, If: ge-0/0/1.0
Out: 10.10.10.32/256 --> 20.20.20.32/65001;gre, If: fe-0/0/2.0

Session ID: 59, Policy name: pptp, Timeout: 1787
In: .10.10.10.32/0 --> 20.20.20.32/260;gre, If: ge-0/0/1.0
Out: 20.20.20.32/260 --> 10.10.10.32/65000;gre, If: fe-0/0/2.0
```

- Meaning**
- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name or number of packets in and out.
 - **Policy name**—Policy name that permitted the traffic.
 - **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and the source interface for this session is ge-0/0/1.0).
 - **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and destination interface for this session is fe-0/0/2.0).

Verifying the PPTP ALG Flow Gate Information

Purpose Verify that the flow gate is opened for TCP data channel connection.

Action From operational mode, enter the **show security flow gate** command.

```
user@host>show security flow gate

Hole: 20.0.172.24-20.0.172.24/0-0->21.0.172.38-21.0.172.38/25750-25750
Translated: 2015::172:24/65000->2005::172:108/360
Protocol: gre
Application: PPTP ALG/69
Age: 118 seconds
Flags: 0x0080
Zone: trust
Reference count: 1
Resource: 12-1-1

Hole: 2005::172:108-0-0->2015::172:24-2432-2432
Translated: 21.0.172.38/65001->20.0.172.24/2432
Protocol: gre
Application: PPTP ALG/69
```

```
Age: 120 seconds
Flags: 0x8080
Zone: untrust
Reference count: 1
Resource: 12-1-2
```

```
Valid gates: 2
Pending gates: 0
Invalidated gates: 0
Gates in other states: 0
Total gates: 2
```

Verifying PPTP ALG

Purpose Verify that the PPTP ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host>show security alg status
ALG Status :
  PPTP      : Enabled
  RSH       : Disabled
  RTSP      : Enabled
  SCCP      : Enabled
  SIP       : Enabled
  TALK      : Enabled
  TFTP      : Enabled
  IKE-ESP   : Disabled
```

Meaning The output shows the PPTP ALG status as follows:

- Enabled—Shows the PPTP ALG is enabled.
- Disabled—Shows the PPTP ALG is disabled.

Verifying the PPTP Resource Manager Group

Purpose Verify the total number of resource manager groups and active groups that are used by the PPTP ALG.

Action From operational mode, enter the **show security resource-manager group active** command.

```
user@host>show security resource-manager group active
Group ID 1: Application - PPTP ALG
      Total groups 19763, active groups 1
```

Verifying the PPTP Resource Information

Purpose Verify the total number of resources and active resources that are used by the PPTP ALG.

Action From operational mode, enter the **show security resource-manager resource active** command.

```
user@host>show security resource-manager resource active
Resource ID 2: Group ID - 1, Application - PPTP ALG
```

Resource ID 1: Group ID - 1, Application - PPTP ALG
Total Resources 93286, active resources 2

Understanding RPC ALGs

Junos OS supports basic Remote Procedure Call Application Layer Gateway (RPC ALG) services. RPC is a protocol that allows an application running in one address space to access the resources of applications running in another address space as if the resources were local to the first address space. The RPC ALG is responsible for RPC packet processing.

The RPC ALG in Junos OS supports the following services and features:

- Sun Microsystems RPC Open Network Computing (ONC)
- Microsoft RPC Distributed Computing Environment (DCE)
- Dynamic port negotiation
- Ability to allow and deny specific RPC services
- Static Network Address Translation (NAT) and source NAT (with no port translation)
- RPC applications in security policies

Use the RPC ALG if you need to run RPC-based applications such as NFS or Microsoft Outlook. The RPC ALG functionality is enabled by default.

- Related Documentation**
- [ALG Overview on page 3](#)
 - [Understanding Sun RPC ALGs on page 62](#)
 - [Understanding Microsoft RPC ALGs on page 67](#)

Understanding Sun RPC ALGs

Sun Microsystems Remote Procedure Call (Sun RPC)—also known as Open Network Computing Remote Procedure Call (ONC RPC)—provides a way for a program running on one host to call procedures in a program running on another host. Because of the large number of RPC services and the need to broadcast, the transport address of an RPC service is dynamically negotiated based on the service's program number and version number. Several binding protocols are defined for mapping the RPC program number and version number to a transport address.

Junos OS supports the Sun RPC as a predefined service and allows and denies traffic based on a security policy you configure. The Application Layer Gateway (ALG) provides the functionality for Juniper Networks devices to handle the dynamic transport address negotiation mechanism of the Sun RPC and to ensure program number-based security policy enforcement. You can define a security policy to permit or deny all RPC requests, or to permit or deny by specific program number. The ALG also supports route mode and Network Address Translation (NAT) mode for incoming and outgoing requests.

When an application or a PC client calls a remote service, it needs to find the transport address of the service. In the case of TCP/UDP, the address is a port number. A typical procedure for this case is as follows:

1. The client sends the GETPORT message to the RPCBIND service on the remote machine. The GETPORT message contains the program number, and version and procedure number of the remote service it is attempting to call.
2. The RPCBIND service replies with a port number.
3. The client calls the remote service using the port number returned.
4. The remote service replies to the client.

A client also can use the CALLIT message to call the remote service directly, without determining the port number of the service. In this case, the procedure is as follows:

1. The client sends a CALLIT message to the RPCBIND service on the remote machine. The CALLIT message contains the program number and the version and procedure number of the remote service it attempting to call.
2. RPCBIND calls the service for the client.
3. RCPBIND replies to the client if the call has been successful. The reply contains the call result and the service's port number.

The Sun RPC ALG dynamically allocates new mapping entries instead of using a default size (512 entries). It also offers a flexible time-based RPC mapping entry that removes the mapping entry (auto-clean) without affecting the associated active RPC sessions, including both control session and data session.

You can define the Sun RPC mapping entry ageout value using the **set security alg sunrpc map-entry-timeout value** command. The ageout value ranges from 1 hour to 72 hours, and the default value is 32 hours.

If the Sun RPC ALG service does not trigger the control negotiation even after 72 hours, the maximum RPC ALG mapping entry value times out and the new data connection to the service fails.

Enabling Sun RPC ALGs (CLI Procedure)

The Sun RPC ALG is enabled by default and requires no configuration.

To disable the Sun RPC ALG, enter the following command:

```
user@host# set security alg sunrpc disable
```

To reenabling the Sun RPC ALG, enter the following command:

```
user@host# delete security alg sunrpc
```

Customizing Sun RPC Applications (CLI Procedure)

All Sun RPC applications can be customized by using a predefined application set.

For example, an application can be customized to open the control session only and not allow any data sessions:

```
application-set junos-sun-rpc {  
  application junos-sun-rpc-tcp;  
  application junos-sun-rpc-udp;  
}
```

In the following example, the predefined application set allows data sessions only. It will not work without the control session:

```
application-set junos-sun-rpc-portmap {  
  application junos-sun-rpc-portmap-tcp;  
  application junos-sun-rpc-portmap-udp;  
}
```

To customize all Sun RPC applications with predefined application sets, use both application sets in the policy:

```
application-set [junos-sun-rpc junos-sun-rpc-portmap]
```

NOTE: MS RPC applications are customized in the same way as SUN RPC applications.

- [Customizing Microsoft RPC Applications \(CLI Procedure\) on page 73](#)

Understanding Sun RPC Services

Sun RPC, also known as Open Network computing remote procedure call (ONC RPC), provides a way for a program running on one host to call procedures in a program running on another host. Sun RPC services are defined by a program identifier. The program identifier is independent of any transport address, and most of the Sun RPC sessions are initiated through TCP or UDP port 111. Each host links the required RPC service to a dynamic TCP or UDP port that is negotiated over the port 111 control channel, allowing the client to connect to either TCP or UDP port 111.

Predefined Sun Microsystems remote procedure call (Sun RPC) services include:

- **junos-sun-rpc-tcp**
- **junos-sun-rpc-udp**

The Sun RPC ALG can be applied by using the following methods:

- ALG default application—Use one of the following predefined applications for control and data connections in your policy:
 - `junos-sun-rpc-any-tcp`
 - `junos-sun-rpc-any-udp`
 - `junos-sun-rpc-mountd-tcp`
 - `junos-sun-rpc-mountd-udp`
 - `junos-sun-rpc-nfs-tcp`
 - `junos-sun-rpc-nfs-udp`
 - `junos-sun-rpc-nlockmgr-tcp`
 - `junos-sun-rpc-nlockmgr-udp`
 - `junos-sun-rpc-portmap-tcp`
 - `junos-sun-rpc-portmap-udp`
 - `junos-sun-rpc-rquotad-tcp`
 - `junos-sun-rpc-rquotad-udp`
 - `junos-sun-rpc-ruserd-tcp`
 - `junos-sun-rpc-ruserd-udp`
 - `junos-sun-rpc-sadmind-tcp`
 - `junos-sun-rpc-sadmind-udp`
 - `junos-sun-rpc-sprayd-tcp`
 - `junos-sun-rpc-sprayd-udp`
 - `junos-sun-rpc-status-tcp`
 - `junos-sun-rpc-status-udp`
 - `junos-sun-rpc-walld-tcp`
 - `junos-sun-rpc-walld-udp`
 - `junos-sun-rpc-yplibind-tcp`
 - `junos-sun-rpc-yplibind-udp`
 - `junos-sun-rpc-ypserv-tcp`
 - `junos-sun-rpc-ypserv-udp`
- Default control application—Use the predefined control through `junos-sun-rpc`:
 - Create an application for data (`USER_DEFINED_DATA`). You can make a set of your own data (for example, `my_rpc_application_set`) and use it in the policy.

- ALG default application set—Use the predefined application set for control and customized data application in the policy:
 - `junos-sun-rpc` (for control sessions)
 - `junos-sun-rpc-any`
 - `junos-sun-rpc-mountd`
 - `junos-sun-rpc-nfs`
 - `junos-sun-rpc-nfs-access`
 - `junos-sun-rpc-nlockmgr`
 - `junos-sun-rpc-portmap` (for data sessions)
 - `junos-sun-rpc-rquotad`
 - `junos-sun-rpc-ruserd`
 - `junos-sun-rpc-sadmind`
 - `junos-sun-rpc-sprayd`
 - `junos-sun-rpc-status`
 - `junos-sun-rpc-walld`
 - `junos-sun-rpc-ypbind`
 - `junos-sun-rpc-ypserv`
- Custom control and custom data application—Use a customized application:
 - Create an application for control (`USER_DEFINED_CONTROL`) and data (`USER_DEFINED_DATA`).
 - In the policy, use the user-defined application set for a control and customized data application:
 - `USER_DEFINED_CONTROL`
 - `USER_DEFINED_DATA`

Table 3 lists predefined Sun RPC services, a program identifier associated with each service, and a description of each service.

Table 3: Predefined Sun RPC Services

Service	Program ID	Description
PORTMAP	100000	Sun RPC Portmapper protocol is a TCP or UDP port-based service that includes TCP or UDP port 111.
NFS	100003	Sun RPC Network File System.
MOUNT	100005	Sun RPC mount process.

Table 3: Predefined Sun RPC Services (*continued*)

Service	Program ID	Description
YPBIND	100007	Sun RPC Yellow Page Bind service.
STATUS	100024	Sun RPC status.

Understanding Microsoft RPC ALGs

Microsoft Remote Procedure Call (MS RPC) is the Microsoft implementation of the Distributed Computing Environment (DCE) RPC. Like the Sun RPC, MS RPC provides a way for a program running on one host to call procedures in a program running on another host. Because of the large number of RPC services and the need to broadcast, the transport address of an RPC service is dynamically negotiated based on the service program's Universal Unique Identifier (UUID). The specific UUID is mapped to a transport address.

Junos OS devices running Junos OS support MS RPC as a predefined service and allow and deny traffic based on a policy you configure. The Application Layer Gateway (ALG) provides the functionality for Juniper Networks devices to handle the dynamic transport address negotiation mechanism of the MS RPC, and to ensure UUID-based security policy enforcement. You can define a security policy to permit or deny all RPC requests, or to permit or deny by specific UUID number. The ALG also supports route mode and Network Address Translation (NAT) mode for incoming and outgoing requests.

When both the MS RPC client and MS RPC server are 64 bit capable (such as MS Exchange 2008), they negotiate to use NDR64 transfer syntax during the network communication. When you use NDR64, the interface parameters should be encoded according to NDR64 syntax, because the packet format for NDR64 is different from the packet format for NDR20 (32 bit version).

In MS RPC, there is a remote activation interface of the DCOM Remote Protocol called ISystemActivator (also known as IRemoteSCMAActivator). It is used by the Windows Management Instrumentation Command-line (WMIC), Internet Information Services (IIS), and many other applications that are used extensively.

The MS-RPC ALG dynamically allocates new mapping entries instead of using a default size (512 entries). It also offers a flexible time-based RPC mapping entry that removes the mapping entry (auto-clean) without affecting the associated active RPC sessions, including both control session and data session.

You can define the MS RPC mapping entry ageout value using the **set security alg msrpc map-entry-timeout value** command. The ageout value ranges from 1 hour to 72 hours, and the default value is 32 hours.

If the MS-RPC ALG service does not trigger the control negotiation even after 72 hours, the maximum RPC ALG mapping entry value times out and the new data connection to the service fails.

Configuring the Microsoft RPC ALG

You can configure the Microsoft RPC ALG using the following three methods:

- [Configuring the MS-RPC ALG with a Predefined Microsoft Application on page 68](#)
- [Configuring the MS-RPC ALG with a Wildcard UUID on page 69](#)
- [Configuring the MS-RPC ALG with a Specific UUID on page 69](#)

Configuring the MS-RPC ALG with a Predefined Microsoft Application

There are several predefined MS applications. To view the predefined Microsoft applications from the CLI, enter the **show configuration groups junos-defaults** command.

```
user@host> show security policies
from-zone trust to-zone untrust {
  policy p1 {
    match {
      source-address any;
      destination-address any;
      application junos-ms-rpc-msexchange;
    }
    then {
      permit;
    }
  }
}
```

After you commit the configuration, from the CLI, enter the **show security alg msrpc object-id-map** command to view the output.

```
user@host> show security alg msrpc object-id-map
UUID                                OID
1544f5e0-613c-11d1-93df-00c04fd7bd09 0x80000001
a4f1db00-ca47-1067-b31f-00dd010662da 0x80000002
f5cc5a18-4264-101a-8c59-08002b2f8426 0x80000003
```

The output shows that the UUID has been applied for the policy.

Configuring the MS-RPC ALG with a Wildcard UUID

To permit the configuration for any MS RPC application, add the **application junos-ms-rpc-any** statement to the Permit configuration.

```
user@host> show security policies
from-zone trust to-zone untrust {
  policy p1 {
    match {
      source-address any;
      destination-address any;
      application junos-ms-rpc-any;
    }
    then {
      permit;
    }
  }
}
```

After you commit the configuration, from the CLI, enter the **show security alg msrpc object-id-map** command to view the output.

```
user@host> show security alg msrpc object-id-map
UUID                                OID
ffffffff-ffff-ffff-ffff-fffffffffff 0x80000004
```

Configuring the MS-RPC ALG with a Specific UUID

For applications that have not been predefined, you need to manually configure a specific UUID. For example, to permit a NETLOGON application that has not been predefined, you add the **application msrpc-netlogon** statement to the Permit configuration.

```
user@host> show applications
application msrpc-netlogon {
  term t1 protocol tcp uuid 12345678-1234-abcd-ef00-01234567cffb;
  term t2 protocol udp uuid 12345678-1234-abcd-ef00-01234567cffb;
  term t3 protocol tcp uuid 12345778-1234-abcd-ef00-0123456789ab;
}
user@host> show security policies
from-zone trust to-zone untrust {
  match {
    source-address any;
    destination-address any;
    application msrpc-netlogon;
  }
  then {
    permit;
  }
}
```

After you commit the configuration, from the CLI, enter the **show security alg msrpc object-id-map** command to verify the Microsoft Universal Unique Identifier to Object ID

(UUID-to-OID) mapping table. The Microsoft RPC ALG monitors packets on TCP port 135.

```
user@host> show security alg msrpc object-id-map
UUID                                OID
12345778-1234-abcd-ef00-0123456789ab 0x80000006
12345678-1234-abcd-ef00-01234567cfff 0x80000005
be617c0-31a5-11cf-a7d8-00805f48a135 0x80000020
e3514235-4b06-11d1-ab04-00c04fc2dcd2 0x80000002
67df7c70-0f04-11ce-b13f-00aa003bac6c 0x80000014
```

NOTE: The `show security alg msrpc object-id-map` CLI command has a chassis cluster node option to permit the output to be restricted to a particular node or to query the entire cluster. The `show security alg msrpc object-id-map node` CLI command options are `<node-id | all | local | primary>`.

Understanding Microsoft RPC Services

MS RPC is the Microsoft implementation of the Distributed Computing Environment (DCE) RPC. Like the Sun RPC, the MS RPC provides a way for a program running on one host to call procedures in a program running on another host. The MS RPC is dynamically negotiated based on the service program's universal unique identifier (UUID). The specific UUID is mapped to a transport address.

Predefined Microsoft remote procedure call (MS RPC) services include:

- **junos-ms-rpc-epm**
- **junos-ms-rpc-tcp**
- **junos-ms-rpc-udp**

MS RPC application defaults include:

- `junos-ms-rpc-iis-com-1`
- `junos-ms-rpc-iis-com-adminbase`
- `junos-ms-rpc-msexchange-directory-nsp`
- `junos-ms-rpc-msexchange-directory-rfr`
- `junos-ms-rpc-msexchange-info-store`
- `junos-ms-rpc-uuid-any-tcp`
- `junos-ms-rpc-uuid-any-udp`
- `junos-ms-rpc-wmic-admin`
- `junos-ms-rpc-wmic-admin2`
- `junos-ms-rpc-wmic-mgmt`
- `junos-ms-rpc-wmic-webm-callresult`
- `junos-ms-rpc-wmic-webm-classobject`
- `junos-ms-rpc-wmic-webm-level1login`
- `junos-ms-rpc-wmic-webm-login-clientid`
- `junos-ms-rpc-wmic-webm-login-helper`
- `junos-ms-rpc-wmic-webm-objectsink`
- `junos-ms-rpc-wmic-webm-refreshing-services`
- `junos-ms-rpc-wmic-webm-remote-refresher`
- `junos-ms-rpc-wmic-webm-services`
- `junos-ms-rpc-wmic-webm-shutdown`

MS RPC application-set defaults include:

- `junos-ms-rpc`
- `junos-ms-rpc-any`
- `junos-ms-rpc-iis-com`
- `junos-ms-rpc-msexchange`
- `junos-ms-rpc-wmic`

[Table 4](#) lists predefined MS RPC services, UUID values associated with each service, and a description of each service.

Table 4: Predefined MS RPC services

Service	UUID	Description
EPM	elaf8308-5d1f-11c9-91a4-08002b14a0fa	MS RPC Endpoint Mapper (EPM) protocol is a TCP/UDP port-based service that includes TCP/UDP port 135.
EXCHANGE-DATABASE	1a190310-bb9c-11cd-90f8-00aa00466520	Microsoft Exchange Database service.
EXCHANGE-DIRECTORY	f5cc5a18-4264-101a-8c59-08002b2f8426 f5cc5a7c-4264-101a-8c59-08002b2f8426 f5cc59b4-4264-101a-8c59-08002b2f8426	Microsoft Exchange Directory service.
WIN-DNS	50abc2a4-574d-40b3-9d66-ee4fd5fba076	Microsoft Windows DNS server.
WINS	5f52c28-7f9f-101a-b52b-08002b2efabe 811109bf-a4e1-11d1-ab54-00a0c91e9b45	Microsoft WINS service.
WMIC-Webm-Level1Login	f309ad18-d86a-11d0-a075-00c04fb68820	This service allows users to connect to the management services interface in a particular namespace.

 - [Customizing Microsoft RPC Applications \(CLI Procedure\) on page 73](#)
 - [Understanding Sun RPC Services on page 64](#)

Customizing Microsoft RPC Applications (CLI Procedure)

MS RPC applications are customized in the same way as SUN RPC applications.

MS RPC services in security policies are:

- 0e4a0156-dd5d-11d2-8c2f-00c04fb6bcde
- 1453c42c-0fa6-11d2-a910-00c04f990f3b
- 10f24e8e-0fa6-11d2-a910-00c04f990f3b
- 1544f5e0-613c-11d1-93df-00c04fd7bd09

The corresponding TCP/UDP ports are dynamic. To permit them, you use the following statement for each number:

```
set applications application-name term term-name uuid hex-number
```

The ALG maps the program numbers into dynamically negotiated TCP/UDP ports based on these four UUIDs and permits or denies the service based on a policy you configure.

CHAPTER 8

Configuring the RSH ALG

- [Understanding the RSH ALG on page 75](#)
- [Example: Configuring the RSH ALG on page 75](#)

Understanding the RSH ALG

The Remote Shell (RSH) Application Layer Gateway (ALG) processes RSH packets that initiate requests and open two gates to allow return packets from the reverse direction to the client. One gate is used for an identification (ident) session to apply authorization and the other gate is used for a standard error (stderr) session to transfer an error message.

NOTE: The RSH ALG does not work if Port Address Translation (PAT) is configured. The RSH requires the port range to be between 512 to 1024. The source NAT module cannot match this port range.

Related Documentation

- [Example: Configuring the RSH ALG on page 75](#)

Example: Configuring the RSH ALG

This example shows how to configure the RSH ALG in route or NAT mode. The configuration allows RSH traffic to pass through a device, and it transfers remote commands and results between a client and a server located on opposite sides of a Juniper Networks device.

- [Requirements on page 75](#)
- [Overview on page 76](#)
- [Configuration on page 77](#)
- [Verification on page 85](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device

- Two PCs (server and client)

Before you begin:

- Understand the concepts behind ALGs. See [“ALG Overview” on page 3](#)
- Understand the basics of RSH ALG. See the [“Understanding the RSH ALG” on page 75](#)

Overview

In this example, first you configure network interfaces on the device. Create security zones and assign interfaces to the zones, and configure a policy to allow RSH traffic to go through an SRX Series device.

Then you create a static NAT rule set `rs1` with a rule `r1` to match with the destination address `40.0.172.10/32`, and you create a static NAT prefix with address `40.0.172.45/32`.

Next you create a source NAT pool `src-p1` with a source rule set `src-rs1` to translate packets from interface `fe-3/0/0.0` to interface `fe-3/0/1.0`. For matching packets, the source address is translated to an IP address in the `src-p1` pool.

Then you create a destination NAT pool `des-p1` with a destination rule set `des-rs1` to translate packets from zone `trust` to destination address `40.0.172.10/32`. For matching packets, the destination address is translated to an IP address in the `des-p1` pool. Finally, you enable RSH ALG trace options.

Topology

Figure 4 shows the RSH ALG topology.

Figure 4: RSH ALG Topology

Configuration

To configure the RSH ALG, perform these tasks:

- [Configuring a Route Mode on page 78](#)
- [Configuring a Static NAT Rule Set on page 80](#)
- [Configuring a Source NAT Pool and Rule Set without PAT on page 81](#)
- [Configuring a Destination NAT Pool and Rule Set on page 83](#)
- [Enabling RSH ALG Trace Options on page 84](#)

Configuring a Route Mode

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.208.172.58/21
set interfaces fe-3/0/0 unit 0 family inet address 30.3.3.149/8
set interfaces fe-3/0/1 unit 0 family inet address 40.4.4.149/8
set security zones security-zone trust host-inbound-traffic system-services all
set security zones security-zone trust host-inbound-traffic protocols all
set security zones security-zone trust interfaces fe-3/0/0.0
set security zones security-zone untrust host-inbound-traffic system-services all
set security zones security-zone untrust host-inbound-traffic protocols all
set security zones security-zone untrust interfaces fe-3/0/1.0
set security policies from-zone trust to-zone untrust policy rsh match source-address any
set security policies from-zone trust to-zone untrust policy rsh match destination-address any
set security policies from-zone trust to-zone untrust policy rsh match application junos-rsh
set security policies from-zone trust to-zone untrust policy rsh then permit
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure route mode:

1. Configure interfaces.

```
[edit interfaces]
user@host#set ge-0/0/0 unit 0 family inet address 10.208.172.58/21
user@host#set fe-3/0/0 unit 0 family inet address 30.3.3.149/8
user@host#set fe-3/0/1 unit 0 family inet address 40.4.4.149/8
```

2. Configure zones and assign interfaces to the zones.

```
[edit security zones security-zone]
user@host#set trust host-inbound-traffic system-services all
user@host#set trust host-inbound-traffic protocols all
user@host#set trust interfaces fe-3/0/0.0
user@host#set untrust host-inbound-traffic system-services all
user@host#set untrust host-inbound-traffic protocols all
user@host#set untrust interfaces fe-3/0/1.0
```

3. Configure an RSH policy that allows RSH traffic from the trust zone to the untrust zone.

```
[edit security policies from-zone trust to-zone untrust]
user@host#set policy rsh match source-address any
user@host#set policy rsh match destination-address any
user@host#set policy rsh match application junos-rsh
user@host#set policy rsh then permit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, and **show security policies** commands. If the output does not display

the intended configuration, repeat the configuration instructions in this example for correction.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 10.208.172.58/21;
    }
  }
}
fe-3/0/0 {
  unit 0 {
    family inet {
      address 30.3.3.149/8;
    }
  }
}
fe-3/0/1 {
  unit 0 {
    family inet {
      address 40.4.4.149/8;
    }
  }
}

[edit]
user@host# show security zones
..
security-zone trust {
  host-inbound-traffic {
    system-services {
      all;
    }
    protocols {
      all;
    }
  }
  interfaces {
    fe-3/0/0.0;
  }
}
security-zone untrust {
  host-inbound-traffic {
    system-services {
      all;
    }
    protocols {
      all;
    }
  }
  interfaces {
```

```

        fe-3/0/1.0;
    }
}
...

[edit]
user@host# show security policies
from-zone trust to-zone untrust {
    policy rsh {
        match {
            source-address any;
            destination-address any;
            application junos-rsh;
        }
        then {
            permit;
        }
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Static NAT Rule Set

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat static rule-set rs1 from zone trust
set security nat static rule-set rs1 rule r1 match destination-address 40.0.172.10/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 40.0.172.45/32

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a static NAT rule set:

1. Create a static NAT rule set.

```

[edit security nat static rule-set rs1]
user@host# set from zone trust

```
2. Define the rule to match with the destination address.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 match destination-address 40.0.172.10/32

```
3. Define the static NAT prefix for the device.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 then static-nat prefix 40.0.172.45/32

```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
static {
  rule-set rs1 {
    from zone trust;
    rule r1 {
      match {
        destination-address 40.0.172.10/32;
      }
      then {
        static-nat {
          prefix {
            40.0.172.45/32;
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Source NAT Pool and Rule Set without PAT

CLI Quick Configuration

NOTE: The RSH ALG does not support PAT configuration. The RSH ALG requires the stderr port range to be between 512 to 1024. The source NAT module cannot match this port range.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source pool src-p1 address 40.0.172.100/32 to 40.0.172.101/32
set security nat source pool src-p1 port no-translation
set security nat source rule-set src-rs1 from interface fe-3/0/0.0
set security nat source rule-set src-rs1 to interface fe-3/0/1.0
set security nat source rule-set src-rs1 rule r1 match source-address 30.0.0.0/8
set security nat source rule-set src-rs1 rule r1 match destination-address 40.0.0.0/8
set security nat source rule-set src-rs1 rule r1 then source-nat pool src-p1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a source NAT pool and rule set:

1. Create a source NAT pool.

```
[edit security nat source]
user@host# set pool src-p1 address 40.0.172.100/32 to 40.0.172.101/32
```
2. Create a source NAT pool with no port translation.

```
[edit security nat source ]
set pool src-p1 port no-translation
```
3. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set src-rs1 from interface fe-3/0/0.0
user@host# set rule-set src-rs1 to interface fe-3/0/1.0
```
4. Configure a rule that matches packets and translates the source address to an address in the source pool.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 match source-address 30.0.0.0/8
```
5. Configure a rule that matches packets and translates the destination address to an address in the source pool.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 match destination-address 40.0.0.0/8
```
6. Configure a source NAT pool in the rule.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 then source-nat pool src-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
  pool src-p1 {
    address {
      40.0.172.100/32 to 40.0.172.101/32;
    }
    port no-translation;
  }
}
rule-set src-rs1 {
  from interface fe-3/0/0.0;
  to interface fe-3/0/1.0;
  rule r1 {
    match {
      source-address 30.0.0.0/8;
      destination-address 40.0.0.0/8;
```

```

    }
    then {
        source-nat {
            pool {
                src-p1;
            }
        }
    }
}
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Destination NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat destination pool des-p1 address 40.0.172.45/32
set security nat destination rule-set des-rs1 from zone trust
set security nat destination rule-set des-rs1 rule des-r1 match source-address 30.0.172.12/32
set security nat destination rule-set des-rs1 rule des-r1 match destination-address 40.0.172.10/32
set security nat destination rule-set des-rs1 rule des-r1 then destination-nat pool des-p1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a destination NAT pool and rule set:

1. Create a destination NAT pool.

```

[edit security nat destination]
user@host# set pool des-p1 address 40.0.172.45/32

```
2. Create a destination NAT rule set.

```

[edit security nat destination]
user@host# set rule-set des-rs1 from zone trust

```
3. Configure a rule that matches packets and translates the source address to the address in the pool.

```

[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match source-address 30.0.172.12/32

```
4. Configure a rule that matches packets and translates the destination address to the address in the pool.

```

[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match destination-address 40.0.172.10/32

```
5. Configure a source NAT pool in the rule.

```

[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 then destination-nat pool des-p1

```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
destination {
  pool des-p1 {
    address {
      40.0.172.45/32;
    }
  }
}
rule-set des-rs1 {
  from zone trust;
  rule des-r1 {
    match {
      source-address 30.0.172.12/32;
      destination-address 40.0.172.10/32;
    }
    then {
      destination-nat {
        pool {
          des--p1;
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Enabling RSH ALG Trace Options

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security alg rsh traceoptions flag all
set security alg traceoptions file trace
set security alg traceoptions file size 1g
set security alg traceoptions level verbose
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To enable RSH ALG trace options:

1. Enable RSH ALG trace options.

```
[edit security alg]
user@host#set sql traceoptions flag all
```

2. Configure a filename to receive output from the tracing operation.

```
[edit security alg]
user@host#set traceoptions file trace
```

3. Specify the maximum trace file size.

```
[edit security alg]
user@host#set traceoptions file size 1g
```

4. Specify the level of tracing output.

```
[edit security alg]
user@host#set traceoptions level verbose
```

Results From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security alg
traceoptions {
  file trace size 1g;
  level verbose;
}
rsh traceoptions flag all;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the RSH ALG Control Session on page 85](#)
- [Verifying the RSH ALG on page 86](#)
- [Verifying the RSH ALG Resource Manager Group on page 87](#)
- [Verifying the RSH ALG Resource Information on page 87](#)

Verifying the RSH ALG Control Session

Purpose Verify that the RSH command is executed and all the RSH control and data sessions are created.

Action From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
Session ID: 2924, Policy name: rsh/6, Timeout: 2, Valid
Resource information : RSH ALG, 2, 0
  In: 30.0.172.12/1023 --> 40.0.172.45/514;tcp, If: fe-3/0/0.0, Pkts: 7, Bytes:
320
  Out: 40.0.172.45/514 --> 30.0.172.12/1023;tcp, If: fe-3/0/1.0, Pkts: 7, Bytes:
314

Session ID: 2925, Policy name: rsh/6, Timeout: 2, Valid
Resource information : RSH ALG, 2, 24
  In: 40.0.172.45/44864 --> 30.0.172.12/113;tcp, If: fe-3/0/1.0, Pkts: 5, Bytes:
```

```

278
  Out: 30.0.172.12/113 --> 40.0.172.45/44864;tcp, If: fe-3/0/0.0, Pkts: 5, Bytes:
345

```

```

Session ID: 2926, Policy name: rsh/6, Timeout: 2, Valid

```

```

Resource information : RSH ALG, 2, 23

```

```

  In: 40.0.172.45/1023 --> 30.0.172.12/1022;tcp, If: fe-3/0/1.0, Pkts: 4, Bytes:
216

```

```

  Out: 30.0.172.12/1022 --> 40.0.172.45/1023;tcp, If: fe-3/0/0.0, Pkts: 3, Bytes:
164

```

```

Total sessions: 3

```

- Meaning**
- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name, number of packets in and out.
 - **Policy name**—Policy name that permitted the traffic.
 - **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and source interface for this session is fe-3/0/0.0).
 - **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and destination interface for this session is fe-3/0/1.0).

Verifying the RSH ALG

Purpose Verify that the RSH ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```

user@host>show security alg status

```

```

ALG Status :

```

```

  PPTP      : Enabled
  RSH       : Disabled
  RTSP      : Enabled
  SCCP      : Enabled
  SIP       : Enabled
  TALK      : Enabled
  TFTP      : Enabled
  IKE-ESP   : Disabled

```

NOTE: The RSH ALG is disabled by default. To enable the RSH ALG, enter the **set security alg rsh** command in the configuration mode.

Meaning The output shows the RSH ALG status as follows:

- **Enabled**—Shows the RSH ALG is enabled.
- **Disabled**—Shows the RSH ALG is disabled.

Verifying the RSH ALG Resource Manager Group

Purpose Verify the total number of resource manager groups and active groups that are used by the RSH ALG.

Action From operational mode, enter the **show security resource-manager group active** command.

```
user@host>show security resource-manager group active
Group ID 1: Application - RSH ALG
Total groups 677, active groups 1
```

Verifying the RSH ALG Resource Information

Purpose Verify the total number of resources and active resources that are used by the RSH ALG.

Action From operational mode, enter the **show security resource-manager resource active** command.

```
user@host>show security resource-manager resource active
Resource ID 2: Group ID - 1, Application - RSH ALG

Resource ID 1: Group ID - 1, Application - RSH ALG
Total Resources 4044, active resources 2
```

Understanding the RTSP ALG

- [Overview on page 89](#)
- [RTSP Modes on page 90](#)

Overview

RTSP (Real-Time Streaming Protocol) is an Application Layer protocol for controlling the delivery of data with real-time properties. It is similar in syntax and operation to HTTP/1.1. Unlike SIP and H.323, the purpose of RTSP is to access existing media files over the network and to control the replay of the media. The typical communication is between a client (running RealPlayer for example) and a streaming media server. Commands include the ability to pause and play media files from the remote server.

RTSP is a control channel protocol between the media client and media server. The data channel uses a different protocol, usually Real-Time Transport Protocol (RTP) or RTP Control Protocol (RTCP).

In RTSP standard mode, the client sets up three network channels with the RTSP server when media data is delivered using RTP over UDP.

RTSP runs over TCP. RTP and RTCP run over UDP. The ports for RTP and RTCP packets are dynamically negotiated by the client and server using RTSP. Because RTP and RTCP ports are dynamic, these ports cannot be allowed by a static policy. The main purpose of introducing an RTSP ALG to a firewall is to create dynamic policy (pinhole) according to the result of client/server negotiation so that RTP and RTCP traffic can pass through.

When the client and server reside in different realms, they might not be able to determine how to route to the address of the RTP or RTCP offer given by the peer. In this case, ALG needs to be involved to do translation for the RTP or RTCP offer address and modify it in the payload.

After the connection is established, the RTSP ALG monitors the messages exchanged between the client and server, tracks the status change of the dialog, and returns all the resources it acquired to support an RTSP dialog back to the system after the dialog has completed or failed.

RTSP Modes

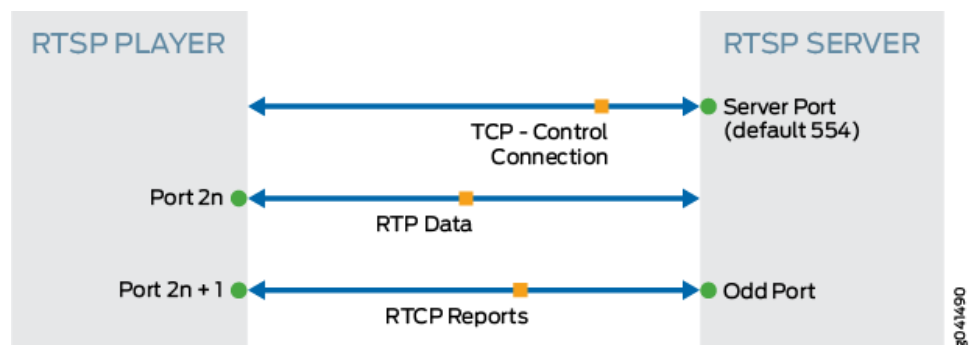

Standard Mode

In RTSP standard mode, the client sets up three network channels with the RTSP server when media data is delivered using RTP over UDP.

A full-duplex TCP connection is used for control and negotiation. A full-duplex UDP channel is used for media data delivery using the RTP packet format. In most cases, RTP is initiated from the server. A full-duplex UDP channel called RTCP is used to provide synchronization information to the client and packet loss information to the server.

Figure 5 shows the RTSP ALG standard mode.

Figure 5: RTSP ALG Standard Mode

Interleave Mode

In RTSP interleave mode, media data can be made into packets using RTP or RDT over TCP. In this scenario, a single full-duplex TCP connection is used for both control and for media data delivery from the RTSP server to the client. The data stream is interleaved with the RTSP control stream.

Figure 6 shows the RTSP ALG interleave mode.

Figure 6: RTSP ALG Interleave Mode

Understanding IPv6 Support for RTSP ALG

IPv6 is supported on the RTSP ALG along with NAT-PT mode and NAT64 address translation.

This feature enables the RTSP ALG to parse IPv6 RTSP packets, open an IPv6 pattern pinhole, and translate the Layer 7 IPv6 address according to the NAT configuration. Also, support for IPv6 RTSP transaction pass through under permission policy and IPv6 RTSP transaction pass through under NAT-PT and NAT 64 are enabled.

The RTSP ALG with IPv6 support has the following limitations:

- Real-Time Streaming Protocol (RTSP) is an Application Layer protocol for controlling the delivery of data with real-time properties. The RTSP ALG supports a peer client, and the server transmits real-time media; it does not support third-party endpoints involved in the transaction.
- In case of destination NAT or NAT64 for IP address translation, if the RTSP message (including the Session Description Protocol [SDP] application content) length exceeds 2500 bytes, then the RTSP ALG processes only the first 2500 bytes of the message and ignores the rest of the message. In this scenario, the IP address in the RTSP message is not translated if the IP address does not appear in the first 2500 bytes.

Related Documentation

- [Understanding the RTSP ALG on page 89](#)

Understanding RTSP ALG Messages

- [RTSP Messages Format on page 91](#)
- [RTSP Methods on page 92](#)
- [RTSP Status Code on page 92](#)
- [RTSP Header on page 93](#)

RTSP Messages Format

RTSP is text based and uses the ISO 10646 character set in UTF-8 encoding. Lines are terminated by CRLF, and an empty line is the separator of the message and body.

The first line is called the start-line. For request messages from client to server, the start-line represents the RTSP method. For the response message from server to client, the start-line represents the RTSP status code as the reply of method. The status code element is a 3-digit integer result code.

RTSP Methods

There are nine types of methods during one transaction.

- **OPTION**—Represents a request for information about the communication options available on the request/response chain identified by the Request-URL. This method allows the client to determine the options, requirements, or both associated with a resource, or the capabilities of a server, without implying a resource action or initiating a resource retrieval.
- **DESCRIBE**—Retrieves the description of a presentation or media object identified by the request URL from a server. This method might use the Accept header to specify the description formats that the client interprets.
- **ANNOUNCE**—Request sent from client to server, this method posts the description of a presentation or media object identified by the request URL to a server. When request sent from server to client, this method updates the session description in real-time.
- **SETUP**—Requests a URI and specifies the transport mechanism to be used for the streamed media.
- **PLAY**—Informs the server to start sending data using the mechanism specified in SETUP.
- **PAUSE**—Requests the stream delivery to be interrupted temporarily.
- **TEARDOWN**—Stops the stream delivery for the given URI, freeing the resource associated with it.
- **GET_PARAMETER**—Retrieves the value of a parameter of a presentation or stream specified in the URI.
- **SET_PARAMETER**—Sets the value of a parameter for a presentation or stream specified by the URI.

RTSP Status Code

The first digit of the status code defines the class of response.

- **1****: Informational—Request received, continuing process.
- **2****: Success
- **3****: Redirection—Further action must be taken in order to complete the request.
- **4****: Client Error—The request contains bad syntax or cannot be fulfilled.
- **5****: Server Error—The server failed to fulfill an apparently valid request.

RTSP Header

The RTSP header consists of the following fields:

- **CSeq**—Specifies the sequence number for an RTSP request-response pair. For every RTSP request containing the given sequence number, there will be a corresponding response having the same number.
- **Content-Length**—Contains the length of the content of the method, that is, after the double CRLF following the last header.
- **TRANSPORT**—Indicates which transport protocol is to be used and configures its parameters.
- **SESSION**—Identifies an RTSP session started by the media server in a SETUP response and concluded by TEARDOWN on the presentation URL.

Understanding RTSP ALG Conversation and NAT

This topic provides details on typical RTSP ALG conversation.

In general, RTP and RTCP packets are bidirectional, which means that either the client or server could initiate an RTP or an RTCP session.

[Figure 7](#) describes an example of a sample packet capture in a standard RTSP conversation.

Figure 7: RTSP ALG Conversation

The RTSP ALG performs the following actions for a RTSP sample packet capture in a standard RTSP conversation:

1. Monitors SETUP and 200 OK messages.
2. Receives negotiated ports (6543 and 8765 in this example)
3. Opens a pinhole for UDP media data from server to client.
4. Receives the IP address in payload and translates the address if NAT is required.

Table 5 describes the RTSP payload IP NAT.

Table 5: RTSP Payload IP NAT

	Forward(C->S)	Reverse(S->C)	Pinhole	Payload IP Translate	Payload Port Translate
No NAT	A/4321->B/554	A/4321<-B/554	B/9876->A/5678 A/5678->B/9876	N/A	N/A
Source NAT (IPv4)	A/4321->B/554	A'/P'<-B/554	B/9876->A'/P'' A/5678->B/9876	N/A (*)	5678<->P'
Destination NAT (IPv4)	A/4321->B/554	A/4321<-B/554	B/9876->A/5678 A/5678->B/9876	B' -> B (**)	N/A

Table 5: RTSP Payload IP NAT (*continued*)

	Forward(C->S)	Reverse(S->C)	Pinhole	Payload IP Translate	Payload Port Translate
NAT64	A/4321->B"/554	A"/Q'<-B/554	B/9876->A"/Q"	B'(IPv6)->B(IPv4)	5678<->Q'
			A/5678->B"/9876		
NAT46	A/4321->B"/554	A"/R'<-B/554	B/9876->A"/R"	B'(IPv4)->B(IPv6)	5678<->R'
			A/5678->B"/9876		

In [Table 5](#), the following letters and symbols are used:

- A—RTSP client IP address
- A'—Translated IPv4 or IPv6 address of RTSP client
- A"—Translated IPv4 address
- A"—Translated IPv6 address
- B—RTSP server IP address
- B'—RTSP server IP address before destination NAT
- B"—RTSP server IP address at IPv6 realm
- B"—RTSP server IP address at IPv4 realm
- P—Translated Port(translates from 4321) of RTSP client
- P"—Translated Port(translates from 5678 in message payload) of RTSP client
- Q—Translated (IPv6 to IPv4) Port(translates from 4321) of RTSP client
- Q"—Translated (IPv6 to IPv4) Port (translates from 5678 in message payload) of RTSP client
- R—Translated (IPv4 to IPv6) Port (translates from 4321) of RTSP client
- R"—Translated (IPv4 to IPv6) Port (translates from 5678 in message payload) of RTSP client
- (*)—RTSP server IP address B appears in payload message; it does not need to translate
- (**)—IP address B' appears in payload message from client to server; it needs to translate to B

Example: Configuring the RTSP ALG

This example shows how to configure the RTSP ALG to pass through RTSP traffic with a source NAT pool on Juniper Networks devices.

- [Requirements on page 96](#)
- [Overview on page 96](#)
- [Configuration on page 96](#)
- [Verification on page 99](#)

Requirements

- Configure proxy ARP for all IP addresses in the source NAT pool.
- Enable the RTSP ALG.
- Understand the basics concepts of the RTSP ALG. See "[Understanding the RTSP ALG](#)" on page 89.

Overview

In this example, the RTSP ALG is configured to monitor and allow RTSP traffic transferring media between client and server located on opposite sides of a Juniper Networks device.

Configuration

- [Enabling RTSP ALG on page 96](#)
- [Configuring a NAT Source Pool and Rule Set and a Policy on page 96](#)
- [Configuring RTSP ALG trace options on page 98](#)

Enabling RTSP ALG

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

To configure proxy ARP for all IP addresses in the source NAT pool and to enable RTSP ALG:

```
set security nat proxy-arp interface <interface-name> address 10.10.10.1/32 to 10.10.10.10/32
set security alg rtsp
```

Enter **commit** from configuration mode.

Configuring a NAT Source Pool and Rule Set and a Policy

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your

network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
set security zones security-zone green address-book address sa1 1.1.1.0/24
set security zones security-zone red address-book address da1 2.2.2.0/24
set security nat source rule-set rs1 from zone green
set security nat source rule-set rs1 to zone red
set security nat source rule-set rs1 rule r1 match source-address 1.1.1.0/24
set security nat source rule-set rs1 rule r1 match destination-address 2.2.2.0/24
set security nat source rule-set rs1 rule r1 then source-nat pool pool1
```

```
set security policy from-zone green to-zone red policy pol1 match destination-address da1
set security policy from-zone green to-zone red policy pol1 match source-address sa1
set security policy from-zone green to-zone red policy pol1 match application junos-rtsp
set security policy from-zone green to-zone red policy pol1 then permit
```

Enter **commit** from configuration mode.

NOTE: If you are not sure of the RTSP client and server IP address, you can replace “da1” and “sa1” with “any”.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT pool:

1. Create a NAT source pool.

```
[edit security]
user@host# set nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
```
2. Configure security zone address book entries.

```
[edit security zones security-zone]
user@host# set green address-book address sa1 1.1.1.0/24
user@host# set red address-book address da1 2.2.2.0/24
```
3. Create a NAT source rule set.

```
[edit security nat source rule-set rs1]
user@host# set from zone green
user@host# set to zone red
user@host# set rule r1 match source-address 1.1.1.0/24
user@host# set rule r1 match destination-address 2.2.2.0/24
user@host# set rule r1 then source-nat pool pool1
```
4. Configure a policy.

```
[edit security policies from-zone green to-zone red policy pol1]
user@host# set match source-address sa1
user@host# set match destination-address da1
user@host# set match application junos-rtsp
user@host# set then permit
```

Results From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit ]
user@host# show security nat
source {
  pool pool1 {
    address {
      10.10.10.1/32 to 10.10.10.10/32;
    }
  }
}
rule-set rs1 {
  from zone green;
  to zone red;
  rule r1 {
    match {
      source-address 1.1.1.0/24;
      destination-address 2.2.2.0/24;
    }
    then {
      source-nat {
        pool {
          pool1;
        }
      }
    }
  }
}
}

[edit]
user@host# show security policies
from-zone green to-zone red {policy pool1 {
  policy pool1 {
    match {
      source-address sa1;
      destination-address da1;
      application [junos-rtsp];
    }
    then {
      permit;
    }
  }
}
default-policy {
  permit-all;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring RTSP ALG trace options

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security alg rtsp traceoptions flag all
set security alg traceoptions file trace
set security alg traceoptions file size 1g
set security alg traceoptions level verbose
```

Step-by-Step Procedure

To configure RTSP ALG trace options:

1. Enable RTSP ALG trace options.

```
[edit security alg]
user@host# set rtsp traceoptions flag all
```
2. Configure a filename to receive output from the tracing operation.

```
[edit security alg]
user@host# set traceoptions file trace
```
3. Specify the maximum trace file size.

```
[edit security alg]
user@host# set traceoptions file size 1g
```
4. Specify the level of tracing output.

```
[edit security alg]
user@host# set traceoptions level verbose
```

Results From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security alg
traceoptions {
  file trace size 1g;
  level verbose;
}
rtsp traceoptions flag all;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying RTSP ALG on page 100](#)
- [Verifying the RTSP ALG Control Session on page 100](#)
- [Verifying the RTSP ALG Flow Gate Information on page 101](#)
- [Verifying the RTSP Resource Manager Group on page 102](#)
- [Verifying the RTSP Resource Information on page 102](#)

Verifying RTSP ALG

Purpose Verify that the RTSP ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
```

```
DNS      : Enabled
FTP      : Enabled
H323     : Enabled
RTSP     : Enabled
```

Meaning The output shows the RTSP ALG status as follows:

- Enabled—Shows the RTSP ALG is enabled.
- Disabled—Shows the RTSP ALG is disabled.

Verifying the RTSP ALG Control Session

Purpose Verify that the control session is created and all the RTSP control and data sessions are created.

Action From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
```

```
Flow Sessions on FPC5 PIC0:
```

```
Session ID: 100004087, Policy name: dns-alg/4, Timeout: 1798, Valid
Resource information : RTSP ALG, 1, 0

```

```
  Out: 1.1.0.202/554 --> 1.1.0.100/59889;tcp, If: ge-0/0/2.0, Pkts: 27, Bytes:
24304
```

```
Session ID: 100004088, Policy name: dns-alg/4, Timeout: 120, Valid
```

```
Resource information : RTSP ALG, 1, 1
```

```
  In: 1.1.0.202/5004 --> 1.1.0.100/62092;udp, If: ge-0/0/2.0, Pkts: 19, Bytes:
17013
```

```
  Out: 1.1.0.100/62092 --> 1.1.0.202/5004;udp, If: ge-0/0/1.0, Pkts: 0, Bytes: 0
```

```
Session ID: 100004089, Policy name: dns-alg/4, Timeout: 120, Valid
```

```
Resource information : RTSP ALG, 1, 4
```

```
  In: 1.1.0.202/5004 --> 1.1.0.100/62094;udp, If: ge-0/0/2.0, Pkts: 433, Bytes:
346183
```

```
  Out: 1.1.0.100/62094 --> 1.1.0.202/5004;udp, If: ge-0/0/1.0, Pkts: 0, Bytes: 0
```

```
Session ID: 100004090, Policy name: dns-alg/4, Timeout: 120, Valid
```

```
Resource information : RTSP ALG, 1, 3
```

```
  In: 1.1.0.100/62093 --> 1.1.0.202/5005;udp, If: ge-0/0/1.0, Pkts: 2, Bytes: 260
```

```
  Out: 1.1.0.202/5005 --> 1.1.0.100/62093;udp, If: ge-0/0/2.0, Pkts: 0, Bytes: 0
```

```
Total sessions: 4
```

- Meaning**
- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name or number of packets in and out.
 - **Policy name**—Policy name that permitted the traffic.
 - **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and the source interface for this session is ge-0/0/1.0).
 - **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and destination interface for this session is fe-0/0/2.0).

Verifying the RTSP ALG Flow Gate Information

Purpose Verify that the flow gate is opened for TCP data channel connection.

Action From operational mode, enter the **show security flow gate** command.

```
user@host>show security flow gate
```

```
Flow Gates on FPC5 PIC0:
```

```
Hole: 1.1.0.202-1.1.0.202/5005-5005->1.1.0.100-1.1.0.100/62093-62093
Translated: 0.0.0.0/0->0.0.0.0/0
Protocol: udp
Application: RTSP ALG/11
Age: 32 seconds
Flags: 0x0080
Zone: untrust
Reference count: 1
Resource: 4-1-2
```

```

```

```
Zone: trust
Reference count: 1
Resource: 4-1-5
```

```
Valid gates: 4
Pending gates: 0
Invalidated gates: 0
Gates in other states: 0
Total gates: 4
```

Meaning The sample output shows that the flow gate is opened for TCP data channel connection.

Verifying the RTSP Resource Manager Group

Purpose Verify the total number of resource manager groups and active groups that are used by the RTSP ALG.

Action From operational mode, enter the **show security resource-manager group active** command.

```
user@host>show security resource-manager group active
Group ID 1: Application - RTSP ALG
Total groups 19763, active groups 1
```

Meaning The sample output shows the total number of resource manager groups and active groups that are used by the RTSP ALG.

Verifying the RTSP Resource Information

Purpose Verify the total number of resources and active resources that are used by the RTSP ALG.

Action From operational mode, enter the **show security resource-manager resource active** command.

```
user@host>show security resource-manager resource active
Resource ID 2: Group ID - 1, Application - RTSP ALG

Resource ID 1: Group ID - 1, Application - RTSP ALG
Total Resources 93286, active resources 2
```

Meaning The sample output shows the total number of resources and active resources that are used by the RTSP ALG.

CHAPTER 10

Configuring the SQLNET ALG

- [Understanding the SQLNET ALG on page 103](#)
- [Example: Configuring the SQLNET ALG on page 104](#)

Understanding the SQLNET ALG

The SQLNET Application Layer Gateway (ALG) processes Transparent Network Substrate (TNS) REDIRECT packets for IP addresses and port information. The SQLNET ALG performs Network Address Translation (NAT) on the payload of the TNS REDIRECT packet, opens a pinhole for a new connection from a client to a server, and transfers data between a client and a server located on opposite sides of a Juniper Networks device.

SQLNET ALG supports the following types of data transfer modes:

- Redirect mode — connect-redirect type
- Interleave mode — connect-accept type
- Load balance — connect-redirect-connect-redirect type

SQLNET allows remote data access between applications and the Oracle database, or among multiple Oracle databases. SQLNET primarily establishes and maintains connection between a client application and an Oracle database server. SQLNET has several communication layers that enable clients and database servers to share, modify, and manipulate data.

Oracle SQL servers use the SQLNET protocol to execute SQL commands from clients, including load balancing and application-specific services. The SQLNET protocol uses TNS as its networking architecture, and all SQLNET traffic is encapsulated into TNS packet format.

The SQLNET ALG monitors control packets, opens pinhole for data traffic, and performs NAT and port rewrites. Support of stateful firewall and NAT services are required to configure the SQLNET ALG for TCP port 1521.

Related Documentation

- [Example: Configuring the SQLNET ALG on page 104](#)

Example: Configuring the SQLNET ALG

The SQLNET ALG processes TNS REDIRECT packets, performs NAT, and opens a pinhole for a new connection from a client to a server.

This example shows how to configure the SQLNET ALG in route or NAT mode, allow SQLNET traffic to pass through a device, and transfer data between a client and a server located on opposite sides of a Juniper Networks device.

- [Requirements on page 104](#)
- [Overview on page 104](#)
- [Configuration on page 105](#)
- [Verification on page 113](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device
- Two PCs (client and server)

Before you begin:

- Understand the concepts behind ALGs. See [“ALG Overview” on page 3](#).
- Understand the basics of SQLNET ALG. See [“Understanding the SQLNET ALG” on page 103](#).

Overview

In this example, first you configure network interfaces on the device. Create security zones and assign interfaces to the zones, and configure a policy to allow SQLNET traffic to go through an SRX Series device.

Then you create a static NAT rule set `rs1` with a rule `r1` to match with the destination address `40.0.172.10/32`, and you create a static NAT prefix with address `40.0.172.45/32`.

Next you create a source NAT pool `src-p1` with a source rule set `src-rs1` to translate packets from interface `fe-3/0/0.0` to interface `fe-3/0/1.0`. For matching packets, the source address is translated to an IP address in the `src-p1` pool.

Then you create a destination NAT pool `des-p1` with a destination rule set `des-rs1` to translate packets from zone `trust` to destination address `40.0.172.10/32`. For matching packets, the destination address is translated to an IP address in the `des-p1` pool. Finally, you enable SQLNET ALG trace options.

Topology

Figure 8 shows the SQLNET ALG topology.

Figure 8: SQLNET ALG Topology

Configuration

To configure the SQLNET ALG, perform these tasks:

- [Configuring a Route Mode on page 106](#)
- [Configuring a Static NAT Rule Set on page 108](#)
- [Configuring a Source NAT Pool and Rule Set on page 109](#)
- [Configuring a Destination NAT Pool and Rule Set on page 110](#)
- [Enabling SQLNET ALG Trace Options on page 112](#)

Configuring a Route Mode

}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Static NAT Rule Set

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat static rule-set rs1 from zone trust
set security nat static rule-set rs1 rule r1 match destination-address 40.0.172.10/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 40.0.172.45/32

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a static NAT rule set:

1. Create a static NAT rule set.

```

[edit security nat static rule-set rs1]
user@host# set from zone trust

```
2. Define a rule to match with the destination address.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 match destination-address 40.0.172.10/32

```
3. Define a static NAT prefix for the device.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 then static-nat prefix 40.0.172.45/32

```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
static {
  rule-set rs1 {
    from zone trust;
    rule r1 {
      match {
        destination-address 40.0.172.10/32;
      }
      then {
        static-nat {
          prefix {
            40.0.172.45/32;
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Source NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source pool src-p1 address 40.0.172.100/32 to 40.0.172.101/32
set security nat source rule-set src-rs1 from interface fe-3/0/0.0
set security nat source rule-set src-rs1 to interface fe-3/0/1.0
set security nat source rule-set src-rs1 rule r1 match source-address 30.0.0.0/8
set security nat source rule-set src-rs1 rule r1 match destination-address 40.0.0.0/8
set security nat source rule-set src-rs1 rule r1 then source-nat pool src-p1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a source NAT pool and rule set:

1. Create a source NAT pool.

```
[edit security nat source]
user@host# set pool src-p1 address 40.0.172.100/32 to 40.0.172.101/32
```

2. Create a source NAT rule set.

```
[edit security nat source]
user@host# set rule-set src-rs1 from interface fe-3/0/0.0
user@host# set rule-set src-rs1 to interface fe-3/0/1.0
```

3. Configure a rule that matches packets and translates the source address to an address in the source pool.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 match source-address 30.0.0.0/8
```

4. Configure a rule that matches packets and translates the destination address to an address in the source pool.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 match destination-address 40.0.0.0/8
```

5. Configure a source NAT pool in the rule.

```
[edit security nat source]
user@host# set rule-set src-rs1 rule r1 then source-nat pool src-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
  pool src-p1 {
    address {
      40.0.172.100/32 to 40.0.172.101/32;
    }
  }
  rule-set src-rs1 {
    from interface fe-3/0/0.0;
    to interface fe-3/0/1.0;
    rule r1 {
      match {
        source-address 30.0.0.0/8;
        destination-address 40.0.0.0/8;
      }
      then {
        source-nat {
          pool {
            src-p1;
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Destination NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat destination pool des-p1 address 40.0.172.45/32
set security nat destination rule-set des-rs1 from zone trust
set security nat destination rule-set des-rs1 rule des-r1 match source-address 30.0.172.12/32
set security nat destination rule-set des-rs1 rule des-r1 match destination-address 40.0.172.10/32
set security nat destination rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a destination NAT pool and rule set:

1. Create a destination NAT pool.

```
[edit security nat destination]
user@host# set pool des-p1 address 40.0.172.45/32
```
2. Create a destination NAT rule set.

```
[edit security nat destination]
user@host# set rule-set des-rs1 from zone trust
```
3. Configure a rule that matches packets and translates the source address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match source-address 30.0.172.12/32
```
4. Configure a rule that matches packets and translates the destination address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match destination-address 40.0.172.10/32
```
5. Configure a source NAT pool in the rule.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
destination {
  pool des-p1 {
    address {
      40.0.172.45/32;
    }
  }
  rule-set des-rs1 {
    from zone trust;
    rule des-r1 {
      match {
```

```

        source-address 30.0.172.12/32;
        destination-address 40.0.172.10/32;
    }
    then {
        destination-nat {
            pool {
                des-p1;
            }
        }
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Enabling SQLNET ALG Trace Options

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security alg sql traceoptions flag all
set security alg traceoptions file trace
set security alg traceoptions file size 1g
set security alg traceoptions level verbose

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To enable SQLNET ALG trace options:

1. Enable SQLNET ALG trace options.

```

[edit security alg]
user@host#set sql traceoptions flag all

```
2. Configure a filename to receive output from the tracing operation.

```

[edit security alg]
user@host#set traceoptions file trace

```
3. Specify the maximum trace file size.

```

[edit security alg]
user@host#set traceoptions file size 1g

```
4. Specify the level of tracing output.

```

[edit security alg]
user@host#set traceoptions level verbose

```

Results

From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security alg
  traceoptions {
    file trace size 1g;
    level verbose;
  }
sql traceoptions flag all;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the SQLNET ALG Control Session on page 113](#)
- [Verifying the SQLNET ALG on page 114](#)
- [Verifying the SQLNET ALG Resource Manager Group on page 114](#)
- [Verifying the SQLNET ALG Resource Information on page 114](#)

Verifying the SQLNET ALG Control Session

Purpose Verify that the SQL command is executed and all the SQL control and data sessions are created.

Action From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
Session ID: 10880, Policy name: sql, Timeout: 2, Valid
  In: 30.0.172.12/52315 --> 40.0.172.35/1521;tcp, If: fe-3/0/0.0, Pkts: 6, Bytes:
    492
  Out: 40.0.172.35/1521 --> 30.0.172.12/52315;tcp, If: fe-3/0/1.0, Pkts: 4, Bytes:
    227

Session ID: 10881, Policy name: sql, Timeout: 1800, Valid
Resource information : SQLV2 ALG, 5, 18
  In: 30.0.172.12/45944 --> 40.0.172.35/1114;tcp, If: fe-3/0/0.0, Pkts: 18, Bytes:
    4240
  Out: 40.0.172.35/1114 --> 30.0.172.12/45944;tcp, If: fe-3/0/1.0, Pkts: 15,
    Bytes: 3989
Total sessions: 2
```

Meaning

- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name, number of packets in and out.
- **Policy name**—Policy name that permitted the traffic.
- **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and source interface for this session is fe-3/0/0.0).
- **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and destination interface for this session is fe-3/0/1.0).

Verifying the SQLNET ALG

Purpose Verify that the SQLNET ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host>show security alg status
ALG Status :
  DNS      : Enabled
  FTP      : Enabled
  H323     : Disabled
  MGCP     : Disabled
  MSRPC    : Enabled
  PPTP     : Enabled
  RSH      : Disabled
  RTSP     : Disabled
  SCCP     : Disabled
  SIP      : Disabled
  SQL      : Enabled
  SUNRPC   : Enabled
  TALK     : Enabled
  TFTP     : Enabled
  IKE-ESP  : Disabled
```

Meaning The output shows the SQLNET ALG status as follows:

- Enabled—Shows the SQLNET ALG is enabled
- Disabled—Shows the SQLNET ALG is disabled.

Verifying the SQLNET ALG Resource Manager Group

Purpose Verify the total number of resource manager groups and active groups that are used by the SQLNET ALG.

Action From operational mode, enter the **show security resource-manager group active** command.

```
user@host>show security resource-manager group active
Group ID 1: Application - SQL ALG
  Total groups 677, active groups 1
```

Verifying the SQLNET ALG Resource Information

Purpose Verify the total number of resources and active resources that are used by the SQLNET ALG.

Action From operational mode, enter the **show security resource-manager resource active** command.

```
user@host>show security resource-manager resource active
Resource ID 2: Group ID - 1, Application - SQL ALG

  Resource ID 1: Group ID - 1, Application - SQL ALG
  Total Resources 4044, active resources 2
```

CHAPTER 11

Configuring the TALK ALG

- [Understanding the TALK ALG on page 117](#)
- [Example: Configuring the TALK ALG on page 117](#)

Understanding the TALK ALG

The TALK ALG is a virtual communication program used for interactive communication between two users. The TALK ALG processes TALK packets, performs Network Address Translation (NAT), and opens two gates (TCP and UDP) on the receiver side. One gate is used for the next LOOKUP packet. The other gate is used for make a connection from a client to a server and to initiate communication between a client and a server located on opposite sides of a Juniper Networks device.

There are two types of TALK servers: `ntalkd` and `talkd`.

The TALK ALG processes both `ntalk` and `talkd` packets. The TALK ALG uses port UDP517 and port UDP518 to establish a connection between a client and a server.

Related Documentation

- [Example: Configuring the TALK ALG on page 117](#)

Example: Configuring the TALK ALG

This example show how to configure the TALK ALG in route or NAT mode, allow the TALK traffic to pass through a device, and initiate communication between a client and a server located on opposite sides of a Juniper Networks device.

- [Requirements on page 117](#)
- [Overview on page 118](#)
- [Configuration on page 119](#)
- [Verification on page 127](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device

- Two PCs (client and server)

Before you begin:

- Understand the concepts behind ALGs. See [“ALG Overview” on page 3](#).
- Understand the basics of TALK ALG. See [“Understanding the TALK ALG” on page 117](#).

Overview

In this example, first you configure network interfaces on the device, create security zones and assign interfaces to the zones, and configure a policy to allow TALK traffic to go through an SRX Series device.

Then you create a static NAT rule set `rs1` with a rule `r1` to match the destination address `40.5.2.120/32`, and you create a static NAT prefix with address `20.5.2.120/32`.

Next you create a source NAT pool `src-p1` with a source rule set `src-rs1` to translate packets from zone `trust` to zone `untrust`. For matching packets, the source address is translated to an IP address in the `src-p1` pool.

Then you create a destination NAT pool `des-p1` with a destination rule set `des-rs1` to translate packets from zone `trust` to destination address `40.5.2.121/32`. For matching packets, the destination address is translated to an IP address in the `des-p1` pool. Finally, you configure TALK ALG trace options.

Topology

Figure 9 shows the TALK ALG topology.

Figure 9: TALK ALG Topology

Configuration

To configure the TALK ALG, perform these tasks:

- [Configuring a Route Mode on page 120](#)
- [Configuring a Static NAT Rule Set on page 122](#)
- [Configuring a Source NAT Pool and Rule Set on page 123](#)
- [Configuring a Destination NAT Pool and Rule Set on page 125](#)
- [Configuring TALK ALG trace options on page 126](#)

Configuring a Route Mode

    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Static NAT Rule Set

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat static rule-set rs1 from zone trust
set security nat static rule-set rs1 rule r1 match destination-address 40.5.2.120/32
set security nat static rule-set rs1 rule r1 then static-nat prefix 20.5.2.120/32

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a static NAT rule set:

1. Create a static NAT rule set.

```

[edit security nat static rule-set rs1]
user@host# set from zone trust

```
2. Define the rule to match with the destination address.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 match destination-address 40.5.2.120/32

```
3. Define the static NAT prefix for the device.

```

[edit security nat static rule-set rs1]
user@host# set rule r1 then static-nat prefix 20.5.2.120/32

```

Results

From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security nat
static {
  rule-set rs1 {

```

```

from zone trust;
rule r1 {
  match {
    destination-address 40.5.2.120/32
  }
  then {
    static-nat {
      prefix {
        20.5.2.120/32;
      }
    }
  }
}
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Source NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security nat source pool src-p1 address 40.5.1.120/32
set security nat source rule-set src-rs1 from zone trust
set security nat source rule-set src-rs1 to zone untrust
set security nat source rule-set src-rs1 rule src-r1 match source-address 20.5.1.120/32
set security nat source rule-set src-rs1 rule src-r1 match destination-address 20.5.2.120/32
set security nat source rule-set src-rs1 rule src-r1 then source-nat pool src-p1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a source NAT pool and rule set:

1. Create a source NAT pool.

```

[edit security nat source]
user@host# set pool src-p1 address 40.5.1.120/32

```
2. Create a source NAT rule set.

```

[edit security nat source]
user@host# set rule-set src-rs1 from zone trust
user@host# set rule-set src-rs1 to zone untrust

```
3. Configure a rule that matches packets and translates the source address to an address in the source pool.

```

[edit security nat source]
user@host# set rule-set src-rs1 rule src-r1 match source-address 20.5.1.120/32

```
4. Configure a rule that matches packets and translates the destination address to an address in the source pool.

```
[edit security nat source]
```

```
user@host# set rule-set src-rs1 rule src-r1 match destination-address 20.5.2.120/32
```

5. Configure a source NAT pool in the rule.

```
[edit security nat source]
```

```
user@host# set rule-set src-rs1 rule src-r1 then source-nat pool src-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
```

```
user@host# show security nat
```

```
source {
```

```
  pool src-p1 {
```

```
    address {
```

```
      40.5.1.120/32;
```

```
    }
```

```
  }
```

```
rule-set src-rs1 {
```

```
  from zone trust;
```

```
  to zone untrust;
```

```
  rule src-r1 {
```

```
    match {
```

```
      source-address 20.5.1.120/32;
```

```
      destination-address 20.5.2.120/32;
```

```
    }
```

```
    then {
```

```
      source-nat {
```

```
        pool {
```

```
          src-p1;
```

```
        }
```

```
      }
```

```
    }
```

```
  }
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring a Destination NAT Pool and Rule Set

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat destination pool des-p1 address 20.5.2.120/32
set security nat destination rule-set des-rs1 from zone trust
set security nat destination rule-set des-rs1 rule des-r1 match source-address 20.5.1.120/32
set security nat destination rule-set des-rs1 rule des-r1 match destination-address 40.5.2.120/32
set security nat destination rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a destination NAT pool and rule set:

1. Create a destination NAT pool.

```
[edit security nat destination]
user@host# set pool des-p1 address 20.5.2.120/32
```
2. Create a destination NAT rule set.

```
[edit security nat destination]
user@host# set rule-set des-rs1 from zone trust
```
3. Configure a rule that matches packets and translates the source address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match source-address 20.5.1.120/32
```
4. Configure a rule that matches packets and translates the destination address to the address in the pool.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 match destination-address 40.5.2.120/32
```
5. Configure a source NAT pool in the rule.

```
[edit security nat destination]
user@host# set rule-set des-rs1 rule des-r1 then destination-nat pool des-p1
```

Results From configuration mode, confirm your configuration by entering the **show security nat** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
destination {
  pool des-p1 {
    address {
      20.5.2.120/32;
    }
  }
}
```

```

}
rule-set des-rs1 {
  from zone trust;
  rule des-r1 {
    match {
      source-address 20.5.1.120/32;
      destination-address 40.5.2.120/32;
    }
    then {
      destination-nat {
        pool {
          des-p1;
        }
      }
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring TALK ALG trace options

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security alg talk traceoptions flag all
set security alg traceoptions file trace
set security alg traceoptions file size 1g
set security alg traceoptions level verbose

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure TALK ALG trace options:

1. Enable TALK ALG trace options.

```

[edit security alg]
user@host#set talk traceoptions flag all

```
2. Configure the filename to receive output from the tracing operation.

```

[edit security alg]
user@host#set traceoptions file trace

```
3. Specify the maximum trace file size.

```

[edit security alg]
user@host#set traceoptions file size 1g

```
4. Specify the level of tracing output.

```

[edit security alg]
user@host#set traceoptions level verbose

```

Results From configuration mode, confirm your configuration by entering the **show security alg** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security alg
traceoptions {
  file trace size 1g;
  level verbose;
}
talk traceoptions flag all;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the TALK ALG Control Session on page 127](#)
- [Verifying the TALK Flow Gate Information on page 128](#)
- [Verifying TALK ALG on page 129](#)
- [Verifying the TALK Resource Manager Group on page 129](#)
- [Verifying the TALK Resource Information on page 129](#)

Verifying the TALK ALG Control Session

Purpose Verify that the TALK control session is created and all the TALK control and data sessions are created.

Action From operational mode, enter the **show security flow session** command.

```
user@host>show security flow session
```

```
Session ID: 128570, Policy name: p11/4, Timeout: 56, Valid

  In: 6.1.1.200/51430 --> 5.1.1.200/32905;tcp, If: ge-0/0/2.0, Pkts: 4, Bytes:
219
  Out: 5.1.1.200/32905 --> 6.1.1.200/51430;tcp, If: ge-0/0/1.0, Pkts: 3, Bytes:
167
```

- Meaning**
- **Session ID**—Number that identifies the session. Use this ID to get more information about the session such as policy name or number of packets in and out.
 - **Policy name**—Policy name that permitted the traffic.
 - **In**—Incoming flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and the source interface for this session is ge-0/0/1.0).
 - **Out**—Reverse flow (source and destination IP addresses with their respective source and destination port numbers, session is TCP, and destination interface for this session is fe-0/0/2.0).

Verifying the TALK Flow Gate Information

Purpose Verify that the gates are opened for TCP data channel and reverse UDP reply.

Action From operational mode, enter the **show security flow gate** command.

```
user@host>show security flow gate
Hole: 6.1.1.200-6.1.1.200/0-0->5.1.1.200-5.1.1.200/518-518
Translated: 0.0.0.0/0->0.0.0.0/0
Protocol: udp
Application: TALK ALG/65
Age: 110 seconds
Flags: 0x0080
Zone: untrust
Reference count: 1
Resource: 11-2-2

Hole: 6.1.1.200-6.1.1.200/0-0->5.1.1.200-5.1.1.200/32905-32905
Translated: 0.0.0.0/0->0.0.0.0/0
Protocol: tcp
Application: TALK ALG/65
Age: 110 seconds
Flags: 0x0080
Zone: untrust
Reference count: 1
Resource: 11-2-3
```

- Meaning**
- **Hole**—Range of flows permitted by the pinhole.
 - **Translated**—Tuples used to create the session if it matches the pinhole (source and destination IP addresses with their respective source and destination port numbers).
 - **Protocol**—Application protocol, such as UDP or TCP.
 - **Application**—Name of the application.
 - **Age**—Idle timeout for the pinhole.
 - **Flags**—Internal debug flags for the pinhole.
 - **Zone**—Security zone such as from zone and to zone.
 - **Reference count**—Number of resource manager references to the pinhole.
 - **Resource**—Resource manager information about the pinhole.

Verifying TALK ALG

Purpose Verify that the TALK ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host>show security alg status
ALG Status :
  PPTP      : Enabled
  RSH       : Disabled
  RTSP      : Enabled
  SCCP      : Enabled
  SIP       : Enabled
  TALK      : Enabled
  TFTP      : Enabled
  IKE-ESP   : Disabled
```

Meaning The output shows the TALK ALG status as follows:

- Enabled—Shows the TALK ALG is enabled.
- Disabled—Shows the TALK ALG is disabled.

Verifying the TALK Resource Manager Group

Purpose Verify the total number of resource manager groups and active groups that are used by the TALK ALG.

Action From operational mode, enter the **show security resource-manager group active** command.

```
user@host>show security resource-manager group active
Group ID 2: Application - TALK ALG
      Total groups 3276, active groups 1
```

Verifying the TALK Resource Information

Purpose Verify the total number of resources and active resources that are used by the TALK ALG.

Action From operational mode, enter the **show security resource-manager resource active** command.

```
user@host>show security resource-manager resource active
Resource ID 3: Group ID - 2, Application - TALK ALG

Resource ID 2: Group ID - 2, Application - TALK ALG
Total Resources 6015, active resources 2
```

Understanding the TFTP ALG

- [Overview on page 131](#)
- [TFTP Packets on page 131](#)
- [TFTP Session on page 132](#)

Overview

Trivial File Transfer Protocol (TFTP) is a simple protocol used for files transfer (*RFC 1350*). TFTP is implemented on top of UDP, with destination port 69 as the well-known port. The TFTP Application Layer Gateway (ALG) processes TFTP packets that initiate the request and creates pinholes to allow return packets from the reverse direction.

In flow processing there are two sessions for one TFTP conversation, one is the TFTP control session created by a read request (RRQ) or write request (WRQ) packet; the other one is the TFTP data session created by a DATA packet (for RRQ) or acknowledgment (ACK) packet (for WRQ).

In a Junos OS firewall, the TFTP control session is permitted through the `junos-tftp` application policy. The data session is permitted through the TFTP ALG open pinhole from any port of the server to the TID (port) of the client when the control session packet is received. No NAT translation is required, because the NAT translation has already been performed and the information is available from the session data structure.

On SRX210 and SRX240 devices, broadcast TFTP is not supported when flow is enabled on the device.

TFTP Packets

Any transfer begins with a request to read or write a file. A data packet of less than 512 bytes signals termination of a transfer.

TFTP supports five types of packets:

- Read request (RRQ)
- Write request (WRQ)
- Data (DATA)
- Acknowledgment (ACK)
- Error (ERROR)

TFTP Session

The TFTP ALG is based on UDP, which is a stateless transport protocol. In a firewall, the TFTP ALG acts as a UDP session with timeout. If there is no packet refresh session, the session is terminated after timeout. Although the TFTP client and server determine the termination of a TFTP conversation, they are sometimes unaware of the session in Firewall. Therefore, the client and server could request a new TFTP conversation in this scenario.

The TFTP ALG session can proceed in any of the following ways:

- When the TFTP control session reaches timeout, the session is not terminated if the data session is still alive.
- A TFTP session might terminate or get corrupted by the **clear security flow session all** or the **clear specific session** CLI commands regardless of whether the data session is ongoing or not.
- If a new TFTP session request arrives and reaches the existing session, the TFTP ALG will open the pinhole again for the new request.
- If the pinhole already exists, the TFTP ALG will not open the pinhole again and there will be no packet drop.
- The TFTP ALG will not drop any packet.

Related Documentation

- [ALG Overview on page 3](#)
- [Understanding TFTP ALG Conversation on page 132](#)
- [Understanding IPv6 Support for the TFTP ALG on page 133](#)
- [Example: Configuring the TFTP ALG on page 134](#)

Understanding TFTP ALG Conversation

By default TFTP servers listen for incoming requests from TFTP clients on port 69. A TFTP client chooses its source tunnel identifier (TID) port and sends its initial request to the server. In response, the server uses the TID chosen as the source port and sends a response to the client's TID as the destination port. The two TIDs ports are then used for the rest of the data transfer.

Read file conversation steps:

1. Host A (client) sends an RRQ packet to host B (server) with A's TID as source and port 69 as destination.
2. Host B (server) sends a DATA packet to host A (client) with B's TID as source and A's TID as destination.
3. Host A (client) sends an ACK packet to host B (server) with A's TID as source and B's TID as destination.
4. DATA and ACK packets conversation continues until file data transferring is complete.

Write file conversation steps:

1. Host A (client) sends a WRQ packet to host B (server) with A's TID as source and port 69 as destination.
2. Host B (server) sends an ACK packet to host A (client) with B's TID as source and A's TID as destination.
3. Host A (client) sends a DATA packet to host B (server) with A's TID as source and B's TID as destination.
4. Host B (server) sends an ACK packet to host A (client) with B's TID as source and A's TID as destination.

- [Example: Configuring the TFTP ALG on page 134](#)

Understanding IPv6 Support for the TFTP ALG

Trivial File Transfer Protocol (TFTP) Application Layer Gateway (ALG) has been enhanced to support IPv6 and IPv4 TFTP conversation, which has IPv6 and IPv4 addresses for both the source IP address and destination IP address.

TFTP ALG processes packets that initiate the routing request and create pinholes to allow return packets from the reverse direction to the port that sent the request.

The data session is set up by the first packet from the client to the server. TFTP ALG monitors the first packet and opens a pinhole from any port on the server to the client. This process helps the return packets from the server and subsequent data packets to pass through.

- [Example: Configuring the TFTP ALG on page 134](#)

Example: Configuring the TFTP ALG

The TFTP ALG processes TFTP packets that initiate the request and opens a gate to allow return packets from the reverse direction to the port that sends the request.

This example shows how to configure the TFTP ALG to pass through TFTP traffic with a source NAT pool on Juniper Networks devices.

- [Requirements on page 134](#)
- [Overview on page 134](#)
- [Configuration on page 134](#)
- [Verification on page 136](#)

Requirements

- Configure proxy ARP for all IP addresses in the source NAT pool.
- Understand the basic concepts of TFTP ALG. See [“Understanding the TFTP ALG” on page 131](#).

Overview

In this example, the TFTP ALG is configured to monitor and allow TFTP traffic, transferring files between the client and server located on opposite sides of a Juniper Networks device.

Configuration

Configuring a NAT Source Pool, Rule Set, and a Policy

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
set security zones security-zone green address-book address sa1 1.1.1.0/24
set security zones security-zone red address-book address da1 2.2.2.0/24
set security nat source rule-set rs1 from zone green
set security nat source rule-set rs1 to zone red
set security nat source rule-set rs1 rule r1 match source-address 1.1.1.0/24
set security nat source rule-set rs1 rule r1 match destination-address 2.2.2.0/24
set security nat source rule-set rs1 rule r1 then source-nat pool pool1
```

```
set security policy from-zone green to-zone red policy pol1 match destination-address da1
set security policy from-zone green to-zone red policy pol1 match source-address sa1
set security policy from-zone green to-zone red policy pol1 match application junos-tftp
set security policy from-zone green to-zone red policy pol1 then permit
```

Enter **commit** from configuration mode.

NOTE: If you are not sure of the TFTP client and server IP address, you can replace “da1” and “sa1” with “any”.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT pool:

1. Create a NAT source pool.

```
[edit security]
user@host# set nat source pool pool1 address 10.10.10.1/32 to 10.10.10.10/32
```
2. Configure security zone address book entries.

```
[edit security zones security-zone]
user@host# set green address-book address sa1 1.1.1.0/24
user@host# set red address-book address da1 2.2.2.0/24
```
3. Create a NAT source rule set.

```
[edit security nat source rule-set rs1]
user@host# set from zone green
user@host# set to zone red
user@host# set rule r1 match source-address 1.1.1.0/24
user@host# set rule r1 match destination-address 2.2.2.0/24
user@host# set rule r1 then source-nat pool pool1
```
4. Configure a policy

```
[edit security policies from-zone green to-zone red policy pol1]
user@host# set match source-address sa1
user@host# set match destination-address da1
user@host# set match application junos-tftp
user@host# set then permit
```

Results From configuration mode, confirm your configuration by entering the **show security nat** and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security nat
source {
  pool pool1 {
    address {
      10.10.10.1/32 to 10.10.10.10/32;
    }
  }
}
rule-set rs1 {
  from zone green;
  to zone red;
  rule r1 {
    match {
      source-address 1.1.1.0/24;
      destination-address 2.2.2.0/24;
    }
    then {
      source-nat {
        pool {
```

```
        pool1;
    }
}
}
}

[edit]
user@host# show security policies
from-zone green to-zone red {policy pol1 {
  policy pol1 {
    match {
      source-address sa1;
      destination-address da1;
      application [junos-tftp];
    }
    then {
      permit;
    }
  }
}
default-policy {
  permit-all;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the NAT Source Pool and Rule Set on page 136](#)
- [Verifying TFTP ALG on page 136](#)

Verifying the NAT Source Pool and Rule Set

Purpose Verify that the NAT source pool and rule set used to support the TFTP ALG are working properly.

Action From operational mode, enter the **show security nat static rule r1** command.

Verifying TFTP ALG

Purpose Verify that the TFTP ALG is enabled.

Action From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
```

```
DNS      : Enabled
FTP      : Enabled
H323     : Enabled
TFTP     : Enabled
```

Meaning The output shows the TFTP ALG status as follows:

- Enabled—Shows the TFTP ALG is enabled.
- Disabled—Shows the TFTP ALG is disabled.

Understanding VoIP ALG Types

Junos OS supports voice-over-IP Application Layer Gateways (VoIP ALGs) and basic data ALGs. (Note that supported ALG types vary depending on which hardware device you are using.)

VoIP ALGs provide stateful Application Layer inspection and Network Address Translation (NAT) capabilities to VoIP signaling and media traffic. The ALG inspects the state of transactions, or calls, and forwards or drops packets based on those states.

Junos OS supports the following VoIP ALGs:

- **H.323**—The H.323 ALG provides support for the H.323 legacy VoIP protocol. The ALG lets you secure VoIP communication between terminal hosts, such as IP phones and multimedia devices. In such a telephony system, the gatekeeper device manages call registration, admission, and call status for VoIP calls. Gatekeepers can reside in the two different zones or in the same zone.
- **SIP**—The SIP ALG provides support for the Session Initiation Protocol (SIP). SIP is an Internet Engineering Task Force (IETF)-standard protocol for initiating, modifying, and terminating multimedia sessions over the Internet. Such sessions might include conferencing, telephony, or multimedia, with features such as instant messaging and application-level mobility in network environments.
- **SCCP**—The SCCP ALG provides support for Skinny Client Control Protocol (SCCP). SCCP is a Cisco proprietary protocol for call signaling. Skinny is based on a call-agent-based call-control architecture. The control protocol uses binary-coded frames encoded on TCP frames sent to well-known TCP port number destinations to set up and tear down RTP media sessions.
- **MGCP**—The MGCP ALG provides support for Media Gateway Control Protocol (MGCP). MGCP is a text-based Application Layer protocol used for call setup and call control between the media gateway and the media gateway controller (MGC).

For information about enabling and configuring each of these ALGs through J-Web, select the **Configure>Security>ALG** page in the J-Web user interface and click **Help**.

CHAPTER 14

Configuring VoIP Rewrite Rules

- [Understanding VoIP DSCP Rewrite Rules on page 143](#)
- [Example: Configuring VoIP DSCP Rewrite Rules on page 144](#)

Understanding VoIP DSCP Rewrite Rules

This topic describes the voice over IP Application Layer Gateway (VoIP ALG) mechanism for modifying the Differentiated Services Code Point (DSCP) field of Real-Time Transport Protocol (RTP) packets. The VoIP ALG mechanism is applicable for the RTP session, which is recognized by the ALG.

DSCP is a modification of the type of service byte for class of service (CoS). Six bits of this byte are reallocated for use as the DSCP field, where each DSCP specifies a particular per-hop behavior that is applied to a packet.

To avoid VoIP quality degradation caused by network congestion, the RTP packets are required to mark the DSCP bit to ensure they get higher routing priority. A downstream router can put those packets in a higher priority queue for faster forwarding. To provide this functionality, there needs to be a per-VoIP mechanism for modifying the DSCP field of RTP packets according to the specific configuration. This will ensure that all RTP packets based on User Datagram Protocol/Transport Control Protocol (UDP/TCP) that encounter the ALG will be assigned a specific DSCP bit.

A rewrite rule modifies the appropriate CoS bits in an outgoing packet to meet the requirements of the targeted peer. Each rewrite rule reads the current CoS value that is configured at the VoIP ALG level. Every packet that hits the VoIP ALG is marked by this CoS value.

This feature supports ALG DSCP marking for H323, Session Initiation Protocol (SIP), Media Gateway Control Protocol (MGCP), and Skinny Client Control Protocol (SCCP). It provides a 6-bit DSCP value configuration for each of these. When the first RTP packet hits the ALG, this feature receives the 6-bit DSCP value from the configuration and sets it to the RTP session that the packet has created. This first RTP packet and the following RTP packets passing through the RTP session are marked according to the 6-bit DSCP value in the session.

Related Documentation

- [Example: Configuring VoIP DSCP Rewrite Rules on page 144](#)

Example: Configuring VoIP DSCP Rewrite Rules

This example shows how to configure VoIP DSCP.

- [Requirements on page 144](#)
- [Overview on page 144](#)
- [Configuration on page 144](#)
- [Verification on page 144](#)

Requirements

This example uses an SRX210 device. The example assumes that the ALG has been enabled.

Overview

This example shows how to configure four ALG DSCP markings; SIP, H323, MGCP, and SCCP. You set the 6-bit DSCP value configuration for each ALG DSCP.

Configuration

Step-by-Step Procedure

To configure VoIP DSCP rewrite rules:

1. Set the DSCP for each VoIP ALG.

[edit]

```
user@host# set security alg sip dscp-rewrite code-point 101010
user@host# set security alg h323 dscp-rewrite code-point 010101
user@host# set security alg mgcp dscp-rewrite code-point 111000
user@host# set security alg sccp dscp-rewrite code-point 000111
```

2. If you are done configuring the device, commit the configuration.

[edit]

```
user@host# commit
```

Verification

To verify that the configuration is working properly, enter the **show security alg** command.

- [Example: Allowing Unknown H.323 ALG Message Types on page 179](#)

Understanding H.323 ALG

The H.323 standard is a legacy voice-over-IP (VoIP) protocol defined by the International Telecommunication Union (ITU-T). H.323 consists of a suite of protocols (such as H.225.0 and H.245) that are used for call signaling and call control for VoIP.

H.323 uses the ASN.1 coding format. It sets up the dynamic links for data, video, and audio streams, following the protocols Q.931 (with port number 1720) and H.245. There are three major processes in H.323:

- **Gatekeeper Discovery**—An endpoint finds its gatekeeper through the gatekeeper discovery process, through broadcast or unicast (to a known IP and the well-known UDP port 1719). (Junos OS supports unicast only.)
- **Endpoint Registration, Admission, and Status**—An endpoint registers to a gatekeeper and asks for its management. Before making a call, an endpoint asks its gatekeeper for permission to place the call. In both registration and admission phases, the

Registration, Admission, and Status (RAS) channel is used. The Transport Service Access Point (TSAP) can be either the well-known UDP port (1719) or a dynamically assigned port from the discovery or registration phase.

- **Call Control and Call Setup**—Calls can be established within a zone or across two zones, or even across multiple zones (multipoint conference). The call setup and tear down is performed through the call signaling channel whose TSAP is the well-known TCP port (1720). The call control, including opening/closing media channels between two endpoints, is performed through the call control channel whose TSAP is dynamically assigned from the previous call signaling process. H.245 messages are used in the call control channel, and are encoded using ASN.1.

NOTE: Detailed information on H.323 can be found in ITU-T Recommendation H.323.

The H.323 Application Layer Gateway (ALG) lets you secure VoIP communication between terminal hosts, such as IP phones and multimedia devices. In such a telephony system, the gatekeeper device manages call registration, admission, and call status for VoIP calls. Gatekeepers can reside in the two different zones or in the same zone. (See [Figure 10](#).)

Figure 10: H.323 ALG for VoIP Calls

NOTE: The illustration uses IP phones for illustrative purposes, although it is possible to make configurations for other hosts that use VoIP, such as Microsoft NetMeeting multimedia devices.

**Related
Documentation**

- [ALG Overview on page 3](#)
- [Understanding the Avaya H.323 ALG on page 147](#)
- [H.323 ALG Configuration Overview on page 149](#)

Understanding the Avaya H.323 ALG

The H.323 standard is a legacy voice-over-IP (VoIP) protocol defined by the International Telecommunication Union (ITU-T). H.323 consists of a suite of protocols (such as H.225.0 and H.245) that are used for call signaling and call control for VoIP. The processes for configuring the H.323 standard Application Layer Gateway (ALG) and the proprietary Avaya H.323 ALG are the same.

However, Avaya H.323 ALG has some special features. To understand and configure the Avaya H.323-specific features listed here, see the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.

This topic contains the following sections:

- [Avaya H.323 ALG-Specific Features on page 147](#)
- [Call Flow Details in the Avaya H.323 ALG on page 148](#)

Avaya H.323 ALG-Specific Features

Avaya H.323-specific features are as follows:

- H.323 Fast Connect
- H.323 asymmetric media
- Call waiting
- Call forwarding
- Voice mail
- Call identification
- Conference calling

Call Flow Details in the Avaya H.323 ALG

- Connecting the Phone into the Network—Avaya performs the Q.931 Setup/Connect negotiation when the phone is wired into the network rather than when a call is being initiated.
- Making a call—When a call is made, because the PBX has already stored the capabilities for each phone when the phone is connected to the network, no further Q.931 and PBX negotiations are required to set up the call. It no longer exchanges Q.931 Setup and Connect messages with the PBX. The phone and the PBX exchange H.323 Facility messages to set up the call.
- Registering with a CM—When a call has been made, Avaya H.323 registers with the Avaya Communication Manager (CM). The registration process is similar to a generic H.323 standard registration process.

NOTE: The direct mode and tunnel mode are not defined by Avaya H.323 ALG.

For a call to work, the CM must be deployed with Avaya Endpoints. During the call, RAS and Q.931 messages are exchanged between the CM and the Avaya Endpoints.

NOTE: For Avaya H.323 with a source Network Address Translation (NAT) pool, the registration process allows only one IP address in the pool.

- Setting up Real-Time Transport Protocol (RTP)/Real-Time Control Protocol (RTCP) ports—The Q.931 Setup, Facility and Information messages are used to set up RTP/RTCP ports. The hierarchy for an Avaya H.323 session is Q.931, RTP/RTCP, Parent, and then Child.

NOTE: H.245 ports are not used in an Avaya call flow process.

- Using Avaya H.323 counters—The counters for calls and active calls are not applicable to the Avaya H.323 ALG. The call creation and tearing down is done by Facility messages afterward. When resources are allocated for a call, all counters for calls and active calls increment. If resources are allocated for a call multiple times, messages belonging to the same call that pass the firewall multiple times will trigger multiple increments of the counters. In other words, messages that belong to the same call and pass the firewall multiple times might trigger multiple increments of the counters if the resource for a call needs to be allocated multiple times.

For example, in the two-zone case, the setup and connect message pair allocates one call resource. The active call counter is increased once. Each time the setup and connect message pair passes the firewall, a different call resource with unique interfaces and NAT is allocated. Therefore, the counter increments twice in a three-zone scenario.

H.323 ALG Configuration Overview

The H.323 Application Layer Gateway (ALG) is enabled by default on the device—no action is required to enable it. However, you might choose to fine-tune H.323 ALG operations by using the following instructions:

1. Specify how long an endpoint registration entry remains in the Network Address Translation (NAT) table. For instructions, see [“Example: Setting H.323 ALG Endpoint Registration Timeouts” on page 175](#).
2. Enable media traffic on a narrow or wide range of ports. For instructions, see [“Example: Setting H.323 ALG Media Source Port Ranges” on page 176](#).
3. Protect the H.323 gatekeeper from denial-of-service (DoS) flood attacks. For instructions, see [“Example: Configuring H.323 ALG DoS Attack Protection” on page 178](#).
4. Enable unknown messages to pass when the session is in NAT mode and route mode. For instructions, see [“Example: Allowing Unknown H.323 ALG Message Types” on page 179](#).

- [Verification on page 153](#)

Requirements

Before you begin:

- Understand and configure any Avaya H.323-specific features. See the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.
- Configure security zones. See “Understanding Security Zones” on page 1030.

Overview

This example shows how to set up two policies that allow H.323 traffic to pass between IP phone hosts and a gatekeeper in the private zone, and an IP phone host (2.2.2.5/32) in the public zone. The connection to the device can either be with or without NAT. See Figure 11.

Figure 11: H.323 Gatekeeper in the Private Zone

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone public address-book address ip_phone 2.2.2.5/32
set security zones security-zone private address-book address gateway 2.2.2.5/32
set security policies from-zone private to-zone public policy P1 match source-address any
set security policies from-zone private to-zone public policy P1 match destination-address IP_Phone
```

```

set security policies from-zone private to-zone public policy P1 match application
  junos-h323
set security policies from-zone private to-zone public policy P1 then permit
set security policies from-zone public to-zone private policy P2 match source-address
  any
set security policies from-zone public to-zone private policy P2 match destination-address
  gateway
set security policies from-zone public to-zone private policy P2 match application
  junos-h323
set security policies from-zone public to-zone private policy P2 then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the device to pass H.323 ALG traffic to a gatekeeper in the private zone:

1. Configure two address books.

[edit]

```

user@host# set security zones security-zone public address-book address ip_phone
2.2.2.5/32

```

```

set security zones security-zone private address-book address gateway 2.2.2.5/32

```

2. Configure policy P1 from the private zone to the public zone.

[edit]

```

user@host# set security policies from-zone private to-zone public policy P1 match
source-address any

```

```

user@host# set security policies from-zone private to-zone public policy P1 match
destination-address IP_Phone

```

```

user@host# set security policies from-zone private to-zone public policy P1 match
application junos-h323

```

```

user@host# set security policies from-zone private to-zone public policy P1 then
permit

```

3. Configure policy P2 from the public zone to the private zone.

[edit]

```

user@host# set security policies from-zone public to-zone private policy P2 match
source-address any

```

```

user@host# set security policies from-zone public to-zone private policy P2 match
destination-address gateway

```

```

user@host# set security policies from-zone public to-zone private policy P2 match
application junos-h323

```

```
user@host# set security policies from-zone public to-zone private policy P2 then
permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this show output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security policies
...
from-zone trust to-zone trust {
  policy default-permit {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      permit;
    }
  }
}
from-zone trust to-zone untrust {
  policy default-permit {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      permit;
    }
  }
}
from-zone untrust to-zone trust {
  policy default-deny {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      deny;
    }
  }
}
from-zone private to-zone public {
  policy P1 {
    match {
      source-address any;
      destination-address IP_Phone;
      application junos-h323;
    }
    then {
      permit;
    }
  }
}
```

```

}
from-zone public to-zone private {
  policy P2 {
    match {
      source-address any;
      destination-address gateway;
      application junos-h323;
    }
    then {
      permit;
    }
  }
}
...

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying H.323 ALG Configurations on page 153](#)

Verifying H.323 ALG Configurations

Purpose Display information about active calls.

NOTE: H.323 counters for calls and active calls in the output to this show security command do not apply to the proprietary Avaya implementation of H.323. This is because Q.931 setup and connect messages are exchanged right after the phone is powered up and call creation and tear down is done by Facility messages.

Counters for calls and active calls are increased when the resources allocated for calls are increased—that is, messages belonging to the same call and that pass the firewall multiple times increment the counters. This applies when resources for a call need to be allocated multiple times. For example, in a two-zone scenario the setup and connect message pair allocates one call resource, and the active call counter is increased by one. But in a three-zone scenario the setup and connect message pair passes the firewall twice, each time allocating different call resources. In this case, the counter is incremented.

Action From the J-Web interface, select **Monitor>ALGs>H323**. Alternatively, from the CLI, enter the **show security alg h323 counters** command.

Counters for H.245 messages received also will not be accurate in the case of H.245 tunneling. Because H.245 messages are encapsulated in Q.931 packets, the counter for

H.245 messages received will remain zero even when there are H.245 messages. The **Other H245** counter will, however, reflect these packet transmissions.

```

- Configure security zones. See “Understanding Security Zones” on page 1030.

Overview

Because route mode does not require address mapping of any kind, a device configuration for a gatekeeper in the external, or public, zone is usually identical to the configuration for a gatekeeper in an internal, or private, zone. This example shows how to set up two policies to allow H.323 traffic to pass between IP phone hosts in the internal zone, and the IP phone at IP address 2.2.2.5/32 (and the gatekeeper) in the external zone. The device can be in transparent or route mode. See Figure 12.

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the device to pass H.323 ALG traffic to a gatekeeper in the external zone:

1. Configure two address books.

```

[edit]
user@host# set security zones security-zone external address-book address
    IP_Phone 2.2.2.5/32
user@host# set security zones security-zone internal address-book address
    gatekeeper 2.2.2.10/32

```

2. Configure policy P1 from the internal zone to the external zone.

```

[edit]
user@host# set security policies from-zone internal to-zone external policy P1 match
    source-address any
user@host# set security policies from-zone internal to-zone external policy P1 match
    destination-address IP_Phone
user@host# set security policies from-zone internal to-zone external policy P1 match
    application junos-h323
user@host# set security policies from-zone internal to-zone external policy P1 then
    permit

```

3. Configure policy P2 to allow traffic between the internal zone and the gatekeeper in the external zone.

```
[edit]
user@host# set security policies from-zone internal to-zone external policy P2 match
source-address any
user@host# set security policies from-zone internal to-zone external policy P2 match
destination-address gatekeeper
user@host# set security policies from-zone internal to-zone external policy P2 match
application junos-h323
user@host# set security policies from-zone internal to-zone external policy P2 then
permit
```

4. Configure policy P3 to allow traffic between phones in the internal zone and the external zone.

```
[edit]
user@host# set security policies from-zone external to-zone internal policy P3 match
source-address IP_Phone
user@host# set security policies from-zone external to-zone internal policy P3 match
destination-address any
user@host# set security policies from-zone external to-zone internal policy P3 match
application junos-h323
user@host# set security policies from-zone external to-zone internal policy P3 then
permit
```

5. Configure policy P4 to allow traffic between phones in the internal zone and the gatekeeper in the external zone.

```
[edit]
user@host# set security policies from-zone external to-zone internal policy P4
match source-address gatekeeper
user@host# set security policies from-zone external to-zone internal policy P4
match destination-address any
user@host# set security policies from-zone external to-zone internal policy P4
match application junos-h323
user@host# set security policies from-zone external to-zone internal policy P4 then
permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this show output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security policies
...
from-zone internal to-zone external {
  policy P1 {
    match {
      source-address any;
      destination-address IP_Phone;
      application junos-h323;
    }
    then {
      permit;
    }
  }
}
```

```
    }  
  }  
  policy P2 {  
    match {  
      source-address any;  
      destination-address gatekeeper;  
      application junos-h323;  
    }  
    then {  
      permit;  
    }  
  }  
}  
from-zone external to-zone internal {  
  policy P3 {  
    match {  
      source-address IP_Phone;  
      destination-address any;  
      application junos-h323;  
    }  
    then {  
      permit;  
    }  
  }  
  policy P4 {  
    match {  
      source-address gatekeeper;  
      destination-address any;  
      application junos-h323;  
    }  
    then {  
      permit;  
    }  
  }  
}  
...  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

Example: Using NAT with the H.323 ALG to Enable Incoming Calls

This example shows how to configure NAT with the H.323 ALG to enable calls from a public to a private network.

- [Requirements on page 160](#)
- [Overview on page 160](#)
- [Configuration on page 161](#)
- [Verification on page 166](#)

Requirements

Before you begin, understand H.323 ALGs. See [“Understanding H.323 ALG” on page 145](#).

Overview

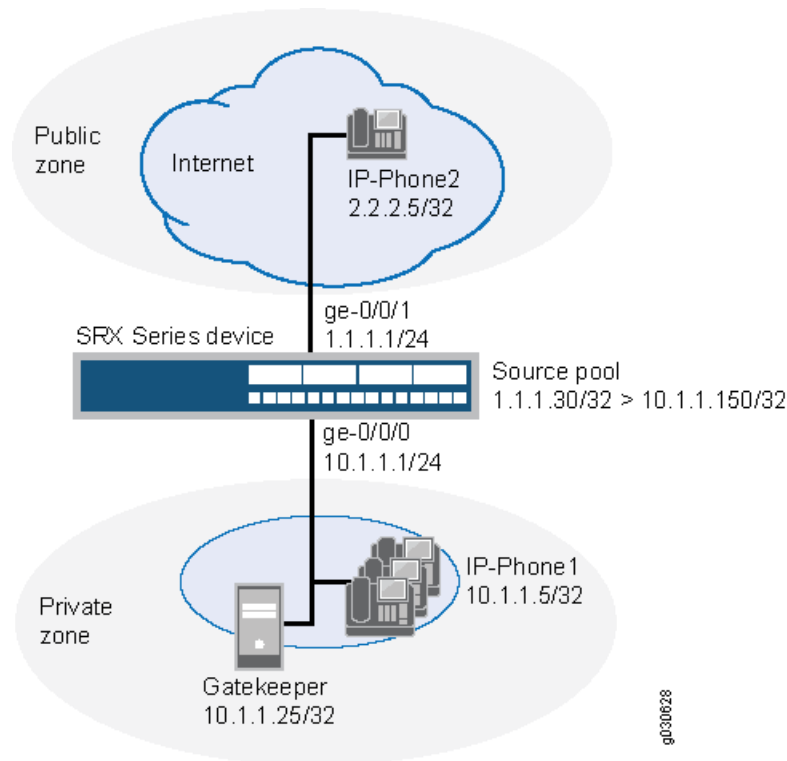

In a two-zone scenario with a server in the private zone, you can use NAT for incoming calls by configuring a NAT pool on the interface to the public zone.

In this example (see [Figure 13](#)), IP-Phone1 and a server called gatekeeper are in the private zone, and IP-Phone2 is in the public zone. You configure a static nat rule set and a source NAT pool to do NAT. You also create two policies, private-to-public and public-to-private, to permit ALG H.323 traffic from and to the private and public zones.

Topology

Figure 13 shows NAT with the H.323 ALG incoming calls.

Figure 13: NAT with the H.323 ALG—Incoming Calls

In this example, you configure source NAT as follows:

- Create a static NAT rule set called gatekeeper with a rule called gatekeeper to match packets from the public zone with the destination address 1.1.1.25/32. For matching packets, the destination IP address is translated to the private address 10.1.1.25/32.
- Define a source NAT pool called h323-nat-pool to contain the IP address range from 1.1.1.30/32 through 1.1.1.150/32.
- Create a source NAT rule set called h323-nat with rule h323-r1 to match packets from the private zone to the public zone with the source IP address 10.1.1.0/24. For matching packets, the source address is translated to the IP address in h323-nat-pool.
- Configure proxy ARP for the addresses 1.1.1.30/32 through 1.1.1.150/32 on interface ge-0/0/1.0. This allows the system to respond to ARP requests received on the interface for these addresses.

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your

network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/1 unit 0 family inet address 1.1.1.1/24

set security policies from-zone public to-zone private policy public-to-private match
  source-address IP-Phone2
set security policies from-zone public to-zone private policy public-to-private match
  destination-address IP-Phone1
set security policies from-zone public to-zone private policy public-to-private match
  destination-address gatekeeper
set security policies from-zone public to-zone private policy public-to-private match
  application junos-h323
set security policies from-zone public to-zone private policy public-to-private then permit

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure NAT with H.323 ALG to enable calls from a public to a private network:

1. Configure interfaces.

```

[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 1.1.1.1/24

```

2. Configure zones and assign addresses to them.

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone private address-book address IP-Phone1 10.1.1.5/32
user@host# set security-zone private address-book address gatekeeper 10.1.1.25/32
user@host# set security-zone public interfaces ge-0/0/1.0
user@host# set security-zone public address-book address IP-Phone2 2.2.2.5/32

```

3. Create a static NAT rule set.

```
[edit security nat static rule-set ip-phones]
user@host# set from zone public
user@host# set match destination-address 1.1.1.25/32
user@host# set then static-nat prefix 10.1.1.25/32
```
4. Configure proxy ARP.

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/1.0 address 1.1.1.25/32
```
5. Configure a source NAT rule set.

```
[edit security nat]
set source pool h323-nat-pool address 1.1.1.30/32 to 1.1.1.150/32
set source address-persistent
set source rule-set h323-nat from zone private
set source rule-set h323-nat to zone public
set source rule-set h323-nat rule h323-r1 match source-address 10.1.1.0/24
set source rule-set h323-nat rule h323-r1 then source-nat pool h323-nat-pool
set proxy-arp interface ge-0/0/1.0 address 1.1.1.30/32 to 1.1.1.150/32
```
6. Configure policies for outgoing traffic.

```
[edit security policies from-zone private to-zone public policy private-to-public]
user@host# set match source-address IP-Phone1
user@host# set match source-address gatekeeper
user@host# set match destination-address IP-Phone2
user@host# set match application junos-h323
user@host# set then permit
```
7. Configure policies for incoming traffic.

```
[edit security policies from-zone public to-zone private policy public-to-private]
user@host# set match source-address IP-Phone2
user@host# set match destination-address IP-Phone1
user@host# set match destination-address gatekeeper
user@host# set match application junos-h323
user@host# set then permit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]

            application junos-h323;
        }
        then {
            permit;
        }
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying H.323 ALG Status on page 166](#)
- [Verifying Security ALG H.323 Counters on page 166](#)
- [Verifying Source NAT Rule Usage on page 167](#)

Verifying H.323 ALG Status

Purpose Verify that H.323 ALG is enabled on your system.

Action From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
ALG Status :
  DNS      : Enabled
  FTP      : Enabled
  H323     : Enabled
  MGCP     : Enabled
  MSRPC    : Enabled
  PPTP     : Enabled
  RSH      : Disabled
  RTSP     : Enabled
  SCCP     : Enabled
  SIP      : Enabled
  SQL      : Enabled
  SUNRPC   : Enabled
  TALK     : Enabled
  TFTP     : Enabled
  IKE-ESP  : Disabled
```

Meaning The output shows the H323 ALG status as follows:

- Enabled—Shows the H323 ALG is enabled.
- Disabled—Shows the H323 ALG is disabled.

Verifying Security ALG H.323 Counters

Purpose Verify that there is a security counters for ALG H323.

Action From operational mode, enter the **show security alg h323 counters** command.

```
user@host> show security alg h323 counters

H.323 counters summary:
Packets received :4060
Packets dropped :24
RAS message received :3690
Q.931 message received :202
H.245 message received :145
Number of calls :25
Number of active calls :0

H.323 Error Counters:
```

```

Decoding errors :24
Message flood dropped :0
NAT errors :0
Resource manager errors :0

```

H.323 Message Counters:

```

RRQ : 431
RCF : 49
ARQ : 60
ACF : 33
URQ : 34
UCF : 25
DRQ : 55
DCF : 44
oth RAS : 2942
Setup : 28
Alert : 9
Connect : 25
CallPrcd : 18
Info : 0
RelCmpl : 39
Facility : 14
Progress : 0
Empty : 65
OLC : 20
OLC-ACK : 20

```

Meaning The sample output gives the rundown of security ALG H.323 counters expressing that, there are security counters for ALG H323.

Verifying Source NAT Rule Usage

Purpose Verify that there is traffic matching the source NAT rule.

Action From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

```

user@host> show security nat source rule all
source NAT rule: h323-r1      Rule-set: h323-nat
  Rule-Id                     : 1
  Rule position               : 1
  From zone                   : private
  To zone                     : public
  Match
    Source addresses          : 0.0.0.0      - 255.255.255.255
    Destination port          : 0            - 0
  Action                      : interface
  Persistent NAT type         : N/A
  Persistent NAT mapping type : address-port-mapping
  Inactivity timeout          : 0
  Max session number          : 0
  Translation hits            : 0
    Successful sessions       : 0
    Failed sessions           : 0
  Number of sessions          : 0

```

Meaning The **Translation hits** field shows that, there is no traffic matching the source NAT rule.

- Related Documentation**

 - [H.323 ALG Configuration Overview on page 149](#)

Example: Using NAT with the H.323 ALG to Enable Outgoing Calls

This example shows how to configure static NAT with H.323 ALG to enable calls from a private to a public network.

- [Requirements on page 168](#)
- [Overview on page 168](#)
- [Configuration on page 169](#)
- [Verification on page 173](#)

Requirements

Before you begin, understand the H.323 ALG and its processes. See “[Understanding H.323 ALG](#)” on page 145.

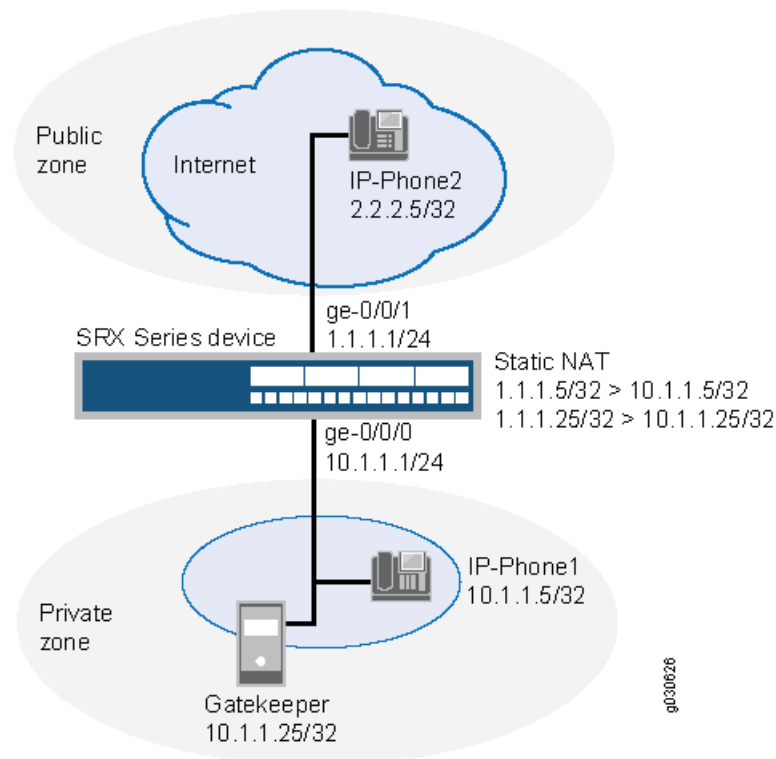

Overview

In this example (see [Figure 14](#)), IP-Phone 1 and a server called gatekeeper are in the private zone and IP-Phone2 is in the public zone. You configure static NAT to enable IP-Phone1 and gatekeeper to call IP-Phone2 in the public zone. You then create a policy called public-to-private to allow ALG H.323 traffic from the public zone to the private zone and a policy called private-to-public to allow ALG H.323 traffic from the private zone to the public zone.

Topology

Figure 14 shows NAT with the H.323 ALG outgoing calls.

Figure 14: NAT with the H.323 ALG—Outgoing Calls

In this example, you configure static NAT as follows:

- Create a static NAT rule set called `ip-phones` with a rule called `phone1` to match packets from the public zone with the destination address `1.1.1.5/32`. For matching packets, the destination IP address is translated to the private address `10.1.1.5/32`.
- Define a second rule called `gatekeeper` to match packets from the public zone with the destination address `1.1.1.25/32`. For matching packets, the destination IP address is translated to the private address `10.1.1.25/32`.
- Create proxy ARP for the addresses `1.1.1.5/32` and `1.1.1.25/32` on interface `ge-0/0/1`. This allows the system to respond to ARP requests received on the specified interface for these addresses.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
```

```

set interfaces ge-0/0/1 unit 0 family inet address 1.1.1/24
set security zones security-zone private address-book address IP-Phone1 10.1.1.5/32
set security zones security-zone private address-book address gatekeeper 10.1.1.25/32
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public address-book address IP-Phone2 2.2.2.5/32
set security zones security-zone public interfaces ge-0/0/1.0
set security nat static rule-set ip-phones from zone public
set security nat static rule-set ip-phones rule phone1 match destination-address 1.1.1.5/32
set security nat static rule-set ip-phones rule phone1 then static-nat prefix 10.1.1.5/32
set security nat static rule-set ip-phones rule gatekeeper match destination-address
  1.1.1.25/32
set security nat static rule-set ip-phones rule gatekeeper then static-nat prefix 10.1.1.25/32
set security nat proxy-arp interface ge-0/0/1.0 address 1.1.1.5/32
set security nat proxy-arp interface ge-0/0/1.0 address 1.1.1.25/32
set security policies from-zone public to-zone private policy public-to-private match
  source-address IP-Phone2
set security policies from-zone public to-zone private policy public-to-private match
  destination-address gatekeeper
set security policies from-zone public to-zone private policy public-to-private match
  application junos-h323
set security policies from-zone public to-zone private policy public-to-private then permit
set security policies from-zone private to-zone public policy private-to-public match
  source-address IP-Phone1
set security policies from-zone private to-zone public policy private-to-public match
  source-address gatekeeper
set security policies from-zone private to-zone public policy private-to-public match
  destination-address IP-Phone2
set security policies from-zone private to-zone public policy private-to-public match
  application junos-h323
set security policies from-zone private to-zone public policy private-to-public then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure static NAT with the H.323 ALG to enable calls from a private to a public network:

1. Configure interfaces.

```

user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 1.1.1.1/24

```

2. Create zones and assign addresses to them.

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/1.0
user@host# set security-zone private address-book address IP-Phone1 10.1.1.5/32
user@host# set security-zone private address-book address gatekeeper 10.1.1.25/32
user@host# set security-zone public address-book address IP-Phone2 2.2.2.5/32

```

3. Configure static NAT rule set with rules.

```

[edit security nat static rule-set ip-phones]

```

```

user@host# set from zone public
user@host# set rule phone1 match destination-address 1.1.1.5/32
user@host# set rule phone1 then static-nat prefix 10.1.1.5/32
user@host# set rule gatekeeper match destination-address 1.1.1.25/32
user@host# set rule gatekeeper then static-nat prefix 10.1.1.25/32

```

4. Configure proxy ARP.

```

[edit security nat]
user@host# set proxy-arp interface ge-0/0/1 address 1.1.1.5/32
user@host# set proxy-arp interface ge-0/0/1 address 1.1.1.25/32

```

5. Configure a security policy for incoming traffic.

```

[edit security policies from-zone public to-zone private policy public-to-private]
user@host# set match source-address IP-Phone2
user@host# set match destination-address gatekeeper
user@host# set match application junos-h323
user@host# set then permit

```

6. Configure a security policy for outgoing traffic.

```

[edit security policies from-zone private to-zone public policy private-to-public]
user@host# set match source-address IP-Phone1
user@host# set match source-address gatekeeper
user@host# set match destination-address IP-Phone2
user@host# set match application junos-h323
user@host# set then permit

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 10.1.1.1/24;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 1.1.1.1/24;
    }
  }
}
[edit]
user@host# show security zones

    address gatekeeper 10.1.1.25/32;
  }
}

```

```
    interfaces {
      ge-0/0/0.0;
    }
  }
  security-zone public {
    address-book {
      address IP-Phone2 2.2.2.5/32;
    }
    interfaces {
      ge-0/0/1.0;
    }
  }
[edit]
user@host# show security nat
static {
  rule-set ip-phones {
    from zone public;
    rule phone1 {
      match {
        destination-address 1.1.1.5/32;
      }
      then {
        static-nat prefix 10.1.1.5/32;
      }
    }
  }
  rule gatekeeper {
    match {
      destination-address 1.1.1.25/32;
    }
    then {
      static-nat prefix 10.1.1.25/32;
    }
  }
}
}
proxy-arp {
  interface ge-0/0/1.0 {
    address {
      1.1.1.5/32;
      1.1.1.25/32;
    }
  }
}
[edit]
user@host# show security policies
from-zone public to-zone private {
  policy public-to-private {
    match {
      source-address IP-Phone2;
      destination-address gatekeeper;
      application junos-h323;
    }
    then {
      permit;
    }
  }
}
```

```

    }
    from-zone private to-zone public {
      policy private-to-public {
        match {
          source-address [ IP-Phone1 gatekeeper ];
          destination-address IP-Phone2;
          application junos-h323;
        }
        then {
          permit;
        }
      }
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying H.323 ALG Status on page 173](#)
- [Verifying Security ALG H.323 Counters on page 173](#)

Verifying H.323 ALG Status

Purpose Verify that H.323 ALG is enabled on your system.

Action From operational mode, enter the **show security alg status** command.

```

user@host> show security alg status
ALG Status :
  DNS      : Enabled
  FTP      : Enabled
  H323     : Enabled
  MGCP     : Enabled
  MSRPC    : Enabled
  PPTP     : Enabled
  RSH      : Enabled
  RTSP     : Enabled
  SCCP     : Enabled
  SIP      : Enabled
  SQL      : Enabled
  SUNRPC   : Enabled
  TALK     : Enabled
  TFTP     : Enabled
  IKE-ESP  : Disabled

```

Meaning The output shows the H323 ALG status as follows:

- Enabled—Shows the H323 ALG is enabled.
- Disabled—Shows the H323 ALG is disabled.

Verifying Security ALG H.323 Counters

Purpose Verify that there is a security counters for ALG H323.

Action From operational mode, enter the **show security alg h323 counters** command.

```
user@host> show security alg h323 counters

Understanding H.323 ALG Endpoint Registration Timeouts

In Network Address Translation (NAT) mode, when endpoints in the protected network behind the Juniper Networks device register with the H.323 gatekeeper, the device adds an entry to the NAT table containing a mapping of the public-to-private address for each endpoint. These entries make it possible for endpoints in the protected network to receive incoming calls.

You set an endpoint registration timeout to specify how long an endpoint registration entry remains in the NAT table. To ensure uninterrupted incoming call service, set the endpoint registration timeout to a value equal to or greater than the keepalive value the administrator configures on the gatekeeper. The range is 10 to 50,000 seconds, the default value is 3600 seconds.

Example: Setting H.323 ALG Endpoint Registration Timeouts

This example shows how to specify the endpoint registration timeout.

- [Requirements on page 175](#)
- [Overview on page 175](#)
- [Configuration on page 175](#)
- [Verification on page 176](#)

Requirements

Before you begin, understand and configure any Avaya H.323-specific features. See the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.

Overview

You set an endpoint registration timeout range to specify how long an endpoint registration entry remains in the NAT table. The range is 10 to 50,000 seconds, and the default value is 3600 seconds.

Configuration

GUI Step-by-Step Procedure

To specify the H.323 ALG endpoint registration timeout:

1. Select **Configure>Security>ALG**.
2. Select the **H323** tab.
3. In the Timeout for endpoints box, type **5000**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

1. If you are done configuring the device, commit the configuration.
[edit]
user@host# commit

Verification

To verify the configuration is working properly, enter the **show security alg h323 counters** command.

- [Understanding H.323 ALG Endpoint Registration Timeouts on page 174](#)
 - [H.323 ALG Configuration Overview on page 149](#)

Understanding H.323 ALG Media Source Port Ranges

The media source port feature enables you to configure the device to allow media traffic on a narrow or wide range of ports. By default, the device listens for H.323 traffic on a wide range of ports. If your endpoint equipment allows you to specify a sending port and a listening port, you might want to narrow the range of ports the device allows media traffic on. This enhances security by opening a smaller pinhole for H.323 traffic.

Example: Setting H.323 ALG Media Source Port Ranges

This example shows how to enable the H.323 ALG media source port feature.

- [Requirements on page 176](#)
- [Overview on page 176](#)
- [Configuration on page 177](#)
- [Verification on page 177](#)

Requirements

Before you begin, understand and configure any Avaya H.323-specific features. See the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.

Overview

The media source port feature enables you to configure the device to allow media traffic on a narrow or wide range of ports. By default, the device listens for H.323 traffic on a narrow range of ports. This example shows how to configure the device to open a wide gate for media traffic by enabling the media source port feature.

Understanding H.323 ALG DoS Attack Protection

You can protect the H.323 gatekeeper from denial-of-service (DoS) flood attacks by limiting the number of Registration, Admission, and Status (RAS) messages per second it will attempt to process. Incoming RAS request messages exceeding the threshold you specify are dropped by H.323 Application Layer Gateway (ALG). The range is 2 to 50,000 messages per second, the default value is 1000.

|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example: Configuring H.323 ALG DoS Attack Protection

This example shows how to configure the H.323 ALG DoS attack protection feature.

- [Requirements on page 178](#)
- [Overview on page 178](#)
- [Configuration on page 178](#)
- [Verification on page 179](#)

Requirements

Before you begin, understand and configure any Avaya H.323-specific features. See the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.

Overview

You can protect the H.323 gatekeeper from DoS flood attacks by limiting the range of Registration, Admission, and Status (RAS) messages per second it will attempt to process. The range is 2 to 50,000 messages per second, and the default value is 1000. This example limits the number of incoming RAS request messages to 5000 messages per second.

Configuration

GUI Step-by-Step Procedure

To configure the H.323 ALG DoS attack protection feature:

1. Select **Configure>Security>ALG**.
2. Select the **H323** tab.
3. In the Message flood gatekeeper threshold box, type **5000**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To configure the H.323 ALG DoS attack protection feature:

1. Configure the gatekeeper for the H.323 ALG and set the threshold.

```
[edit]  
user@host# set security alg h323 application-screen message-flood gatekeeper  
threshold 5000
```
2. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg h323 counters** command.

Understanding H.323 ALG Unknown Message Types

This feature enables you to specify how unidentified H.323 messages are handled by the device. The default is to drop unknown (unsupported) messages.

You can protect the H.323 gatekeeper from denial-of-service (DoS) flood attacks by limiting the number of Registration, Admission, and Status (RAS) messages per second it will attempt to process. Incoming RAS request messages exceeding the threshold you specify are dropped by the H.323 Application Layer Gateway (ALG). The range is 2 to 50,000 messages per second, the default value is 1000.

We do not recommend permitting unknown messages because they can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment. Permitting unknown H.323 messages can help you get your network operational, so that you can analyze your voice-over-IP (VoIP) traffic to determine why some messages were being dropped. The unknown H.323 message type feature enables you to configure the device to accept H.323 traffic containing unknown message types in both Network Address Translation (NAT) mode and route mode.

NOTE: This option applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol and you have configured the device to permit unknown message types, the message is forwarded without processing.

- [H.323 ALG Configuration Overview on page 149](#)
- [Example: Allowing Unknown H.323 ALG Message Types on page 179](#)

Example: Allowing Unknown H.323 ALG Message Types

This example shows how to configure the device to allow unknown H.323 message types in both route and NAT modes.

- [Requirements on page 180](#)
- [Overview on page 180](#)

- [Configuration on page 180](#)
- [Verification on page 181](#)

Requirements

Before you begin, understand and configure any Avaya H.323-specific features. See the *Administrator Guide for Avaya Communication Manager*, *Avaya IP Telephony Implementation Guide*, and *Avaya Application Solutions IP Telephony Deployment Guide* at <http://support.avaya.com>.

Overview

This feature enables you to specify how unidentified H.323 messages are handled by the device. The default is to drop unknown (unsupported) messages. The Enable Permit NAT applied option and the **permit-nat-applied** configuration statement specify that unknown messages be allowed to pass if the session is in NAT mode. The Enable Permit routed option and the **permit-routed** configuration statement specify that unknown messages be allowed to pass if the session is in route mode. (Sessions in transparent mode are treated as route mode.)

Configuration

GUI Step-by-Step Procedure

To configure the device to allow unknown H.323 message types in both route and NAT modes:

1. Select **Configure>Security>ALG**.
2. Select the **H323** tab.
3. Select the **Enable Permit NAT applied** check box.
4. Select the **Enable Permit routed** check box.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To configure the device to allow unknown H.323 message types in both route and NAT modes:

1. Specify that unknown messages be allowed to pass if the session is in NAT mode.
[edit]
user@host# set security alg h323 application-screen unknown-message permit-nat-applied
2. Specify that unknown messages be allowed to pass if the session is in route mode.
[edit]
user@host# set security alg h323 application-screen unknown-message permit-routed
3. If you are done configuring the device, commit the configuration.
[edit]
user@host# commit

Verification

To verify the configuration is working properly, enter the **show security alg h323** command and the **show security alg h323 counters** command.

Understanding the MGCP ALG

The Media Gateway Control Protocol (MGCP) is a text-based Application Layer protocol used for call setup and call control between the media gateway and the media gateway controller (MGC).

The protocol is based on a master/slave call control architecture: the MGC (call agent) maintains call control intelligence, and media gateways carry out the instructions from the call agent. Both signaling packets and media packets are transmitted over UDP. Junos OS supports MGCP in route mode and Network Address Translation (NAT) mode.

The MGCP Application Layer Gateway (ALG) performs the following procedures:

- Conducts voice-over-IP (VoIP) signaling payload inspection. The payload of the incoming VoIP signaling packet is fully inspected based on related RFCs and proprietary standards. Any malformed packet attack is blocked by the ALG.
- Conducts MGCP signaling payload inspection. The payload of the incoming MGCP signaling packet is fully inspected in accordance with RFC 3435. Any malformed-packet attack is blocked by the ALG.

- Provides stateful processing. The corresponding VoIP-based state machines are invoked to process the parsed information. Any out-of-state or out-of-transaction packet is identified and properly handled.
- Performs NAT. Any embedded IP address and port information in the payload is properly translated based on the existing routing information and network topology, and is then replaced with the translated IP address and port number, if necessary.
- Manages pinholes for VoIP traffic. To keep the VoIP network secure, the IP address and port information used for media or signaling is identified by the ALG, and any needed pinhole is dynamically created and closed during call setup.

This topic contains the following sections:

- [MGCP Security on page 184](#)
- [Entities in MGCP on page 184](#)
- [Commands on page 186](#)
- [Response Codes on page 188](#)

MGCP Security

The MGCP ALG includes the following security features:

- Denial-of-service (DoS) attack protection. The ALG performs stateful inspection at the UDP packet level, the transaction level, and the call level. MGCP packets matching the RFC 3435 message format, transaction state, and call state, are processed. All other messages are dropped.
- Security policy enforcement between gateway and gateway controller (signaling policy).
- Security policy enforcement between gateways (media policy).
- Per-gateway MGCP message flooding control. Any malfunctioning or hacked gateway will not disrupt the whole VoIP network. Combined with per-gateway flooding control, damage is contained within the impacted gateway.
- Per-gateway MGCP connection flooding control.
- Seamless switchover/failover if calls, including calls in progress, are switched to the standby firewall in case of system failure.

Entities in MGCP

There are four basic entities in MGCP:

- [Endpoint on page 185](#)
- [Connection on page 185](#)
- [Call on page 185](#)
- [Call Agent on page 185](#)

Endpoint

A media gateway is a collection of endpoints. An endpoint can be an analog line, trunk, or any other access point. An endpoint contains the following elements:

`local-endpoint-name@domain-name`

The following examples are some valid endpoint IDs:

`group1/Trk8@example.net`
`group2/Trk1/*@[192.168.10.8]` (wild-carding)
`$@example.net` (any endpoint within the media gateway)
`*@example.net` (all endpoints within the media gateway)

Connection

Connections are created on each endpoint by an MG during call setup. A typical VoIP call involves two connections. A complex call, for example a three-party call or conference call, might require more connections. The MGC can instruct media gateways to create, modify, delete, and audit a connection.

A connection is identified by its connection ID, which is created by the MG when it is requested to create a connection. Connection ID is presented as a hexadecimal string, and its maximum length is 32 characters.

Call

A call is identified by its call ID, which is created by the MGC when establishing a new call. Call ID is a hexadecimal string with a maximum length of 32 characters. Call ID is unique within the MGC. Two or more connections can have the same call ID if they belong to the same call.

Call Agent

One or more call agents (also called media gateway controllers) are supported in MGCP to enhance reliability in the VoIP network. The following two examples are of call agent names:

`CallAgent@voipCA.example.com`
`voipCA.example.com`

Several network addresses can be associated under one domain name in the Domain Name System (DNS). By keeping track of the time to live (TTL) of DNS query/response data and implementing retransmission using other alternative network addresses, switchover and failover is achieved in MGCP.

The concept of a *notified entity* is essential in MGCP. The notified entity for an endpoint is the call agent currently controlling that endpoint. An endpoint should send any MGCP command to its notified entity. However, different call agents might send MGCP commands to this endpoint.

The notified entity is set to a provisioned value upon startup, but can be changed by a call agent through the use of the **NotifiedEntity** parameter contained in an MGCP message. If the notified entity for an endpoint is empty or has not been set explicitly, its value

defaults to the source address of the last successful non-audit MGCP command received for that endpoint.

Commands

The MGCP protocol defines nine commands for controlling endpoints and connections. All commands are composed of a command header, optionally followed by Session Description Protocol (SDP) information. A command header has the following elements:

- A command line: command verb + transaction ID + endpointId + MGCP version.
- Zero or more parameter lines, composed of a parameter name followed by a parameter value.

Table 6 lists supported MGCP commands and includes a description of each, the command syntax, and examples. Refer to RFC 2234 for a complete explanation of command syntax.

Table 6: MGCP Commands

Command	Description	Command Syntax	Example
EPCF	EndpointConfiguration—Used by a call agent to inform a gateway of coding characteristics (a-law or mu-law) expected by the line side of the endpoint.	ReturnCode [PackageList] EndpointConfiguration (EndpointId,[BearerInformation])	EPCF 2012 wxx/T2@example.com MGCP 1.0B: e:mu

Table 6: MGCP Commands (*continued*)

Command	Description	Command Syntax	Example
RSIP	RestartInProgress—Used by a gateway to notify a call agent that one or more endpoints are being taken out of service or placed back in service.	ReturnCode , [NotifiedEntity ,] [PackageList] RestartInProgress (EndpointId , RestartMethod , [RestartDelay ,] [ReasonCode])	RSIP 5200 aaln/1@rg2-25.example.net MGCP 1.0RM: gracefulRD: 300

Response Codes

Every command sent by the calling agent or gateway, whether successful or not, requires a response code. The response code is in the header of the response message, and optionally is followed by session description information.

The response header is composed of a response line, followed by zero or more parameter lines, each containing a parameter name letter followed by its value. The response header is composed of a three-digit response code, transaction ID, and optionally followed by commentary. The response header in the following response message shows response code 200 (successful completion), followed by ID 1204 and the comment:OK.

```
200 1204 OK
I: FDE234C8
v=0
o=- 25678 753849 IN IP4 128.96.41.1
s=-
c=IN IP4 128.96.41.1
t=0 0
m=audio 3456 RTP/AVP 96
a=rtpmap:96 G726-32/8000
```

The ranges of response codes are defined as follows:

- 000 — 099 indicate a response acknowledgement.
- 100 — 199—indicate a provisional response.
- 200 — 299 indicate a successful completion (final response).
- 400 — 499 indicate a transient error (final response).
- 500 — 599 indicate a permanent error (final response).

Refer to RFC 3661 for detailed information about response codes.

A response to a command is sent to the source address of the command, not to the current notified entity. A media gateway can receive MGCP commands from various network addresses simultaneously, and send back responses to corresponding network addresses. However, it sends all MGCP commands to its current notified entity.

MGCP ALG Configuration Overview

The Media Gateway Control Protocol (MGCP ALG) is enabled by default on the device—no action is required to enable it. However, you might choose to fine-tune MGCP ALG operations by using the following instructions:

1. Free up bandwidth when calls fail to properly terminate. See [“Example: Setting MGCP ALG Call Duration” on page 209](#).
2. Control how long a call can remain active without any media traffic. See [“Example: Setting MGCP ALG Inactive Media Timeout” on page 210](#).
3. Track and clear signaling traffic when it times out. See [“Example: Setting MGCP ALG Transaction Timeout” on page 211](#).
4. Protect the media gateway from denial-of-service (DoS) flood attacks. See [“Example: Configuring MGCP ALG DoS Attack Protection” on page 213](#).
5. Enable unknown messages to pass when the session is in Network Address Translation (NAT) mode and route mode. See [“Example: Allowing Unknown MGCP ALG Message Types” on page 214](#).

Related Documentation

Example: Configuring Media Gateways in Subscriber Homes Using MGCP ALGs

This example shows how to configure media gateways in subscriber homes using MGCP ALGs.

- [Requirements on page 189](#)
- [Overview on page 190](#)
- [Configuration on page 191](#)
- [Verification on page 194](#)

Requirements

Before you begin:

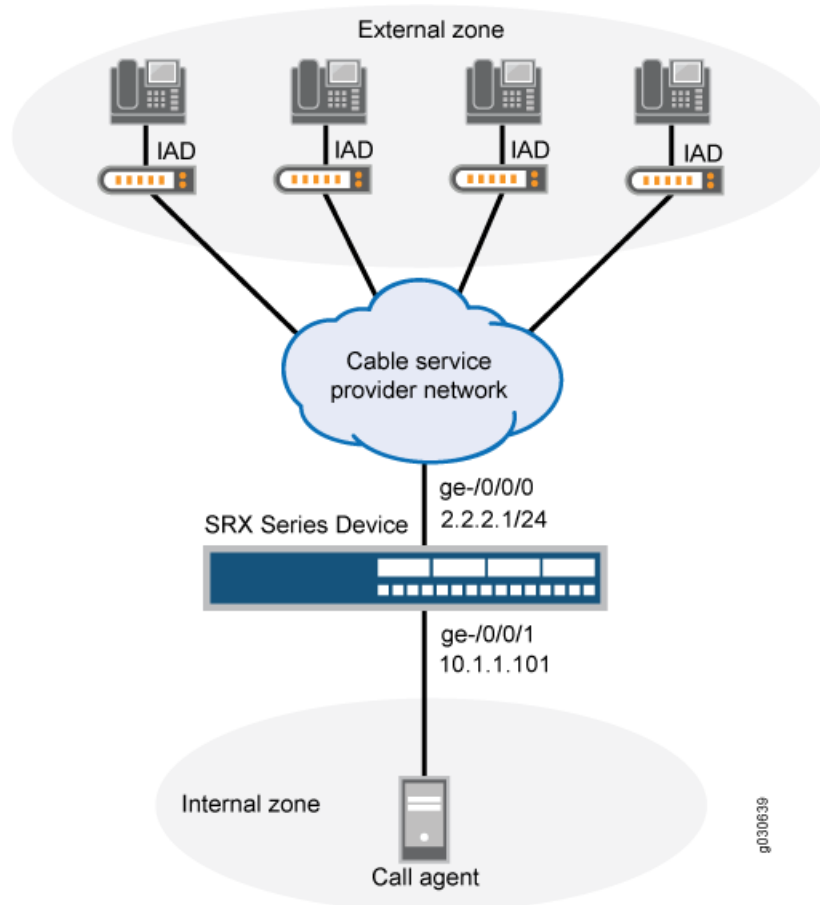

- Configure zones. See [“Example: Creating Security Zones”](#) on page 1031.
- Configure addresses and interfaces. See [“Example: Configuring Address Books and Address Sets”](#) on page 1056.
- Configure security policies. See [“Security Policies Configuration Overview”](#) on page 1073.

Overview

When a cable service provider offers MGCP services to residential subscribers, they locate the Juniper Networks device and call agent on their premises and install a set-top box, in each subscriber's home. The set-top boxes act as gateways for the residences.

After creating zones—`external_subscriber` for the customer and `internal_ca` for the service provider—you configure addresses, then interfaces, and finally policies to allow signaling between endpoints. Note that although gateways frequently reside in different zones, requiring policies for media traffic, in this example both gateways are in the same subnet. Note also that because RTP traffic between the gateways never passes through the device, no policy is needed for the media. See [Figure 15](#).

Figure 15: Media Gateway in Subscriber Homes

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security zones security-zone external-subscriber host-inbound-traffic system-services
  all
set security zones security-zone external-subscriber host-inbound-traffic protocols all
set security zones security-zone internal-ca host-inbound-traffic system-services all
set security zones security-zone internal-ca host-inbound-traffic protocols all
set interfaces ge-0/0/1 unit 0 family inet address 2.2.2.1/24
set interfaces ge-0/0/0 unit 0 family inet
set security zones security-zone external-subscriber interfaces ge-0/0/0
set security zones security-zone internal-ca interfaces ge-0/0/1
set security address-book book1 address ca-agent 110.1.1.101/32
set security address-book book1 attach zone internal-ca

set security policies from-zone internal-ca to-zone internal-ca policy intra-ca match
  application any
set security policies from-zone internal-ca to-zone internal-ca policy intra-ca then permit
set security policies from-zone external-subscriber to-zone external-subscriber policy
  intra-subscriber match source-address any
set security policies from-zone external-subscriber to-zone external-subscriber policy
  intra-subscriber match destination-address any
set security policies from-zone external-subscriber to-zone external-subscriber policy
  intra-subscriber match application any
set security policies from-zone external-subscriber to-zone external-subscriber policy
  intra-subscriber then permit

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure media gateways in subscriber homes using MGCP ALGs:

1. Create security zones for the customer and the service provider.

```
[edit security zones security-zone external-subscriber]
user@host# set host-inbound-traffic system-services all
user@host# set host-inbound-traffic protocols all
```

```
[edit security zones security-zone internal-ca]
user@host# set host-inbound-traffic system-services all
user@host# set host-inbound-traffic protocols all
```

2. Configure interfaces for the zones.

```
[edit]
user@host# edit security zones security-zone external-subscriber interfaces
ge-0/0/0
user@host# set interfaces ge-0/0/0 unit 0 family inet
user@host# set security zones security-zone internal-ca interfaces ge-0/0/1
user@host# set interfaces ge-0/0/1 unit 0 family inet address 2.2.2.1/24
```

3. Configure address books and attach zones to them.

```
[edit security address-book book1]
user@host# set address ca-agent 110.1.1.101/32
user@host# set attach zone internal-ca

[edit security address-book book2]
user@host# set address subscriber-subnet 2.2.2.1/24
user@host# set attach zone external-subscriber
```

4. Configure policies for traffic from the internal to the external zone.

```
[edit security policies from-zone internal-ca to-zone external-subscriber policy
ca-to-subscribers]
user@host# edit match source-address ca-agent-1
user@host# set match destination-address subscriber-subnet
user@host# set match application junos-mgcp
user@host# set then permit
```

5. Configure policies for traffic from the external to the internal zone.

```
[edit security policies from-zone external-subscriber to-zone internal-ca policy
subscriber-to-ca]
user@host# edit match source-address subscriber-subnet
user@host# set match destination-address ca-agent-1
user@host# set match application junos-mgcp
user@host# set then permit
```

6. Configure policies for traffic between two internal zones.

```
[edit security policies from-zone internal-ca to-zone internal-ca policy intra-ca]
user@host# edit match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set then permit
```

7. Configure policies for traffic between two external zones.

```
[edit security policies from-zone external-subscriber to-zone external-subscriber
  policy intra-subscriber]
user@host# edit match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set then permit
```

Results From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
from-zone internal-ca to-zone external-subscriber {
  policy ca-to-subscribers {
    match {
      source-address ca-agent-1;
      destination-address subscriber-subnet;
      application junos-mgcp;
    }
    then {
      permit;
    }
  }
}
from-zone external-subscriber to-zone internal-ca {
  policy subscriber-to-ca {
    match {
      source-address subscriber-subnet;
      destination-address ca-agent-1;
      application junos-mgcp;
    }
    then {
      permit;
    }
  }
}
from-zone internal-ca to-zone internal-ca {
  policy intra-ca {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      permit;
    }
  }
}
from-zone external-subscriber to-zone external-subscriber {
  policy intra-subscriber {
    match {
      source-address any;
      destination-address any;
      application any;
    }
  }
}
```

```

    }
    then {
        permit;
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying MGCP ALGs on page 194](#)
- [Verifying MGCP ALG Calls on page 194](#)
- [Verifying MGCP ALG Endpoints on page 195](#)
- [Verifying MGCP ALG Counters on page 195](#)

Verifying MGCP ALGs

Purpose Verify the MGCP ALG verification options.

Action From operational mode, enter the **show security alg mgcp ?** command.

```

user@host> show security alg mgcp ?
Possible completions:
  calls          Show MGCP calls
  counters       Show MGCP counters
  endpoints      Show MGCP endpoints

```

Meaning The output shows a list of all MGCP verification parameters. Verify the following information:

- All MGCP calls
- Counters for all MGCP calls
- Information about all MGCP endpoints

Verifying MGCP ALG Calls

Purpose Verify information about active MGCP calls.

Action From operational mode, enter the **show security alg mgcp calls** command.

```

user@host> show security alg mgcp calls
Endpoint@GW      Zone      Call ID      RM Group
d001@101.50.10.1 Trust     10d55b81140e0f76  512
  Connection Id> 0
    Local SDP>  o: 101.50.10.1      x_o: 101.50.10.1
                  c: 101.50.10.1/32206  x_c: 101.50.10.1/32206
    Remote SDP> c: 3.3.3.5/16928    x_c: 3.3.3.5/16928
Endpoint@GW      Zone      Call ID      RM Group
d001@3.3.3.5     Untrust   3a104e9b41a7c4c9  511
  Connection Id> 0

```

```

Local SDP> o: 3.3.3.5                x_o: 3.3.3.5
              c: 3.3.3.5/16928        x_c: 3.3.3.5/16928
Remote SDP> c: 101.50.10.1/32206      x_c: 101.50.10.1/32206

```

Meaning The output displays information about all MGCP calls. Verify the following information:

- Endpoint
- Zone
- Call identifier
- Resource Manager group

Verifying MGCP ALG Endpoints

Purpose Verify information about MGCP endpoints.

Action From operational mode, enter the **show security alg mgcp endpoints** command.

```

user@host> show security alg mgcp endpoints
Gateway: 101.50.10.1 Zone: Trust IP: 101.50.10.1 -> 101.50.10.1
  Endpoint      Trans #  Call #  Notified Entity
  d001          1         1       0.0.0.0/0->0.0.0.0/0
Gateway: 3.3.3.5 Zone: Untrust IP: 3.3.3.5 -> 3.3.3.5
  Endpoint      Trans #  Call #  Notified Entity
  d001          1         1       0.0.0.0/0->0.0.0.0/0

```

Meaning The output displays information about all MGCP endpoints. Verify the following information:

- Gateway IP address and zone of both endpoints
- Endpoint identifier, transaction number, call number, and notified entity for each gateway

Verifying MGCP ALG Counters

Purpose Verify information about MGCP counters.

Action From operational mode, enter the **show security alg mgcp counters** command.

```

user@host> show security alg mgcp counters
MGCP counters summary:
Packets received           :284
Packets dropped            :0
Message received           :284
Number of connections      :4
Number of active connections :3
Number of calls            :4
Number of active calls     :3
Number of transactions     :121
Number of active transactions:52
Number of re-transmission  :68
MGCP Error Counters:
Unknown-method             :0
Decoding error             :0

```

```

Transaction error           :0
Call error                  :0
Connection error            :0
Connection flood drop       :0
Message flood drop          :0
IP resolve error            :0
NAT error                   :0
Resource manager error      :0
MGCP Packet Counters:
CRCX      :4      MDCX      :9      DLCX      :2
AUEP      :1      AUCX      :0      NTFY      :43

Example: Configuring Three-Zone ISP-Hosted Service Using MGCP ALG and NAT

This example shows how to configure a three-zone configuration using MGCP ALG and NAT.

- [Requirements on page 196](#)
- [Overview on page 196](#)
- [Configuration on page 198](#)
- [Verification on page 206](#)

Requirements

Before you begin, understand NAT support with MGCP ALG. See [“Understanding the MGCP ALG” on page 183](#).

Overview

Typically, a three-zone configuration is used when an ISP in one geographical location provides service to two networks in different geographical locations.

In this example (see [Figure 16](#)), an ISP located on the USA West Coast provides MGCP service to customers in separate networks in Asia and San Francisco. Asia customers are in the asia-3 zone and are supported by the asia-gw gateway; San Francisco customers are in the sf-2 zone and are supported by the sf-gw gateway. A call agent, west-ca, is in the DMZ. The gateways and the call agent are listed in [Table 7](#), showing the corresponding IP address, interface, and zone.

In this example, after creating zones and setting addresses for the gateways and the call agent, you associate the zones to interfaces, and then configure static NAT to the call agent and source NAT for communication from an IP phone in the sf-2 zone to phones in the asia-3 zone. You also configure a policy between the zones to allow the communication.

Topology

Figure 16 shows three zone ISP hosted service.

Figure 16: Three-Zone ISP-Hosted Service

Table 7: Three-Zone ISP-Host Service

Gateway	IP Address	Interface	Zone
sf-gw	192.168.3.201	ge-0/0/0	sf-2
asia-gw	3.3.3.101	ge-0/0/1	asia-3
west-ca	10.1.1.101	ge-0/0/2	DMZ

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 192.168.3.10/24
set interfaces ge-0/0/1 unit 0 family inet address 3.3.3.10/24

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a three-zone configuration using MGCP ALG and NAT:

1. Configure interfaces.

```

[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 192.168.3.10/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 3.3.3.10/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 10.1.1.2/24

```
2. Create security zones.

```

[edit security zones]
user@host# set security-zone sf-2 interfaces ge-0/0/0
user@host# set security-zone asia-3 interfaces ge-0/0/1
user@host# set security-zone dmz interfaces ge-0/0/2

```
3. Create address books and assign zones to them.

```

[edit security address-book book1]
user@host# set address sf-gw 192.168.3.201/32
user@host# set attach zone sf-2

[edit security address-book book2]
user@host# set address asia-gw 3.3.3.101/32
user@host# set attach zone asia-3

[edit security address-book book3]
user@host# set address west-ca 10.1.1.101/32
user@host# set attach zone dmz

```
4. Create a static NAT rule set and set the match conditions and actions for it.

```

[edit security nat static rule-set to-callagent]
user@host# set from zone asia-3
user@host# set rule phone1 match destination-address 3.3.3.101/32
user@host# set rule phone1 then static-nat prefix 10.1.1.101/32

```
5. Configure proxy ARP for address 3.3.3.101/32 on interface ge-0/0/1.0.

```

[edit security nat ]
user@host# set proxy-arp interface ge-0/0/1.0 address 3.3.3.101/32

```

6. Create a source NAT pool.

```
[edit security nat]
user@host# set source pool ip-phone-pool address 3.3.3.20/32
```
7. Create a source NAT rule set and set the match conditions and actions for it.

```
[edit security nat source rule-set phones]
user@host# set from zone sf-2
user@host# set to zone asia-3
user@host# set rule phone1 match source-address 192.168.3.10/32
user@host# set rule phone1 match destination-address 3.3.3.101/32
user@host# set rule phone1 then source-nat pool ip-phone-pool
```
8. Configure proxy ARP for address 3.3.3.20/32 on interface ge-0/0/1.0.

```
[edit security nat ]
user@host# set proxy-arp interface ge-0/0/1.0 address 3.3.3.20/32
```
9. Configure a policy to allow traffic from DMZ to Asia.

```
[edit security policies from-zone dmz to-zone asia-3 policy pol-dmz-to-asia-3]
user@host# set match source-address west-ca
user@host# set match destination-address asia-gw
user@host# set match application junos-mgcp
user@host# set then permit
```
10. Configure a policy to allow traffic from Asia to DMZ.

```
[edit security policies from-zone asia-3 to-zone dmz policy pol-asia-3-to-dmz]
user@host# set match source-address asia-gw
user@host# set match destination-address west-ca
user@host# set match application junos-mgcp
user@host# set then permit
```
11. Configure a policy to allow traffic from San Francisco to DMZ.

```
[edit security policies from-zone sf-2 to-zone dmz policy pol-sf-2-to-dmz]
user@host# set match source-address sf-gw
user@host# set match destination-address west-ca
user@host# set match application junos-mgcp
user@host# set then permit
```
12. Configure a policy to allow traffic from DMZ to San Francisco.

```
[edit security policies from-zone dmz to-zone sf-2 policy pol-dmz-to-sf-2]
user@host# set match source-address west-ca
user@host# set match destination-address sf-gw
user@host# set match application junos-mgcp
user@host# set then permit
```
13. Configure a policy to allow traffic from San Francisco to Asia.

```
[edit security policies from-zone sf-2 to-zone asia-3 policy pol-sf-2-to-asia-3]
user@host# set match source-address sf-gw
user@host# set match destination-address asia-gw
user@host# set match application junos-mgcp
user@host# set then permit
```
14. Configure a policy to allow traffic from Asia to San Francisco.

```
[edit security policies from-zone asia-3 to-zone sf-2 policy pol-asia-3-to-sf-2]
```

```

user@host# set match source-address asia-gw
user@host# set match destination-address sf-gw
user@host# set match application junos-mgcp
user@host# set then permit

```

15. Configure a policy to allow traffic on devices within San Francisco.

```

[edit security policies from-zone sf-2 to-zone sf-2 policy pol-intra-sf-2]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set then permit

```

16. Configure a policy to allow traffic on devices within Asia.

```

[edit security policies from-zone asia-3 to-zone asia-3 policy pol-intra-asia-3]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set then permit

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security address-book**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces

      destination-address any;
```

```

        application any;
    }
    then {
        permit;
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying MGCP ALG on page 206](#)
- [Verifying MGCP Calls on page 206](#)
- [Verifying MGCP ALG Statistics on page 207](#)
- [Verifying MGCP Endpoints on page 207](#)

Verifying MGCP ALG

Purpose Verify if the MGCP ALG is enabled.

Action From operational mode, enter the **show security alg status | match mgcp** command.

```

user@host> show security alg status | match mgcp
MGCP      : Enabled

```

Meaning The output shows the MGCPALG status as follows:

- Enabled—Shows the MGCP ALG is enabled.
- Disabled—Shows the MGCP ALG is disabled.

Verifying MGCP Calls

Purpose Verify the MGCP calls that are currently active.

Action From operational mode, enter the **show security alg mgcp calls** command.

```

user@host> show security alg mgcp calls

```

Endpoint@GW	Zone	Call ID	RM Group
d001@101.50.10.1	Trust	10d55b81140e0f76	512
Connection Id> 0			
Local SDP> o: 101.50.10.1		x_o: 101.50.10.1	
c: 101.50.10.1/32206		x_c: 101.50.10.1/32206	
Remote SDP> c: 3.3.3.5/16928		x_c: 3.3.3.5/16928	
Endpoint@GW	Zone	Call ID	RM Group
d001@3.3.3.5	Untrust	3a104e9b41a7c4c9	511
Connection Id> 0			
Local SDP> o: 3.3.3.5		x_o: 3.3.3.5	
c: 3.3.3.5/16928		x_c: 3.3.3.5/16928	
Remote SDP> c: 101.50.10.1/32206		x_c: 101.50.10.1/32206	

Meaning The output displays information about all MGCP calls. Verify the following information:

- Endpoint
- Zone
- Call identifier
- Resource Manager group

Verifying MGCP ALG Statistics

Purpose Verify the MGCP ALG statistics.

Action From operational mode, enter the **show security alg mgcp counters** command.

```
user@host> show security alg mgcp counters

MGCP counters summary:
Packets received           :284
Packets dropped            :0
Message received           :284
Number of connections      :4
Number of active connections :3
Number of calls            :4
Number of active calls     :3
Number of transactions     :121
Number of active transactions:52
Number of re-transmission  :68
MGCP Error Counters:
Unknown-method             :0
Decoding error             :0
Transaction error          :0
Call error                 :0
Connection error           :0
Connection flood drop      :0
Message flood drop         :0
IP resolve error           :0
NAT error                  :0
Resource manager error     :0
MGCP Packet Counters:
CRCX      :4      MDCX      :9      DLCX      :2
AUPEP     :1      AUCX      :0      NTFY      :43
RSIP      :79     EPCF      :0      RQNT      :51
000-199   :0      200-299 :95     300-999 :0
```

Meaning The output displays information about all MGCP counters. Verify the following information:

- Summary of MGCP counters
- MGCP error counters
- MGCP packet counters

Verifying MGCP Endpoints

Purpose Verify the MGCP endpoints.

Action From operational mode, enter the **show security alg mgcp endpoints** command.

```
user@host> show security alg mgcp endpoints

Gateway: 101.50.10.1 Zone: Trust IP: 101.50.10.1 -> 101.50.10.1
Endpoint      Trans #  Call #  Notified Entity
d001          1        1      0.0.0.0/0->0.0.0.0/0
Gateway: 3.3.3.5 Zone: Untrust IP: 3.3.3.5 -> 3.3.3.5
Endpoint      Trans #  Call #  Notified Entity
d001          1        1      0.0.0.0/0->0.0.0.0/0
```

Meaning The output displays information about all MGCP endpoints. Verify the following information:

- Gateway IP address and zone of both endpoints
- Endpoint identifier, transaction number, call number, and notified entity for each gateway

Understanding MGCP ALG Call Duration and Timeouts

The call duration feature gives you control over Media Gateway Control Protocol (MGCP) call activity and helps you to manage network resources.

Typically a Delete Connection (DLCX) message will be sent out to delete a connection. The MGCP Application Layer Gateway (ALG) intercepts it and removes all media sessions for that connection.

A call can have one or more voice channels. Each voice channel has two sessions (or two media streams), one for Real-Time Transport Protocol (RTP) traffic and one for Real-Time Control Protocol (RTCP) signaling. When managing the sessions, the device considers the sessions in each voice channel as one group. Timeouts and call duration settings apply to a group as opposed to each session.

The following parameters govern MGCP call activity:

- **maximum-call-duration**—This parameter sets the absolute maximum length of a call. When a call exceeds this parameter setting, the MGCP ALG tears down the call and releases the media sessions. The default setting is 720 minutes, and the range is 3 through 720 minutes. This setting also frees up bandwidth in cases where calls fail to properly terminate.
- **inactive-media-timeout**—This parameter indicates the maximum length of time (in seconds) a call can remain active without any media (RTP or RTCP) traffic within a group. Each time an RTP or RTCP packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the MGCP ALG gates opened for media are closed. The default setting is 120 seconds, and the range is 10 through 2550 seconds. Note that upon timeout, while resources for media (sessions and pinholes) are removed, the call is not terminated.

NOTE: The **inactive-media-timeout** value should be less than the **maximum-call-duration** value.

Related Documentation

- **transaction-timeout**—A transaction is a command and its mandatory response. For example, an NTFY from the gateway to the call agent or a 200 OK from the call agent to the gateway. The Juniper Networks device tracks these transactions and clears them when they time out. The timeout range for MGCP transactions is 3 through 50 seconds and the default is 30 seconds.
- [Understanding the MGCP ALG on page 183](#)
- [MGCP ALG Configuration Overview on page 189](#)
- [Example: Setting MGCP ALG Call Duration on page 209](#)
- [Example: Setting MGCP ALG Inactive Media Timeout on page 210](#)
- [Example: Setting MGCP ALG Transaction Timeout on page 211](#)

Example: Setting MGCP ALG Call Duration

This example shows how to set call duration for the MGCP ALG.

- [Requirements on page 209](#)
- [Overview on page 209](#)
- [Configuration on page 209](#)
- [Verification on page 210](#)

Requirements

Before you begin, determine the type of parameter used to control the MGCP call activity and manage its network resources. See “[Understanding MGCP ALG Call Duration and Timeouts](#)” on page 208.

Overview

The **maximum-call-duration** parameter governs MGCP call activity and sets the absolute maximum length of a call. When a call exceeds this parameter setting, the MGCP ALG tears down the call and releases the media sessions. The default setting is 720 minutes, and the range is 3 through 720 minutes. This setting also frees up bandwidth in cases where calls fail to properly terminate. In this example, the call duration is set to 600 minutes.

Configuration

GUI Step-by-Step Procedure

To set call duration for the MGCP ALG:

1. Select **Configure > Security > ALG**.
2. Select the **MGCP** tab.

3. In the Maximum call duration box, enter **600**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options >Commit**.

Step-by-Step Procedure

To set call duration for the MGCP ALG:

1. Configure the MGCP ALG call duration.

```
[edit]  
user@host# set security alg mgcp maximum-call-duration 600
```
2. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg mgcp** command.

Related Documentation

Example: Setting MGCP ALG Inactive Media Timeout

This example shows how to set the inactive media timeout value for the MGCP ALG.

- [Requirements on page 210](#)
- [Overview on page 210](#)
- [Configuration on page 211](#)
- [Verification on page 211](#)

Requirements

Before you begin, determine the type of parameter used to control the MGCP call activity and manage its network resources. See “[Understanding MGCP ALG Call Duration and Timeouts](#)” on page 208.

Overview

The **inactive-media-timeout** parameter governs MGCP call activity and indicates the maximum length of time (in seconds) a call can remain active without any media (RTP or RTCP) traffic within a group. Each time an RTP or RTCP packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the MGCP ALG gates opened for media are closed. The default setting is 120 seconds, and the range is from 10 to 2550 seconds. Note that upon timeout, while resources for media (sessions and pinholes) are removed, the call is not terminated. In this example, the inactive media timeout is set to 90 seconds.

Configuration

- GUI Step-by-Step Procedure** To set the inactive media timeout for the MGCP ALG:
1. Select **Configure>Security>ALG**.
 2. Select the **MGCP** tab.
 3. In the Inactive Media Timeout box, enter **90**.
 4. Click **OK** to check your configuration and save it as a candidate configuration.
 5. If you are done configuring the device, click **Commit Options>Commit**.

- Step-by-Step Procedure** To set the inactive media timeout for the MGCP ALG:
1. Configure the MGCP ALG inactive media timeout value.

```
[edit]
user@host# set security alg mgcp inactive-media-timeout 90
```
 2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg mgcp** command.

Example: Setting MGCP ALG Transaction Timeout

This example shows how to set the transaction timeout for the MGCP ALG.

- [Requirements on page 211](#)
- [Overview on page 211](#)
- [Configuration on page 212](#)
- [Verification on page 212](#)

Requirements

Before you begin, determine the type of parameter used to control the MGCP call activity and manage its network resources. See “[Understanding MGCP ALG Call Duration and Timeouts](#)” on page 208.

Overview

The **transaction-timeout** parameter governs MGCP call activity and is a signaling message; for example, a NOTIFY from the gateway to the call agent or a 200 OK from the call agent

to the gateway. The Juniper Networks device tracks these transactions, and clears them when they time out. The timeout range for MGCP transactions is from 3 to 50 seconds, and the default is 30 seconds. In this example, the transaction timeout is set to 20 seconds.

Configuration

GUI Step-by-Step Procedure

To set the transaction timeout for the MGCP ALG:

1. Select **Configure>Security>ALG**.
2. Select the **MGCP** tab.
3. In the Transaction Timeout box, enter **20**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To set the transaction timeout for the MGCP ALG:

1. Configure the MGCP ALG transaction timeout value.

[edit]
user@host# **set security alg mgcp transaction-timeout 20**
2. If you are done configuring the device, commit the configuration.

[edit]
user@host# **commit**

Verification

To verify the configuration is working properly, enter the **show security alg mgcp** command.

Understanding MGCP ALG DoS Attack Protection

You can protect the Media Gateway Control Protocol (MGCP) media gateway from denial-of-service (DoS) flood attacks by limiting the number of remote access service (RAS) messages and connections per second it will attempt to process.

When you configure MGCP message flood protection, the MGCP Application Layer Gateway (ALG) drops any messages exceeding the threshold you set. The range is 2 to 50,000 messages per second per media gateway, and the default is 1000 messages per second per media gateway.

When you configure MGCP connection flood protection, the MGCP ALG drops any connection request exceeding the threshold you set. This limits the rate of processing of **CreateConnection (CRCX)** commands, thereby indirectly limiting pinhole creation. The

range is 2 to 10,000 connection requests per second per media gateway, the default is 200.

Related Documentation

- [Understanding the MGCP ALG on page 183](#)
- [MGCP ALG Configuration Overview on page 189](#)
- [Example: Configuring MGCP ALG DoS Attack Protection on page 213](#)

Example: Configuring MGCP ALG DoS Attack Protection

This example shows how to configure connection flood protection for the MGCP ALG.

- [Requirements on page 213](#)
- [Overview on page 213](#)
- [Configuration on page 213](#)
- [Verification on page 214](#)

Requirements

Before you begin, determine whether to protect the MGCP media gateway from DoS flood attacks. See "[Understanding MGCP ALG DoS Attack Protection](#)" on page 212.

Overview

In this example, you configure the MGCP ALG to drop any message requests exceeding 10,000 requests per second and to drop any connection requests exceeding 4000 per second.

Configuration

GUI Step-by-Step Procedure

To configure connection flood protection for the MGCP ALG:

1. Select **Configure>Security>ALG**.
2. Select the **MGCP** tab.
3. In the Message flood gatekeeper threshold box, type **10000**.
4. In the Connection flood threshold box, type **4000**.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To configure connection flood protection for the MGCP ALG:

1. Configure the connection flood threshold value.

```
[edit]
user@host# set security alg mgcp application-screen message-flood threshold
10000
user@host# set security alg mgcp application-screen connection-flood threshold
4000
```

2. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg mgcp** command.

Understanding MGCP ALG Unknown Message Types

To accommodate on-going development of the Media Gateway Control Protocol (MGCP), you might want to allow traffic containing new MGCP message types. The unknown MGCP message type feature enables you to configure the Juniper Networks device to accept MGCP traffic containing unknown message types in both Network Address Translation (NAT) mode and route mode.

This feature enables you to specify how unidentified MGCP messages are handled by the Juniper Networks device. The default is to drop unknown (unsupported) messages. Unknown messages can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment. Permitting unknown MGCP messages can help you get your network operational so that you can later analyze your voice-over-IP (VoIP) traffic to determine why some messages were being dropped.

Note that this command applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol and you have configured the device to permit unknown message types, the message is forwarded without processing.

- Related Documentation**
- [Understanding the MGCP ALG on page 183](#)
 - [MGCP ALG Configuration Overview on page 189](#)
 - [Example: Allowing Unknown MGCP ALG Message Types on page 214](#)

Example: Allowing Unknown MGCP ALG Message Types

This example shows how to configure the MGCP ALG to allow unknown MGCP message types in both NAT mode and route mode.

- [Requirements on page 215](#)
- [Overview on page 215](#)
- [Configuration on page 215](#)
- [Verification on page 215](#)

Requirements

Before you begin, determine whether to accommodate new and unknown MGCP message types for the device. See [“Understanding MGCP ALG Unknown Message Types” on page 214](#).

Overview

This feature enables you to specify how unidentified MGCP messages are handled by a Juniper Networks device. The default is to drop unknown (unsupported) messages, because unknown messages can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment.

Configuration

GUI Step-by-Step Procedure

To configure the MGCP ALG to allow unknown message types:

1. Select **Configure>Security>ALG**.
2. Select the **MGCP** tab.
3. Select the **Enable Permit NAT applied** check box.
4. Select the **Enable Permit routed** check box.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To configure the MGCP ALG to allow unknown message types:

1. Allow unknown message types to pass if the session is in either NAT mode or in route mode.

```
[edit]
user@host# set security alg mgcp application-screen unknown-message
permit-nat-applied permit-routed
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg mgcp** command.

Understanding SCCP ALGs

Skinny Client Control Protocol (SCCP) is a Cisco proprietary protocol for call signaling. Skinny is based on a call-agent-based call-control architecture. The control protocol uses binary-coded frames encoded on TCP frames sent to well-known TCP port number destinations to set up and tear down RTP media sessions.

The SCCP protocol, in the same way as other call control protocols, negotiates media endpoint parameters—specifically the Real-Time Transport Protocol (RTP) port number and the IP address of media termination—by embedding information in the control packets. The SCCP Application Layer Gateway (ALG) parses these control packets and facilitates media and control packets to flow through the system.

The SCCP ALG also implements rate limiting of calls and helps protect critical resources from overloading and denial-of-service (DoS) attacks.

The following functions are implemented by the SCCP ALG in Junos OS:

- Validation of SCCP protocol data units
- Translation of embedded IP address and port numbers
- Allocation of firewall resources (pinholes and gates) to pass media
- Aging out idle calls

- Configuration API for SCCP ALG parameters
- Operational mode API for displaying counters, status and statistics

In the SCCP architecture, a proxy, known as the Call Manager, does most of the processing. IP phones, also called End Stations, run the SCCP client and connect to a primary (and, if available, a secondary) Call Manager over TCP on port 2000 and register with the primary Call Manager. This connection is then used to establish calls coming to or from the client.

The SCCP ALG supports the following:

- Call flow from a SCCP client, through the Call Manager, to another SCCP client.
- Seamless failover—Switches over all calls in process to the standby firewall during failure of the primary.
- Voice-over-IP (VoIP) signaling payload inspection—Fully inspects the payload of incoming VoIP signaling packets. Any malformed packet attack is blocked by the ALG.
- SCCP signaling payload inspection—Fully inspects the payload of incoming SCCP signaling packets. Any malformed-packet attack is blocked by the ALG.
- Stateful processing—Invokes the corresponding VoIP-based state machines to process the parsed information. Any out-of-state or out-of-transaction packet is identified and properly handled.
- Network Address Translation (NAT)—Translates any embedded IP address and port information in the payload, based on the existing routing information and network topology, with the translated IP address and port number, if necessary.
- Pinhole creation and management for VoIP traffic—Identifies IP address and port information used for media or signaling and dynamically opens (and closes) pinholes to securely stream the media.

This topic includes the following sections:

- [SCCP Security on page 218](#)
- [SCCP Components on page 219](#)
- [SCCP Transactions on page 220](#)
- [SCCP Version on page 221](#)
- [SCCP Control Messages and RTP Flow on page 221](#)
- [SCCP Messages on page 221](#)

SCCP Security

The SCCP ALG includes the following security features:

- Stateful inspection of SCCP control messages over TCP and validation of the message format, and message validity for the current call state. Invalid messages are dropped.
- Security policy enforcement between Cisco IP phones and Cisco Call Manager.

- Protect against call flooding by rate limiting the number of calls processed by the ALG.
- Seamless failover of calls, including the ones in progress in case of device failure in a clustered deployment.

SCCP Components

The principal components of the SCCP VoIP architecture include the following:

- [SCCP Client on page 219](#)
- [Call Manager on page 219](#)
- [Cluster on page 219](#)

SCCP Client

The SCCP client runs on an IP phone, also called an *End Station*, which uses SCCP for signaling and for making calls. For an SCCP client to make a call, it must first register with a Primary Call Manager (and a secondary, if available). The connection between the client and the Call Manager is over TCP on port 2000. This connection is then used to establish calls to or from the client. Transmission of media is over RTP, UDP, and IP.

Call Manager

The Call Manager implements SCCP call control server software and has overall control of all devices and communication in the SCCP VoIP network. Its functions include defining, monitoring and controlling SCCP groups, regions of numbers, and route plans; providing initialization, admission, and registration of devices on the network; providing a redundant database that contains addresses, phone numbers, and number formats; and initiating contact with called devices or their agents to establish logical sessions in which voice communication can flow.

Cluster

A *cluster* is a collection of SCCP clients and a Call Manager. The Call Manager in the cluster detects all SCCP clients in the cluster. There can be more than one Call Manager for backup in a cluster. Call Manager behavior varies in each of the following cluster scenarios:

- Intra-Cluster, in which the Call Manager detects each SCCP client, and the call is between SCCP clients of the same cluster.
- Inter-Cluster, in which the Call Manager needs to communicate with another Call Manager using H.323 for call setup.
- Inter-Cluster calls using the gatekeeper for admission control and address resolution.

Call Manager behavior also varies with calls between an SCCP client and a phone in a public switched telephone network (PSTN), and with calls between an SCCP client and a phone in another administrative domain that is using H.323.

SCCP Transactions

SCCP transactions are the processes that need to take place in order for an SCCP call to proceed. SCCP transactions include the following processes:

- [Client Initialization on page 220](#)
- [Client Registration on page 220](#)
- [Call Setup on page 220](#)
- [Media Setup on page 220](#)

Client Initialization

To initialize, the SCCP client needs to determine the IP address of the Call Manager, its own IP address, and other information about the IP gateway and DNS servers. Initialization takes place on the local LAN. The client sends a Dynamic Host Control Protocol (DHCP) request to get an IP address, the DNS server address, and the TFTP server name and address. The client needs the TFTP server name to download the configuration file called *sepmacaddr.cnf*. If the TFTP name is not given, the client uses the default filename in the IP phone. The client then downloads the .cnf (xml) configuration file from TFTP server. CNF files contain the IP address or addresses of the primary and secondary Cisco Call Manager. With this information, the client contacts the Call Manager to register.

Client Registration

The SCCP client, after initialization, registers with the Call Manager over a TCP connection on well-known default port 2000. The client registers by providing the Call Manager with its IP address, the MAC address of the phone, and other information, such as protocol and version. The client cannot initiate or receive calls until it is registered. Keepalive messages keep this TCP connection open between the client and Call Manager so that the client can initiate or receive calls at any time, provided that a policy on the device allows this.

Call Setup

IP phone-to-IP phone call setup using SCCP is always handled by the Call Manager. Messages for call setup are sent to the Call Manager, which returns messages appropriate to the status of the call. If call setup is successful, and a policy on the device allows the call, the Call Manager sends the media setup messages to the client.

Media Setup

The Call Manager sends the IP address and port number of the called party to the calling party. The Call Manager also sends the media IP address and port number of the calling party to the called party. After media setup, media is transmitted directly between clients. When the call ends, the Call Manager is informed and terminates the media streams. At no time during this process does the Call Manager hand over call-setup function to the client. Media is streamed directly between clients through RTP/UDP/IP.

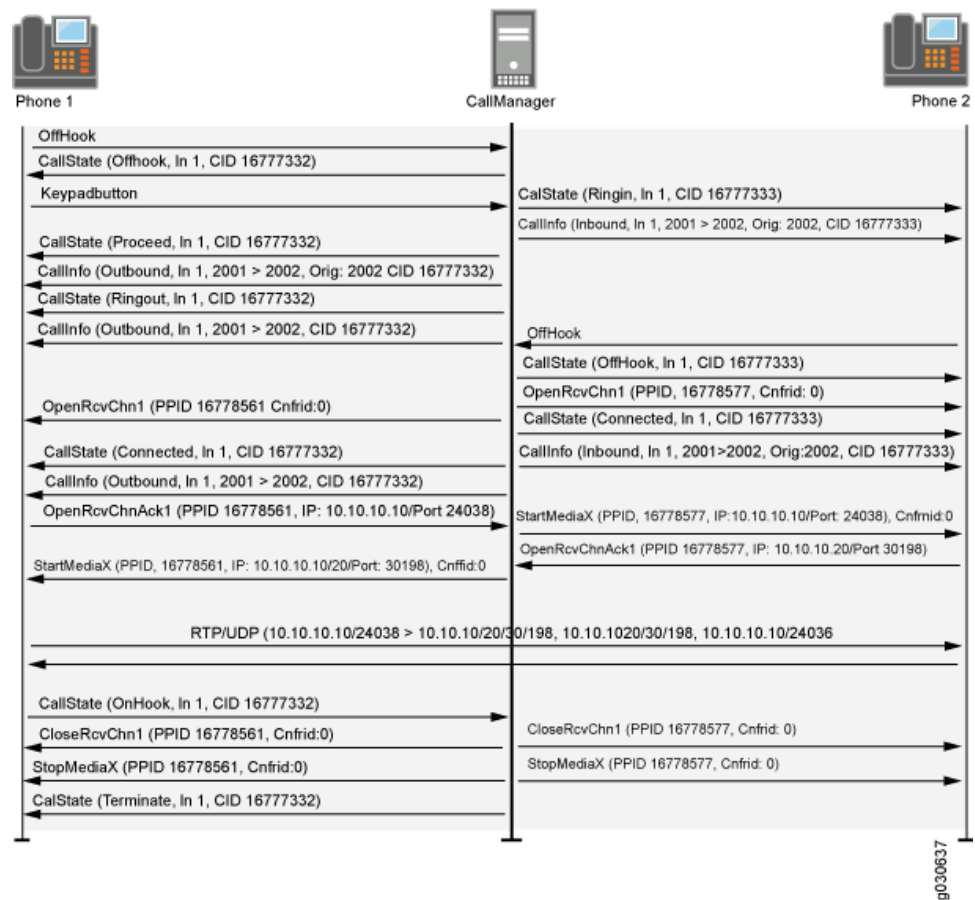

SCCP Version

Starting in Junos OS Release 12.1X46-D10, the SCCP ALG supports SCCP versions 16, 17, and 20 and several SCCP messages have been updated with a new format. Cisco Call Manager (CM) version 7 uses SCCP version 20.

SCCP Control Messages and RTP Flow

Figure 17 shows the SCCP control messages used to set up and tear down a simple call between Phone 1 and Phone 2. Except for the OffHook message initiating the call from Phone 1 and the OnHook message signaling the end of the call, all aspects of the call are controlled by the Call Manager.

Figure 17: Call Setup and Teardown

SCCP Messages

Table 8, Table 9, Table 10, and Table 11 list the SCCP call message IDs in the four intervals allowed by the device.

Table 8: Station to Call Manager Messages

#define STATION_REGISTER_MESSAGE	0x00000001

- The limitations for SCCP ALGs are as follows:
 - The SCCP is a Cisco proprietary protocol. So, any changes to the protocol by Cisco cause the SCCP ALG implementation to break. However, workarounds are provided to bypass strict decoding and allow any protocol changes to be handled gracefully.
 - Any changes to the policies will drop the sessions and impact already established SCCP calls.

- The SCCP ALG opens pinholes that are collapsed during traffic or media inactivity. This means that during a temporary loss of connectivity, media sessions are not reestablished.
- Call Manager (CM) version 6.x and later does not support TCP probe packets in chassis cluster mode. As a result, the existing SCCP sessions will break when there is a failover. You can still create new SCCP sessions during failover.

SCCP ALG Configuration Overview

The Skinny Client Control Protocol Application Layer Gateway (SCCP ALG) is enabled by default on the device—no action is required to enable it. However, you might choose to fine-tune SCCP ALG operations by using the following instructions:

1. Conserve network resources and maximize throughput.
2. Enable unknown messages to pass when the session is in Network Address Translation (NAT) mode and route mode.
3. Protect the SCCP clients from denial-of-service (DoS) flood attacks.

- Related Documentation**
- [Understanding SCCP ALGs on page 217](#)
 - [Verifying SCCP ALG Configurations on page 237](#)

Example: Configuring the SCCP ALG Call Manager or TFTP Server in the Private Zone

This example shows how to configure static NAT on the outgoing interface of a Juniper Networks device to allow callers in a public zone to register with an SCCP ALG Call Manager or a TFTP server located in a private zone.

- [Requirements on page 223](#)
- [Overview on page 223](#)
- [Configuration on page 225](#)
- [Verification on page 230](#)

Requirements

Before you begin, understand NAT support with SCCP ALG. See “[Understanding SCCP ALGs](#)” on page 217.

Overview

In this example (see [Figure 18](#)), a single device is serving as a Call Manager or a TFTP server. The Call Manager or TFTP server and phone1 are attached to the private zone,

and phone2 is attached to the public zone. You configure a static NAT rule set for the Call Manager or TFTP server so that when phone2 boots up it contacts the TFTP server and obtains the IP address of the Call Manager. You then create a policy called in-pol to allow SCCP traffic from the public to the private zone and a policy called out-pol to allow phone1 to call out.

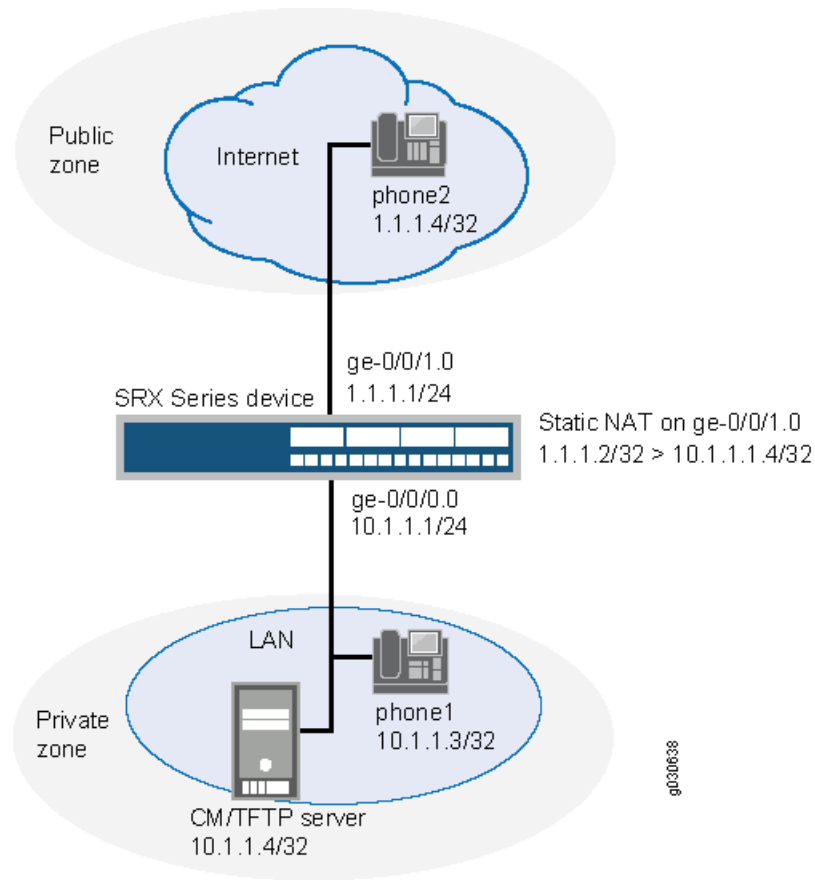

NOTE: We recommend that you change the IP address of the Call Manager, which resides in the TFTP server configuration file (`sep <mac_addr>.cnf`), to the NAT IP address of the Call Manager.

Topology

Figure 18 shows call manager or TFTP server in the private zone.

Figure 18: Call Manager or TFTP Server in the Private Zone

In this example, you configure NAT as follows:

- Create a static NAT rule set called `to-proxy` with a rule called `phone2` to match packets from the public zone with the destination address 1.1.1.2/32. For matching packets, the destination IP address is translated to the private address 10.1.1.4/32.
- Configure proxy ARP for the address 1.1.1.2/32 on interface `ge-0/0/1.0`. This allows the system to respond to ARP requests received on the interface for these addresses.
- Configure a second rule set called `phones` with a rule called `phone1` to enable interface NAT for communication from phone1 to phone2.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/1 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public interfaces ge-0/0/1.0
set security address-book book1 address phone1 10.1.1.3/32
set security address-book book1 address cm-tftp_server 10.1.1.4/32
set security address-book book1 attach zone private
set security address-book book2 address phone2 1.1.1.4/32
set security address-book book2 attach zone public
set security nat source rule-set phones from zone private
set security nat source rule-set phones to zone public
set security nat source rule-set phones rule phone1 match source-address 10.1.1.3/32
set security nat static rule-set to-proxy from zone public
set security nat static rule-set to-proxy rule phone2 match destination-address 1.1.1.2/32
set security nat static rule-set to-proxy rule phone2 then static-nat prefix 10.1.1.4/32
set security nat proxy-arp interface ge-0/0/1.0 address 1.1.1.2/32
set security policies from-zone public to-zone private policy in-pol match source-address
    phone2
set security policies from-zone public to-zone private policy in-pol match
    destination-address cm-tftp_server
set security policies from-zone public to-zone private policy in-pol match
    destination-address phone1
set security policies from-zone public to-zone private policy in-pol match application
    junos-sccp
set security policies from-zone public to-zone private policy in-pol then permit
set security policies from-zone private to-zone public policy out-pol match source-address
    any
set security policies from-zone private to-zone public policy out-pol match
    destination-address phone2
set security policies from-zone private to-zone public policy out-pol match application
    junos-sccp
set security policies from-zone private to-zone public policy out-pol then permit
set security policies from-zone private to-zone private policy tftp-pol match
    source-address any
set security policies from-zone private to-zone private policy tftp-pol match
    destination-address any
set security policies from-zone private to-zone private policy tftp-pol match application
    junos-tftp
set security policies from-zone private to-zone private policy tftp-pol then permit

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure NAT for an SCCP ALG Call Manager or a TFTP server located in a private zone:

1. Configure interfaces.

[edit]

```

user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 1.1.1.1/24

```

2. Create security zones.

- ```
[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/1.0
```
3. Create address books and attach zones to them.
 

```
[edit security address-book book1]
user@host# set address phone1 10.1.1.3/32
user@host# set address cm-tftp_server 10.1.1.4/32
user@host# set attach zone private

[edit security address-book book2]
user@host# set address phone2 1.1.1.4/32
user@host# set attach zone public
```
  4. Create a rule set for static NAT and assign a rule to it.
 

```
[edit security nat static rule-set to-proxy]
user@host# set from zone public
user@host# set rule phone2 match destination-address 1.1.1.2/32
user@host# set rule phone2 then static-nat prefix 10.1.1.4/32
```
  5. Configure proxy ARP.
 

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/1.0 address 1.1.1.2/32
```
  6. Configure interface NAT for communication from phone1 to phone2.
 

```
[edit security nat source rule-set phones]
user@host# set from zone private
user@host# set to zone public
user@host# set rule phone1 match source-address 10.1.1.3/32
user@host# set rule phone1 then source-nat interface
```
  7. Configure a policy to allow traffic from the public zone to the private zone.
 

```
[edit security policies from-zone public to-zone private policy in-pol]
user@host# set match source-address phone2
user@host# set match destination-address cm-tftp_server
user@host# set match destination-address phone1
user@host# set match application junos-sccp
user@host# set then permit
```
  8. Configure a policy to allow traffic from the private zone to the public zone.
 

```
[edit security policies from-zone private to-zone public policy out-pol]
user@host# set match source-address any
user@host# set match destination-address phone2
user@host# set match application junos-sccp
user@host# set then permit
```
  9. Configure a policy to allow traffic from phone1 to the CM/TFTP server.
 

```
[edit security policies from-zone private to-zone private policy tftp-pol]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos-tftp
user@host# set then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security address-book**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.1/24;
 }
 }
}
ge-0/0/1 {
 unit 0 {
 family inet {
 address 1.1.1.1/24;
 }
 }
}
[edit]
user@host# show security zones
security-zone private {
 interfaces {
 ge-0/0/0.0;
 }
}

 }
 }
 }
}
static {
 rule-set to-proxy {
 from zone public;
 rule phone2 {
 match {
 destination-address 1.1.1.2/32;
 }
 then {
 static-nat prefix 10.1.1.4/32;
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/1.0 {
 address {
 1.1.1.2/32;
 }
 }
}
[edit]
user@host# show security policies
from-zone public to-zone private {
 policy in-pol {
 match {
 source-address phone2;
 destination-address cm-tftp_server;
 destination-address phone1;
 application junos-sccp;
 }
 then {
 permit;
 }
 }
}
from-zone private to-zone public {
 policy out-pol {
 match {
 source-address any;
 destination-address phone2;
 application junos-sccp;
 }
 then {
 permit;
 }
 }
}

```

```

 }
 }
 from-zone private to-zone private {
 policy tftp-pol {
 match {
 source-address any;
 destination-address any;
 application junos-tftp;
 }
 then {
 permit;
 }
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Rule Usage on page 230](#)
- [Verifying Static NAT Configuration on page 231](#)
- [Verifying Static NAT Configuration on page 231](#)
- [Verifying SCCP ALG on page 232](#)
- [Verifying the Security Polices of SIP ALG on page 232](#)

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command.

```

user@host> show security nat source rule all

Total rules: 2
Total referenced IPv4/IPv6 ip-prefixes: 3/0
source NAT rule: r1 Rule-set: rs1
 Rule-Id : 1
 Rule position : 1
 From interface : ge-0/0/5.0
 : ge-0/0/6.0
 To interface : ge-0/0/2.0
 Match
 Source addresses : 30.0.0.0 - 30.0.0.255
 40.0.0.0 - 40.0.0.255
 Destination port : 0 - 0
 Action : interface
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
 Translation hits : 0
source NAT rule: phone1 Rule-set: phones
 Rule-Id : 3
 Rule position : 2

```

```

From zone : private
To zone : public
Match
 Source addresses : 10.1.1.3 - 10.1.1.3
 Destination port : 0 - 0
Action : interface
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
Translation hits : 0

```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule.

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule phone1** command.

```

user@host> show security nat static rule phone1

source NAT rule: phone1 Rule-set: phones
Rule-Id : 3
Rule position : 2
From zone : private
To zone : public
Match
 Source addresses : 10.1.1.3 - 10.1.1.3
 Destination port : 0 - 0
Action : interface
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
Translation hits : 0

```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule set.

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule phone2** command.

```

user@host> show security nat static rule phone2

Static NAT rule: phone2 Rule-set: to-proxy
Rule-Id : 1
Rule position : 1
From zone : public
Destination addresses : 1.1.1.2
Host addresses : 10.1.1.4
Netmask : 32
Host routing-instance : N/A
Translation hits : 0

```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule set.

### Verifying SCCP ALG

**Purpose** Verify that the SCCP ALG is enabled.

**Action** From operational mode, enter the **show security alg status | match sccp** command.

```
user@host> show security alg status | match sccp
SCCP : Enabled
```

**Meaning** The output shows the SCCP ALG status as follows:

- Enabled—Shows the SCCP ALG is enabled.
- Disabled—Shows the SCCP ALG is disabled.

### Verifying the Security Polices of SIP ALG

**Purpose** Verify that the static NAT between public zone and private zone is set.

**Action** From operational mode, enter the **show security policies** command.

```
user@host> show security policies
from-zone private to-zone public {
 policy out-pol {
 match {
 source-address any;
 destination-address phone2;
 application junos-sccp;
 }
 then {
 permit;
 }
 }
}
from-zone public to-zone private {
 policy in-pol {
 match {
 source-address phone2;
 destination-address [cm-tftp_server phone1];
 application junos-sccp;
 }
 then {
 permit;
 }
 }
}
from-zone private to-zone private {
 policy tftp-pol {
 match {
 source-address any;
 destination-address any;
 application junos-tftp;
 }
 then {
```

```

 permit;
 }
}

```

**Meaning** The sample output shows that the static NAT between public zone and private zone is set.

## Understanding SCCP ALG Inactive Media Timeouts

The inactive media timeout feature helps you to conserve network resources and maximize throughput.

This parameter indicates the maximum length of time (in seconds) a call can remain active without any media traffic within a group. Each time a Real-Time Transport Protocol (RTP) or Real-Time Control Protocol (RTCP) packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the gates the Skinny Client Control Protocol (SCCP) opened for media are closed. The default setting is 120 seconds, and the range is from 10 to 2550 seconds. Note that upon timeout, while resources for media (sessions and pinholes) are removed, the call is not terminated.

**Related Documentation**

- [Understanding SCCP ALGs on page 217](#)
- [SCCP ALG Configuration Overview on page 223](#)
- [Example: Setting SCCP ALG Inactive Media Timeouts on page 233](#)

## Example: Setting SCCP ALG Inactive Media Timeouts

This example shows how to set the inactive media timeout value for the SCCP ALG.

- [Requirements on page 233](#)
- [Overview on page 233](#)
- [Configuration on page 234](#)
- [Verification on page 234](#)

### Requirements

Before you begin, review the parameter used to indicate the maximum length of time (in seconds) a call can remain active without any media traffic within a group. See [“Understanding SCCP ALG Inactive Media Timeouts” on page 233](#).

### Overview

Each time an RTP or RTCP packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the gates the SCCP opened for media are closed. This example sets the media inactivity timeout to 90 seconds.

## Configuration

- GUI Step-by-Step Procedure** To set the inactive media timeout for the SCCP ALG:
1. Select **Configure>Security>ALG**.
  2. Select the **SCCP** tab.
  3. In the Inactive Media Timeout box, enter **90**.
  4. Click **OK** to check your configuration and save it as a candidate configuration.
  5. If you are done configuring the device, click **Commit Options>Commit**.

- Step-by-Step Procedure** To set the inactive media timeout for the SCCP ALG:
1. Configure the SCCP ALG inactive media timeout value.  

```
[edit]
user@host# set security alg sccp inactive-media-timeout 90
```
  2. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security alg sccp** command.

- Related Documentation**

## Understanding SCCP ALG Unknown Message Types

To accommodate on-going development of the Skinny Client Control Protocol (SCCP), you might want to allow traffic containing new SCCP message types. The unknown SCCP message type feature enables you to configure the device to accept SCCP traffic containing unknown message types in both Network Address Translation (NAT) mode and route mode.

This feature enables you to specify how unidentified SCCP messages are handled by the device. The default is to drop unknown (unsupported) messages. We do not recommend permitting unknown messages because they can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment. Permitting unknown SCCP messages can help you get your network operational so that you can later analyze your voice-over-IP (VoIP) traffic to determine why some messages were being dropped.

Note that this command applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as

a supported protocol and you have configured the device to permit unknown message types, the message is forwarded without processing.

**Related Documentation**

- [Understanding SCCP ALGs on page 217](#)
- [SCCP ALG Configuration Overview on page 223](#)
- [Example: Allowing Unknown SCCP ALG Message Types on page 235](#)

## Example: Allowing Unknown SCCP ALG Message Types

This example shows how to configure the SCCP ALG to allow unknown SCCP message types in both NAT mode and route mode.

- [Requirements on page 235](#)
- [Overview on page 235](#)
- [Configuration on page 235](#)
- [Verification on page 236](#)

### Requirements

Before you begin, determine whether to accommodate new and unknown SCCP message types for the device. See [“Understanding SCCP ALG Unknown Message Types” on page 234](#).

### Overview

This feature enables you to specify how unidentified SCCP messages are handled by a Juniper Networks device. The default is to drop unknown (unsupported) messages because unknown messages can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment.

### Configuration

**GUI Step-by-Step Procedure**

To configure the SCCP ALG to allow unknown message types:

1. Select **Configure>Security>ALG**.
2. Select the **SCCP** tab.
3. Select the **Enable Permit NAT applied** check box.
4. Select the **Enable Permit routed** check box.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

**Step-by-Step Procedure**

To configure the SCCP ALG to allow unknown message types:

1. Allow unknown message types to pass if the session is in either NAT mode or in route mode.

[edit]

```
user@host# set security alg sccp application-screen unknown-message
permit-nat-applied permit-routed
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security alg sccp** command.

## Understanding SCCP ALG DoS Attack Protection

You can protect Skinny Client Control Protocol Application Layer Gateway (SCCP ALG) clients from denial-of-service (DoS) flood attacks by limiting the number of calls they attempt to process.

When you configure SCCP call flood protection, the SCCP ALG drops any calls exceeding the threshold you set. The range is 2 to 1000 calls per second per client, the default is 20.

### Related Documentation

- [Understanding SCCP ALGs on page 217](#)
- [SCCP ALG Configuration Overview on page 223](#)
- [Example: Configuring SCCP ALG DoS Attack Protection on page 236](#)

---

## Example: Configuring SCCP ALG DoS Attack Protection

This example shows how to configure connection flood protection for the SCCP ALG.

- [Requirements on page 236](#)
- [Overview on page 236](#)
- [Configuration on page 237](#)
- [Verification on page 237](#)

## Requirements

Before you begin, determine whether to protect the SCCP media gateway from DoS flood attacks. See [“Understanding SCCP ALG DoS Attack Protection” on page 236](#).

## Overview

In this example, the device is configured to drop any calls exceeding 500 per second per client.

## Configuration

- GUI Step-by-Step Procedure** To configure call flood protection for the SCCP ALG:
1. Select **Configure>Security>ALG**.
  2. Select the **SCCP** tab.
  3. In the Call flood threshold box, type **500**.
  4. Click **OK** to check your configuration and save it as a candidate configuration.
  5. If you are done configuring the device, click **Commit Options>Commit**.
- Step-by-Step Procedure** To configure call flood protection for the SCCP ALG:
1. Configure the DoS attack protection:
 

```
[edit]
user@host# set security alg sccp application-screen call-flood threshold 500
```
  2. If you are done configuring the device, commit the configuration.
 

```
[edit]
user@host# commit
```

## Verification

To verify the configuration is working properly, enter the **show security alg sccp** command.

- Related Documentation**
- [Understanding SCCP ALG DoS Attack Protection on page 236](#)

## Verifying SCCP ALG

- Purpose** Display SCCP verification options.
- Action** From the CLI, enter the **show security alg sccp** command.
- ```
user@host> show security alg sccp ?
Possible completions:
  calls          Show SCCP calls
  counters       Show SCCP counters
```

Meaning The output shows a list of all SCCP verification parameters. Verify the following information:

- All SCCP calls
- Counters for all SCCP calls

Verifying SCCP ALG Calls

Purpose Display a list of all SCCP calls

Action From the CLI, enter the **show security alg sccp calls** command.

```
user@host> show security alg sccp calls
```

Possible completions:

calls	Show SCCP calls
counters	Show SCCP counters
endpoints	Show SCCP endpoints

Meaning The output shows a list of all SCCP verification parameters. Verify the following information:

- All SCCP calls
- Counters for all SCCP calls
- Information about all SCCP endpoints

Verifying SCCP ALG Call Details

Purpose Display details about all SCCP calls.

Action From the CLI, enter the **show security alg sccp calls detail** command.

```
user@host> show security alg sccp calls detail
```

```

Understanding the SIP ALG

Session Initiation Protocol (SIP) is an Internet Engineering Task Force (IETF)-standard protocol for initiating, modifying, and terminating multimedia sessions over the Internet.

Such sessions might include conferencing, telephony, or multimedia, with features such as instant messaging and application-level mobility in network environments.

Junos OS supports SIP as a service, allowing and denying it based on a policy that you configure. SIP is a predefined service in Junos OS and uses port 5060 as the destination port.

One of SIP's functions is to distribute session-description information and, during the session, to negotiate and modify the parameters of the session. SIP is also used to terminate a multimedia session, signal a call establishment, provide failure indication, and provide methods for endpoint to register.

Session-description information is included in INVITE and ACK messages and indicates the multimedia type of the session; for example, whether it is voice or video. Although SIP can use different description protocols to describe the session, the Juniper Networks SIP Application Layer Gateway (ALG) supports only the Session Description Protocol (SDP).

SDP provides information that a system can use to join a multimedia session. SDP might include information such as IP addresses, port numbers, times, and dates. Note that the IP address and port number in the SDP header (the c= and m= fields, respectively) are the address and port where the client wants to receive the media streams and not the IP address and port number from which the SIP request originates (although they can be the same).

SIP messages consist of requests from a client to a server and responses to the requests from a server to a client with the purpose of establishing a session (or a call). A User Agent (UA) is an application that runs at the endpoints of the call and consists of two parts:

- User Agent Client (UAC), which sends SIP requests on behalf of the user
- User Agent Server (UAS), which listens to the responses and notifies the user when they arrive

UAC and UAS are defined in relation to the role a particular agent is playing in a negotiation.

Examples of UAs are SIP proxy servers and phones.

This topic contains the following sections:

- [SIP ALG Operation on page 242](#)
- [SDP Session Descriptions on page 244](#)
- [Pinhole Creation on page 244](#)

SIP ALG Operation

There are two types of SIP traffic, the signaling and the media stream. SIP signaling traffic consists of request and response messages between client and server and uses transport protocols such as UDP. The media stream carries the data (audio data, for example) using transport protocols.

NOTE: The SIP ALG does not support TCP.

By default, Junos OS supports SIP signaling messages on port 5060. You can configure the port. You can simply create a policy that permits SIP service, and the software filters SIP signaling traffic like any other type of traffic, permitting or denying it. The media stream, however, uses dynamically assigned port numbers that can change several times during the course of a call. Without fixed ports, it is insecure to create a static policy to control media traffic. In this case, the device invokes the SIP ALG. The device transport ports used for the media sessions are not known in advance, however, the ports used for the SIP negotiation are well-known (or predefined). The ALG registers interest in packets from the control session which can be easily distinguished from the other packets and inspects the negotiation looking for the transport information used for the media session (both IP addresses and ports).

NOTE: Pinholes are created when a matching port, transport address, and protocol is determined (whatever information is known at the time the pinhole is opened).

The SIP ALG monitors SIP transactions and dynamically creates and manages pinholes based on the information it extracts from these transactions. The Juniper Networks SIP ALG supports all SIP methods and responses. You can allow SIP transactions to traverse the Juniper Networks firewall by creating a static policy that permits SIP service. If the policy is configured to inspect SIP traffic (or, more appropriately, if the policy sends some traffic to the SIP ALG for inspection) the allowed actions are to permit the traffic (in which case the appropriate pinholes are opened) or to deny the traffic.

The SIP ALG intercepts SIP messages that contain SDP and, using a parser, extracts the information it requires to create pinholes. The SIP ALG examines the SDP portion of the packet, and a parser extracts information such as IP addresses and port numbers, which the SIP ALG records in a pinhole table. The SIP ALG uses the IP addresses and port numbers recorded in the pinhole table to open pinholes and allow media streams to traverse the device.

NOTE: When the device is performing NAT, the transport addresses that the user agents employ are incorrect. ALG modifies the transport addresses based on the translated ports and addresses allocated by the NAT-ing device. When SDP is encrypted, the device cannot either extract nor modify the contents of the message and therefore cannot correct the transport addresses. To provide a workaround, the STUN protocol has been deployed (which requires NAT devices to do some form of cone-NAT) which allows the clients to determine the translated addresses and use those newly discovered addresses in the SDP messages.

NEC SIP products are conditionally supported.

SDP Session Descriptions

An SDP session description is a well defined format for conveying sufficient information to discover and participate in a multimedia session. A session is described by a series of attribute/value pairs, one per line. The attribute names are single characters, followed by '=', and a value. Optional values are specified with '*'. Values are either an ASCII string, or a sequence of specific types separated by spaces. Attribute names are only unique within the associated syntactic construct, such as within the session, time, or media only.

NOTE: In the SDP session description, the media-level information begins with the **m=** field.

Of the many fields in the SDP description, two are particularly useful to the SIP ALG because they contain Transport Layer information.

- **c=** for connection information

This field can appear at the session or media level. It displays in this format:

`c=<network-type><address-type><connection-address>`

Currently, Junos OS supports only "IN" (for Internet) as the network type, "IP4" as the address type, and a unicast IP address or domain name as the destination (connection) IP address.

If the destination IP address is a unicast IP address, the SIP ALG creates pinholes using the IP address and port numbers specified in the media description field **m=**.

- **m=** for media announcement

This field appears at the media level and contains the description of the media. It displays in this format:

`m=<media><port><transport><fmt list>`

Currently, Junos OS supports only "audio" as the media and "RTP" as the Application Layer transport protocol. The port number indicates the destination port of the media stream (the origin is allocated by the remote user agent). The format list (fmt list) provides information on the Application Layer protocol that the media uses.

The software opens ports only for RTP and Real-Time Control Protocol (RTCP). Every RTP session has a corresponding RTCP session. Therefore, whenever a media stream uses RTP, the SIP ALG must reserve ports (create pinholes) for both RTP and RTCP traffic. By default, the port number for RTCP is one higher than the RTP port number.

Pinhole Creation

Both pinholes for the RTP and RTCP traffic share the same destination IP address. The IP address comes from the **c=** field in the SDP session description. Because the **c=** field can appear in either the session-level or media-level portion of the SDP session

description, the parser determines the IP address based on the following rules (in accordance with SDP conventions):

- First, the SIP ALG parser verifies if there is a `c=` field containing an IP address in the media level. If there is one, the parser extracts that IP address, and the SIP ALG uses it to create a pinhole for the media.
- If there is no `c=` field in the media level, the SIP ALG parser extracts the IP address from the `c=` field in the session level, and the SIP ALG uses it to create a pinhole for the media. If the session description does not contain a `c=` field in either level, this indicates an error in the protocol stack, and the device drops the packet and logs the event.

SIP ALG also open pinholes for signal traffic. These signal pinholes are useful after the previous signal session timeout, and they are also useful for the signal traffic sent to the third party address which does not match with the previous signal session.

These SIP ALG signal pinholes are wide open gate which never age out unlike RTP/RTCP pinhole lifetime, with only destination IP and destination port specified.

SIP ALG will open signal pinholes for following headers if needed:

- VIA
- CONTACT
- ROUTE
- RECORD-ROUTE

The SIP ALG needs the following information to create a pinhole. This information comes from the SDP session description and parameters on the device:

- Protocol—UDP.
- Source IP—Unknown.
- Source port—Unknown.
- Destination IP—The parser extracts the destination IP address from the `c=` field in the media or session level.
- Destination port—The parser extracts the destination port number for RTP from the `m=` field in the media level and calculates the destination port number for RTCP using the following formula:

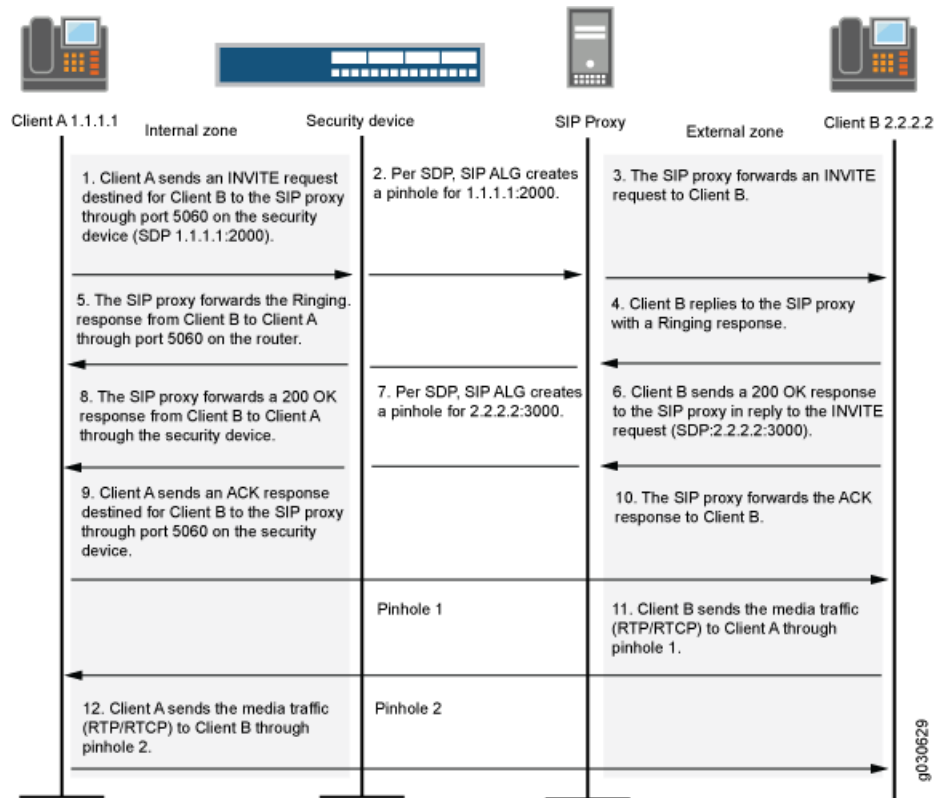

RTP port number + one

- Lifetime—This value indicates the length of time (in seconds) during which a pinhole is open to allow a packet through. A packet must go through the pinhole before the lifetime expires. When the lifetime expires, the SIP ALG removes the pinhole.

When a packet goes through the pinhole within the lifetime period, immediately afterwards the SIP ALG removes the pinhole for the direction from which the packet came.

Figure 19 describes a call setup between two SIP clients and how the SIP ALG creates pinholes to allow RTP and RTCP traffic. The illustration assumes that the device has a policy that permits SIP, thus opening port 5060 for SIP signaling messages.

Figure 19: SIP ALG Call Setup

NOTE: The SIP ALG does not create pinholes for RTP and RTCP traffic when the destination IP address is 0.0.0.0, which indicates that the session is on hold. To put a session on hold during a telephone communication, for example, user A sends user B a SIP message in which the destination IP address is 0.0.0.0. Doing so indicates to user B that it should not send any media until further notice. If user B sends media anyway, the device drops the packets.

Understanding IPv6 Support for SIP ALG

IPv6 is supported on the SIP ALG along with NAT-PT mode and NAT64 address translation.

The SIP ALG processes the IPv6 address in the same way it processes the IPv4 address for updating the payload if NAT is configured and opening pinholes for future traffic.

Special processing occurs for the following formats:

- **IPv6 in SIP URIs**—The SIP URI looks the same as a URI with IPv4 addresses. As in all URIs, an IPv6 address is enclosed in square brackets. The IPv6 address blocks are separated by colons. In many notations, a colon separates the hostname or IP address from the protocol port. To parse the full IPv6 address and separate the port, the address is encapsulated within square brackets
- **IPv6 in SDP**—IPv6 addresses in the Session Description Protocol (SDP) have the IP6 marker.
- The SIP ALG with IPv6 support has the following limitation:
 - When NAT64 with persistent NAT is implemented, the SIP ALG adds the NAT translation to the persistent NAT binding table if NAT is configured on the Address of Record (AOR). Because persistent NAT cannot duplicate the address configured, coexistence of NAT66 and NAT64 configured on the same address is not supported. Only one binding is created for the same source IP address.

Understanding SIP ALG Request Methods

The Session Initiation Protocol (SIP) transaction model includes a number of request and response messages, each of which contains a *method* field that denotes the purpose of the message.

Junos OS supports the following method types and response codes:

- **INVITE**—A user sends an INVITE request to invite another user to participate in a session. The body of an INVITE request can contain the description of the session.
- **ACK**—The user from whom the INVITE originated sends an ACK request to confirm reception of the final response to the INVITE request. If the original INVITE request did not contain the session description, the ACK request must include it.
- **OPTIONS**—The User Agent (UA) obtains information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.
- **BYE**—A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.

- **CANCEL**—A user sends a CANCEL request to cancel a pending INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE had sent a final response for the INVITE before it received the CANCEL.
- **REGISTER**—A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. A SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user.
- **Info**—Used to communicate mid-session signaling information along the signaling path for the call.
- **Subscribe**—Used to request current state and state updates from a remote node.
- **Notify**—Sent to inform subscribers of changes in state to which the subscriber has a subscription.
- **Refer**—Used to refer the recipient (identified by the Request-URI) to a third party by the contact information provided in the request.

For example, if user A in a private network refers user B, in a public network, to user C, who is also in the private network, the SIP Application Layer Gateway (ALG) allocates a new IP address and port number for user C so that user C can be contacted by user B. If user C is registered with a registrar, however, its port mapping is stored in the ALG Network Address Translation (NAT) table and is reused to perform the translation.

- **Update**—Used to open pinhole for new or updated SDP information. The Via:, From:, To:, Call-ID:, Contact:, Route:, and Record-Route: header fields are modified.
- **1xx, 202, 2xx, 3xx, 4xx, 5xx, 6xx Response Codes**—Used to indicate the status of a transaction. Header fields are modified.

SIP ALG Configuration Overview

The Session Initiation Protocol Application Layer Gateway (SIP ALG) is disabled by default on high-end devices—it should be enabled using the CLI if required. On other devices, it is enabled by default. To fine-tune SIP ALG operations use the following instructions:

1. Control SIP call activity. For instructions, see [“Example: Setting SIP ALG Call Duration and Timeouts” on page 250](#).
2. Protect the SIP proxy server from denial-of-service (DoS) flood attacks. For instructions, see [“Example: Configuring SIP ALG DoS Attack Protection” on page 252](#).
3. Enable unknown messages to pass when the session is in Network Address Translation (NAT) mode and route mode. For instructions, see [“Example: Allowing Unknown SIP ALG Message Types” on page 254](#).

4. Accommodate proprietary SIP call flows. For instructions, see:

- [Retaining SIP ALG Hold Resources \(J-Web Procedure\) on page 256](#)
- [Retaining SIP ALG Hold Resources \(CLI Procedure\) on page 255](#)

Understanding SIP ALG Call Duration and Timeouts

The call duration and timeout features give you control over Session Initiation Protocol (SIP) call activity and help you to manage network resources.

Typically a call ends when one of the clients sends a BYE or CANCEL request. The SIP Application Layer Gateway (ALG) intercepts the BYE or CANCEL request and removes all media sessions for that call. There could be reasons or problems preventing clients in a call from sending BYE or CANCEL requests, for example, a power failure. In this case, the call might go on indefinitely, consuming resources on the device.

A call can have one or more voice channels. Each voice channel has two sessions (or two media streams), one for Real-Time Transport Protocol (RTP) traffic and one for Real-Time Control Protocol (RTCP) signaling. When managing the sessions, the device considers the sessions in each voice channel as one group. Timeouts and call duration settings apply to a group as opposed to each session.

The following parameters govern SIP call activity:

- **inactive-media-timeout**—This parameter indicates the maximum length of time (in seconds) a call can remain active without any media (RTP or RTCP) traffic within a group. Each time an RTP or RTCP packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the temporary openings (pinholes) in the firewall the SIP ALG opened for media are closed. The default setting is 120 seconds, and the range is 10 through 2550 seconds. Note that upon timeout, resources for media (sessions and pinholes) are removed and SIP calls on the device will also be terminated if all the media resources of this call are removed.
- **maximum-call-duration**—This parameter sets the absolute maximum length of a call. When a call exceeds this parameter setting, the SIP ALG tears down the call and releases the media sessions. The default setting is 720 minutes, and the range is 3 through 720 minutes.
- **t1-interval**—This parameter specifies the roundtrip time estimate, in seconds, of a transaction between endpoints. The default is 500 milliseconds. Because many SIP timers scale with the t1-interval (as described in RFC 3261), when you change the value of the t1-interval timer, those SIP timers also are adjusted.
- **t4-interval**—This parameter specifies the maximum time a message remains in the network. The default is 5 seconds and the range is 5 through 10 seconds. Because

many SIP timers scale with the t4-interval (as described in RFC 3261), when you change the value of the t4-interval timer, those SIP timers also are adjusted.

- **c-timeout**—This parameter specifies the INVITE transaction timeout at the proxy, in minutes; the default is 3. Because the SIP ALG is in the middle, instead of using the INVITE transaction timer value B (which is $(64 * T1) = 32$ seconds), the SIP ALG gets its timer value from the proxy.

Related Documentation

- [Example: Setting SIP ALG Call Duration and Timeouts on page 250](#)

Example: Setting SIP ALG Call Duration and Timeouts

This example shows how to set the call duration and the media inactivity timeout.

Requirements

Before you begin, review the call duration and timeout features used to control SIP call activity. See “[Understanding SIP ALG Call Duration and Timeouts](#)” on page 249.

Overview

The call duration and inactivity media timeout features help you to conserve network resources and maximize throughput.

The **maximum-call-duration** parameter sets the maximum allowable length of time a call can be active. When the duration is exceeded, the SIP ALG tears down the call and releases the media sessions. The default setting is 720 minutes, and the range is 3 through 720 minutes. This setting also frees up bandwidth in cases where calls fail to properly terminate.

The **inactive-media-timeout** parameter indicates the maximum length of time (in seconds) a call can remain active without any media (RTP or RTCP) traffic within a group. Each time an RTP or RTCP packet occurs within a call, this timeout resets. When the period of inactivity exceeds this setting, the SIP ALG temporary openings (pinholes) for media in the firewall are closed. The default setting is 120 seconds, and the range is 10 through 2550 seconds. Upon timeout, while resources for media (sessions and pinholes) are removed, the call is not terminated.

In this example, the call duration is set to 36000 seconds and the media inactivity timeout is set to 90 seconds.

Configuration

GUI Step-by-Step Procedure

To set the SIP ALG call duration and the media inactivity timeout:

1. Select **Configure > Security > ALG**.
2. Select the **SIP** tab.

3. In the Maximum call duration field, type **600**.
4. In the Inactive media timeout field, enter **90**.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options >Commit**.

Step-by-Step Procedure

To set the SIP ALG call duration and the media inactivity timeout:

1. Configure the SIP ALG call duration.

```
[edit]
user@host# set security alg sip maximum-call-duration 600
```
2. Configure the SIP ALG inactivity media timeout.

```
[edit]
user@host# set security alg sip inactive-media-timeout 90
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg sip** command.

Understanding SIP ALG DoS Attack Protection

The ability of the Session Initiation Protocol (SIP) proxy server to process calls can be impacted by repeat SIP INVITE requests—requests that it initially denied. The denial-of-service (DoS) protection feature enables you to configure the device to monitor INVITE requests and proxy server replies to them. If a reply contains a 3xx, 4xx, or 5xx response code other than 401, 407, 487, and 488 that are not real failure responses, then the request should not be blocked. See [“Classes of SIP Responses” on page 263](#). The ALG stores the source IP address of the request and the IP address of the proxy server in a table. Subsequently, the device checks all INVITE requests against this table and, for a configurable number of seconds (the default is 3), discards any packets that match entries in the table. You can configure the device to monitor and deny repeat INVITE requests to all proxy servers, or you can protect a specific proxy server by specifying the destination IP address. SIP attack protection is configured globally.

NOTE: IPv6 is supported on the SIP ALG along with Network Address Translation Protocol Translation (NAT-PT) mode and NAT64 address translation.

The type of the <destination-ip-address> is changed from IPv4 address to IP prefix to support all kinds of IP addresses, and correspondingly a prefix is supported to allow multiple IP addresses.

Related Documentation

- [Understanding the SIP ALG on page 241](#)
- [SIP ALG Configuration Overview on page 248](#)
- [Example: Configuring SIP ALG DoS Attack Protection on page 252](#)

Example: Configuring SIP ALG DoS Attack Protection

This example shows how to configure the DoS attack protection feature.

Requirements

Before you begin, review the DoS attack protection feature used to control SIP call activity. See [“Understanding SIP ALG DoS Attack Protection” on page 251](#).

Overview

The ability of the SIP proxy server to process calls can be impacted by repeat SIP INVITE requests—requests that the server initially denied. The DoS protection feature enables you to configure the device to monitor INVITE requests and proxy server replies to them.

In this example, the device is configured to protect a single SIP proxy server (1.1.1.3) from repeat INVITE requests to which it has already been denied service. Packets are dropped for a period of 5 seconds, after which the device resumes forwarding INVITE requests from those sources.

Configuration

GUI Step-by-Step Procedure

To configure SIP ALG DoS attack protection:

1. Select **Configure>Security>ALG**.
2. Select the **SIP** tab.
3. In the Enable attack protection area, click the **Selected servers** option.
4. In the Destination IP box, enter **1.1.1.3** and click **Add**.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To configure SIP ALG DoS attack protection:

1. Configure the device to protect a single SIP proxy server.

```
[edit]
user@host# set security alg sip application-screen protect deny destination-ip 1.1.1.3
```

NOTE: IPv6 is supported on the SIP ALG along with Network Address Translation Protocol Translation (NAT-PT) mode and NAT64 address translation.

The type of the <destination-ip-address> is changed from IPv4 address to IP prefix to support all kinds of IP addresses, and correspondingly a prefix is supported to allow multiple IP addresses.

2. Configure the device for the deny timeout period.

```
[edit]
user@host# set security alg sip application-screen protect deny timeout 5
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg sip** command.

Understanding SIP ALG Unknown Message Types

This feature enables you to specify how unidentified Session Initiation Protocol (SIP) messages are handled by the device. The default is to drop unknown (unsupported) messages.

We do not recommend permitting unknown messages because they can compromise security. However, in a secure test or production environment, this command can be useful for resolving interoperability issues with disparate vendor equipment. Permitting unknown SIP messages can help you get your network operational so you can later analyze your voice-over-IP (VoIP) traffic to determine why some messages were being dropped. The unknown SIP message type feature enables you to configure the device to accept SIP traffic containing unknown message types in both Network Address Translation (NAT) mode and route mode.

NOTE: This option applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol and you have configured the device to permit unknown message types, the message is forwarded without processing.

Related Documentation

Example: Allowing Unknown SIP ALG Message Types

This example shows how to allow unknown message types.

Requirements

Before you begin, review how unidentified SIP messages are handled by the device. See [“Understanding SIP ALG Unknown Message Types” on page 253](#).

Overview

In this example, you configure the device to allow unknown message types in SIP traffic in both NAT mode and route mode. The default is to drop unknown (unsupported) messages.

Configuration

GUI Step-by-Step Procedure

- To allow unknown SIP ALG message types:
1. Select **Configure>Security>ALG**.
 2. Select the **SIP** tab.
 3. Select the **Enable Permit NAT applied** check box.
 4. Select the **Enable Permit routed** check box.
 5. Click **OK** to check your configuration and save it as a candidate configuration.
 6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

- To allow unknown SIP ALG message types:
1. Configure the device to allow unknown message types in SIP traffic.

```
[edit]
user@host# set security alg sip application-screen unknown-message
permit-nat-applied permit-routed
```
 2. If you are done configuring the device, commit the configuration.

```
[edit]
```

```
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security alg sip** command.

Understanding SIP ALG Hold Resources

When a user puts a call on hold, the Session Initiation Protocol Application Layer Gateway (SIP ALG) releases Session Description Protocol (SDP) media resources, such as pinholes and translation contexts. When the user resumes the call, an INVITE request message negotiates a new SDP offer and answer and the SIP ALG reallocates resources for the media stream. This can result in new translated IP address and port numbers for the media description even when the media description is the same as the previous description. This is compliant with *RFC 3264 An Offer/Answer Model with the Session Description Protocol (SDP)*.

Some proprietary SIP implementations have designed call flows so that the User Agent (UA) module ignores the new SDP INVITE offer and continues to use the SDP offer of the previous negotiation. To accommodate this functionality, you must configure the device to retain SDP media resources when a call is put on hold for reuse when the call is resumed.

Understanding the SIP ALG and NAT

The Network Address Translation (NAT) protocol enables multiple hosts in a private subnet to share a single public IP address to access the Internet. For outgoing traffic, NAT replaces the private IP address of the host in the private subnet with the public IP address. For incoming traffic, the public IP address is converted back into the private address, and the message is routed to the appropriate host in the private subnet.

Using NAT with the Session Initiation Protocol (SIP) service is more complicated because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When using NAT with the SIP service, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. The device translates SDP information for allocating resources to send and receive the media.

How IP addresses and port numbers in SIP messages are replaced depends on the direction of the message. For an outgoing message, the private IP address and port number of the client are replaced with the public IP address and port number of the Juniper Networks firewall. For an incoming message, the public address of the firewall is replaced with the private address of the client.

When an INVITE message is sent out across the firewall, the SIP Application Layer Gateway (ALG) collects information from the message header into a call table, which it uses to forward subsequent messages to the correct endpoint. When a new message arrives, for example an ACK or 200 OK, the ALG compares the "From:", "To:", and "Call-ID:" fields against the call table to identify the call context of the message. If a new INVITE message arrives that matches the existing call, the ALG processes it as a REINVITE.

When a message containing SDP information arrives, the ALG allocates ports and creates a NAT mapping between them and the ports in the SDP. Because the SDP requires sequential ports for the Real-Time Transport Protocol (RTP) and Real-Time Control Protocol (RTCP) channels, the ALG provides consecutive even-odd ports. If it is unable to find a pair of ports, it discards the SIP message.

IPv6 is supported on the SIP ALG along with NAT-PT mode and NAT64 address translation.

Outgoing Calls

When a SIP call is initiated with a SIP request message from the internal to the external network, NAT replaces the IP addresses and port numbers in the SDP and binds the IP addresses and port numbers to the Juniper Networks firewall. Via, Contact, Route, and Record-Route SIP header fields, if present, are also bound to the firewall IP address. The ALG stores these mappings for use in retransmissions and for SIP response messages.

The SIP ALG then opens pinholes in the firewall to allow media through the device on the dynamically assigned ports negotiated based on information in the SDP and the Via, Contact, and Record-Route header fields. The pinholes also allow incoming packets to reach the Contact, Via, and Record-Route IP addresses and ports. When processing return traffic, the ALG inserts the original Contact, Via, Route, and Record-Route SIP fields back into packets.

Incoming Calls

Incoming calls are initiated from the public network to public static NAT addresses or to interface IP addresses on the device. Static NATs are statically configured IP addresses that point to internal hosts; interface IP addresses are dynamically recorded by the ALG as it monitors REGISTER messages sent by internal hosts to the SIP registrar. When the device receives an incoming SIP packet, it sets up a session and forwards the payload of the packet to the SIP ALG.

The ALG examines the SIP request message (initially an INVITE) and, based on information in the SDP, opens gates for outgoing media. When a 200 OK response message arrives, the SIP ALG performs NAT on the IP addresses and ports and opens pinholes in the outbound direction. (The opened gates have a short time-to-live, and they time out if a 200 OK response message is not received quickly.)

When a 200 OK response arrives, the SIP proxy examines the SDP information and reads the IP addresses and port numbers for each media session. The SIP ALG on the device performs NAT on the addresses and port numbers, opens pinholes for outbound traffic, and refreshes the timeout for gates in the inbound direction.

When the ACK arrives for the 200 OK, it also passes through the SIP ALG. If the message contains SDP information, the SIP ALG ensures that the IP addresses and port numbers are not changed from the previous INVITE—if they are, the ALG deletes old pinholes and creates new pinholes to allow media to pass through. The ALG also monitors the Via, Contact, and Record-Route SIP fields and opens new pinholes if it determines that these fields have changed.

Forwarded Calls

A forwarded call is when, for example, user A outside the network calls user B inside the network, and user B forwards the call to user C outside the network. The SIP ALG processes the INVITE from user A as a normal incoming call. But when the ALG examines the forwarded call from B to C outside the network and notices that B and C are reached using the same interface, it does not open pinholes in the firewall, because media will flow directly between user A and user C.

Call Termination

The BYE message terminates a call. When the device receives a BYE message, it translates the header fields just as it does for any other message. But because a BYE message must be acknowledged by the receiver with a 200 OK, the ALG delays call teardown for 5 seconds to allow time for transmission of the 200 OK.

Call Re-INVITE Messages

Re-INVITE messages add new media sessions to a call and remove existing media sessions. When new media sessions are added to a call, new pinholes are opened in the firewall and new address bindings are created. The process is identical to the original call setup. When all the media sessions or media pinholes are removed from a call, the call is removed when a BYE message is received.

Call Session Timers

As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the device is protected should one of the following events occur:

- End systems crash during a call and a BYE message is not received.
- Malicious users never send a BYE in an attempt to attack a SIP ALG.
- Poor implementations of SIP proxy fail to process Record-Route and never send a BYE message.
- Network failures prevent a BYE message from being received.

Call Cancellation

Either party can cancel a call by sending a CANCEL message. Upon receiving a CANCEL message, the SIP ALG closes pinholes through the firewall—if any have been opened—and releases address bindings. Before releasing the resources, the ALG delays the control channel age-out for approximately 5 seconds to allow time for the final 200 OK to pass through. The call is terminated when the 5-second timeout expires, regardless of whether a 487 or non-200 response arrives.

Forking

Forking enables a SIP proxy to send a single INVITE message to multiple destinations simultaneously. When the multiple 200 OK response messages arrive for the single call, the SIP ALG parses but updates call information with the first 200 OK messages it receives.

SIP Messages

The SIP message format consists of a SIP header section and the SIP body. In request messages, the first line of the header section is the request line, which includes the method type, request-URI, and protocol version. In response messages, the first line is the status line, which contains a status code. SIP headers contain IP addresses and port numbers used for signaling. The SIP body, separated from the header section by a blank line, is reserved for session description information, which is optional. Junos OS currently supports the SDP only. The SIP body contains IP addresses and port numbers used to transport the media.

SIP Headers

In the following sample SIP request message, NAT replaces the IP addresses in the header fields to hide them from the outside network.

```
INVITE bob@10.150.20.5 SIP/2.0
Via: SIP/2.0/UDP 10.150.20.3:5434
From: alice@10.150.20.3
To: bob@10.150.20.5
Call-ID: a12abcde@10.150.20.3
Contact: alice@10.150.20.3:5434
```

Route: <sip:netscreen@10.150.20.3:5060>
 Record-Route: <sip:netscreen@10.150.20.3:5060>

How IP address translation is performed depends on the type and direction of the message. A message can be any of the following:

- Inbound request
- Outbound response
- Outbound request
- Inbound response

Table 12 shows how NAT is performed in each of these cases. Note that for several of the header fields the ALG determine more than just whether the messages comes from inside or outside the network. It must also determine what client initiated the call, and whether the message is a request or response.

Table 12: Requesting Messages with NAT Table

Inbound Request (from public to private)	To:	Replace domain with local address
	From:	None
	Call-ID:	None
	Via:	None
	Request-URI:	Replace ALG address with local address
	Contact:	None
	Record-Route:	None
	Route:	None
Outbound Response (from private to public)	To:	Replace ALG address with local address
	From:	None
	Call-ID:	None
	Via:	None
	Request-URI:	N/A
	Contact:	Replace local address with ALG address
	Record-Route:	Replace local address with ALG address
	Route:	None

Table 12: Requesting Messages with NAT Table (*continued*)

Outbound Request (from private to public)	To:	None
	From:	Replace local address with ALG address
	Call-ID:	None
	Via:	Replace local address with ALG address
	Request-URI:	None
	Contact:	Replace local address with ALG address
	Record-Route:	Replace local address with ALG address
	Route:	Replace local address with ALG address
Outbound Response (from public to private)	To:	None
	From:	Replace ALG address with local address
	Call-ID:	None
	Via:	Replace ALG address with local address
	Request-URI:	N/A
	Contact:	None
	Record-Route:	Replace ALG address with local address
	Route:	Replace ALG address with local address

SIP Body

The SDP information in the SIP body includes IP addresses the ALG uses to create channels for the media stream. Translation of the SDP section also allocates resources, that is, port numbers to send and receive the media.

The following excerpt from a sample SDP section shows the fields that are translated for resource allocation.

```
o=user 2344234 55234434 IN IP4 10.150.20.3
c=IN IP4 10.150.20.3
m=audio 43249 RTP/AVP 0
```

SIP messages can contain more than one media stream. The concept is similar to attaching multiple files to an e-mail message. For example, an INVITE message sent from a SIP client to a SIP server might have the following fields:

```
c=IN IP4 10.123.33.4
```

```

m=audio 33445 RTP/AVP 0
c=IN IP4 10.123.33.4
m=audio 33447 RTP/AVP 0
c=IN IP4 10.123.33.4
m=audio 33449 RTP/AVP 0

```

Junos OS supports up to 6 SDP channels negotiated for each direction, for a total of 12 channels per call. For more information, see [“SDP Session Descriptions” on page 244](#).

SIP NAT Scenario

[Figure 20](#) and [Figure 21](#) show a SIP call INVITE and 200 OK. In [Figure 20](#), ph1 sends a SIP INVITE message to ph2. Note how the IP addresses in the header fields—shown in bold font—are translated by the device.

The SDP section of the INVITE message indicates where the caller is willing to receive media. Note that the Media Pinhole contains two port numbers, 52002 and 52003, for RTCP and RTP. The Via/Contact Pinhole provides port number 5060 for SIP signaling.

Observe how, in the 200 OK response message in [Figure 21](#), the translations performed in the INVITE message are reversed. The IP addresses in this message, being public, are not translated, but gates are opened to allow the media stream access to the private network.

Figure 20: SIP NAT Scenario 1

Figure 21: SIP NAT Scenario 2

Classes of SIP Responses

SIP responses provide status information about SIP transactions and include a response code and a reason phrase. SIP responses are grouped into the following classes:

- Informational (100 to 199)—Request received, continuing to process the request.
- Success (200 to 299)—Action successfully received, understood, and accepted.
- Redirection (300 to 399)—Further action required to complete the request.
- Client Error (400 to 499)—Request contains bad syntax or cannot be fulfilled at this server.
- Server Error (500 to 599)—Server failed to fulfill an apparently valid request.
- Global Failure (600 to 699)—Request cannot be fulfilled at any server.

Table 13 provides a complete list of current SIP responses.

Table 13: SIP Responses

Informational	100 Trying	180 Ringing	181 Call is being forwarded
	182 Queued	183 Session progress	
Success	200 OK	202 Accepted	
Redirection	300 Multiple choices	301 Moved permanently	302 Moved temporarily
	305 Use proxy	380 Alternative service	
Client Error	400 Bad request	401 Unauthorized	402 Payment required
	403 Forbidden	404 Not found	405 Method not allowed
	406 Not acceptable	407 Proxy authentication required	408 Request time-out
	409 Conflict	410 Gone	411 Length required
	413 Request entity too large	414 Request URL too large	415 Unsupported media type
	420 Bad extension	480 Temporarily not available	481 Call leg/transaction does not exist
	482 Loop detected	483 Too many hops	484 Address incomplete
	485 Ambiguous	486 Busy here	487 Request canceled
	488 Not acceptable here		
Server Error	500 Server internal error	501 Not implemented	502 Bad gateway
	502 Service unavailable	504 Gateway time-out	505 SIP version not supported
Global Failure	600 Busy everywhere	603 Decline	604 Does not exist anywhere
	606 Not acceptable		

NAT Mode in Pure IPv6 Mode (NAT66) for SIP IPv6 ALG

The SIP IPv6 ALG supports NAT66 just like NAT44. NAT66 (IPv6 NAT) provides source NAT and static NAT functions similar to NAT44 (IPv4 NAT).

NAT-PT

Network Address Translation Protocol Translation (NAT-PT) (RFC 2766) is a protocol translation mechanism that allows communication between IPv6-only and IPv4-only nodes through protocol-independent translation of IPv4 and IPv6 datagrams, requiring no state information for the session.

NAT-PT is implemented by normal NAT from IPv6 address to IPv4 address and vice versa. The SIP ALG processes those address translations in the payload just as the addresses are processed in normal NAT.

NAT-PT binds the addresses in the IPv6 network with addresses in the IPv4 network and vice versa to provide transparent routing for the datagrams traversing between address realms.

The main advantage of NAT-PT is that the end devices and networks can run either IPv4 addresses or IPv6 addresses and traffic can be started from any side.

NAT64

NAT64 is a mechanism to allow IPv6 hosts to communicate with IPv4 servers. NAT64 is required to keep the IPv6 to IPv4 address mapping. Such address mapping is either statically configured by the system administrator (stateless translation), or more frequently, created automatically when the first packet from the IPv6 network reaches NAT64 to be translated (stateful).

On SRX Series devices, NAT64 is implemented by persistent NAT. When the first SIP request message (first packet should be only from IPv6) transverses the DUT, address binding is created and then the packets can flow in both directions.

The NAT64 mechanism translates IPv6 packets to IPv4 packets and vice versa, which allows IPv6 clients to contact to the IPv4 servers using unicast UDP, TCP, or ICMP. The NAT-PT and NAT64 behavior seems similar, but these mechanisms are implemented differently.

When NAT64 with persistent NAT is implemented, the SIP ALG with IPv6 support adds the NAT translation to the persistent NAT binding table if NAT is configured on the address of record. Because persistent NAT cannot duplicate the address configured, coexistence of NAT66 and NAT64 configured on the same address is not supported.

Only one binding is created for the same source IP address.

STUN and SIP ALG

Session Traversal Utilities for NAT (STUN) is a solution to make VoIP work through NAT and firewall.

Previously STUN worked without the SIP ALG. This means that the SIP ALG was not involved when persistent NAT was configured.

STUN can coexist with the SIP ALG and SIP ALG is involved when persistent NAT is configured.

Understanding Incoming SIP ALG Call Support Using the SIP Registrar and NAT

Session Initiation Protocol (SIP) registration provides a discovery capability by which SIP proxies and location servers can identify the location or locations where users want to be contacted. A user registers one or more contact locations by sending a REGISTER message to the registrar. The To and Contact fields in the REGISTER message contain the address-of-record Uniform Resource Identifier (URI) and one or more contact URIs, as shown in [Figure 22](#). Registration creates bindings in a location service that associates the address-of-record with the contact address or addresses.

The device monitors outgoing REGISTER messages, performs Network Address Translation (NAT) on these addresses, and stores the information in an Incoming NAT table. Then, when an INVITE message is received from outside the network, the device uses the Incoming NAT table to identify which internal host to route the INVITE message to. You can take advantage of SIP proxy registration service to allow incoming calls by configuring interface source NAT or NAT pools on the egress interface of the device. Interface source NAT is adequate for handling incoming calls in a small office, whereas we recommend setting up source NAT pools for larger networks or an enterprise environment.

NOTE: Incoming call support using interface source NAT or a source NAT pool is supported for SIP and H.323 services only. For incoming calls, Junos OS currently supports UDP and TCP only. Domain name resolution is also currently not supported; therefore, URIs must contain IP addresses, as shown in [Figure 22](#).

- [Understanding the SIP ALG and NAT on page 256](#)
- [SIP ALG Configuration Overview on page 248](#)

Example: Configuring Interface Source NAT for Incoming SIP Calls

This example shows how to configure a source NAT rule on a public zone interface allowing NAT to be used for incoming SIP calls.

- [Requirements on page 268](#)
- [Overview on page 268](#)
- [Configuration on page 269](#)
- [Verification on page 272](#)

Requirements

Before you begin, understand how NAT works with the SIP ALG. See [“Understanding the SIP ALG and NAT”](#) on page 256.

Overview

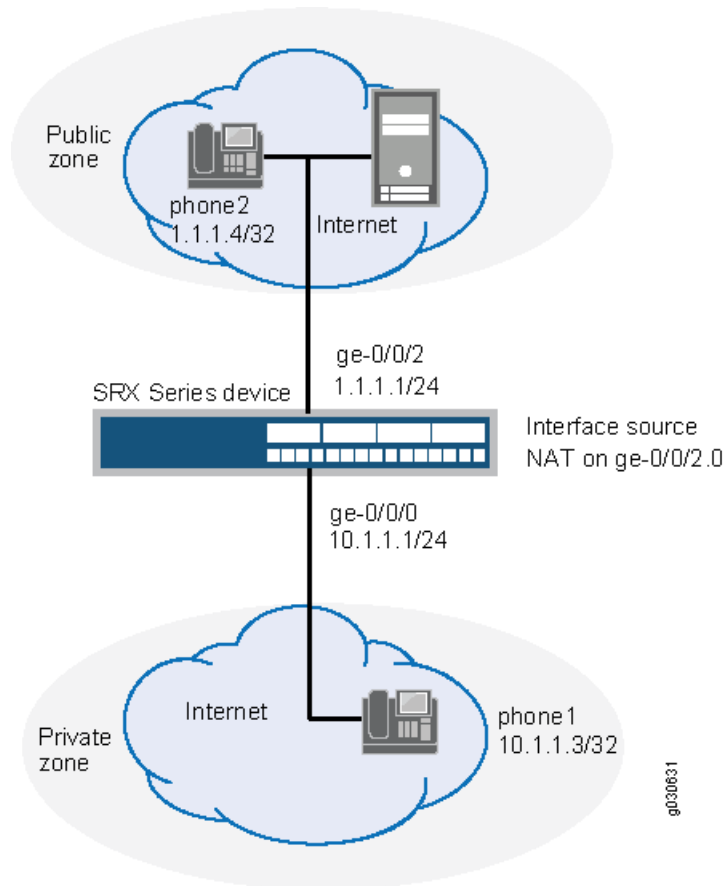

In a two-zone scenario with the SIP proxy server in an external zone, you can use NAT for incoming calls by configuring a source NAT rule on the interface in the public or external zone.

In this example (see [Figure 23](#)), phone1 is on the ge-0/0/0 interface in the private zone, and phone2 and the proxy server are on the ge-0/0/2 interface in the public zone. You configure a source NAT rule on the public interface ge-0/0/2.0.

Topology

[Figure 23](#) shows source NAT for incoming SIP calls.

Figure 23: Source NAT for Incoming SIP Calls

In this example, after creating zones called private and public and assigning them to interfaces, you configure address books to be used in the source NAT rule set. Then you configure source NAT by defining a rule set called sip-phones and a rule called phone1 that matches any packets from the source address 10.1.1.3/32.

Finally, you create security policies to allow all SIP traffic between the private and public zones.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private address-book address phone1 10.1.1.3/32
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public address-book address proxy 1.1.1.3/32
set security zones security-zone public address-book address phone2 1.1.1.4/32
set security zones security-zone public interfaces ge-0/0/2.0
set security nat source rule-set sip-phones from zone private
set security nat source rule-set sip-phones to zone public
set security nat source rule-set sip-phones rule phone1 match source-address 10.1.1.3/32
set security nat source rule-set sip-phones rule phone1 then source-nat interface
set security policies from-zone private to-zone public policy outgoing match
    source-address phone1
set security policies from-zone private to-zone public policy outgoing match
    destination-address phone2
set security policies from-zone private to-zone public policy outgoing match
    destination-address proxy
set security policies from-zone private to-zone public policy outgoing match application
    junos-sip
set security policies from-zone private to-zone public policy outgoing then permit
set security policies from-zone public to-zone private policy incoming match
    source-address phone2
set security policies from-zone public to-zone private policy incoming match
    destination-address phone1
set security policies from-zone public to-zone private policy incoming match
    source-address proxy
set security policies from-zone public to-zone private policy incoming match application
    junos-sip
set security policies from-zone public to-zone private policy incoming then permit
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT rule on a public zone interface:

1. Configure interfaces.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
```

- ```

user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1/24

```
2. Configure zones and assign them to the interfaces.
 

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/2.0

```
  3. Configure address books and create addresses.
 

```

[edit security zones]
user@host# set security-zone private address-book address phone1 10.1.1.3/32
user@host# set security-zone public address-book address proxy 1.1.1.3/32
user@host# set security-zone public address-book address phone2 1.1.1.4/32

```
  4. Configure a source NAT rule set.
 

```

[edit security nat source]
user@host# set rule-set sip-phones from zone private
user@host# set rule-set sip-phones to zone public
user@host# set rule-set sip-phones rule phone1 match source-address 10.1.1.3/32
user@host# set rule-set sip-phones rule phone1 then source-nat interface

```
  5. Enable persistent source NAT translation.
 

```

[edit security nat source]
user@host# set address-persistent

```
  6. Configure a security policy to allow outgoing SIP traffic.
 

```

[edit security policies from-zone private to-zone public policy outgoing]
user@host# set match source-address phone1
user@host# set match destination-address phone2
user@host# set match destination-address proxy
user@host# set match application junos-sip
user@host# set then permit

```
  7. Configure a security policy to allow incoming SIP traffic.
 

```

[edit security policies from-zone public to-zone private policy incoming]
user@host# set match source-address phone2
user@host# set match destination-address phone1
user@host# set match source-address proxy
user@host# set match application junos-sip
user@host# set then permit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security policies**, and **show security nat** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1/24;
 }
 }
}

```

```

}
ge-0/0/2 {
 unit 0 {
 family inet {
 address 1.1.1.1/24;
 }
 }
}

[edit]
user@host# show security zones
security-zone private {
 address-book {
 address phone1 10.1.1.3/32;
 }
 interfaces {
 ge-0/0/0.0;
 }
}
security-zone public {
 address-book {
 address proxy 1.1.1.3/32;
 address phone2 2.2.2.4/32;
 }
 interfaces {
 ge-0/0/2.0;
 }
}

[edit]
user@host# show security nat
source {
 rule-set sip-phones {
 from zone private;
 to zone public;
 rule phone1 {
 match {
 source-address 10.1.1.3/32;
 }
 then {
 source-nat {
 interface;
 }
 }
 }
 }
}

[edit]
user@host# show security policies
from-zone private to-zone public {
 policy outgoing {
 match {
 source-address phone1;
 destination-address [phone2 proxy];
 application junos-sip;
 }
 then {

```

```

 permit;
 }
}
}
from-zone public to-zone private {
 policy incoming {
 match {
 source-address [phone2 proxy];
 destination-address phone1;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Rule Usage on page 272](#)
- [Verifying SIP ALG Status on page 273](#)

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

```

user@host> show security nat source rule all
source NAT rule: phone1 Rule-set: sip-phones
 Rule-Id : 1
 Rule position : 1
 From zone : private
 To zone : public
 Match
 Source addresses : 0.0.0.0 - 255.255.255.255
 Destination port : 0 - 0
 Action : interface
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
 Translation hits : 0
 Successful sessions : 0
 Failed sessions : 0
 Number of sessions : 0

```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule.

### Verifying SIP ALG Status

---

**Purpose** Verify that SIP ALG is enabled on your system.

**Action** From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
ALG Status :
 DNS : Enabled
 FTP : Enabled
 H323 : Disabled
 MGCP : Disabled
 MSRPC : Enabled
 PPTP : Enabled
 RSH : Disabled
 RTSP : Disabled
 SCCP : Disabled
 SIP : Enabled
 SQL : Enabled
 SUNRPC : Enabled
 TALK : Enabled
 TFTP : Enabled
 IKE-ESP : Disabled
```

**Meaning** The output shows the SIP ALG status as follows:

- Enabled—Shows the SIP ALG is enabled.
- Disabled—Shows the SIP ALG is disabled.

**Related Documentation**

- [Verifying SIP ALG Configurations on page 302](#)

## Decreasing Network Complexity by Configuring a Source NAT Pool for Incoming SIP Calls

---

This example shows how to decrease network complexity by configuring a source NAT pool on an external interface to enable NAT for incoming SIP calls.

- [Requirements on page 273](#)
- [Overview on page 273](#)
- [Configuration on page 275](#)
- [Verification on page 279](#)

### Requirements

Before you begin, understand how NAT works with the SIP ALG. See [“Understanding the SIP ALG and NAT” on page 256](#).

### Overview

In a two-zone scenario with the SIP proxy server in an external or public zone, you can use NAT for incoming calls by configuring a NAT pool on the interface to the public zone.

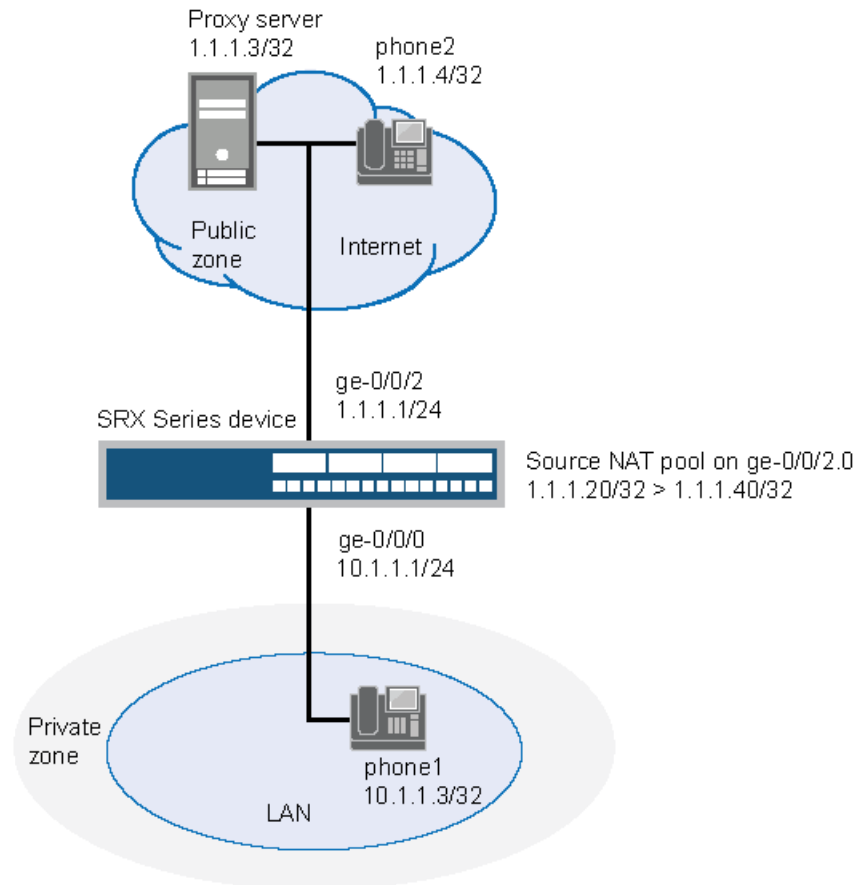

In this example (see [Figure 24](#)), phone1 is in the private zone, and phone2 and the proxy server are in the public zone. You configure a source NAT pool to do NAT. You also create a policy that permits SIP traffic from the private to the public zone. This enables phone1 in the private zone to register with the proxy server in the public zone, and it also enables incoming calls from the public zone to the private zone.

## Topology

Figure 24 shows source NAT pool for incoming calls.

Figure 24: Source NAT Pool for Incoming SIP Calls

In this example, you configure source NAT as follows:

- Define source NAT pool called sip-nat-pool to contain the IP address range from 1.1.1.20/32 through 1.1.1.40/32.
- Create a source NAT rule set called sip-nat with a rule sip-r1 to match packets from the private zone to the public zone with the source IP address 10.1.1.3/24. For matching packets, the source address is translated to one of the IP address in sip-nat-pool.
- Configure proxy ARP for the addresses 1.1.1.20/32 through 1.1.1.40/32 on interface ge-0/0/2.0. This allows the system to respond to ARP requests received on the interface for these addresses.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your

network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private address-book address phone1 10.1.1.3/32
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public address-book address proxy 1.1.1.3/32
set security zones security-zone public address-book address phone2 1.1.1.4/32
set security zones security-zone public interfaces ge-0/0/2.0
set security nat source pool sip-nat-pool address 1.1.1.20/32 to 1.1.1.40/32
set security nat source address-persistent
set security nat source rule-set sip-nat from zone private
set security nat source rule-set sip-nat to zone public
set security nat source rule-set sip-nat rule sip-r1 match source-address 10.1.1.3/24
set security nat source rule-set sip-nat rule sip-r1 then source-nat pool sip-nat-pool
set security nat proxy-arp interface ge-0/0/2.0 address 1.1.1.20/32 to 1.1.1.40/32
set security policies from-zone private to-zone public policy outgoing match
 source-address phone1
set security policies from-zone private to-zone public policy outgoing match
 destination-address any
set security policies from-zone private to-zone public policy outgoing match application
 junos-sip
set security policies from-zone private to-zone public policy outgoing then permit
set security policies from-zone public to-zone private policy incoming match
 source-address phone2
set security policies from-zone public to-zone private policy incoming match
 destination-address phone1
set security policies from-zone public to-zone private policy incoming match application
 junos-sip
set security policies from-zone public to-zone private policy incoming then permit
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a source NAT pool for incoming calls:

1. Configure interfaces.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
```

2. Configure zones and assign interfaces to them.

```
[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/2.0
```

3. Configure address books.

```
[edit security zones]
user@host# set security-zone private address-book address phone1 10.1.1.3/32
user@host# set security-zone public address-book address proxy 1.1.1.3/32
user@host# set security-zone public address-book address phone2 1.1.1.4/32
```

4. Configure a source NAT pool.
 

```
[edit security nat]
user@host# set source pool sip-nat-pool address 1.1.1.20/32 to 1.1.1.40/32
```
5. Configure a source NAT rule set with a rule.
 

```
[edit security nat source rule-set sip-nat]
user@host# set from zone private
user@host# set to zone public
user@host# set rule sip-r1 match source-address 10.1.1.3/24
user@host# set rule sip-r1 then source-nat pool sip-nat-pool
```
6. Enable persistent NAT.
 

```
[edit security nat]
user@host# set source address-persistent
```
7. Configure proxy ARP.
 

```
[edit security nat]
user@host# set proxy-arp interface ge-0/0/2.0 address 1.1.1.20/32 to 1.1.1.40/32
```
8. Configure a security policy to allow outgoing SIP traffic.
 

```
[edit security policies from-zone private to-zone public policy outgoing]
set match source-address phone1
set match destination-address any
set match application junos-sip
set then permit
```
9. Configure a security policy to allow incoming SIP traffic.
 

```
[edit security policies from-zone public to-zone private policy incoming]
set match source-address phone2
set match destination-address phone1
set match application junos-sip
set then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.1/24;
 }
 }
}
ge-0/0/2 {
 unit 0 {
 family inet {
 address 1.1.1.1/24;
 }
 }
}
```

```
}
[edit]
user@host# show security zones
security-zone private {
 address-book {
 address phone1 10.1.1.3/32;
 }
 interfaces {
 ge-0/0/0.0;
 }
}
security-zone public {
 address-book {
 address proxy 1.1.1.3/32;
 address phone2 1.1.1.4/32;
 }
 interfaces {
 ge-0/0/2.0;
 }
}
user@host# show security nat
source {
 pool sip-nat-pool {
 address {
 1.1.1.20/32 to 1.1.1.40/32;
 }
 }
 address-persistent;
 rule-set sip-nat {
 from zone private;
 to zone public;
 rule sip-r1 {
 match {
 source-address 10.1.1.3/24;
 }
 then {
 source-nat {
 pool {
 sip-nat-pool;
 }
 }
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/2.0 {
 address {
 1.1.1.20/32 to 1.1.1.40/32;
 }
 }
}
[edit]
user@host# show security policies
from-zone private to-zone public {
 policy outgoing {
```

```

 match {
 source-address phone1;
 destination-address any;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
from-zone public to-zone private {
 policy incoming {
 match {
 source-address phone2;
 destination-address phone1;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Pool Usage on page 279](#)
- [Verifying Source NAT Rule Usage on page 280](#)
- [Verifying SIP ALG Status on page 280](#)
- [Verifying the Security Policies of SIP ALG on page 281](#)

### Verifying Source NAT Pool Usage

**Purpose** Verify that there is traffic using IP addresses from the source NAT pool.

**Action** From operational mode, enter the **show security nat source pool all** command.

```

user@host> show security nat source pool all

Total pools: 1
Pool name : sip-nat-pool
Pool id : 4
Routing instance : default
Host address base : 0.0.0.0
Port : [1024, 63487]
port overloading : 1
Total addresses : 21
Translation hits : 0
Address range 1.1.1.20 - 1.1.1.40
Single Ports 0
Twin Ports 0

```

**Meaning** The **Translation hits** field shows that there is no traffic used by IP addresses from the source NAT pool.

### Verifying Source NAT Rule Usage

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command.

```
user@host> show security nat source rule all

source NAT rule: sip-r1 Rule-set: sip-nat
Rule-Id : 1
Rule position : 1
From zone : private
To zone : public
Match
 Source addresses : 0.0.0.0 - 255.255.255.255
 Destination port : 0 - 0
Action : interface
Persistent NAT type : N/A
Persistent NAT mapping type : address-port-mapping
Inactivity timeout : 0
Max session number : 0
Translation hits : 0
Successful sessions : 0
Failed sessions : 0
Number of sessions : 0
```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule.

### Verifying SIP ALG Status

**Purpose** Verify that SIP ALG is enabled on your system.

**Action** From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status

ALG Status :
DNS : Enabled
FTP : Enabled
H323 : Disabled
MGCP : Disabled
MSRPC : Enabled
PPTP : Enabled
RSH : Disabled
RTSP : Disabled
SCCP : Disabled
SIP : Enabled
SQL : Enabled
SUNRPC : Enabled
TALK : Enabled
TFTP : Enabled
IKE-ESP : Disabled
```

**Meaning** The output shows the SIP ALG status as follows:

- Enabled—Shows the SIP ALG is enabled.
- Disabled—Shows the SIP ALG is disabled.

### Verifying the Security Policies of SIP ALG

**Purpose** Verify that the source NAT between public zone and private zone is set.

**Action** From operational mode, enter the **show security policies** command.

```
user@host> show security policies

from-zone private to-zone public {
 policy outgoing {
 match {
 source-address phone1;
 destination-address any;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}

from-zone public to-zone private {
 policy incoming {
 match {
 source-address phone2;
 destination-address phone1;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
```

**Meaning** The sample output shows that the source NAT between public zone and private zone is set.

### Example: Configuring Static NAT for Incoming SIP Calls

This example shows how to configure a static NAT mapping that allows callers in the private zone to register with the proxy server in the public zone.

- [Requirements on page 282](#)
- [Overview on page 282](#)
- [Configuration on page 283](#)
- [Verification on page 287](#)

## Requirements

Before you begin, understand how NAT works with the SIP ALG. See [“Understanding the SIP ALG and NAT” on page 256](#).

## Overview

When a SIP proxy server is located in an external or public zone, you can configure static NAT on the public interface to enable callers in the private zone to register with the proxy server.

In this example (see [Figure 25](#)), phone1 is on the ge-0/0/0 interface in the private zone, and phone2 and the proxy server are on the ge-0/0/2 interface in the public zone. You create a static NAT rule set called incoming-sip with a rule called phone1 to match packets from the public zone with the destination address 1.1.1.3/32. For matching packets, the destination IP address is translated to the private address 10.1.1.3/32. You also create proxy ARP for the address 1.1.1.3/32 on interface ge-0/0/2.0. This allows the system to respond to ARP requests received on the interface for these addresses. Finally, you create a security policy called incoming that allows SIP traffic from the public zone to the private zone.

.....

**NOTE:** When configuring static NAT for incoming SIP calls, make sure to configure one public address for each private address in the private zone.

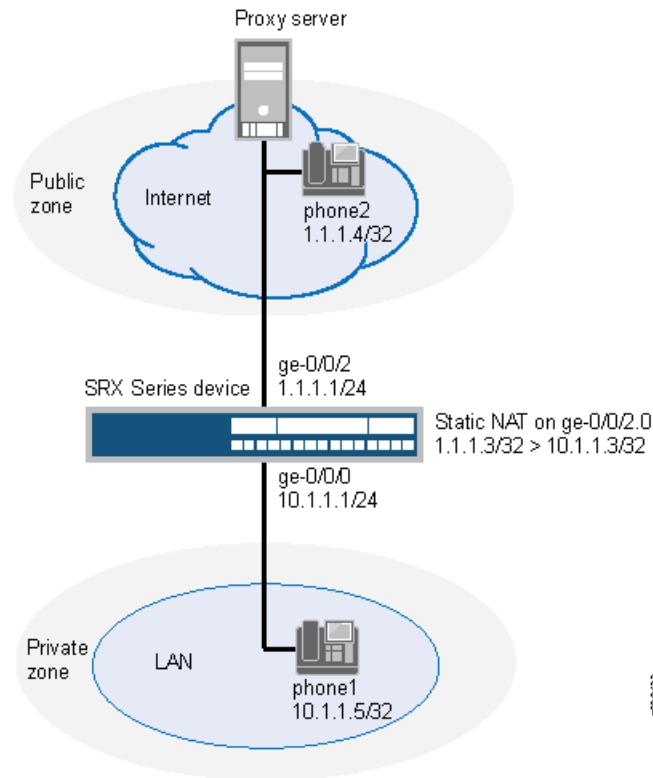

.....

## Topology

Figure 25 shows static NAT for incoming calls.

Figure 25: Static NAT for Incoming Calls

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone private address-book address phone1 10.1.1.5/32
set security zones security-zone public interfaces ge-0/0/2.0
set security zones security-zone public address-book address proxy 1.1.1.3/32
set security zones security-zone public address-book address phone2 1.1.1.4/32
set security nat static rule-set incoming-sip from zone public
set security nat static rule-set incoming-sip rule phone1 match destination-address
 1.1.1.3/32
set security nat static rule-set incoming-sip rule phone1 then static-nat prefix 10.1.1.3/32
set security nat proxy-arp interface ge-0/0/2.0 address 1.1.1.3/32
set security policies from-zone public to-zone private policy incoming match
 source-address phone2
```

```

set security policies from-zone public to-zone private policy incoming match
 source-address proxy
set security policies from-zone public to-zone private policy incoming match
 destination-address phone1
set security policies from-zone public to-zone private policy incoming match application
 junos-sip
set security policies from-zone public to-zone private policy incoming then permit
set security policies from-zone private to-zone public policy outgoing match
 source-address phone1
set security policies from-zone private to-zone public policy outgoing match
 destination-address phone2
set security policies from-zone private to-zone public policy outgoing match
 destination-address proxy
set security policies from-zone private to-zone public policy outgoing match application
 junos-sip
set security policies from-zone private to-zone public policy outgoing then permit

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure static NAT for incoming calls:

1. Configure interfaces.
 

```

[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24

```
2. Create security zones.
 

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/2.0

```
3. Assign addresses to the security zones.
 

```

[edit security zones]
user@host# set security-zone private address-book address phone1 10.1.1.5/32
user@host# set security-zone public address-book address proxy 1.1.1.3/32
user@host# set security-zone public address-book address phone2 1.1.1.4/32

```
4. Create a static NAT rule set with a rule.
 

```

[edit security nat static rule-set incoming-sip]
user@host# set from zone public
user@host# set rule phone1 match destination-address 1.1.1.3/32
user@host# set rule phone1 then static-nat prefix 10.1.1.3/32

```
5. Configure proxy ARP.
 

```

[edit security nat]
user@host# set proxy-arp interface ge-0/0/2.0 address 1.1.1.3/32

```
6. Define a security policy to allow incoming SIP traffic.
 

```

[edit security policies from-zone public to-zone private policy incoming]
user@host# set match source-address phone2
user@host# set match source-address proxy
user@host# set match destination-address phone1

```

```

user@host# set match application junos-sip
user@host# set then permit

```

7. Define a security policy to allow outgoing SIP traffic.

```

[edit security policies from-zone private to-zone public policy outgoing]
user@host# set match source-address phone1
user@host# set match destination-address phone2
user@host# set match destination-address proxy
user@host# set match application junos-sip
user@host# set then permit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.1/24;
 }
 }
}
ge-0/0/2 {
 unit 0 {
 family inet {
 address 1.1.1.1/24;
 }
 }
}

[edit]
user@host# show security zones
security-zone private {
 address-book {
 address phone1 10.1.1.5/32;
 }
 interfaces {
 ge-0/0/0.0;
 }
}
security-zone public {
 address-book {
 address proxy 1.1.1.3/32;
 address phone2 1.1.1.4/32;
 }
 interfaces {
 ge-0/0/2.0;
 }
}

[edit]
user@host# show security nat

```

```
static {
 rule-set incoming-sip {
 from zone public;
 rule phone1 {
 match {
 destination-address 1.1.1.3/32;
 }
 then {
 static-nat prefix 10.1.1.3/32;
 }
 }
 }
}

proxy-arp {
 interface ge-0/0/2.0 {
 address {
 1.1.1.3/32;
 }
 }
}

[edit]
user@host# show security policies
from-zone public to-zone private {
 policy incoming {
 match {
 source-address phone2;
 destination-address phone1;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
from-zone private to-zone public {
 policy outgoing {
 match {
 source-address phone1;
 destination-address [phone2 proxy];
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Static NAT Configuration on page 287](#)
- [Verifying SIP ALG Status on page 287](#)
- [Verifying the Security Polices of SIP ALG on page 288](#)

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule all** command.

```
user@host> show security nat static rule all

Static NAT rule: phone1 Rule-set: incoming-sip
Rule-Id : 1
Rule position : 1
From zone : trust
Source addresses : 40.10.10.0 - 40.10.10.3
 : addr1
Source ports : 200 - 300
Destination addresses : 20.1.1.0
Host addresses : 3.3.3.0
Netmask : 24
Host routing-instance : N/A
Translation hits : 4
Successful sessions : 4
Failed sessions : 0
Number of sessions : 4
```

**Meaning** The **Translation hits** field shows that there is traffic matching the static NAT rule set.

### Verifying SIP ALG Status

**Purpose** Verify that SIP ALG is enabled on your system.

**Action** From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status

ALG Status :
DNS : Enabled
FTP : Enabled
H323 : Disabled
MGCP : Disabled
MSRPC : Enabled
PPTP : Enabled
RSH : Disabled
RTSP : Disabled
SCCP : Disabled
SIP : Enabled
SQL : Enabled
SUNRPC : Enabled
TALK : Enabled
```

```
TFTP : Enabled
IKE-ESP : Disabled
```

**Meaning** The output shows the SIP ALG status as follows:

- Enabled—Shows the SIP ALG is enabled.
- Disabled—Shows the SIP ALG is disabled.

---

### Verifying the Security Policies of SIP ALG

**Purpose** Verify that the static NAT between public zone and private zone is set.

**Action** From operational mode, enter the **show security policies** command.

```
user@host> show security policies
from-zone public to-zone private {
 policy incoming {
 match {
 source-address [phone2 proxy];
 destination-address phone1;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
from-zone private to-zone public {
 policy outgoing {
 match {
 source-address phone1;
 destination-address [phone2 proxy];
 application junos-sip;
 }
 then {
 permit;
 }
 }
}
```

**Meaning** The sample output shows that the static NAT between public zone and private zone is set.

**Related Documentation**

- [Verifying SIP ALG Configurations on page 302](#)

---

## Example: Configuring the SIP Proxy in the Private Zone and NAT in the Public Zone

This example shows how to configure a SIP proxy server in a private zone and static NAT in a public zone to allow callers in the public zone to register with the proxy server.

- [Requirements on page 289](#)
- [Overview on page 289](#)

- [Configuration on page 290](#)
- [Verification on page 293](#)

## Requirements

Before you begin, understand how NAT works with the SIP ALG. See [“Understanding the SIP ALG and NAT” on page 256](#).

## Overview

With the SIP proxy server in the private zone, you can configure static NAT on the external, or public, interface to allow callers in the public zone to register with the proxy server.

In this example (see [Figure 26](#)), phone1 and the SIP proxy server are on the ge-0/0/0 interface in the private zone, and phone2 is on the ge-0/0/2 interface in the public zone. You configure a static NAT rule for the proxy server to allow phone2 to register with the proxy server, and then create a policy called outgoing that allows SIP traffic from the public to the private zone to enable callers in the public zone to register with the proxy server. You also configure a policy called incoming from the private to the public zone to allow phone1 to call out.

## Topology

[Figure 26](#) shows configuring SIP proxy in the private zone and NAT in public zone.

**Figure 26: Configuring SIP Proxy in the Private Zone and NAT in Public Zone**

In this example, you configure NAT as follows:

- Configure static NAT on the ge-0/0/2 interface to the proxy server with a rule set called incoming-sip with a rule called proxy to match packets from the public zone with the destination address 1.1.1.4/32. For matching packets, the destination IP address is translated to the private address 10.1.1.4/32.
- Configure a second rule set called sip-phones with a rule called phone1 to enable interface NAT for communication from phone1 to phone2.

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private address-book address phone1 10.1.1.3/32
set security zones security-zone private address-book address proxy 10.1.1.5/32
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public address-book address phone2 1.1.1.4/32
set security zones security-zone public interfaces ge-0/0/2.0
set security nat source rule-set sip-phones from zone private
set security nat source rule-set sip-phones to zone public
set security nat source rule-set sip-phones rule phone1 match source-address 10.1.1.3/32
set security nat source rule-set sip-phones rule phone1 then source-nat interface
set security nat static rule-set incoming-sip from zone public
set security nat static rule-set incoming-sip rule proxy match destination-address 1.1.1.4/32
set security nat static rule-set incoming-sip rule proxy then static-nat prefix 10.1.1.4/32
set security policies from-zone private to-zone public policy outgoing match
 source-address any
set security policies from-zone private to-zone public policy outgoing match
 destination-address phone2
set security policies from-zone private to-zone public policy outgoing match application
 junos-sip
set security policies from-zone private to-zone public policy outgoing then permit
set security policies from-zone public to-zone private policy incoming match
 source-address phone2
set security policies from-zone public to-zone private policy incoming match
 destination-address proxy
set security policies from-zone public to-zone private policy incoming match application
 junos-sip
set security policies from-zone public to-zone private policy incoming then permit
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure static NAT for incoming calls:

1. Configure interfaces.

**[edit]**

```

user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24

```

2. Configure security zones.

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/2.0

```

3. Assign addresses to the security zones.

```

[edit security zones]
user@host# set security-zone private address-book address phone1 10.1.1.3/32
user@host# set security-zone private address-book address proxy 10.1.1.5/32
user@host# set security-zone public address-book address phone2 1.1.1.4/32

```

4. Create a rule set for static NAT and assign a rule to it.

```

[edit security nat static rule-set incoming-sip]
user@host# set from zone public
user@host# set rule proxy match destination-address 1.1.1.4/32
user@host# set rule proxy then static-nat prefix 10.1.1.4/32

```

5. Configure the second rule set and assign a rule to it.

```

[edit security nat source rule-set sip-phones]
user@host# set from zone private
user@host# set to zone public
user@host# set rule phone1 match source-address 10.1.1.3/32
user@host# set rule phone1 then source-nat interface

```

6. Configure a security policy for outgoing traffic.

```

[edit security policies from-zone private to-zone public policy outgoing]
user@host# set match source-address any
user@host# set match destination-address phone2
user@host# set match application junos-sip
user@host# set then permit

```

7. Configure a security policy for incoming traffic.

```

[edit security policies from-zone public to-zone private policy incoming]
user@host# set match source-address phone2
user@host# set match destination-address proxy
user@host# set match application junos-sip
user@host# set then permit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.1/24;
 }
 }
}

```

```
}
}

 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Static NAT Configuration on page 293](#)
- [Verifying SIP ALG Status on page 294](#)

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule all** command. View the Translation hits field to check for traffic that matches the rule.

```

user@host> show security nat source rule all
source NAT rule: phone1 Rule-set: sip-phones
 Rule-Id : 1
 Rule position : 1
 From zone : private
 To zone : public
 Match
 Source addresses : 0.0.0.0 - 255.255.255.255
 Destination port : 0 - 0
 Action : interface

```

```
Persistent NAT type : N/A
Persistent NAT mapping type : address-port-mapping
Inactivity timeout : 0
Max session number : 0
Translation hits : 0
Successful sessions : 0
Failed sessions : 0
Number of sessions : 0
```

**Meaning** The **Translation hits** field shows that, there is no traffic matching the source NAT rule.

---

### Verifying SIP ALG Status

**Purpose** Verify that SIP ALG is enabled on your system.

**Action** From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
ALG Status :
DNS : Enabled
FTP : Enabled
H323 : Disabled
MGCP : Disabled
MSRPC : Enabled
PPTP : Enabled
RSH : Disabled
RTSP : Disabled
SCCP : Disabled
SIP : Enabled
SQL : Enabled
SUNRPC : Enabled
TALK : Enabled
TFTP : Enabled
IKE-ESP : Disabled
```

**Meaning** The output shows the SIP ALG status as follows:

- Enabled—Shows the SIP ALG is enabled.
- Disabled—Shows the SIP ALG is disabled.

## Example: Configuring a Three-Zone SIP ALG and NAT Scenario

This example shows how to configure a SIP proxy server in a private zone and static NAT in a public zone to allow callers in the public zone to register with the proxy server.

- [Requirements on page 295](#)
- [Overview on page 295](#)
- [Configuration on page 296](#)
- [Verification on page 300](#)

## Requirements

Before you begin, understand how NAT works with the SIP ALG. See [“Understanding the SIP ALG and NAT”](#) on page 256.

## Overview

In a three-zone SIP configuration, the SIP proxy server is typically in a different zone from the calling and called systems. Such a scenario requires additional address and zone configuration, and policies to ensure that all systems have access to each other and to the proxy server.

In this example, phone1 is on the ge-0/0/0.0 interface in the private zone, phone2 is on the ge-0/0/2.0 interface in the public zone, and the proxy server is on the ge-0/0/1.0 interface in the DMZ. You configure static NAT rule for phone1 in the private zone. You then create policies for traffic traversing from the private zone to the DMZ and from the DMZ to the private zone, from the public zone to the DMZ and from the DMZ to the public zone, and from the private zone to the public zone. The arrows in [Figure 27](#) show the flow of SIP signaling traffic when phone2 in the public zone places a call to phone1 in the private zone. After the session is initiated, the data flows directly between phone1 and phone2.

**Figure 27: Three-Zone SIP Configuration with Proxy in the DMZ**

In this example, you configure NAT as follows:

- Configure a static NAT rule set called incoming-sip with a rule phone1 to match packets from the public zone with the destination address 2.2.2.3/32. For matching packets, the destination IP address is translated to the private address 10.1.1.3/32.
- Configure proxy ARP for the address 2.2.2.3/32 on interface ge-0/0/1.0 allowing the system to respond to ARP requests received on the interface for this address.

- Configure a second rule set called sip-phones with a rule r1 to enable interface NAT for communication from phone1 to the proxy server and from phone1 to phone2.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
set interfaces ge-0/0/1 unit 0 family inet address 2.2.2.2/24
set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24
set security zones security-zone private address-book address phone1 10.1.1.3/32
set security zones security-zone private interfaces ge-0/0/0.0
set security zones security-zone public address-book address phone2 1.1.1.4/32
set security zones security-zone public interfaces ge-0/0/2.0
set security zones security-zone dmz address-book address proxy 2.2.2.4/32
set security zones security-zone dmz interfaces ge-0/0/1.0
set security nat source rule-set sip-phones from zone private
set security nat source rule-set sip-phones rule r1 match source-address 10.1.1.3/32
set security nat source rule-set sip-phones rule r1 then source-nat interface
set security policies from-zone private to-zone dmz policy private-to-proxy match
 source-address phone1
set security policies from-zone private to-zone dmz policy private-to-proxy match
 destination-address proxy
set security policies from-zone private to-zone dmz policy private-to-proxy match
 application junos-sip
set security policies from-zone private to-zone dmz policy private-to-proxy then permit
set security policies from-zone public to-zone dmz policy public-to-proxy match
 source-address phone2
set security policies from-zone public to-zone dmz policy public-to-proxy match
 destination-address proxy
set security policies from-zone public to-zone dmz policy public-to-proxy match application
 junos-sip
set security policies from-zone public to-zone dmz policy public-to-proxy then permit
set security policies from-zone private to-zone public policy private-to-public match
 source-address phone1
set security policies from-zone private to-zone public policy private-to-public match
 destination-address phone2
set security policies from-zone private to-zone public policy private-to-public match
 application junos-sip
set security policies from-zone private to-zone public policy private-to-public then permit
set security policies from-zone dmz to-zone private policy proxy-to-private match
 source-address proxy
set security policies from-zone dmz to-zone private policy proxy-to-private match
 destination-address phone1
set security policies from-zone dmz to-zone private policy proxy-to-private match
 application junos-sip
set security policies from-zone dmz to-zone private policy proxy-to-private then permit
set security policies from-zone dmz to-zone public policy proxy-to-public match
 source-address proxy
set security policies from-zone dmz to-zone public policy proxy-to-public match
 destination-address phone2

```

```

set security policies from-zone dmz to-zone public policy proxy-to-public match application
 junos-sip
set security policies from-zone dmz to-zone public policy proxy-to-public then permit

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a SIP proxy server in a private zone and static NAT in a public zone:

1. Configure interfaces.
 

```

[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 10.1.1.1/24
user@host# set interfaces ge-0/0/1 unit 0 family inet address 2.2.2.2/24
user@host# set interfaces ge-0/0/2 unit 0 family inet address 1.1.1.1/24

```
2. Configure security zones.
 

```

[edit security zones]
user@host# set security-zone private interfaces ge-0/0/0.0
user@host# set security-zone public interfaces ge-0/0/2.0
user@host# set security-zone dmz interfaces ge-0/0/1.0

```
3. Assign addresses to the security zones.
 

```

[edit security zones]
user@host# set security-zone private address-book address phone1 10.1.1.3/32
user@host# set security-zone public address-book address phone2 1.1.1.4/32
user@host# set security-zone dmz address-book address proxy 2.2.2.4/32

```
4. Configure interface NAT for communication from phone1 to proxy.
 

```

[edit security nat source rule-set sip-phones]
user@host# set from zone private
user@host# set to zone dmz
user@host# set rule r1 match source-address 10.1.1.3/32
user@host# set rule r1 then source-nat interface

```
5. Configure a security policy to allow traffic from zone private to zone DMZ.
 

```

[edit security policies from-zone private to-zone dmz policy private-to-proxy]
user@host# set match source-address phone1
user@host# set match destination-address proxy
user@host# set match application junos-sip
user@host# set then permit

```
6. Configure a security policy to allow traffic from zone public to zone DMZ.
 

```

[edit security policies from-zone public to-zone dmz policy public-to-proxy]
user@host# set match source-address phone2
user@host# set match destination-address proxy
user@host# set match application junos-sip
user@host# set then permit

```
7. Configure a security policy to allow traffic from zone private to zone public.
 

```

[edit security policies from-zone private to-zone public policy private-to-public]
user@host# set match source-address phone1
user@host# set match destination-address phone2

```

```
user@host# set match application junos-sip
user@host# set then permit
```

8. Configure a security policy to allow traffic from zone DMZ to zone private.

```
[edit security policies from-zone dmz to-zone private policy proxy-to-private]
user@host# set match source-address proxy
user@host# set match destination-address phone1
user@host# set match application junos-sip
user@host# set then permit
```

9. Configure a security policy to allow traffic from zone DMZ to zone public.

```
[edit security policies from-zone dmz to-zone public policy proxy-to-public]
user@host# set match source-address proxy
user@host# set match destination-address phone2
user@host# set match application junos-sip
user@host# set then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security nat**, and **show security policies** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces
ge-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.1/24;
 }
 }
}
ge-0/0/1 {
 unit 0 {
 family inet {
 address 2.2.2.2/24;
 }
 }
}
ge-0/0/2 {
 unit 0 {
 family inet {
 address 1.1.1.1/24;
 }
 }
}

[edit]
user@host# show security zones
security-zone private {
 address-book {
 address phone1 10.1.1.3/32;
 }
 interfaces {
 ge-0/0/0.0;
 }
}
```

```

}
security-zone public {
 address-book {
 address phone2 1.1.1.4/32;
 }
 interfaces {
 ge-0/0/2.0;
 }
}
security-zone dmz {
 address-book {
 address proxy 2.2.2.4/32;
 }
 interfaces {
 ge-0/0/1.0;
 }
}
[edit]
user@host# show security nat
source {
 rule-set sip-phones {
 from zone private;
 to zone dmz;
 rule r1 {
 match {
 source-address 10.1.1.3/32;
 }
 then {
 source-nat {
 interface;
 }
 }
 }
 }
}
proxy-arp {
 interface ge-0/0/1.0 {
 address {
 2.2.2.3/32;
 }
 }
}
[edit]
user@host# show security policies
from-zone private to-zone dmz {
 policy private-to-proxy {
 match {
 source-address phone1;
 destination-address proxy;
 application junos-sip;
 }
 then {
 permit;
 }
 }
}

```

```
}
 from-zone public to-zone dmz {
 policy public-to-proxy {
 match {
 source-address phone2;
 destination-address proxy;
 application junos-sip;
 }
 then {
 permit;
 }
 }
 }
 from-zone private to-zone public {
 policy private-to-public {
 match {
 source-address phone1;
 destination-address phone2;
 application junos-sip;
 }
 then {
 permit;
 }
 }
 }
 from-zone dmz to-zone private {
 policy proxy-to-private {
 match {
 source-address proxy;
 destination-address phone2;
 application junos-sip;
 }
 then {
 permit;
 }
 }
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Source NAT Rule Usage on page 300](#)
- [Verifying Static NAT Configuration on page 301](#)
- [Verifying SIP ALG Status on page 301](#)

### Verifying Source NAT Rule Usage

---

**Purpose** Verify that there is traffic matching the source NAT rule.

**Action** From operational mode, enter the **show security nat source rule all** command. View the Translation hits field to check for traffic that matches the rule.

```
user@host> show security nat source rule all
source NAT rule: r1 Rule-set: sip-phones
 Rule-Id : 1
 Rule position : 1
 From zone : private
 To zone : public
 Match
 Source addresses : 0.0.0.0 - 255.255.255.255
 Destination port : 0 - 0
 Action
 Action : interface
 Persistent NAT type : N/A
 Persistent NAT mapping type : address-port-mapping
 Inactivity timeout : 0
 Max session number : 0
 Translation hits : 0
 Successful sessions : 0
 Failed sessions : 0
 Number of sessions : 0
```

### Verifying Static NAT Configuration

**Purpose** Verify that there is traffic matching the static NAT rule set.

**Action** From operational mode, enter the **show security nat static rule r1** command. View the Translation hits field to check for traffic that matches the rule.

### Verifying SIP ALG Status

**Purpose** Verify that SIP ALG is enabled on your system.

**Action** From operational mode, enter the **show security alg status** command.

```
user@host> show security alg status
ALG Status :
 DNS : Enabled
 FTP : Enabled
 H323 : Disabled
 MGCP : Disabled
 MSRPC : Enabled
 PPTP : Enabled
 RSH : Disabled
 RTSP : Disabled
 SCCP : Disabled
 SIP : Enabled
 SQL : Enabled
 SUNRPC : Enabled
 TALK : Enabled
 TFTP : Enabled
 IKE-ESP : Disabled
```

**Related Documentation** • [Verifying SIP ALG Configurations on page 302](#)

## Verifying SIP ALG Configurations

---

- [Verifying SIP ALG on page 302](#)
- [Verifying SIP ALG Calls on page 302](#)
- [Verifying SIP ALG Call Details on page 302](#)
- [Verifying SIP ALG Counters on page 303](#)
- [Verifying the Rate of SIP ALG Messages on page 304](#)

### Verifying SIP ALG

**Purpose** Verify SIP ALG verification options.

**Action** From the CLI, enter the **show security alg sip ?** command.

```
user@host> show security alg sip ?
Possible completions:
 calls Show SIP calls
 counters Show SIP counters
 rate Show SIP rate
```

**Meaning** The output shows a list of all SIP verification parameters. Verify the following information:

- Calls—Lists all SIP calls.
- Counters—Provides counters of response codes for each SIP request method and error type.
- Rate—Provides speed and periodicity of SIP signaling messages.

### Verifying SIP ALG Calls

**Purpose** Display information about active calls.

**Action** From the J-Web interface, select **Monitor>ALGs>SIP>Calls**. Alternatively, from the CLI, enter the **show security alg sip calls** command.

```
user@host> show security alg sip calls
Total number of calls: 1
 Call ID: 47090a32@30.2.20.5
 Method: INVITE
```

**Meaning** The output shows a list of all active SIP calls. Verify the User Agent Server (UAS) call ID and local and remote tags, and the state of the call.

### Verifying SIP ALG Call Details

**Purpose** Display address and SDP about active calls.

**Action** From the J-Web interface, select **Monitor>ALGs>SIP>Details**. Alternatively, from the CLI, enter the **show security alg sip calls detail** command.

```
user@host> show security alg sip calls detail
Total number of calls: 1
 Call ID : 47090a32@30.2.20.5
Method : INVITE
State : SETUP
Group ID : 24575
```

**Meaning** The output provides details about all active SIP calls. Verify the following information:

- The total number of calls, their ID and tag information, and state
- Remote group ID
- The IP addresses and port numbers and SDP connection and media details

## Verifying SIP ALG Counters

**Purpose** Display information about SIP counters.

**Action** From the J-Web interface, select **Monitor>ALGs>SIP>Counters**. Alternatively, from the CLI, enter the **show security alg sip counters** command.

```
user@host> show security alg sip counters
```

| Method    | T<br>RT | 1xx<br>RT | 2xx<br>RT | 3xx<br>RT | 4xx<br>RT | 5xx<br>RT | 6xx<br>RT |

|         |   |   |   |   |   |   |   |
|---------|---|---|---|---|---|---|---|
| SERVICE | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|         | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| OTHER   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|         | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

## SIP Error Counters

```

Total Pkt-in :34
Total Pkt dropped on error :0
 Call error :0
IP resolve error :0
NAT error :0
Resource manager error :0
RR header exceeded max :0
Contact header exceeded max :0
Call Dropped due to limit :0
SIP stack error : 0
SIP decode error : 0
SIP unknown method error : 0
RTO message sent : 0
RTO message received : 0
RTO buffer allocation failure : 0
RTO buffer transmit failure : 0
RTO send processing error : 0
RTO receive processing error : 0
RTO receive invalid length : 0
RTO receive call process error : 0
RTO receive call allocation error : 0
RTO receive call register error : 0
RTO receive invalid status error : 0

```

**Meaning** The output provides a count of all SIP response codes transmitted and received, and of SIP errors. Verify the following information:

- A count of transmissions of response codes for each SIP request method
- A count of all possible error types

## Verifying the Rate of SIP ALG Messages

**Purpose** Display information about SIP message rate.

**Action** From the J-Web interface, select **Monitor>ALGs>SIP>Rate**. Alternatively, from the CLI, enter the **show security alg sip rate** command.

```

user@host> show security alg sip rate
CPU ticks per microseconds is 3735928559
Time taken for the last message is 0 microseconds
Total time taken for 0 messages is 0 microseconds(in less than 10 minutes)
Rate: 3735928559 messages/second

```

**Meaning** The output provides information about CPU usage for messages, and speed and periodicity of SIP signaling messages. Verify the following information:

- CPU ticks per US
- Passage time for last message, for all messages, and the rate at which messages transit the network

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | Allow an incoming Domain Name Service (DNS) reply packet without a matched request. By default, if an incoming UDP first-packet has dst-port 53, the device checks the DNS message packet header to verify that the query bit (QR) is 0, which denotes a query message. If the QR bit is 1, which denotes a response message, the device drops the packet, does not create a session, and increments the illegal packet flow counter for the interface. Using the <b>allow-dns-reply</b> statement directs the device to skip the check. |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                    |

## application-screen (Security H323)

---

**Syntax**

```
application-screen {
 message-flood {
 gatekeeper {
 threshold rate;
 }
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
}
```

**Hierarchy Level** [edit security alg h323]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Configure the security screens for the H.323 protocol Application Layer Gateway (ALG).

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## application-screen (Security SIP)

**Syntax**

```

application-screen {
 protect {
 deny {
 all {
 timeout value-in-seconds;
 }
 destination-ip address;
 timeout value-in-seconds;
 }
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
}

```

**Hierarchy Level** [edit security alg sip]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Configure the security screens for the Session Initiation Protocol (SIP) Application Layer Gateway (ALG).

**NOTE:** IPv6 is supported on the SIP ALG along with Network Address Translation Protocol Translation (NAT-PT) mode and NAT64 address translation.

The type of the <destination-ip-address> is changed from IPv4 address to IP prefix to support all kinds of IP addresses, and correspondingly a prefix is supported to allow multiple IP addresses.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b> | Statement modified in Junos OS Release 9.6.                                                 |
| <b>Description</b>         | Specify a destination address to match the rule. You can configure one address or a subnet. |

### NOTE:

- If the destination address is IPv4 and the pool is an IPv6 prefix, the length of the IPv6 prefix must be 96.
- If the destination address is an IPv6 prefix and the pool is an IPv6 prefix, their length must be the same.

**Hierarchy Level** [edit interfaces *interface* unit *unit* ]

**Release Information** Statement introduced in a prior release of Junos OS.

**Description** Assign an IP address to a logical interface.

**Options** *ipaddress*—Specifies the IP address for the interface.

**NOTE:** You use family inet to assign an IPv4 address. You use family inet6 to assign an IPv6 address. An interface can be configured with both an IPv4 and IPv6 address.

**Required Privilege Level** **interface**—To view this statement in the configuration.  
**interface-control**—To add this statement to the configuration.

## ftp (Access)

**Syntax**

```

ftp {
 banner {
 fail string;
 login string;
 success string;
 }
}

```

**Hierarchy Level** [edit access firewall-authentication pass-through]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Configure banners for the FTP login prompt, successful authentication, and failed authentication.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** **access**—To view this statement in the configuration.  
**access-control**—To add this statement to the configuration.

```
Syntax h323 {
 application-screen {
 message-flood {
 gatekeeper {
 threshold rate;
 }
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
 }
 disable;
 dscp-rewrite {
 code-point string;
 }
 endpoint-registration-timeout value-in-seconds;
 media-source-port-any;
 traceoptions {
 flag flag <detail | extensive | terse>;
 }
 }
```

**Hierarchy Level** [edit security alg]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Specify the H.323 Application Layer Gateway (ALG) on the device. H.323 is a control-signaling protocol used to exchange messages between H.323 endpoints.

**Options** **disable**—Disable the H.323 ALG. By default, H.323 ALG is enabled.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Syntax</b>                   | message-flood {<br>gatekeeper {<br>threshold <i>rate</i> ;<br>}<br>}                                                                                                                       |
| <b>Hierarchy Level</b>          | [edit security alg h323 application-screen]                                                                                                                                                |
| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                              |
| <b>Description</b>              | Limit the rate per second at which remote access server (RAS) requests to the gatekeeper are processed. Messages exceeding the threshold are dropped. This feature is disabled by default. |
| <b>Options</b>                  | <b>gatekeeper threshold <i>rate</i></b> —Maximum number of RAS connection requests per second allowed per gateway.<br><b>Range:</b> 1 through 65,535<br><b>Default:</b> 1000               |
| <b>Required Privilege Level</b> | security—To view this statement in the configuration.<br>security-control—To add this statement to the configuration.                                                                      |
| <b>Related Documentation</b>    | • <a href="#">h323 on page 360</a>                                                                                                                                                         |

## mgcp

**Syntax**

```
mgcp {
 application-screen {
 connection-flood {
 threshold rate;
 }
 message-flood {
 threshold rate;
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
 }
 disable;
 dscp-rewrite {
 code-point string;
 }
 inactive-media-timeout value-in-seconds;
 maximum-call-duration value-in-minutes;
 traceoptions {
 flag flag <extensive>;
 }
 transaction-timeout value-in-seconds;
}
```

**Hierarchy Level** [edit security alg]

**Release Information** Statement modified in Junos OS Release 9.2.

**Description** Specify the Media Gateway Control Protocol (MGCP) ALG on the device. MGCP is a text-based Application Layer protocol that can be used for call setup and call control.

**Options** **disable**—Disable the MGCP ALG. By default, the MGCP ALG is enabled.

**NOTE:** By default, the MGCP ALG is disabled for SRX Series devices.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | <p>Specify the number of NAT with port address translation (PAT) configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.</p> <p>The master administrator:</p> <ul style="list-style-type: none"> <li>• uses security profiles to provision logical systems with resources.</li> <li>• binds security profiles to user logical systems and the master logical system.</li> <li>• can configure more than one security profile, specifying different amounts of resource allocations in various profiles.</li> </ul> <p>Only the master administrator can create security profiles and bind them to logical systems.</p>                                  |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>maximum <i>amount</i></b>—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.</li> <li>• <b>reserved <i>amount</i></b>—A reserved quota that guarantees that the resource amount specified is always available to the logical system.</li> </ul> |
| <b>Required Privilege Level</b> | <p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

```

**Hierarchy Level** [edit security policies from-zone *zone-name* to-zone *zone-name*]

**Release Information** Statement introduced in Junos OS Release 8.5. The **services-offload** option added in Junos OS Release 11.4. Statement updated with the **source-identity** option and the **description** option added in Junos OS Release 12.1. Support for the **user-firewall** option added in Junos OS Release 12.1X45-D10. Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20.

**Description** Define a security policy.

**Options** *policy-name*—Name of the security policy.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

---

## pptp

**Syntax**

```
pptp {
 disable;
 traceoptions {
 flag {
 all <extensive>;
 }
 }
}
```

**Hierarchy Level** [edit security alg]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Specify the Point-to-Point Tunneling Protocol (PPTP) ALG on the device.

**Options**

- **disable**—Disable the PPTP ALG. By default, the PPTP ALG is enabled.
- **traceoptions**—Configure PPTP ALG tracing options.
  - **flag**—Trace operation to perform.
    - **all**—Trace all events.
    - **extensive**—Display extensive amount of data.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## retain-hold-resource

---

**Syntax** retain-hold-resource;

**Hierarchy Level** [edit security alg sip]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Enable the device to not free media resources for a Session Initiation Protocol (SIP) Application Layer Gateway (ALG), even when a media stream is placed on hold. By default, media stream resources are released when the media stream is held.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## sccp

```
Syntax sccp {
 application-screen {
 call-flood {
 threshold rate;
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
 }
 disable;
 dscp-rewrite {
 code-point string;
 }
 inactive-media-timeout value-in-seconds;
 traceoptions {
 flag flag <extensive>;
 }
 }
```

**Hierarchy Level** [edit security alg]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Specify the Skinny Client Control Protocol (SCCP) ALG on the device.

**Options** **disable**—Disable the SCCP ALG. By default, the SCCP ALG is enabled.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## security-zone

```

Syntax security-zone zone-name {
 address-book {
 address address-name {
 ip-prefix {
 description text;
 }
 description text;
 dns-name domain-name {
 ipv4-only;
 ipv6-only;
 }
 range-address lower-limit to upper-limit;
 wildcard-address ipv4-address/wildcard-mask;
 }
 }
 address-set address-set-name {
 address address-name;
 address-set address-set-name;
 description text;
 }
 }
 application-tracking;
 description text;
 host-inbound-traffic {
 protocols protocol-name {
 except;
 }
 system-services service-name {
 except;
 }
 }
 interfaces interface-name {
 host-inbound-traffic {
 protocols protocol-name {
 except;
 }
 system-services service-name {
 except;
 }
 }
 }
 screen screen-name;
 tcp-rst;
 }

```

**Hierarchy Level** [edit security zones]

**Release Information** Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OS Release 11.1. The **description** option added in Junos OS Release 12.1.

**Description** Define a security zone, which allows you to divide the network into different segments and apply different security options to each segment.

**Options**    *zone-name* —Name of the security zone.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level**    security—To view this statement in the configuration.  
                                         security-control—To add this statement to the configuration.

## sip (Security)

```
Syntax sip {
 application-screen {
 protect {
 deny {
 all {
 timeout value-in-seconds;
 }
 destination-ip address;
 timeout value-in-seconds;
 }
 }
 }
 unknown-message {
 permit-nat-applied;
 permit-routed;
 }
 }
 c-timeout value-in-minutes;
 disable;
 dscp-rewrite {
 code-point string;
 }
 inactive-media-timeout value-in-seconds;
 maximum-call-duration value-in-minutes;
 retain-hold-resource;
 t1-interval value-in-milliseconds;
 t4-interval value-in-seconds;
 traceoptions {
 flag flag <detail | extensive | terse>;
 }
}
```

**Hierarchy Level** [edit security alg]

**Release Information** Statement modified in Junos OS Release 9.2.

**Description** Specify the Session Initiation Protocol (SIP) ALG on the device.

**NOTE:** IPv6 is supported on the SIP ALG along with Network Address Translation Protocol Translation (NAT-PT) mode and NAT64 address translation.

The type of the <destination-ip-address> is changed from IPv4 address to IP prefix to support all kinds of IP addresses, and correspondingly a prefix is supported to allow multiple IP addresses.

**Options** **disable**—Disable the SIP ALG. Use the **set security alg *alg-name* disable** CLI command to disable the SIP ALG.

The remaining statements are explained separately. See [CLI Explorer](#).

**NOTE:** By default, the SIP ALG is disabled for SRX1400, SRX3400, SRX3600, SRX5600, and SRX5800 devices. Use the CLI command `delete security alg alg-name disable` to enable the SIP ALG.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

## source-address (Security Destination NAT)

**Syntax** `source-address [ip-address];`

**Hierarchy Level** [edit security nat destination rule-set *rule-set-name* rule *rule-name* match]

**Release Information** Statement modified in Junos OS Release 9.6.

**Description** Specify source address to match the rule. You can configure multiple addresses or subnets.

**Options** *ip-address* —Source address or a subnet.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

**Related Documentation**

| <b>Description</b>         | <p>Specify the types of incoming system service traffic that can reach the device for all interfaces in a zone. You can do this in one of several ways:</p> <ul style="list-style-type: none"> <li>• You can enable traffic from each system service individually.</li> <li>• You can enable traffic from all system services.</li> <li>• You can enable traffic from all but some system services.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>service-name</b>—System-service for which traffic is allowed. The following system services are supported:           <ul style="list-style-type: none"> <li>• <b>all</b>—Enable traffic from the defined system services available on the Routing Engine (RE). Use the <i>except</i> option to disallow specific system services.</li> <li>• <b>any-service</b>—Enable all system services on entire port range including the system services that are not defined.</li> <li>• <b>bootp</b>—Enable traffic destined to BOOTP and DHCP relay agents.</li> <li>• <b>dhcp</b>—Enable incoming DHCP requests.</li> <li>• <b>dhcipv6</b>—Enable incoming DHCP requests for IPv6.</li> <li>• <b>dns</b>—Enable incoming DNS services.</li> <li>• <b>finger</b>—Enable incoming finger traffic.</li> <li>• <b>ftp</b>—Enable incoming FTP traffic.</li> <li>• <b>http</b>—Enable incoming J-Web or clear-text Web authentication traffic.</li> <li>• <b>https</b>—Enable incoming J-Web or Web authentication traffic over Secure Sockets Layer (SSL).</li> <li>• <b>ident-reset</b>—Enable the access that has been blocked by an unacknowledged identification request.</li> <li>• <b>ike</b>—Enable Internet Key Exchange traffic.</li> <li>• <b>lsping</b>—Enable label switched path ping service.</li> <li>• <b>netconf</b>—Enable incoming NETCONF service.</li> <li>• <b>ntp</b>—Enable incoming Network Time Protocol (NTP) traffic.</li> <li>• <b>ping</b>—Allow the device to respond to ICMP echo requests.</li> <li>• <b>r2cp</b>—Enable incoming Radio Router Control Protocol traffic.</li> </ul> </li> </ul> |

- **reverse-ssh**—Reverse SSH traffic.
- **reverse-telnet**—Reverse Telnet traffic.
- **rlogin**—Enable incoming **rlogin** (remote login) traffic.
- **rpm**—Enable incoming Real-time performance monitoring (RPM) traffic.
- **rsh**—Enable incoming Remote Shell (**rsh**) traffic.
- **snmp**—Enable incoming SNMP traffic (UDP port 161).
- **snmp-trap**—Enable incoming SNMP traps (UDP port 162).
- **ssh**—Enable incoming SSH traffic.
- **telnet**—Enable incoming Telnet traffic.
- **tftp**—Enable TFTP services.
- **traceroute**—Enable incoming traceroute traffic (UDP port 33434).
- **xnm-clear-text**—Enable incoming Junos XML protocol traffic for all specified interfaces.
- **xnm-ssl**— Enable incoming Junos XML protocol-over-SSL traffic for all specified interfaces.
- **except**—(Optional) Enable specific incoming system service traffic but only when the *all* option has been defined . For example, to enable all but FTP and HTTP system service traffic:
 

```
set security zones security-zone trust host-inbound-traffic system-services all
set security zones security-zone trust host-inbound-traffic system-services ftp except
set security zones security-zone trust host-inbound-traffic system-services http except
```

**Required Privilege Level** security—To view this statement in the configuration.  
 security-control—To add this statement to the configuration.

| <b>Description</b>         | Configure ALG tracing options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li>• <b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <code>/var/log</code>. By default, the name of the file is the name of the process being traced.</li> <li>• <b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li>• <b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li>• <b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the <b>trace-file</b> again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the <b>files</b> option and a filename.</p> <p>Syntax: <b>x K</b> to specify KB, <b>x m</b> to specify MB, or <b>x g</b> to specify GB</p> <p>Range: 10 KB through 1 GB</p> |

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **level**—Set the level of debugging the output option.
  - **brief**—Match brief messages
  - **detail**—Match detail messages.
  - **extensive**—Match extensive messages.
  - **verbose**—Match verbose messages.
- **no-remote-trace**—Set remote tracing as disabled.

| <b>Release Information</b> | Statement introduced in Junos OS Release 10.2.                                                                                                                                              |
| <b>Description</b>         | Defines tracing options for DNS services.                                                                                                                                                   |
| <b>Options</b>             | <p><b>category</b>—Specifies the logging category. See <a href="#">Table 15</a> for the different logging categories and their descriptions.</p> <p><b>file</b>—Trace file information.</p> |

Table 15: Category Names

| Category Name   | Description                                             |
|-----------------|---------------------------------------------------------|
| client          | Processing of client requests                           |
| config          | Configuration file parsing and processing               |
| database        | Messages relating to the databases                      |
| default         | Categories for which there is no specific configuration |
| delegation-only | Delegation only                                         |
| dispatch        | Dispatching of incoming packets to the server           |
| dnssec          | DNSSEC and TSIG protocol processing                     |
| edns-disabled   | Log query using plain DNS                               |
| general         | General information                                     |
| lame-servers    | Lame servers                                            |
| network         | Network options                                         |
| notify          | NOTIFY protocol                                         |
| queries         | DNS query resolver                                      |
| resolver        | DNS resolution security                                 |
| security        | Approval and denial of requests                         |
| unmatched       | Unable to determine the class for messages named        |
| update          | Dynamic updates                                         |
| update-security | Approval and denial of update requests                  |
| xfer-in         | Zone transfers that the server is receiving xfer-out    |
| xfer-out        | Zone transfers that the server is sending               |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | <p>Specify how unidentified H.323 messages are handled by the device. The default is to drop unknown (unsupported) messages. Permitting unknown messages can compromise security and is not recommended. However, in a secure test or production environment, this statement can be useful for resolving interoperability issues with disparate vendor equipment. By permitting unknown H.323 (unsupported) messages, you can get your network operational and later analyze your VoIP traffic to determine why some messages were being dropped.</p> <p>This statement applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol, the message is forwarded without processing.</p> |
| <b>Options</b>                  | <ul style="list-style-type: none"><li>• <b>permit-nat-applied</b>—Specify that unknown messages be allowed to pass if the session is in NAT mode.</li><li>• <b>permit-routed</b>—Specify that unknown messages be allowed to pass if the session is in Route mode. (Sessions in Transparent mode are treated as Route mode.)</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | <p>Specify how unidentified Media Gateway Control Protocol (MGCP) messages are handled by the device. The default is to drop unknown (unsupported) messages. Permitting unknown messages can compromise security and is not recommended. However, in a secure test or production environment, this statement can be useful for resolving interoperability issues with disparate vendor equipment. By permitting unknown MGCP (unsupported) messages, you can get your network operational and later analyze your VoIP traffic to determine why some messages were being dropped.</p> <p>This statement applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol, the message is forwarded without processing.</p> |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li>• <b>permit-nat-applied</b>—Specify that unknown messages be allowed to pass if the session is in NAT mode.</li> <li>• <b>permit-routed</b>—Specify that unknown messages be allowed to pass if the session is in Route mode. (Sessions in Transparent mode are treated as Route mode.)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Required Privilege Level</b> | <p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | <p>Specify how unidentified Session Initiation Protocol (SIP) messages are handled by the device. The default is to drop unknown (unsupported) messages. Permitting unknown messages can compromise security and is not recommended. However, in a secure test or production environment, this statement can be useful for resolving interoperability issues with disparate vendor equipment. By permitting unknown SIP (unsupported) messages, you can get your network operational and later analyze your VoIP traffic to determine why some messages were being dropped.</p> <p>This statement applies only to received packets identified as supported VoIP packets. If a packet cannot be identified, it is always dropped. If a packet is identified as a supported protocol, the message is forwarded without processing.</p> |

Table 19 lists the output fields for the **show security alg msrpc** command. Output fields are listed in the approximate order in which they appear.

Table 19: show security alg msrpc Output Fields

| Field Name | Field Description |
|------------|-------------------|
| UUID       | MS RPC ID.        |
| OID        | MS RPC object ID. |

### Sample Output

#### show security alg msrpc object-id-map

```
user@host> show security alg msrpc object-id-map
UUID OID
1be617c0-31a5-11cf-a7d8-00805f48a135 0x80000020
e3514235-4b06-11d1-ab04-00c04fc2dcd2 0x80000002
67df7c70-0f04-11ce-b13f-00aa003bac6c 0x80000014

| <b>Output Fields</b>            | <a href="#">Table 20</a> lists the output fields for the <b>show security alg sccp calls</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Table 20: show security alg sccp calls Output Fields

| Field Name             | Field Description               |
|------------------------|---------------------------------|
| Client IP address      | IP address of the client.       |
| Client zone            | Client zone ID.                 |
| Call manager           | IP address of the call manager. |
| Resource manager group | Resource manager group ID.      |

## Sample Output

### show security alg sccp calls

```

user@host> show security alg sccp calls
Client IP Zone Call Manager Conference ID RM group
11.0.102.91 7 13.0.99.226 16789504 2047
12.0.102.96 8 13.0.99.226 16789505 2048

```

## Sample Output

### show security alg sccp calls detail

```

user@host> show security alg sccp calls detail
Client IP address: 11.0.102.91
Client zone: 7

| <b>Output Fields</b>            | <a href="#">Table 21</a> lists the output fields for the <b>show security alg sccp counters</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 21: show security alg sccp counters Output Fields**

| Field Name             | Field Description                                       |
|------------------------|---------------------------------------------------------|
| Active client sessions | Number of active SCCP ALG client sessions.              |
| Active calls           | Number of active SCCP ALG calls.                        |
| Total calls            | Total number of SCCP ALG calls.                         |
| Packets received       | Number of SCCP ALG packets received.                    |
| PDU's processed        | Number of SCCP ALG protocol data units (PDU) processed. |
| Current call rate      | Number of calls per second.                             |
| Packets dropped        | Number of packets dropped by the SCCP ALG.              |

Table 21: show security alg sccp counters Output Fields (*continued*)

| Field Name                 | Field Description                                         |
|----------------------------|-----------------------------------------------------------|
| Decode errors              | Number of decoding errors.                                |
| Protocol errors            | Number of protocol errors.                                |
| Address translation errors | Number of NAT errors.                                     |
| Policy lookup errors       | Number of errors occurring during policy lookups.         |
| Unknown PDUs               | Number of unknown protocol data units (PDUs).             |
| Maximum calls exceed       | Number of times the maximum number of calls was exceeded. |
| Maximum call rate exceed   | Number of times the maximum call rate was exceeded.       |
| Initialization errors      | Number of call initialization errors.                     |
| Internal errors            | Number of internal errors.                                |
| Nonspecific error          | Number of nonspecific errors.                             |

## Sample Output

### show security alg sccp counters

```

user@host> show security alg sccp counters
SCCP call statistics:
 Active client sessions : 4
 Active calls : 2
 Total calls : 3
 Packets received : 232
 PDUs processed : 232
 Current call rate : 0
Error counters:
 Packets dropped : 0
 Decode errors : 0
 Protocol errors : 0
 Address translation errors : 0
 Policy lookup errors : 0
 Unknown PDUs : 0
 Maximum calls exceeded : 0
 Maximum call rate exceeded : 0
 Initialization errors : 0
 Internal errors : 0
 Nonspecific error : 0

```

| <b>Output Fields</b>            | Table 22 lists the output fields for the <b>show security alg sip calls</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 22: show security alg sip calls Output Fields

| Field Name | Field Description                                  |
|------------|----------------------------------------------------|
| UAS callid | Call Identifier for the SIP ALG user agent server. |
| State      | State of the SIP ALG user agent server.            |

## Sample Output

### show security alg sip calls

```
user@host> show security alg sip calls
```

```
Total number of calls: 1
 Call ID : 1-2468@20.0.0.174
 Method : INVITE
```

## Sample Output

### show security alg sip calls detail

```
user@host> show security alg sip calls detail
Total number of calls: 1
 Call ID : 1-2468@20.0.0.174
 Method : INVITE
 State : SETUP
 Group ID : 307
```

## show security alg sip counters

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Output Fields</b>            | <a href="#">Table 23</a> lists the output fields for the <b>show security alg sip counters</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 23: show security alg sip counters Output Fields**

| Field Name             | Field Description                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INVITE                 | Number of INVITE requests sent. An INVITE request is sent to invite another user to participate in a session.                                                                                                                                       |
| CANCEL                 | Number of CANCEL requests sent. A user can send a CANCEL request to cancel a pending INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE had sent a final response for the INVITE before it received the CANCEL. |
| ACK                    | Number of ACK requests sent. The user from whom the INVITE originated sends an ACK request to confirm reception of the final response to the INVITE request.                                                                                        |
| BYE                    | Number of BYE requests sent. A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.                                                                                                  |
| RR header exceeded max | Number of times the SIP ALG RR (Record-Route) headers exceeded the maximum limit.                                                                                                                                                                   |

Table 23: show security alg sip counters Output Fields (*continued*)

| Field Name   | Field Description                                                                                                                                                                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REGISTER     | Number of REGISTER requests sent. A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. A SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user. |
| OPTIONS      | Number of OPTIONS requests sent. An OPTION request is used by the User Agent (UA) to obtain information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.                                              |
| INFO         | Number of INFO requests sent. AN INFO message is used to communicate mid-session signaling information along the signaling path for the call.                                                                                                                                                                         |
| MESSAGE      | Number of MESSAGE requests sent. SIP messages consist of requests from a client to a server and responses to the requests from a server to a client with the purpose of establishing a session (or a call).                                                                                                           |
| NOTIFY       | Number of NOTIFY requests sent. NOTIFY requests are sent to inform subscribers of changes in state to which the subscriber has a subscription.                                                                                                                                                                        |
| PRACK        | Number of PRACK requests sent. The PRACK request plays the same role as ACK, but for provisional responses.                                                                                                                                                                                                           |
| PUBLISH      | Number of PUBLISH requests sent. The PUBLISH request used for publishing event state. PUBLISH is similar to REGISTER in that it allows a user to create, modify, and remove state in another entity which manages this state on behalf of the user.                                                                   |
| REFER        | Number of REFER requests sent. A REFER request is used to refer the recipient (identified by the Request-URI) to a third party by the contact information provided in the request.                                                                                                                                    |
| SUBSCRIBE    | Number of SUBSCRIBE requests sent. A SUBSCRIBE request is used to request current state and state updates from a remote node.                                                                                                                                                                                         |
| UPDATE       | Number of UPDATE requests sent. AN UPDATE request is used to create a temporary opening in the firewall (pinhole) for new or updates Session Description Protocol (SDP) information. The following fields are modified: Via, From, To, Call-ID, Contact, Route, and Record-Route.                                     |
| BENOTIFY     | Number of BENOTIFY requests sent. A BENOTIFY request is used to reduce the unnecessary SIP signaling traffic on application servers. Applications that do not need a response for a NOTIFY request can enhance performance by enabling BENOTIFY.                                                                      |
| SERVICE      | Number of SERVICE requests sent. The SERVICE method used by a SIP client to request a service of a SIP server. It is a standard SIP message and will be forwarded until it reaches the server or end user which is performing the service.                                                                            |
| OTHER        | Number of OTHER requests sent.                                                                                                                                                                                                                                                                                        |
| Total Pkt-in | Number of SIP ALG total packets received.                                                                                                                                                                                                                                                                             |

Table 23: show security alg sip counters Output Fields (*continued*)

| Field Name                       | Field Description                                                                          |
|----------------------------------|--------------------------------------------------------------------------------------------|
| Total Pkt dropped on error       | Number of SIP ALG total packets dropped while transmission and retransmission of messages. |
| Call error                       | Number of SIP ALG call errors.                                                             |
| IP resolve error                 | Number of SIP ALG IP address resolution errors.                                            |
| NAT error                        | Number of SIP ALG NAT errors.                                                              |
| Resource manager error           | Number of SIP ALG resource manager errors.                                                 |
| Contact header exceeded max      | Number of times the SIP ALG contact headers exceeded the maximum limit.                    |
| Invite Dropped due to call limit | Number of SIP ALG invite dropped due to call limits.                                       |
| SIP msg not processed by stack   | Number of SIP ALG stack errors.                                                            |
| SIP msg not processed by alg     | Number of SIP ALG messages not processed by ALGs.                                          |
| SIP unknown method dropped       | Number of SIP ALG unknown method errors.                                                   |
| Decoding error                   | Number of SIP ALG decoding errors.                                                         |
| Request for disconnected call    | Number of SIP ALG calls disconnected.                                                      |
| Request out of state             | Number of SIP ALG messages out of state errors.                                            |

| <b>Output Fields</b>            | Table 24 lists the output fields for the <b>show security alg sip rate</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 24: show security alg sip rate Output Fields

| Field Name | Field Description                                                                                                                            |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| CPU ticks  | SIP ALG CPU ticks per microsecond.                                                                                                           |
| Time taken | Time, in microseconds, that the last SIP ALG message needed to transit the network.                                                          |
| Total time | Total time, in microseconds, during an interval of less than 10 minutes for the specified number of SIP ALG messages to transit the network. |
| Rate       | Number of SIP ALG messages per second transiting the network.                                                                                |

## Sample Output

### show security alg sip rate

```
user@host> show security alg sip rate
```

```
CPU ticks per us is 166
Time taken for the last message is 1103 us
Total time taken for 3124 messages is 6221482 us (in less than 10 minutes)
Rate: 502 messages/second
```

| <b>Output Fields</b>            | Table 25 lists the output fields for the <b>show security flow gate</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                      |

**Table 25: show security flow gate Output Fields**

| Field Name | Field Description                        |
|------------|------------------------------------------|
| Hole       | Range of flows permitted by the pinhole. |

Table 25: show security flow gate Output Fields (*continued*)

| Field Name            | Field Description                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Translated            | Tuples used to create the session if it matches the pinhole. <ul style="list-style-type: none"> <li>Source address and port</li> <li>Destination address and port</li> </ul> |
| Protocol              | Application protocol, such as UDP or TCP.                                                                                                                                    |
| Application           | Name of the application.                                                                                                                                                     |
| Age                   | Idle timeout for the pinhole.                                                                                                                                                |
| Flags                 | Internal debug flags for the pinhole.                                                                                                                                        |
| Zone                  | Incoming zone.                                                                                                                                                               |
| Reference count       | Number of resource manager references to the pinhole.                                                                                                                        |
| Resource              | Resource manager information about the pinhole.                                                                                                                              |
| Valid gates           | Number of valid gates.                                                                                                                                                       |
| Pending gates         | Number of pending gates.                                                                                                                                                     |
| Invalidated gates     | Number of invalid gates.                                                                                                                                                     |
| Gates in other states | Number of gates in other states.                                                                                                                                             |
| Total gates           | Number of gates in total.                                                                                                                                                    |
| Maximum gates         | Number of maximum gates                                                                                                                                                      |

## Sample Output

### show security flow gate

```

user@host> show security flow gate

| <b>Syntax</b>              | <b>show security flow session</b><br>[ <i>filter</i> ] [ <b>brief</b>   <b>extensive</b>   <b>summary</b> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Release Information</b> | Command introduced in Junos OS Release 8.5. Support for filter and view options added in Junos OS Release 10.2. Application firewall, dynamic application, and logical system filters added in Junos OS Release 11.2. Policy ID filter added in Junos OS Release 12.3X48-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>         | Display information about all currently active security sessions on the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <i>filter</i>—Filter the display by the specified criteria.<br/>The following filters reduce the display to those sessions that match the criteria specified by the filter. Refer to the specific <b>show</b> command for examples of the filtered output.</li> </ul> <p><b>application</b>—Predefined application name</p> <p><b>application-firewall</b>—Application firewall enabled</p> <p><b>application-firewall-rule-set</b>—Application firewall enabled with the specified rule set</p> <p><b>application-traffic-control</b>—Application traffic control session</p> <p><b>application-traffic-control-rule-set</b>—Application traffic control rule set name and rule name</p> <p><b>destination-port</b>—Destination port</p> <p><b>destination-prefix</b>—Destination IP prefix or address</p> <p><b>dynamic-application</b>—Dynamic application</p> <p><b>dynamic-application-group</b>—Dynamic application</p> <p><b>encrypted</b>—Encrypted traffic</p> <p><b>extensive</b>—Display detailed output</p> <p><b>family</b>—Display session by family</p> <p><b>idp</b>—IDP enabled sessions</p> <p><b>interface</b>—Name of incoming or outgoing interface</p> <p><b>logical-system</b> (<b>all</b>   <i>logical-system-name</i>)—Name of a specific logical system or <b>all</b> to display all logical systems</p> <p><b>nat</b>—Display sessions with network address translation</p> <p><b>policy-id</b>—Display session information based on policy ID; the range is 1 through 4,294,967,295</p> |

**protocol**—IP protocol number

**resource-manager**—Resource manager

**root-logical-system**—Display root logical system as default

**security-intelligence**—Display security intelligence sessions

**services-offload**—Display services offload sessions

**session-identifier**—Display session with specified session identifier

**source-port**—Source port

**source-prefix**—Source IP prefix

**summary**—Display output summary

**tunnel**—Tunnel sessions

- **brief | extensive | summary**—Display the specified level of output.
- **none**—Display information about all active sessions.

**Required Privilege Level** view

**Output Fields** Table 26 lists the output fields for the **show security flow session** command. Output fields are listed in the approximate order in which they appear.

**Table 26: show security flow session Output Fields**

| Field Name    | Field Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| Session ID    | Number that identifies the session. Use this ID to get more information about the session.                             |
| CP Session ID | Number that identifies the central point session. Use this ID to get more information about the central point session. |
| Policy name   | Policy that permitted the traffic.                                                                                     |
| Timeout       | Idle timeout after which the session expires.                                                                          |

Table 26: show security flow session Output Fields (*continued*)

| Field Name                           | Field Description                                                                                                                                                                                                               |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| In                                   | Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).                                         |
| Out                                  | Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).                                          |
| Total sessions                       | Total number of sessions.                                                                                                                                                                                                       |
| Status                               | Session status.                                                                                                                                                                                                                 |
| Flag                                 | Internal flag depicting the state of the session, used for debugging purposes. The three available flags are: <ul style="list-style-type: none"> <li>• flag</li> <li>• natflag</li> <li>• natflag2</li> </ul>                   |
| Policy name                          | Name and ID of the policy that the first packet of the session matched.                                                                                                                                                         |
| Source NAT pool                      | The name of the source pool where NAT is used.                                                                                                                                                                                  |
| Dynamic application                  | Name of the application.                                                                                                                                                                                                        |
| Application traffic control rule-set | AppQoS rule set for this session.                                                                                                                                                                                               |
| Rule                                 | AppQoS rule for this session.                                                                                                                                                                                                   |
| Forwarding class                     | The AppQoS forwarding class name for this session that distinguishes the transmission priority                                                                                                                                  |
| DSCP code point                      | Differentiated Services (DiffServ) code point (DSCP) value remarked by the matching rule for this session.                                                                                                                      |
| Loss priority                        | One of four priority levels set by the matching rule to control discarding a packet during periods of congestion. A high loss priority means a high probability that the packet could be dropped during a period of congestion. |
| Rate limiter client to server        | The rate-limiter profile assigned to the client-to-server traffic defining a unique combination of <b>bandwidth-limit</b> and <b>burst-size-limit</b> specifications.                                                           |
| Rate limiter server to client        | The rate-limiter profile assigned to the server-to-client traffic defining a unique combination of <b>bandwidth-limit</b> and <b>burst-size-limit</b> specifications.                                                           |
| Maximum timeout                      | Maximum session timeout.                                                                                                                                                                                                        |
| Current timeout                      | Remaining time for the session unless traffic exists in the session.                                                                                                                                                            |

Table 26: show security flow session Output Fields (*continued*)

| Field Name         | Field Description                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session State      | Session state.                                                                                                                                                                        |
| Start time         | Time when the session was created, offset from the system start time.                                                                                                                 |
| Unicast-sessions   | Number of unicast sessions.                                                                                                                                                           |
| Multicast-sessions | Number of multicast sessions.                                                                                                                                                         |
| Failed-sessions    | Number of failed sessions.                                                                                                                                                            |
| Sessions-in-use    | Number of sessions in use. <ul style="list-style-type: none"> <li>Valid sessions</li> <li>Pending sessions</li> <li>Invalidated sessions</li> <li>Sessions in other states</li> </ul> |
| Maximum-sessions   | Maximum number of sessions permitted.                                                                                                                                                 |

## Sample Output

### show security flow session

```

root> show security flow session
Flow Sessions on FPC10 PIC1:

Session ID: 410000086, Policy name: default-policy-00/2, Timeout: 1790, Valid
 In: 200.0.0.10/41041 --> 60.0.0.2/21;tcp, If: ge-7/1/0.0, Pkts: 6, Bytes: 288,
 CP Session ID: 410000206
 Out: 60.0.0.2/21 --> 200.0.0.10/41041;tcp, If: ge-7/1/1.0, Pkts: 5, Bytes: 291,
 CP Session ID: 410000206
Total sessions: 1

Flow Sessions on FPC10 PIC2:
Total sessions: 0

Flow Sessions on FPC10 PIC3:
Total sessions: 0

```

### show security flow session brief

```

root> show security flow session brief
Flow Sessions on FPC10 PIC1:

Session ID: 410000086, Policy name: default-policy-00/2, Timeout: 1774, Valid
 In: 200.0.0.10/41041 --> 60.0.0.2/21;tcp, If: ge-7/1/0.0, Pkts: 9, Bytes: 414,
 CP Session ID: 410000206
 Out: 60.0.0.2/21 --> 200.0.0.10/41041;tcp, If: ge-7/1/1.0, Pkts: 8, Bytes: 479,
 CP Session ID: 410000206
Total sessions: 1

Flow Sessions on FPC10 PIC2:

**Output Fields** Table 27 lists the output fields for the **show security flow session application** command. Output fields are listed in the approximate order in which they appear.

**Table 27: show security flow session application Output Fields**

| Field Name                | Field Description                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Session ID</b>         | Number that identifies the session. You can use this ID to get additional information about the session.                                                                                |
| <b>Policy name</b>        | Policy that permitted the traffic.                                                                                                                                                      |
| <b>Timeout</b>            | Idle timeout after which the session expires.                                                                                                                                           |
| <b>In</b>                 | Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes). |
| <b>Out</b>                | Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).  |
| <b>Total sessions</b>     | Total number of sessions.                                                                                                                                                               |
| <b>Status</b>             | Session status.                                                                                                                                                                         |
| <b>Flag</b>               | Internal flag depicting the state of the session, used for debugging purposes.                                                                                                          |
| <b>Policy name</b>        | Name and ID of the policy that the first packet of the session matched.                                                                                                                 |
| <b>Source NAT pool</b>    | The name of the source pool where NAT is used.                                                                                                                                          |
| <b>Application</b>        | Name of the application.                                                                                                                                                                |
| <b>Maximum timeout</b>    | Maximum session timeout.                                                                                                                                                                |
| <b>Current timeout</b>    | Remaining time for the session unless traffic exists in the session.                                                                                                                    |
| <b>Session State</b>      | Session state.                                                                                                                                                                          |
| <b>Start time</b>         | Time when the session was created, offset from the system start time.                                                                                                                   |
| <b>Unicast-sessions</b>   | Number of unicast sessions.                                                                                                                                                             |
| <b>Multicast-sessions</b> | Number of multicast sessions.                                                                                                                                                           |
| <b>Failed-sessions</b>    | Number of failed sessions.                                                                                                                                                              |

Table 27: show security flow session application Output Fields (*continued*)

| Field Name       | Field Description                                                                                                                                                                     |

| <b>Output Fields</b>            | <a href="#">Table 28</a> lists the output fields for the <b>show security flow session resource-manager</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                     |

**Table 28: show security flow session resource-manager Output Fields**

| Field Name                  | Field Description                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Session ID</b>           | Number that identifies the session. You can use this ID to get additional information about the session.                                                                                |
| <b>Policy name</b>          | Policy that permitted the traffic.                                                                                                                                                      |
| <b>Timeout</b>              | Idle timeout after which the session expires.                                                                                                                                           |
| <b>Resource information</b> | Information about the session particular to the resource manager, including the name of the ALG, the group ID, and the resource ID.                                                     |
| <b>In</b>                   | Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes). |
| <b>Out</b>                  | Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).  |
| <b>Total sessions</b>       | Total number of sessions.                                                                                                                                                               |

Table 28: show security flow session resource-manager Output Fields (*continued*)

| Field Name               | Field Description                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------|
| Status                   | Session status.                                                                                                        |
| Flag                     | Internal flag depicting the state of the session, used for debugging purposes.                                         |
| Policy name              | Name and ID of the policy that the first packet of the session matched.                                                |
| Source NAT pool          | The name of the source pool where NAT is used.                                                                         |
| Application              | Name of the application.                                                                                               |
| Maximum timeout          | Maximum session timeout.                                                                                               |
| Current timeout          | Remaining time for the session unless traffic exists in the session.                                                   |
| Session State            | Session state.                                                                                                         |
| Start time               | Time when the session was created, offset from the system start time.                                                  |
| Valid sessions           | Number of valid sessions.                                                                                              |
| Pending sessions         | Number of pending sessions.                                                                                            |
| Invalidated sessions     | Number of invalidated sessions.                                                                                        |
| Sessions in other states | Number of sessions in other states.                                                                                    |
| CP Session ID            | Number that identifies the central point session. Use this ID to get more information about the central point session. |

## Sample Output

**Table 29: show security resource-manager group Output Fields**

| Field Name           | Field Description                                           |
|----------------------|-------------------------------------------------------------|
| <b>Total groups</b>  | Total number of groups in the system.                       |
| <b>active groups</b> | Number of active groups.                                    |
| <b>Group ID</b>      | Identification number whose group information is displayed. |

## Sample Output

### show security resource-manager group active

```
user@host> show security resource-manager group active
Total groups 32, active groups 0
```

## Sample Output

### show security resource-manager group active 2048

```
user@host> show security resource-manager group active 2048
Total groups 2048, active groups 1
Group ID 2048: state - Active
 : Virtual System - root
 : Application - SIP ALG
 : Group Timeout - 65535
 : Number of resources - 3
 Resource ID - 8190
 Resource ID - 8188
 Resource ID - 8187
```

## Sample Output

### show security resource-manager group active node primary

```
user@host> show security resource-manager group active node primary
node0:

Group ID 1024: Application - SIP ALG
Total groups 1024, active groups 1
```

## Sample Output

### show security resource-manager group active node all

```
user@host> show security resource-manager group active node all
node0:

Group ID 1024: Application - SIP ALG
Total groups 1024, active groups 1
node1:

Group ID 1024: Application - SIP ALG
Total groups 1024, active groups 1
```

## Sample Output

### show security resource-manager group active 1024 node all

```
user@host> show security resource-manager group active 1024 node all
node0:

Group ID 1024: state - Active
 : Application - SIP ALG
 : Group Timeout - 65535
 : Number of resources - 3
 Resource ID - 8192
 Resource ID - 8188
 Resource ID - 8187
```

node1:

-----  
Group ID 1024: state - Active

**Table 30: show security resource-manager resource Output Fields**

| Field Name       | Field Description                                              |
|------------------|----------------------------------------------------------------|
| Total resources  | Total number of resources in the system.                       |
| active resources | Number of active resources.                                    |
| Resource ID      | Identification number whose resource information is displayed. |

## Sample Output

### show security resource-manager resource active

```
user@host> show security resource-manager resource active
Resource ID 7: Group ID - 2, Application - JSF_sip

Resource ID 6: Group ID - 2, Application - JSF_sip

Resource ID 5: Group ID - 2, Application - JSF_sip

Resource ID 4: Group ID - 2, Application - JSF_sip

Resource ID 3: Group ID - 2, Application - JSF_sip

Resource ID 1: Group ID - 2, Application - JSF_sip

Resource ID 2: Group ID - 2, Application - JSF_sip
Total Resources 4326, active resources 7
```

## Sample Output

### show security resource-manager resource active 5

```
user@host> show security resource-manager resource active 5
Resource ID 5: state - Active
 Application - asl_client
 Parent group - 2
 Policy - 5
 From zone - untrust
 To zone - trust
 Resource timeout - 0
 Number of sessions - 0
 Number of Holes - 1
 Source IP range - {0.0.0.0, 0.0.0.0}
 Source port range - {0, 0}
 Destination IP range - {33.1.0.200, 33.1.0.200}
 Destination port range - {5060, 5060}
 Translated - {0.0.0.0/0 -> 33.1.0.200/5060}
 Protocol - 17
 Reference count - 1
```

## Sample Output

### show security resource-manager resource active node local

```
user@host> show security resource-manager resource active node local
node0:

Resource ID 8192: Group ID - 1024, Application - SIP ALG
Resource ID 8188: Group ID - 1024, Application - SIP ALG
Resource ID 8187: Group ID - 1024, Application - SIP ALG
Total Resources 8192, active resources 3
```

## Sample Output

### show security resource-manager resource active node primary

```
user@host> show security resource-manager resource active node primary
node0:

```

```
Resource ID 8192: Group ID - 1024, Application - SIP ALG
Resource ID 8188: Group ID - 1024, Application - SIP ALG
Resource ID 8187: Group ID - 1024, Application - SIP ALG
Total Resources 8192, active resources 3
```

## show security resource-manager summary

# AppSecure Services Feature Guide for Security Devices

## CHAPTER 21

# Overview

- [Understanding AppSecure Services on page 483](#)

### Understanding AppSecure Services

---

An individual can connect to the network using multiple devices simultaneously, making it impractical to identify a user, an application, or a device by a group of statically allocated IP addresses and port numbers. Junos OS application identification recognizes traffic at different network layers using characteristics other than port number.

Once the application is determined, AppSecure service modules can be configured to monitor and control traffic for tracking, prioritization, access control, detection, and prevention based on the application ID of the traffic.

- AppTrack—Tracks and reports applications passing through the device.
- AppFW—Implements an application firewall using application-based rules.
- AppQoS—Provides quality of service prioritization based on application awareness.
- Intrusion Detection and Prevention (IDP)—Applies appropriate attack objects to applications running on nonstandard ports. Application identification improves IDP performance by narrowing the scope of attack signatures for applications without decoders.

- [Understanding the Junos OS Application Identification Database on page 488](#)

## Understanding Application Identification Techniques

---

Historically, firewalls have used the IP address and port numbers as a way of enforcing policies. That strategy is based on the assumption that users connect to the network from fixed locations and access particular resources using specific port numbers.

Today, wireless networking and mobile devices require a different strategy. The way in which devices connect to the network changes rapidly. An individual can connect to the network using multiple devices simultaneously. It is no longer practical to identify a user, application, or device by a group of statically allocated IP addresses and port numbers.

- [Junos OS Next-Generation Application Identification on page 485](#)
- [Application Signature Mapping on page 486](#)
- [Application Identification Match Sequence on page 486](#)

## Junos OS Next-Generation Application Identification

Next-generation application identification builds on the legacy application identification functionality and provides more effective detection capabilities for evasive applications such as Skype, BitTorrent, and Tor.

Junos OS application identification recognizes Web-based and other applications and protocols at different network layers using characteristics other than port number. Applications are identified by using a protocol bundle containing application signatures and parsing information. The identification is based on protocol parsing and decoding and session management.

The detection mechanism has its own data feed and constructs to identify applications.

The following features are supported in application identification:

- Support for protocols and applications, including video streaming, peer-to-peer communication, social networking, and messaging
- Identification of services within applications

- Ability to distinguish actions launched within an application (such as login, browse, chat, and file transfer)
- Support for all versions of protocols and application decoders and dynamic updates of decoders
- Support for encrypted and compressed traffic and most complex tunneling protocols
- Ability to identify all protocols from Layer 3 to Layer 7 and above Layer 7.

## Application Signature Mapping

Application signature mapping is a precise method of identifying the application that issued traffic on the network. Signature mapping operates at Layer 7 and inspects the actual content of the payload.

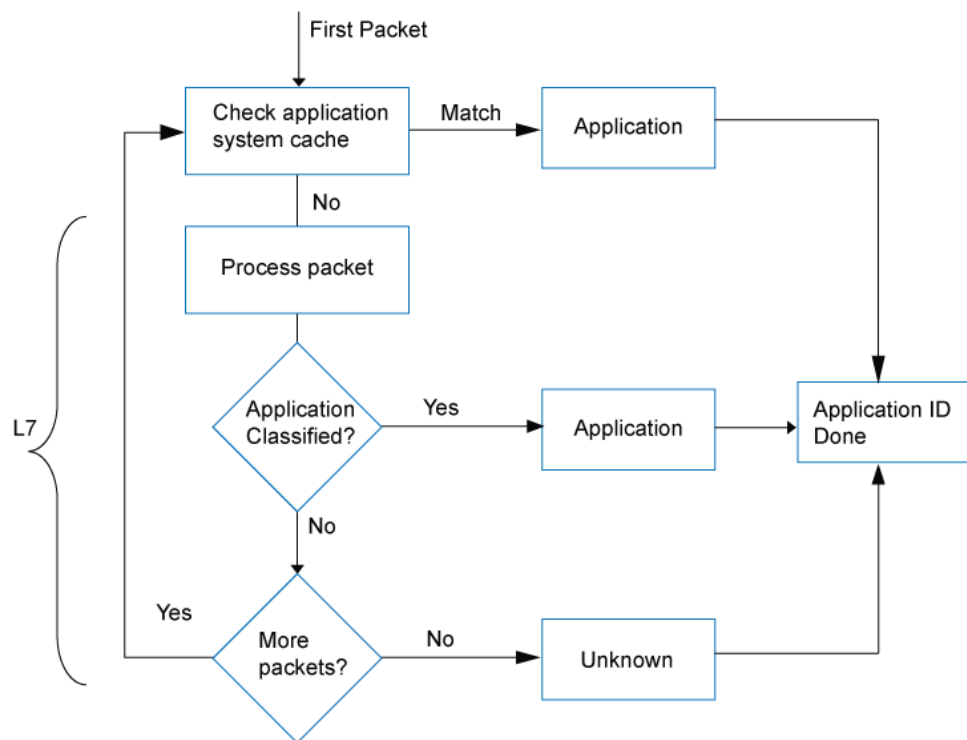

Applications are identified by using a downloadable protocol bundle. Application signatures and parsing information of the first few packets are compared to the content of the database. If the payload contains the same information as an entry in the database, the application of the traffic is identified as the application mapped to that database entry.

Juniper Networks provides a predefined application identification database that contains entries for a comprehensive set of known applications, such as FTP and DNS, and applications that operate over the HTTP protocol, such as Facebook, Kazaa, and many instant messaging programs. A signature subscription allows you to download the database from Juniper Networks and regularly update the content as new predefined signatures are added.

## Application Identification Match Sequence

Figure 28 shows the sequence in which mapping techniques are applied and how the application is determined.

Figure 28: Mapping Sequence

In application identification, every packet in the flow passes through the application identification engine for processing until the application is identified. Application bindings are saved in the application system cache (ASC) to expedite future identification process.

Application signatures identify an application based on protocol grammar analysis in the first few packets of a session. If the application identification engine has not yet identified the application, it passes the packets and waits for more data.

The application identification module matches applications for both client-to-server and server-to-client sessions.

Once the application is determined, AppSecure service modules can be configured to monitor and control traffic for tracking, prioritization, access control, detection, and prevention based on the application ID of the traffic.

- AppTrack—Tracks and reports applications passing through the device.
- Intrusion Detection and Prevention (IDP)—Applies appropriate attack objects to applications running on nonstandard ports. Application identification improves IDP performance by narrowing the scope of attack signatures for applications without decoders.
- AppFW—Implements an application firewall using application-based rules.
- AppQoS—Provides quality of service prioritization based on application awareness.

## Understanding the Junos OS Application Identification Database

---

A predefined signature database is available on the Juniper Networks Security Engineering website. This database includes a library of application signatures.

The predefined signature package provides identification criteria for known application signatures and is updated periodically.

Whenever new applications are added, the protocol bundle is updated and generated for all relevant platforms. It is packaged together with other application signature files. This package will be available for download through the security download website.

A subscription service allows you to regularly download the latest signatures for up-to-date coverage without having to create entries for your own use.

Application identification is enabled by default and is automatically turned on when you configure Intrusion Detection and Prevention (IDP), AppFW, AppQoS, or AppTrack.

**NOTE:** Updates to the Junos OS predefined application signature package are authorized by a separately licensed subscription service. You must install the application identification application signature update license key on your device to download and install the signature database updates provided by Juniper Networks. When your license key expires, you can continue to use the locally stored application signature package contents but you cannot update the package.

## Understanding the Junos OS Application Package Installation

---

Juniper Networks regularly updates the predefined application signature package database and makes it available to subscribers on the Juniper Networks website. This package includes signature definitions of known application objects that can be used to identify applications for tracking, firewall policies, quality of service prioritization, and Intrusion Detection and Prevention (IDP). The database contains application objects such as FTP, DNS, Facebook, Kazaa, and many instant messenger programs.

You need to download and install the application signature package before configuring application services. The application signature package is included in the IDP installation directly and does not need to be downloaded separately.

- If you have IDP enabled and plan to use application identification, you can continue to run the IDP signature database download. To download the IDP signature database, run the following command: **request security idp security-package download**. The application package download can be performed manually or automatically. See

[“Downloading and Installing the Junos OS Application Signature Package As Part of the IDP Security Package” on page 496.](#)

**NOTE:** If you have an IDP-enabled device and plan to use application identification, we recommend that you download only the IDP signature database. This will avoid having two versions of the application database, which could become out of sync.

- If you do not have IDP enabled and plan to use application identification, you can run the following commands: **request services application-identification download** and **request services application-identification install**. These commands will download the application signature database and install it on the device.

You can perform the download manually or automatically. When you download the extracted package manually, you can change the download URL.

After downloading and installing the application signature package, use CLI commands to download and install database updates, and view summary and detailed application information.

See [“Downloading and Installing the Junos OS Application Signature Package Manually” on page 492](#) or [“Example: Scheduling the Application Signature Package Updates” on page 499](#)

**NOTE:** The Junos OS application signature package update is a separately licensed subscription service. You must install the application signature package update license key on your device to download and install the signature database updates provided by Juniper Networks. If your license key expires, you can continue to use the locally stored application signature package content but you cannot update the data.

**NOTE:** On all SRX Series devices, J-Web pages for AppSecure Services are preliminary. We recommend using CLI for configuration of AppSecure features.

## Upgrading to Next-Generation Application Identification

You must install Junos OS Release 12.1X47-D10 to migrate from existing, or legacy, application identification to next-generation application identification.

SRX Series devices installed with Junos OS builds with legacy application identification include legacy application identification security packages. When you upgrade these devices with Junos OS Release 12.1X47-D10, the next-generation application identification security package is installed along with the default protocol bundle. The device is automatically upgraded to next-generation application identification.

**NOTE:**

- The next-generation application identification security package introduces incremental updates to the legacy application identification package. You are not required to remove or uninstall any existing applications.
- Applications supported in previous releases (Junos OS Release 12.1X46 or prior) might have new aliases or alternative names in the new version. So existing configurations using such application works in Junos OS Release 12.1X47; however, related logs and other information will use the new name. You can use the `show services application-identification application detail new-application-name` command to get the details of the applications.
- When you upgrade Junos OS, you can include the `validate` or `no-validate` options with the `request system software add` command. Because the existing features, which are not part of next-generation application identification are deprecated, however, incompatibility issues are not seen.
- Next-generation application identification eliminates the generation of new nested applications and treats existing nested applications as normal applications. In addition, next-generation application identification does not support custom applications or custom application groups. Existing configurations involving any nested applications, custom applications, or custom application groups are ignored with warning messages.

## Installing and Verifying Licenses for an Application Signature Package

The Junos OS application signature package update is a separately licensed subscription service. You must install the application signature package update license key on your device to download and install the signature database updates provided by Juniper Networks. If your license key expires, you can continue to use the locally stored application signature package content.

Licensing is usually ordered when the device is purchased, and this information is bound to the chassis serial number. These instructions assume that you already have the license. If you did not order the license during the purchase of the device, contact your account team or Juniper customer care for assistance. For more information, refer to the Knowledge Base article KB9731 at <http://kb.juniper.net/InfoCenter/index?page=home>.

You can install the license on the SRX Series device using either the automatic method or manual method as follows:

- Install your license automatically on the device.

To install or update your license automatically, your device must be connected to the Internet .

```
user@srx210-host> request system license update
```

Trying to update license keys from https://ae1.juniper.net, use 'show system license' to check status.

- Install the licenses manually on the device.

```
user@srx210-host> request system license add terminal
```

[Type ^D at a new line to end input,  
enter blank line between each license key]

Paste the license key and press Enter to continue.

- Verify the license is installed on your device.

Use the **show system license command** command to view license usage, as shown in the following example:

License usage:

| Feature name   | Licenses<br>used | Licenses<br>installed | Licenses<br>needed | Expiry    |
|----------------|------------------|-----------------------|--------------------|-----------|
| logical-system | 4                | 1                     | 3                  | permanent |

License identifier: JUNOSXXXXXX

License version: 2

Valid for device: AA4XXX005

Features:

appid-sig - APPID Signature  
date-based, 2014-02-17 08:00:00 GMT-8 - 2015-02-11 08:00:00 GMT-8

The output sample is truncated to display only license usage details.

- [Downloading and Installing the Junos OS Application Signature Package As Part of the IDP Security Package on page 496](#)

## Downloading and Installing the Junos OS Application Signature Package Manually

This example shows how to download the application signature package, create a policy, and identify it as the active policy.

- [Requirements on page 493](#)
- [Overview on page 493](#)

- [Configuration on page 493](#)
- [Verification on page 495](#)

## Requirements

Before you begin:

- Ensure that your SRX Series device has a connection to the Internet to download security package updates.

**NOTE:** DNS must be set up because you need to resolve the name of the update server.

- Ensure that you have installed the application identification feature license. See [“Installing and Verifying Licenses for an Application Signature Package” on page 491](#).

This example uses the following hardware and software components:

- An SRX Series device (SRX3600)
- Junos OS Release 12.1X47-D10

## Overview

Juniper Networks regularly updates the predefined application signature package database and makes it available on the Juniper Networks website. This package includes application objects that can be used in Intrusion Detection and Prevention (IDP), application firewall policy, and AppTrack to match traffic.

## Configuration

### CLI Quick Configuration

CLI quick configuration is not available for this example because manual intervention is required during the configuration.

### Downloading and Installing Application Identification

#### Step-by-Step Procedure

1. Download the application package.

```
user@host> request services application-identification download
```

Please use command "request services application-identification download status" to check status

Download retrieves the application package from the Juniper Networks security website <https://signatures.juniper.net/cgi-bin/index.cgi>.

You can also download a specific version of the application package or download the application package from the specific location by using the following options:

- To download a specific version of the application package:

```
user@host>request services application-identification download version
version-number
```

- To change the download URL for the application package from configuration mode:

[edit]

user@host# **set services application-identification download url** *URL or File Path*

**NOTE:** If you change the download URL and you want to keep that change, make sure you commit the configuration.

2. Check the download status.

user@host>**request services application-identification download status**

Application package 2345 is downloaded successfully

**NOTE:** You can also use the system log to view the result of the download.

3. Install the application package.

user@host>**request services application-identification install**

Please use command "request services application-identification install status" to check status and use command "request services application-identification proto-bundle-status" to check protocol bundle status

The application package is installed in the application signature database on the device.

4. Check the installation status of the application package.

The command output displays information about the downloaded and installed versions of the application package and protocol bundle.

- To view the installation status:

user@host>**request services application-identification install status**

Install application package 2345 succeed

- To view the protocol bundle status:

user@host>**request services application-identification proto-bundle-status**

Protocol Bundle Version (1.30.4-22.005 (build date Jan 17 2014)) and application secpack version (2345) is loaded and activated.

NOTE: It is possible that an application signature was removed from the newer version of an application signature database. If this signature is used in an existing application firewall policy on your device, the installation of the new database will fail. An installation status message identifies the signature that is no longer valid. To update the database successfully, remove all references to the deleted signature from your existing policies and groups, and rerun the install command.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Application Identification Status on page 495](#)

### Verifying the Application Identification Status

**Purpose** Verify that the application identification configuration is working properly.

**Action** From operational mode, enter the **show services application-identification status** command.

pic: 1/0

#### Application Identification

|                                |                                    |
|--------------------------------|------------------------------------|
| <b>Status</b>                  | <b>Enabled</b>                     |
| Sessions under app detection   | 0                                  |
| Engine Version                 | 4.18.1-20 (build date Jan 25 2014) |
| Max TCP session packet memory  | 30000                              |
| Max C2S bytes                  | 1024                               |
| Max S2C bytes                  | 0                                  |
| Force packet plugin            | Disabled                           |
| Force stream plugin            | Disabled                           |
| Statistics collection interval | 1 (in minutes)                     |

#### Application System Cache

|                                |                |
|--------------------------------|----------------|
| <b>Status</b>                  | <b>Enabled</b> |
| Negative cache status          | Disabled       |
| Max Number of entries in cache | 131072         |
| Cache timeout in seconds       | 3600           |

#### Protocol Bundle

|                 |                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------|
| Download Server | <a href="https://services.netscreen.com/cgi-bin/index.cgi">https://services.netscreen.com/cgi-bin/index.cgi</a> |
|-----------------|-----------------------------------------------------------------------------------------------------------------|

|            |         |
|------------|---------|
| AutoUpdate | Enabled |
|------------|---------|

#### Slot 1:

|          |                                        |
|----------|----------------------------------------|
| Status   | Active                                 |
| Version  | 1.30.4-22.005 (build date Jan 17 2014) |
| Sessions | 0                                      |

#### Slot 2

|        |      |
|--------|------|
| Status | Free |
|--------|------|

**Meaning** The **Status: Enabled** field shows that application identification is enabled on the device.

## Downloading and Installing the Junos OS Application Signature Package As Part of the IDP Security Package

You can download and install application signatures through intrusion detection and prevention (IDP) security packages.

This example shows how to enhance security by downloading and installing the IDP signatures and application signature package. In this case, both IDP signature pack and application signature pack are downloaded with a single command.

- [Requirements on page 497](#)
- [Overview on page 497](#)
- [Configuration on page 497](#)
- [Verification on page 498](#)

## Requirements

Before you begin:

- Ensure that your SRX Series device has a connection to the Internet to download security package updates.

**NOTE:** DNS must be set up because you need to resolve the name of the update server.

- Ensure that you have installed the application identification feature license. See [“Installing and Verifying Licenses for an Application Signature Package” on page 491](#).

This example uses the following hardware and software components:

- An SRX Series device
- Junos OS Release 12.1X47-D10

## Overview

In this example, you download and install the signature database from the Juniper Networks website.

## Configuration

### Downloading and Installing the Signature Database

#### CLI Quick Configuration

CLI quick configuration is not available for this example because manual intervention is required during the configuration.

#### Step-by-Step Procedure

To download and install application signatures:

1. Download the signature database.

**[edit]**

```
user@host# run request security idp security-package download
```

Will be processed in async mode. Check the status using the status checking CLI

**NOTE:** Downloading the database might take some time depending on the database size and the speed of your Internet connection.

2. Check the security package download status.

**[edit]**

**user@host# run request security idp security-package download status**

Done;Successfully downloaded  
from(<https://services.netscreen.com/cgi-bin/index.cgi>).  
Version info:2230(Mon Feb 4 19:40:13 2013 GMT-8, Detector=12.6.160121210)

3. Install the attack database.

**[edit]**

**user@host# run request security idp security-package install**

Will be processed in async mode. Check the status using the status checking CLI

**NOTE:** Installing the attack database might take some time depending on the security database size.

4. Check the attack database install status. The command output displays information about the downloaded and installed versions of the attack database.

**[edit]**

**user@host# run request security idp security-package install status**

Done;Attack DB update : successful - [UpdateNumber=2230,ExportDate=Mon Feb 4 19:40:13 2013 GMT-8,Detector=12.6.160121210]  
Updating control-plane with new detector : successful  
Updating data-plane with new attack or detector : successful

5. Confirm your IDP security package version.

**[edit]**

**user@host# run show security idp security-package-version**

Attack database version:2230(Mon Feb 4 19:40:13 2013 GMT-8)  
Detector version :12.6.160121210  
Policy template version :2230

6. Confirm your application identification package version.

**[edit]**

**user@host# run show services application-identification version**

Application package version: 1884

## Verification

Confirm that the application signature package is being updated properly.

### Verifying application signature package

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | Verify services application identification version                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Action</b>                | <p>From operational mode, enter the <b>show services application-identification version</b> command.</p> <pre>user@host&gt; show services application-identification version</pre> <p>Application package version: 1884</p>                                                                                                                                                                                                                                                                      |
| <b>Meaning</b>               | The sample output shows that, the services application identification version is 1884.                                                                                                                                                                                                                                                                                                                                                                                                           |

## Example: Scheduling the Application Signature Package Updates

This example shows how to set up automatic updates of the predefined application signature package.

- [Requirements on page 499](#)
- [Overview on page 499](#)
- [Configuration on page 500](#)
- [Verification on page 500](#)

### Requirements

Before you begin:

- Ensure that your SRX Series device has a connection to the Internet to download security package updates.

**NOTE:** DNS must be set up because you need to resolve the name of the update server.

- Ensure that you have installed the application identification feature license. See [“Installing and Verifying Licenses for an Application Signature Package” on page 491](#).

### Overview

In this example, you want to download the current version of the application signature package periodically. The download should start at 11:59 PM on December 10. To maintain

the most current information, you want to update the package automatically every 2 days from your company's intranet site.

## Configuration

### GUI Step-by-Step Procedure

To set up the automatic download and periodic update with the J-Web interface:

1. Enter **Configure>Security>AppSecure Settings** to display the Applications Signature page.
2. Click **Global Settings**.
3. Click the **Download Scheduler** tab, and modify the following fields:
  - URL: **https://signatures.juniper.net/cgi-bin/index.cgi**
  - Enable Schedule Update: Select the check box.
  - Interval: **48**
4. Click **Reset Setting** to clear the existing start time, enter the new start time in MM-DD.hh:mm format, and click **OK**.
  - Start Time: **12-10.23:59**
5. Click **Commit Options>Commit** to commit your changes.
6. Click **Check Status** to monitor the progress of an active download or update, or to check the outcome of the latest update.

### Step-by-Step Procedure

To use the CLI to automatically update the Junos OS application signature package:

1. Specify the URL for the security package. The security package includes the detector and the latest attack objects and groups. The following statement specifies https://signatures.juniper.net/cgi-bin/index.cgi as the URL for downloading signature database updates:  

```
[edit]
user@host# set services application-identification download url
https://signatures.juniper.net/cgi-bin/index.cgi
```
2. Specify the time and interval for download. The following statement sets the interval as 48 hours and the start time as 11:59 pm on December 10:  

```
[edit]
user@host# set services application-identification download automatic interval 48
start-time 12-10.23:59
```
3. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify that the application signature package is being updated properly, enter the **show services application-identification version** command. Review the version number and details for the latest update.

## Scheduling the Application Signature Package Updates As Part of the IDP Security Package

---

The configuration instructions in this example describe how to setup automatic updates of application identification signature package (part of IDP security package) at a specified date and time.

- [Requirements on page 501](#)
- [Overview on page 501](#)
- [Configuration on page 502](#)
- [Verification on page 502](#)

### Requirements

Before you begin:

- Ensure that your SRX Series device has a connection to the Internet to download security package updates.

**NOTE:** DNS must be set up because you need to resolve the name of the update server.

- Ensure that you have installed the application identification feature license. See [“Installing and Verifying Licenses for an Application Signature Package” on page 491](#).

### Overview

In this example, you want to download the current version of the application signature package periodically. The download should start at 11:59 PM on December 10. To maintain the most current information, you want to update the package automatically every 2 days from your company's intranet site.

## Configuration

### GUI Step-by-Step Procedure

To set up the automatic download and periodic update with the J-Web interface:

1. Enter **Configure>Security>IDP>Signature Updates** to display the Security IDP Signature Configuration page.
2. Click **Download Settings** and modify the URL:  
**`https://signatures.juniper.net/cgi-bin/index.cgi`**
3. Click the **Auto Download Settings** tab, and modify the following fields:
  - Interval: **48**
  - Start Time: **2013-12-10.23:59:55**
  - Enable Schedule Update: Select the check box.
4. Click **Reset Setting** to clear the existing fields, enter the new values. Click **OK**.
5. Click **Commit Options>Commit** to commit your changes.
6. Click **Check Status** to monitor the progress of an active download or update, or to check the outcome of the latest update.

### Step-by-Step Procedure

To use the CLI to automatically update the Junos OS application signature package:

1. Specify the URL for the security package. The security package includes the detector and the latest attack objects and groups. The following statement specifies `https://signatures.juniper.net/cgi-bin/index.cgi` as the URL for downloading signature database updates:  
  
[edit]  
user@host# set security idp security-package url  
**`https://signatures.juniper.net/cgi-bin/index.cgi`**
2. Specify the time and interval for download. The following statement sets the interval as 48 hours and the start time as 11:55 pm on December 10, 2013:  
  
[edit]  
user@host# set security idp security-package automatic interval 48 start-time  
**`2013-12-10.23:55:55`**
3. Enable an automatic download and update of the security package.  
  
[edit]  
user@host# set security idp security-package automatic enable
4. If you are done configuring the device, commit the configuration.  
  
[edit]  
user@host# commit

## Verification

Confirm that the application signature package is being updated properly.

### Verifying application signature package

| <b>Purpose</b>               | Verify services application identification version                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Action</b>                | <p>From operational mode, enter the <b>show services application-identification version</b> command.</p> <pre>user@host&gt; show services application-identification version</pre> <p>Application package version: 1884</p>                                                                                                                                                                                                                                                                            |
| <b>Meaning</b>               | The sample output shows that, the services application identification version is 1884.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Related Documentation</b> | <ul style="list-style-type: none"> <li>• <a href="#">Understanding the Junos OS Application Package Installation on page 489</a></li> <li>• <a href="#">Installing and Verifying Licenses for an Application Signature Package on page 491</a></li> <li>• <a href="#">Downloading and Installing the Junos OS Application Signature Package Manually on page 492</a></li> <li>• <a href="#">Verifying the Junos OS Application Identification Extracted Application Package on page 506</a></li> </ul> |

## Example: Downloading and Installing the Application Identification Package in Chassis Cluster Mode

This example shows how to download and install the application signature package database to a device operating in chassis cluster mode.

- [Requirements on page 503](#)
- [Overview on page 504](#)
- [Downloading and Installing the Application Identification Package on page 504](#)

### Requirements

Before you begin:

- Set the chassis cluster node ID and cluster ID. See *Example: Setting the Chassis Cluster Node ID and Cluster ID*.
- Ensure that your SRX Series device has a connection to the Internet to download security package updates.

**NOTE:** DNS must be set up because you need to resolve the name of the update server.

- Ensure that you have installed application identification feature license. See [“Installing and Verifying Licenses for an Application Signature Package” on page 491](#).

## Overview

If you use application identification, you can download the predefined application signature package database. Juniper Networks regularly updates the database and makes it available on the Juniper Networks website. This package includes application objects that can be used to match traffic in IDP, application firewall policies, and application tracking. For more details, see [“Understanding the Junos OS Application Package Installation” on page 489](#).

When you download the application identification security package on a device operating in chassis cluster mode, the security package is downloaded to the primary node and then synchronized to the secondary node.

## Downloading and Installing the Application Identification Package

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To download and install an application package:

1. Download the application package on the primary node.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification download
```

```
Please use command "request services application-identification download status"
to check status
```

2. Check the application package download status.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification download status
```

On a successful download, the following message is displayed

```
Application package 2345 is downloaded successfully
```

The application package is installed in the application signature database on the primary node, and application identification files are synchronized on the primary and secondary nodes.

3. Update the application package using **install** command.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification install
```

```
node0:
```

```

Please use command "request services application-identification install status"
to check status and use command "request services application-identification
proto-bundle-status" to check protocol bundle status
```

```
node1:
```

```

Please use command "request services application-identification install status"
to check status and use command "request services application-identification
```

proto-bundle-status" to check protocol bundle status

4. Check the application package update status. The command output displays information about the downloaded and installed versions of the application package.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification install status
```

```
node0:
```

```

Install application package 2345 succeed
```

```
node1:
```

```

Install application package 2345 succeed
.....
```

**NOTE:** It is possible that an application signature is removed from the new version of an application signature database. If this signature is used in an existing application firewall policy on your device, the installation of the new database will fail. An installation status message identifies the signature that is no longer valid. To update the database successfully, remove all references to the deleted signature from your existing policies and groups, and rerun the install command.

To uninstall an application package:

1. Uninstall the application package using **uninstall** command.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification uninstall
```

```
node0:
```

```

Please use command "request services application-identification uninstall
status" to check status and use command "request services
application-identification proto-bundle-status" to check protocol bundle status
node1:
```

```

Please use command "request services application-identification uninstall
status" to check status and use command "request services
application-identification proto-bundle-status" to check protocol bundle status
.....
```

2. Check the uninstall status of the application package.

```
{primary:node0}[edit]
```

```
user@host> request services application-identification uninstall status
```

```
node0:
```

```

Uninstall application package 2345 succeed
```

```
node1:
```

```

Uninstall application package 2345 succeed
.....
```

3. Check the uninstall status of protocol bundle:

```
user@host>request services application-identification proto-bundle-status
```

```
Protocol Bundle Version (1.30.4-22.005 (build date Jan 17 2014)) and application
secpack version (2345) is unloaded and deactivated
```

## Verifying the Junos OS Application Identification Extracted Application Package

**Purpose** After successful download and installation of the application package, use the following commands to view the predefined application signature package content.

- Action**
- View the current version of the application package:

```
show services application-identification version
```

```
Application package version: 1608
```

- View the current status of the application package:

```
show services application-identification status
```

```
pic: 1/0
```

```
Application Identification
Status Enabled
Sessions under app detection 0
Engine Version 4.18.1-20 (build date Jan 25 2014)
Max TCP session packet memory 30000
Max C2S bytes 1024
Max S2C bytes 0
Force packet plugin Disabled
Force stream plugin Disabled
Statistics collection interval 1 (in minutes)

Application System Cache
Status Enabled
Negative cache status Disabled
Max Number of entries in cache 131072
Cache timeout in seconds 3600

Protocol Bundle
Download Server

## Uninstalling the Junos OS Application Identification Application Package

You can uninstall the predefined application package. The uninstall operation will fail if there are any active security policies referenced in the predefined application signatures in the Junos OS configuration.

To uninstall application package:

1. Uninstall the application package:

```
user@host> request services application-identification uninstall
```

Please use command "request services application-identification uninstall status" to check status and use command "request services application-identification proto-bundle-status" to check protocol bundle status.

2. Check the uninstall operation status of the application package. The command output displays information about the uninstall status of the application package and protocol bundle.

- Check the uninstall status:

```
user@host> request services application-identification uninstall status
```

```
Uninstall application package 2345 succeed
```

- Check the uninstall status of protocol bundle:

```
user@host> request services application-identification proto-bundle-status
```

```
Protocol Bundle Version (1.30.4-22.005 (build date Jan 17 2014)) and
application secpack version (2345) is unloaded and deactivated
```

The application package and protocol bundle are uninstalled on the device. To reinstall application identification, you need to download application package and reinstall it again.

## Disabling and Reenabling Junos OS Application Identification

---

Application identification is enabled by default. You can disable application identification with the CLI.

To disable application identification:

```
user@host# set services application-identification no-application-identification
```

If you want to reenabling application identification, delete the configuration statement that specifies disabling of application identification:

```
user@host# delete services application-identification no-application-identification
```

If you are finished configuring the device, commit the configuration.

To verify the configuration, enter the **show services application-identification** command. See [“Verifying the Junos OS Application Identification Extracted Application Package” on page 506](#).

- [Enabling Application Groups in Junos OS Application Identification on page 510](#)
- [Example: Configuring a Custom Application Group for Junos OS Application Identification for Simplified Management on page 510](#)

## Customizing Application Groups for Junos OS Application Identification

---

In Junos OS, application identification allows you to group applications in policies. Applications can be grouped under predefined and custom application groups. The entire predefined application group can be downloaded as part of the IDP or application identification security package. You can create custom application groups with a set of similar applications for consistent reuse when defining policies.

Application group support associates related applications under a single name for simplified, consistent reuse when using any application services.

The hierarchy of application groups resembles a tree structure with associated applications as the leaf nodes. The group *any* refers to the root node. The group *unassigned* is always situated one level from the root and initially contains all applications. When a group is defined, applications are assigned from the unassigned group to the new group. When a group is deleted, its applications are moved back to the unassigned group.

All predefined application groups have the prefix “junos” in the application group name to prevent naming conflicts with custom application groups. You cannot modify the list of applications within a predefined application group. However, you can copy a predefined application group to use it as a template for creating a custom application group.

To customize a predefined application group, you must first disable the predefined group. Note that a disabled predefined application group remains disabled after an application database update. You can then use the operational command **request services application-identification group** to copy the disabled predefined application group. The copied group is placed in the configuration file, and the prefix “junos” is changed to “my”. At this point, you can modify the list of applications in “my” application group and rename the group with a unique name.

To reassign an application from one custom group to another, you must remove the application from its current custom application group, and then reassign it to the other.

- [Understanding Application Identification Techniques on page 485](#)
  - [Enabling Application Groups in Junos OS Application Identification on page 510](#)
  - [Example: Configuring a Custom Application Group for Junos OS Application Identification for Simplified Management on page 510](#)

---

## Enabling Application Groups in Junos OS Application Identification

---

All application groups are enabled by default. Predefined application groups are enabled at installation.

- For predefined application groups, you can disable and reenabling a group using the **request services application-identification group** command. You cannot delete a predefined signature or signature group.

- To disable a predefined application group:

```
user@host> request services application-identification group disable
predefined-application-group-name
```

- To reenabling a disabled predefined application group:

```
user@host> request services application-identification group enable
predefined-application-group-name
```

- Related Documentation**

---

## Example: Configuring a Custom Application Group for Junos OS Application Identification for Simplified Management

---

This example shows how to configure custom application groups for Junos OS application identification for consistent reuse when defining policies.

- [Requirements on page 510](#)
- [Overview on page 511](#)
- [Configuration on page 511](#)

### Requirements

Before you begin, install an entire signature database from an IDP or an application identification security package. See [“Downloading and Installing the Junos OS Application Signature Package Manually” on page 492](#) or [“Downloading and Installing the Junos OS Application Signature Package As Part of the IDP Security Package” on page 496](#).

## Overview

In this example, you define applications for an application group, delete an application from an application group, and include an application group within another application group.

In Junos OS, application identification allows you to group applications in policies. Applications can be grouped under predefined and custom application groups. The entire predefined application group can be downloaded as part of the IDP or application identification security package. You can create custom application groups with a set of similar applications for consistent reuse when defining policies.

**NOTE:** You cannot modify the applications defined in a predefined application group. However, you can copy a predefined application group using the operational command `request services application-identification group group-name copy` to create a custom application group and modify the list of applications. For more information, see [request services application-identification group](#).

## Configuration

- [Deleting an Application from a User-Defined Application Group on page 513](#)
- [Creating Child Application Groups for an Application Group on page 513](#)

### Configuring Junos OS Application Identification User-Defined Application Groups

#### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services application-identification application-group my_web
set services application-identification application-group my_web applications junos:HTTP
set services application-identification application-group my_web applications junos:FTP
set services application-identification application-group my_web applications
 junos:GOPHER
set services application-identification application-group my_web applications
 junos:AMAZON
set services application-identification application-group my_peer
set services application-identification application-group my_peer applications
 junos:BITTORRENT
set services application-identification application-group my_peer applications
 junos:BITTORRENT-DHT
set services application-identification application-group my_peer applications
 junos:BITTORRENT-UDP
set services application-identification application-group my_peer applications
 junos:BITTRACKER
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a custom application group for application identification:

1. Set the name of your custom application group.

```
[edit services application-identification]
user@host# set application-group my_web
```

2. Add the list of applications that you want to include in your custom application group.

```
[edit services application-identification]
user@host# set application-group my_web applications junos:HTTP
user@host# set application-group my_web applications junos:FTP
user@host# set application-group my_web applications junos:GOPHER
user@host# set application-group my_web applications junos:AMAZON
```

3. Set the name of a second custom application group.

```
[edit services application-identification]
user@host# set application-group my_peer
```

4. Add the list of applications that you want to include in the group.

```
[edit services application-identification]
user@host# set application-group my_peer applications junos:BITTORRENT
user@host# set application-group my_peer applications junos:BITTORRENT-DHT
user@host# set application-group my_peer applications junos:BITTORRENT-UDP
user@host# set application-group my_peer applications junos:BITTRACKER
```

**Results** From configuration mode, confirm your configuration by entering the **show services application-identification group** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services application-identification application-group my_web
applications {
 junos:HTTP;
 junos:FTP;
 junos:GOPHER;
 junos:AMAZON
}
user@host# show services application-identification application-group my_peer
applications {
 junos:BITTORRENT;
 junos:BITTORRENT-DHT;
 junos:BITTORRENT-UDP;
 junos:BITTRACKER;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Deleting an Application from a User-Defined Application Group

**CLI Quick Configuration** To quickly configure this section of the example, copy the following command, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
delete services application-identification application-group my_web applications
junos:AMAZON
```

**Step-by-Step Procedure** To delete an application from a custom application group:

- Delete an application from a custom application group.

```
[edit services application-identification]
user@host# delete application-group my_web applications junos:AMAZON
```

**Results** From configuration mode, confirm your configuration by entering the **show services application-identification application-group detail** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services application-identification group detail
application group my_web {
 junos:HTTP;
 junos:FTP;
 junos:GOPHER;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Creating Child Application Groups for an Application Group

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter **commit** from configuration mode.

```
set services application-identification application-group p2p
set services application-identification application-group p2p application-groups my_web
set services application-identification application-group p2p application-groups my_peer
```

**Step-by-Step Procedure** To configure child application groups for a custom application group:

1. Set the name of the custom application group in which you are configuring the child application groups.

```
[edit services application-identification]
user@host# set application-group p2p
```

2. Add the child application groups.

```
[edit services application-identification]
user@host# set application-group p2p application-groups my_web
uer@host# set application-group p2p application-groups my_peer
```

**Results** From configuration mode, confirm your configuration by entering the **show services application-identification application-group *application-group-name*** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services application-identification application-group p2p
 applications-groups {
 my_web;
 my_peer;
 }
```

If you are done configuring the device, enter **commit** from configuration mode.

## CHAPTER 25

# Configuring Application System Cache

- [Understanding the Application System Cache on page 515](#)
- [Deactivating Application System Cache Information for Application Identification \(CLI Procedure\) on page 515](#)
- [Verifying Application System Cache Statistics on page 516](#)

## Understanding the Application System Cache

---

Application system cache (ASC) saves the mapping between an application type and the corresponding destination IP address, destination port, protocol type, and service.

Once an application is identified, its information is saved in the ASC so that only one matching entry is required for an application running on a particular system, thereby expediting the identification process.

By default, the ASC saves the mapping information for 3600 seconds. However, you can configure the cache timeout value by using the CLI.

To minimize the impact on performance, application system cache is refreshed only when Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) traffic triggers a cache lookup. Without a cache lookup, the entries in the ASC remain unchanged even after cache timeout.

### Related Documentation

- [Understanding Application Identification Techniques on page 485](#)
- [Understanding the Junos OS Application Identification Database on page 488](#)
- [Verifying Application System Cache Statistics on page 516](#)

## Deactivating Application System Cache Information for Application Identification (CLI Procedure)

---

Application caching is turned on by default. You can manually turn this caching off using the CLI.

```
user@host# set services application-identification no-application-system-cache
```

When you use the **show** command in the CLI operation mode for the application system cache (ASC), application cache is listed as **off**. Note that if the cache contains data from the prior implementation, the cached data is also displayed.

```
user@host> show services application-identification application-system-cache
```

```
application-cache: off
nested-application-cache: on
cache-unknown-result: on
cache-entry-timeout: 3600 seconds
```

**Related  
Documentation**

- [Understanding the Junos OS Application Identification Database on page 488](#)

---

## Verifying Application System Cache Statistics

**Purpose** Verify the application system cache (ASC) statistics.

**NOTE:** The application system cache will display the cache for application identification applications.

**Action** From CLI operation mode, enter the **show services application-identification application-system-cache** command.

### Sample Output

```
user@host> show services application-identification application-system-cache
application-cache: on
nested-application-cache: on
cache-unknown-result: on
cache-entry-timeout: 3600 seconds
```

**Meaning** The output shows a summary of the ASC statistics information. Verify the following information:

- IP address—Displays the destination address.
- Port—Displays the destination port on the server.
- Protocol—Displays the protocol type on the destination port.
- Application—Displays the name of the application identified on the destination port.

NOTE: On branch SRX Series devices, when there are a large number of ASC entries (10,000 or more), and the entries are to be listed in the output for the command `show services application-identification application-system-cache`, it results in CLI session timeout.

# Controlling Application Identification Performance

- [Onbox Application Identification Statistics on page 519](#)
- [Understanding Jumbo Frames Support for Junos OS Application Identification Services on page 520](#)
- [Improving the Application Traffic Throughput on page 520](#)

## Onbox Application Identification Statistics

---

Application Identification services provide statistical information per session. These statistics provide customers with an application usage profile. The Onbox Application Identification Statistics feature adds application-level statistics to the AppSecure suite. Application statistics allow an administrator to access cumulative statistics as well as statistics accumulated over user-defined intervals.

With this feature, the administrator can clear the statistics and configure the interval values while maintaining bytes and session count statistics. Because the statistics count occurs at session close event time, the byte and session counts are not updated until the session closes. SRX Series devices support a history of eight intervals that an administrator can use to display application session and byte counts.

If application grouping is supported in your configuration of Junos OS, then the Onbox Application Identification Statistic feature supports onbox per-group matching statistics. The statistics are maintained for predefined groups only.

Reinstalling an application signature package will not clear the application statistics. If the application is disabled, there will not be any traffic for that application, but the application is still maintained in the statistics. It does not matter if you are reinstalling a predefined application, because applications are tracked according to application type. For predefined group statistics, reinstalling a security package will not clear the statistics. However, any changes to group memberships are updated. For example, `junos:web` might have 50 applications in the current release and 60 applications following an upgrade. Applications that are deleted and application groups that are renamed are handled in the same way as applications that are added.

The Application Identification module maintains a 64-bit session counters for each application on each Services Processing Unit (SPU). The counter increments when a

session is identified as a particular application. Another set of 64-bit counters aggregates the total bytes per application on the SPU. Counters for unspecified applications are also maintained. Statistics from multiple SPUs for both sessions and bytes are aggregated on the Routing Engine and presented to the users.

Individual SPUs have interval timers to roll over statistics per *interval* time. To configure the interval for statistics collection, use the **set services application-identification application-statistics interval time** command. Whenever the Routing Engine queries for the required interval, the corresponding statistics are fetched from each SPU, aggregated in the Routing Engine and presented to the user.

Use the **clear-services-application-identification-application-statistics** command to reset the counters manually. Counters reset automatically when a device is upgraded or rebooted, when flowd restarts, or when there is a change in the interval timer.

## Understanding Jumbo Frames Support for Junos OS Application Identification Services

Application identification support the larger jumbo frame size of 9192 bytes. Although jumbo frames are enabled by default, you can adjust the maximum transmission unit (MTU) size by using the **[set interfaces]** command. CPU overhead can be reduced while processing jumbo frames.

## Improving the Application Traffic Throughput

The application traffic throughput can be improved by setting the deep packet inspection (DPI) in performance mode with default packet inspection limit as two packets, including both client-to-server and server-to-client directions. By default, performance mode is disabled on SRX Series devices.

To improve the application traffic throughput:

1. Enable the DPI performance mode.

```
[edit]
user@host# set services application-identification enable-performance-mode
```

2. (Optional) You can set the maximum packet threshold for DPI performance mode, including both client-to-server and server-to-client directions.

You can set the packet inspection limit from 1 through 100.

```
[edit]
user@host# set services application-identification enable-performance-mode
max-packet-threshold value
```

3. Commit the configuration.

```
[edit]
user@host# commit
```

Use the **show services application-identification status** command to display detailed information about application identification status.

#### show services application-identification status (DPI Performance Mode Enabled)

```
user@host> show services application-identification status
pic: 2/1

Application Identification
Status Enabled
Sessions under app detection 0
Engine Version 4.18.2-24.006 (build date Jul 30 2014)
Max TCP session packet memory 30000
Force packet plugin Disabled
Force stream plugin Disabled
DPI Performance mode: Enabled
Statistics collection interval 1 (in minutes)

Application System Cache
Status Enabled
Negative cache status Disabled
Max Number of entries in cache 262144
Cache timeout 3600 (in seconds)

Protocol Bundle
Download Server https://services.netscreen.com/cgi-bin/index.cgi
AutoUpdate Disabled
Slot 1:
Application package version 2399
Status Active
Version 1.40.0-26.006 (build date May 1 2014)
Sessions 0
Slot 2:
Application package version 0
Status Free
Version 0
Sessions 0
```

The DPI Performance mode field displays whether the DPI performance mode is enabled or not. This field is displayed in the CLI command output only if the performance mode is enabled.

If you want to set DPI to default accuracy mode and disable the performance mode, delete the configuration statement that specifies enabling of the performance mode:

To disable the performance mode:

1. Delete the performance mode.

```
[edit]
user@host# delete services application-identification enable-performance-mode
```

2. Commit the configuration.

```
[edit]
user@host# commit
```

## SSL Proxy Overview

---

Secure Sockets Layer (SSL) is an application-level protocol that provides encryption technology for the Internet. SSL, also called Transport Layer Security (TLS), ensures the secure transmission of data between a client and a server through a combination of privacy, authentication, confidentiality, and data integrity. SSL relies on certificates and private-public key exchange pairs for this level of security.

Server authentication guards against fraudulent transmissions by enabling a Web browser to validate the identity of a Web server. Confidentiality mechanisms ensure that communications are private. SSL enforces confidentiality by encrypting data to prevent unauthorized users from eavesdropping on electronic communications. Finally, message integrity ensures that the contents of a communication have not been tampered with.

SSL proxy is a transparent proxy; that is, it performs SSL encryption and decryption between the client and the server, but neither the server nor the client can detect its presence. Existing features like SSL offload and SSL inspection require the servers to share their secret keys to be able to decrypt the SSL traffic. However, sharing server keys is sometimes not feasible or might not be available in certain circumstances, in which case, the SSL traffic cannot be decrypted.

SSL proxy addresses this problem by ensuring that it has the keys to encrypt and decrypt the payload:

- For the server, SSL proxy acts as a client—Because SSL proxy generates the shared pre-master key, it determines the keys to encrypt and decrypt.
- For the client, SSL proxy acts as a server—SSL proxy first authenticates the original server and replaces the public key in the original server certificate with a key that is

known to it. It then generates a new certificate by replacing the original issuer of the certificate with its own identity and signs this new certificate with its own public key (provided as a part of the proxy profile configuration). When the client accepts such a certificate, it sends a shared pre-master key encrypted with the public key on the certificate. Because SSL proxy replaced the original key with its own key, it is able to receive the shared pre-master key. Decryption and encryption take place in each direction (client and server), and the keys are different for both encryption and decryption.

Figure 29 depicts how SSL inspection (on an existing SRX Series IDP module) is typically used to protect servers. SSL inspection requires access to the private keys used by the servers so that the SRX Series device can decrypt the encrypted traffic.

**Figure 29: SSL Inspection on an Existing SRX Series IDP Module**

### SSL inspection

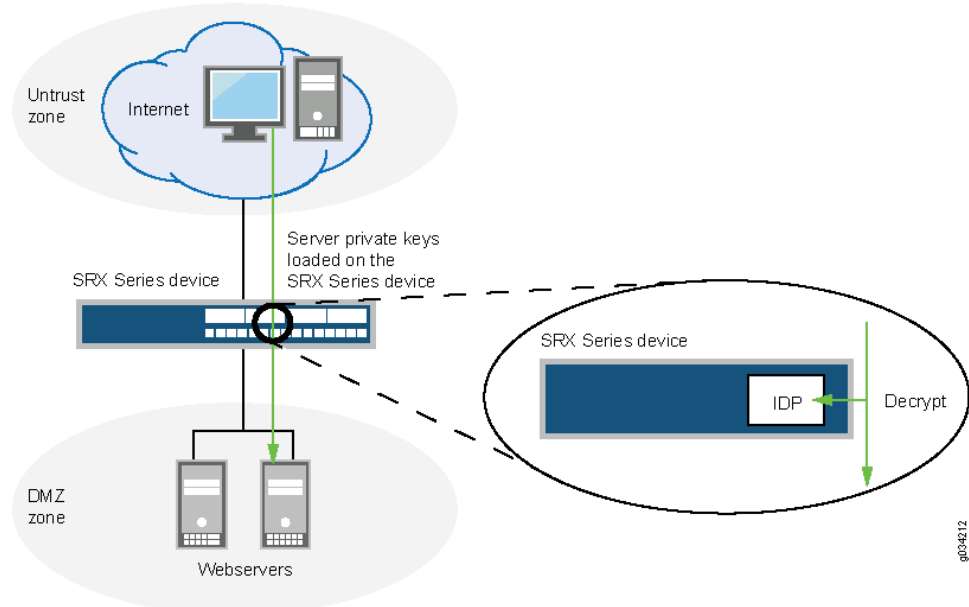

Figure 30 shows how SSL proxy works on an encrypted payload. When application firewall (AppFW), Intrusion Detection and Prevention (IDP), or application tracking (AppTrack) is configured, SSL proxy acts as an SSL server terminating the SSL session from the client and a new SSL session is established to the server. The SRX Series device decrypts and then reencrypts all SSL proxy traffic. SSL proxy uses the following:

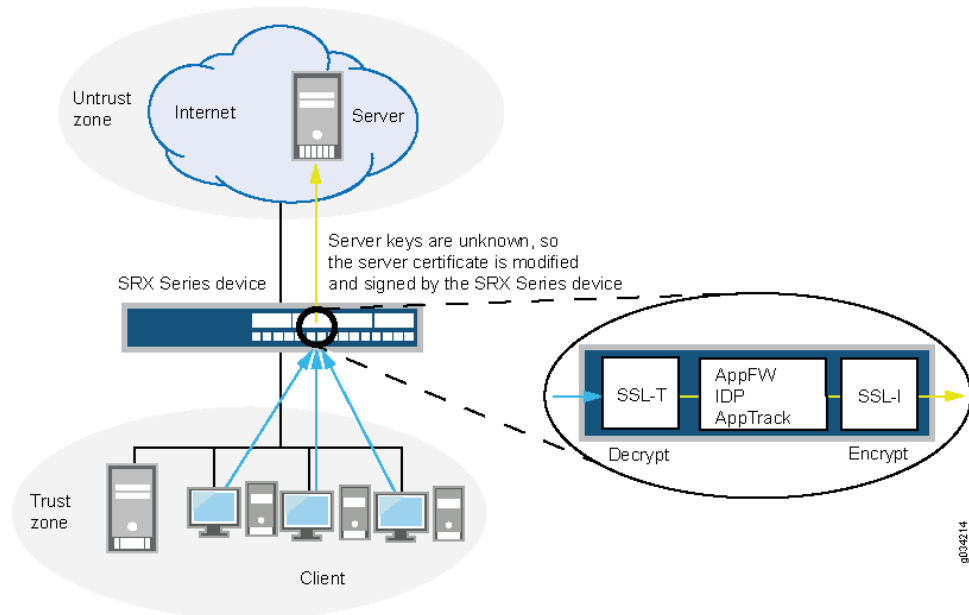

- SSL-T-SSL terminator on the client side.
- SSL-I-SSL initiator on the server side.
- Configured AppFW, IDP, or AppTrack services use the decrypted SSL sessions.

**NOTE:** If none of the services (AppFW, IDP, or AppTrack) are configured, then SSL proxy services are bypassed even if an SSL proxy profile is attached to a firewall policy.

**Figure 30: SSL Proxy on an Encrypted Payload**

**SSL forward proxy**

## Supported Ciphers in Proxy Mode

An SSL cipher comprises encryption ciphers, authentication method, and compression. [Table 34](#) displays a list of supported ciphers. NULL ciphers are excluded.

The following SSL protocols are supported on SRX Series devices:

- TLS version 1.0—Provides secure communication over networks by providing privacy and data integrity between communicating applications
- TLS version 1.1—An Enhanced version TLS 1.0 to provide protection against cipher-block chaining (CBC) attacks.
- TLS version 1.2 —An Enhanced version TLS 1.1 to provide improved flexibility for negotiation of cryptographic algorithms.

**Table 34: Supported SSL Cipher List**

| SSL Cipher           | Key Exchange Algorithm | Data Encryption | Message Integrity           |
|----------------------|------------------------|-----------------|-----------------------------|
| RSA_WITH_RC4_128_MD5 | RSA key exchange       | 128-bit RC4     | Message Digest 5 (MD5) hash |

Table 34: Supported SSL Cipher List (*continued*)

|                                 |                     |                 |                                  |
|---------------------------------|---------------------|-----------------|----------------------------------|
| RSA_WITH_RC4_128_SHA            | RSA key exchange    | 128-bit RC4     | Secure Hash Algorithm (SHA) hash |
| RSA_WITH_DES_CBC_SHA            | RSA key exchange    | DES CBC         | SHA hash                         |
| RSA_WITH_3DES_EDE_CBC_SHA       | RSA key exchange    | 3DES EDE/CBC    | SHA hash                         |
| RSA_WITH_AES_128_CBC_SHA        | RSA key exchange    | 128-bit AES/CBC | SHA hash                         |
| RSA_WITH_AES_256_CBC_SHA        | RSA key exchange    | 256-bit AES/CBC | SHA hash                         |
| RSA_EXPORT_WITH_RC4_40_MD5      | RSA-export          | 40-bit RC4      | MD5 hash                         |
| RSA_EXPORT_WITH_DES40_CBC_SHA   | RSA-export          | 40-bit DES/CBC  | SHA hash                         |
| RSA_EXPORT1024_WITH_DES_CBC_SHA | RSA 1024 bit export | DES/CBC         | SHA hash                         |
| RSA_EXPORT1024_WITH_RC4_56_MD5  | RSA 1024 bit export | 56-bit RC4      | MD5 hash                         |
| RSA_EXPORT1024_WITH_RC4_56_SHA  | RSA 1024 bit export | 56-bit RC4      | SHA hash                         |

**NOTE:** Cipher suites that have “export” in the title are intended for use outside of the United States and might have encryption algorithms with limited key sizes.

## Server Authentication

Implicit trust between the client and the device (because the client accepts the certificate generated by the device) is an important aspect of SSL proxy. It is extremely important that server authentication is not compromised; however, in reality, self-signed certificates and certificates with anomalies are in abundance. Anomalies can include expired certificates, instances of common name not matching a domain name, and so forth. Server authentication is governed by setting the **ignore-server-auth-failure** option in the SSL proxy.

- By default, the **ignore-server-auth-failure** option is not defined as an action in the SSL proxy profile, and the following occurs:
  - If authentication succeeds, a new certificate is generated by replacing the keys and changing the issuer name to the issuer name that is configured in the root CA certificate in the proxy profile.
  - If authentication fails, the connection is dropped.
- If the **ignore-server-auth-failure** option is defined as an action in the SSL proxy profile, the following occurs:

- If the certificate is self-signed, a new certificate is generated by replacing the keys only. The issuer name is not changed. This ensures that the client browser displays a warning that the certificate is not valid.
- If the certificate has expired or if the common name does not match the domain name, a new certificate is generated by replacing the keys and changing the issuer name to `SSL-PROXY: DUMMY_CERT:GENERATED DUE TO SRVR AUTH FAILURE`. This ensures that the client browser displays a warning that the certificate is not valid.

## Trusted CA List

SSL proxy ensures secure transmission of data between a client and a server. Before establishing a secure connection, SSL proxy checks CA certificates to verify signatures on server certificates. For this reason, a reasonable list of trusted CA certificates is required to effectively authenticate servers.

Junos OS provides the following options for trusted CA certificates:

- Loading the default trusted CA list—Junos OS provides a default list of certificates that contains well-known trusted CA certificates similar to the default certificates used by most common browsers. Without these default certificates, browsers would not be able to validate the identity of most websites and would mark them as untrusted sites.

The Junos OS package contains the default CA certificates as a PEM file (for example, `trusted_CA.pem`). After you download the package and reboot your device, you can easily load the default certificates on your system using a CLI command.

We recommend you load the default trusted CA list if you want to trust the same CA certificates as common browsers and avoid importing CA certificates manually.

- Importing the trusted CA list manually—You can import your own trusted CA certificates using the Public Key Infrastructure (PKI). The PKI helps verify and authenticate the validity of the trusted CA certificates. You create CA profile groups that include trusted CA certificates, then import the group on your device for server authentication.
- Ignoring server authentication—You can use the **`ignore-server-auth-failure`** option to ignore server authentication completely. In this case, SSL proxy ignores errors encountered during the server certificate verification process (such as CA signature verification failure, self-signed certificates, and certificate expiry).

We do not recommend this option for authentication, because configuring it results in websites not being authenticated at all. However, you can use this option to effectively identify the root cause for dropped SSL sessions. See [“Enabling Debugging and Tracing for SSL Proxy” on page 544](#).

## Root CA

In a public key infrastructure (PKI) hierarchy, the root CA is at the top of the trust path. The root CA identifies the server certificate as a trusted certificate.

## Client Authentication

Currently, client authentication is not supported in SSL proxy. If a server requests client authentication, a warning is issued that a certificate is not available. The warning lets the server determine whether to continue or to exit.

## Whitelists

Because SSL encryption and decryption are complicated and expensive procedures, network administrators can selectively bypass SSL proxy processing for some sessions. Such sessions mostly include connections and transactions with trusted servers or domains with which network administrators are very familiar. There are also legal requirements to exempt financial and banking sites. Such exemptions are achieved by configuring the IP addresses or domain names of the servers under whitelists.

## Dynamic Resolution of Domain Names

The IP addresses associated with domain names are dynamic and can change at any time. Whenever a domain IP address changes, it is propagated to the SSL proxy configuration (similar to what is done in the firewall policy configuration).

## Session Resumption

An SSL session refers to the set of parameters and encryption keys created by performing a full handshake. A connection is the conversation or active data transfer that occurs within the session. The computational overhead of a complete SSL handshake and generation of master keys is considerable. In short-lived sessions, the time taken for the SSL handshake can be more than the time for data transfer.

To improve throughput and still maintain an appropriate level of security, SSL session resumption provides a session caching mechanism so that session information, such as the pre-master secret key and agreed-upon ciphers, can be cached for both the client and server. The cached information is identified by a session ID. In subsequent connections both parties agree to use the session ID to retrieve the information rather than create a new pre-master secret key. Session resumption shortens the handshake process and accelerates SSL transactions.

## Session Renegotiation

After a session is created and SSL tunnel transport has been established, a change in SSL parameters requires renegotiation. SSL proxy supports both secure (RFC 5746) and nonsecure (TLS v1.0, TLS v1.1, and TLS v1.2) renegotiation. When session resumption is enabled, session renegotiation is useful in the following situations:

- Cipher keys need to be refreshed after a prolonged SSL session.
- Stronger ciphers need to be applied for a more secure connection.

A change in an SSL proxy profile that modifies a certificate, cipher strength, or trusted CA list flushes cache entries when the modified policy is committed. When a session is resumed, the SSL parameters associated with its session ID are retrieved from the cache. If the SSL proxy profile is not altered, cache entries corresponding to that profile are not

flushed and the session continues. If the cache has been flushed, however, a full handshake must be performed to establish the new SSL parameters. (There is no impact to non-SSL sessions.)

## SSL Proxy Logs

When logging is enabled in an SSL proxy profile, SSL proxy can generate the messages shown in [Table 35](#).

**Table 35: SSL Proxy Logs**

| Syslog Type                 | Description                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------|
| SSL_PROXY_SSL_SESSION_DROP  | Logs generated when a session is dropped by SSL proxy.                                             |
| SSL_PROXY_SSL_SESSION_ALLOW | Logs generated when a session is processed by SSL proxy even after encountering some minor errors. |
| SSL_PROXY_SESSION_IGNORE    | Logs generated if non-SSL sessions are initially mistaken as SSL sessions.                         |
| SSL_PROXY_SESSION_WHITELIST | Logs generated when a session is whitelisted.                                                      |
| SSL_PROXY_ERROR             | Logs used for reporting errors.                                                                    |
| SSL_PROXY_WARNING           | Logs used for reporting warnings.                                                                  |
| SSL_PROXY_INFO              | Logs used for reporting general information.                                                       |

All logs contain similar information as shown in the following example (actual order of appearance):

```
logical-system-name, session-id, source-ip-address, source-port,
destination-ip-address, destination-port,
nat-source-ip-address, nat-source-port, nat-destination-ip-address,
nat-destination-port, proxy profile name, source-zone-name,
source-interface-name, destination-zone-name, destination-interface-name, message
```

The **message** field contains the reason for the log generation. One of three prefixes shown in [Table 36](#) identifies the source of the message. Other fields are descriptively labeled.

**Table 36: SSL Proxy Log Prefixes**

| Prefix            | Description                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| system            | Logs generated due to errors related to the device or an action taken as part of the SSL proxy profile. Most logs fall into this category. |
| openssl error     | Logs generated during the handshaking process if an error is detected by the openssl library.                                              |
| certificate error | Logs generated during the handshaking process if an error is detected in the certificate (x509 related errors).                            |

Sample logs:

```
Jun 1 05:11:13 4.0.0.254 junos-ssl-proxy: SSL_PROXY_SSL_SESSION_DROP: 1sys:root
23 <4.0.0.1/35090->5.0.0.1/443> NAT:< 4.0.0.1/35090->5.0.0.1/443 >
ssl-inspect-profile <untrust:ge-0/0/0.0->trust:ge-0/0/1.0> message:certificate
error: self signed certificate
```

**NOTE:** These logs capture sessions that are dropped by SSL proxy, not sessions that are marked by other modules that also use SSL proxy services.

For `SSL_PROXY_SESSION_WHITELIST` messages, an additional **host** field is included after the **session-id** and contains the IP address of the server or domain that has been whitelisted.

```
Jun 1 05:25:36 4.0.0.254 junos-ssl-proxy: SSL_PROXY_SESSION_WHITELIST: 1sys:root
24 host:5.0.0.1 <4.0.0.1/35090->5.0.0.1/443> NAT:< 4.0.0.1/35090->5.0.0.1/443
> ssl-inspect-profile <untrust:ge-0/0/0.0->trust:ge-0/0/1.0> message:system:
session whitelisted
```

## Leveraging Dynamic Application Identification

SSL proxy uses application identification services to dynamically detect if a particular session is SSL encrypted. SSL proxies are allowed only if a session is SSL encrypted. The following rules apply for a session:

- Session is marked **Encrypted=Yes** in the application system cache. If the session is marked **Encrypted=Yes**, it indicates that the final match from application identification for that session is SSL encrypted, and SSL proxy transitions to a state where proxy functionality can be initiated.
- Session is marked **Encrypted=No** in the application system cache. If a non-SSL entry is found in the application system cache, it indicates that the final match from application identification for that session is non-SSL and SSL proxy ignores the session.
- An entry is not found in the application system cache. This can happen on the first session, or when the application system cache has been cleaned or has expired. In such a scenario, SSL proxy cannot wait for the final match (requires traffic in both directions). In SSL proxy, traffic in reverse direction happens only if SSL proxy has initiated an SSL handshake. Initially, for such a scenario SSL proxy tries to leverage prematch or aggressive match results from application identification, and if the results indicate SSL, SSL proxy will go ahead with the handshake.
- Application identification fails due to resource constraints and other errors. Whenever the result from application identification is not available, SSL proxy will assume static port binding and will try to initiate SSL handshake on the session. This will succeed for actual SSL sessions, but it will result in dropped sessions for non SSL sessions.

## Logical Systems Support

It is possible to enable SSL proxy on firewall policies that are configured using logical systems; however, note the following limitations:

- The “services” category is currently not supported in logical systems configuration. Because SSL proxy is under “services,” you cannot configure SSL proxy profiles on a per-logical-system basis.
- Because proxy profiles configured at a global level (within “services ssl proxy”) are visible across logical system configurations, it is possible to configure proxy profiles at a global level and then attach them to the firewall policies of one or more logical systems.

## Limitations

The following limitations currently apply to SSL proxy:

- Only TLS v1.0, TLS v1.1, and TLS v1.2 are supported.

**NOTE:** On all high-end SRX Series devices, for a particular session, the SSL proxy is only enabled if a relevant feature related to SSL traffic is also enabled. Features that are related to SSL traffic are IDP, application identification, application firewall, and application tracking. If none of the above listed features are active on a session, the SSL proxy bypasses the session and logs are not generated in this scenario

**NOTE:** On all SRX Series devices, the current SSL proxy implementation has the following connectivity limitations:

- The SSLv2 protocol is not supported. SSL sessions using SSLv2 are dropped
- SSL sessions where client certificate authentication is mandatory are dropped
- SSL sessions where renegotiation is requested are dropped

## Application Firewall, IDP, and Application Tracking with SSL Proxy Overview

With the implementation of SSL proxy, AppID can identify applications encrypted in SSL. SSL proxy can be enabled as an application service in a regular firewall policy rule. Intrusion Detection and Prevention (IDP), application firewall (AppFW), and application tracking (AppTrack) services can use the decrypted content from SSL proxy. On the SSL payload, IDP can inspect attacks and anomalies; for example, HTTP chunk length overflow on HTTPS. On encrypted applications, such as Facebook, AppFW can enforce policies and

AppTrack (when configured in the from and to zones) can report logging issues based on dynamic applications.

**NOTE:** If none of the services (AppFW, IDP, or AppTrack) are configured, then SSL proxy services are bypassed even if an SSL proxy is attached to a firewall policy.

**NOTE:** The IDP module will not perform an SSL inspection on a session if an SSL proxy is enabled for that session. That is, if both SSL inspection and SSL proxy are enabled on a session, SSL proxy will always take precedence.

---

## Working with the Certificate Revocation Lists for SSL Proxy

---

A certificate issued by a certificate authority (CA) is supposed to be valid until the expiration of the validity period. In the normal course of business, a CA can revoke an issued certificate. A certificate is revoked if it is suspected that the certificate has been compromised. Some of the examples are:

- Unspecified (no particular reason is given).
- Private key associated with the certificate was compromised.
- Private key associated with the CA that issued the certificate was compromised.
- The owner of the certificate is no longer affiliated with the issuer of the certificate and does not have rights to access the certificate or does not require it any longer.
- Another certificate replaces the original certificate.
- The CA that issued the certificate has ceased to operate.
- The certificate is on hold pending further action. It is treated as revoked but might be accepted in the future.

Once the CA determines to revoke a certificate, it publishes the information by some means so that the enduser certificate can use the information to validate a certificate. The CA can publish this information using certificate revocation list (CRL).

The CRL contains the list of digital certificates that have been canceled before their expiration date. When a participating device uses a digital certificate, it checks the certificate signature and validity. It also acquires the most recently issued CRL and checks that the certificate serial number is not on that CRL. By default, CRL verification is enabled on SSL proxy profile.

CRL validation on SRX Series device involves checking for revoked certificates from servers. You can enable or disable the CRL validation to meet your specific security requirements.

- [Disabling CRL Verification on page 533](#)
- [Allowing Sessions When CRL Information Is Not Available on page 533](#)
- [Allowing Sessions When CRL Status Is Unknown on page 533](#)

## Disabling CRL Verification

In order to enhance security, the certificate revocation checking feature has been enabled by default on SRX Series devices on any SSL proxy profile. You can enable or disable the CRL validation to meet your specific security requirements.

- To disable CRL verification:

```
[edit]
user@host# set services ssl proxy profile profile-name actions crl disable
```

You can reenable CRL validation by using the **delete services ssl proxy profile *profile-name* actions **crl disable**** command.

## Allowing Sessions When CRL Information Is Not Available

Sometimes CRL information might not be available because of various reasons. For example:

- CRL download failed and the PKI daemon did not or could not fetch the CRL from the CA.
- The CRL path was not available from the configuration and it is not present in the root or intermediate certificate, or no URL was configured.

You can allow or drop the sessions when a CRL information is not available.

- To ensure that the sessions are not dropped for any reason when CRL information is not available:

```
[edit]
user@host# edit set services ssl proxy profile profile-name actions crl if-not-present allow
```

- To drop the sessions when CRL information is not available:

```
[edit]
user@host# edit set services ssl proxy profile profile-name actions crl if-not-present drop
```

## Allowing Sessions When CRL Status Is Unknown

You can configure how an SRX Series device will respond when updated CRL information is not available, and the server certificate that is currently offered is not known to be revoked from a previous query. Certificates are presumed not to be revoked, by default, which means they are valid, and a temporary failure to obtain a CRL does not

automatically result in an SSL handshake failure. By default, sessions are allowed if CRL status is unknown.

You can configure an SRX Series device to accept a certificate without a reliable confirmation available on the revocation status.

- To allow the sessions when a certificate is revoked and the revocation reason is on hold:

[edit]

```
user@host# edit set services ssl proxy profile profile-name actions crl
ignore-hold-instruction-code
```

## Configuring SSL Proxy

SSL proxy works transparently between the client and the server. All requests from a client first go to the proxy server; the proxy server evaluates the request, and if the request is valid, forwards the request to the outbound side. Similarly, inbound requests are also evaluated by the proxy server. Both client and server interpret that they are communicating with each other; however, it is the SSL proxy that functions between the two.

SSL proxies provide encryption and decryption by residing between the server and the client. Because SSL proxies are hidden from both the server and the client, secret keys are shared between the two to decrypt the SSL traffic. Proxies are known as *forward proxies* because proxy servers are used to hide any detailed information from the servers.

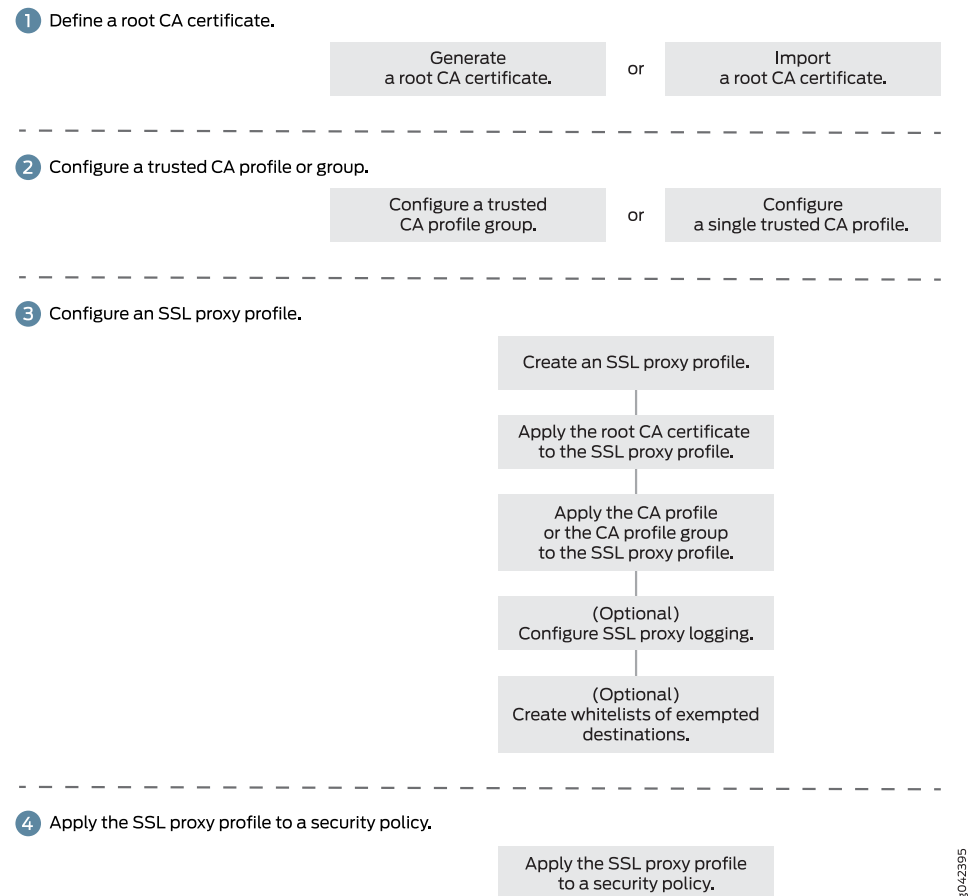

Integrity, confidentiality, and authenticity of traffic are validated through PKI, which includes digital certificates issued by the CA, certificate validity and expiration dates, details about the certificate owner and issuer, and security policies.

## SSL Proxy Configuration Overview

Figure 31 displays an overview of how SSL proxy is configured. It includes some required steps, such as configuring the root CA certificate, loading a CA profile group, and applying an SSL proxy profile to a security policy, and some optional steps, such as creating whitelists and SSL proxy logging.

Figure 31: SSL Proxy Configuration Overview

8042395

## Configuring a Root CA Certificate

A CA can issue multiple certificates in the form of a tree structure. A root certificate is the topmost certificate of the tree, the private key of which is used to *sign* other certificates. All certificates immediately below the root certificate inherit the signature or trustworthiness of the root certificate. This is somewhat like the *notarizing* of an identity.

You can configure a root CA certificate by first obtaining a root CA certificate (by either generating a self-signed one or importing one) and then applying it to an SSL proxy profile. There are two ways you can obtain a root CA certificate—by using the Junos OS CLI on an SRX Series device or by using OpenSSL on a UNIX device.

To generate a root CA certificate using the Junos OS CLI, follow these steps on an SRX Series device:

1. From operational mode, generate a PKI public/private key pair for a local digital certificate.

```
user@host>request security pki generate-key-pair certificate-id certificate-id size size
type type
```

2. From operational mode, define a self-signed certificate. Specify certificate details such as the certificate identifier (generated in the previous step), a fully qualified domain name for the certificate, and an e-mail address of the entity owning the certificate. You can also specify other information such as the common name and the organization involved. By configuring the **add-ca-constraint** option, you make sure that the certificate can be used for signing other certificates.

```
user@host>request security pki local-certificate generate-self-signed certificate-id
certificate-id domain-name domain-name subject subject email email-id
add-ca-constraint
```

3. From configuration mode, apply the loaded certificate as root-ca in the SSL proxy profile.

```
[edit]
user@host# set services ssl proxy profile profile-name root-ca certificate-id
```

4. Import the root CA as a trusted CA into client browsers. This is required for the client browsers to trust the certificates signed by the SRX Series device. See [“Importing a Root CA Certificate into a Browser” on page 539](#).

To generate a root CA certificate using OpenSSL, follow these steps on a UNIX device:

1. Create folders **keys** and **certs**.

```
mkdir /etc/pki/tls/keys
mkdir /etc/pki/tls/certs
```

2. Change to the **openssl** directory.

```
cd /etc/pki/tls
```

3. Create a CA certificate key. The following command creates an RSA key using the 3DES encryption named **ca.key** that is 2048 in length. You also need to enter a password that is used to encrypt the private key. This is critical to security if the key is lost because it will still be encrypted.

```
% openssl genrsa -des3 -out keys/ssl-proxy-ca.key 2048
```

4. Create a CA certificate based on the CA private key (created in the previous step). The expiration date for this certificate is 3 years or 1095 days. However, you can set it to a different value. When creating the certificate, you need to enter the password and the certificate information that includes distinguished name (DN), country name, and so forth.

```
% openssl req -new -x509 -days 1095 -key keys/ssl-proxy-ca.key -out
certs/ssl-inspect-ca.cer
```

5. Import the CA private and public keys into the SRX Series device. Copy the **ca.key** and **ca.cer** keys to the **/var/tmp** directory on the SRX Series device. You can copy using SCP, or open the files and copy them into “vi” on the SRX Series device to create new files.

```
user@host> request security pki local-certificate load certificate-id ssl-inspect-ca key
/var/tmp/ssl-inspect-ca.key filename /var/tmp/ssl-inspect-ca.cer passphrase
password
```

6. From configuration mode, apply the loaded certificate as root-ca in the SSL proxy profile.

```
[edit]
user@host# set services ssl proxy profile ssl-inspect-profile root-ca ssl-inspect-ca
```

7. Import the root CA as a trusted CA into client browsers. This is required for the client browsers to trust the certificates signed by the SRX Series device. See [“Importing a Root CA Certificate into a Browser” on page 539](#).

## Configuring a CA Profile Group

The CA profile defines the certificate information to be used for authentication. It includes the public key that SSL proxy uses when generating a new certificate. Junos OS allows you to create a group of CA profiles and load multiple certificates in one action, view information about all certificates in a group, and delete unwanted CA groups.

You can load a group of CA profiles by obtaining a list of trusted CA certificates, defining a CA group, and attaching the CA group to the SSL proxy profile.

1. Obtain a list of trusted CA certificates by following one of these methods:
  - Junos OS provides a default list of trusted CA certificates that you can load on your system using the **default** command option. The Junos OS package contains the default CA certificates as a PEM file (for example, **trusted\_CA.pem**). After you download the Junos OS package and reboot your device, the default certificates are available on your system.

From operational mode, load the default trusted CA certificates (the group name identifies the CA profile group):

```
user@host> request security pki ca-certificate ca-profile-group load ca-group-name
group-name filename default
```

- Alternatively, you can define your own list of trusted CA certificates and import them on your system. You get the list of trusted CAs in a single PEM file (for example **IE-all.pem**) and save the PEM file in a specific location (for example, **/var/tmp**). See [Knowledge Base Article KB23144](#).

From operational mode, load the trusted list to the device (the group name identifies the CA profile group):

```
user@host> request security pki ca-certificate ca-profile-group load ca-group-name
group-name filename /var/tmp/IE-all.pem
```

2. From configuration mode, attach the CA profile group to the SSL proxy profile. You can attach one or all CA profile groups at a time:

- To attach one CA profile group (the group name identifies the CA profile group):

```
[edit]
user@host# set services ssl proxy profile profile-name trusted-ca group-name
```

- To attach all CA profile groups:

```
[edit]
user@host# set services ssl proxy profile profile-name trusted-ca all
```

You can easily display information about all certificates in a CA profile group:

```
user@host> show security pki ca-certificates ca-profile-group group-name
```

You can delete a CA profile group. Remember that deleting a CA profile group deletes all certificates that belong to that group:

```
user@host> clear security pki ca-certificates ca-profile-group group-name
```

## Configuring a Trusted CA Profile

Typically, you import a list of trusted CA certificates by creating a group of CA profiles. However, you can also configure a single CA profile (containing one or multiple certificates) and import it using PKI commands. This section shows you how to import a trusted CA certificate from your browser's certificate store into your SRX Series device. The certificate that is configured under the trusted CA is loaded using the PKI commands and is used for validating the server certificate chain.

1. From configuration mode, configure the CA profile used for loading the certificate.

```
[edit]
user@host# set security pki ca-profile profile-name ca-identity ca-identity
```

2. From operational mode, load the certificate using PKI commands.

```
user@host> request security pki ca-certificate load ca-profile profile-name filename
filename
```

3. From configuration mode, disable the revocation check.

**NOTE:** CRL checks are not supported; we recommend that you disable revocation checks.

```
[edit]
user@host# set security pki ca-profile profile-name ca-identity ca-identity
revocation-check disable
```

4. From configuration mode, configure the loaded certificate as a trusted CA in the SSL proxy profile.

```
[edit]
user@host# set services ssl proxy profile ssl-proxy-profile-name trusted-ca
ca-profile-name
```

**NOTE:** More than one trusted CA can be configured for a profile.

5. (Optional) If you have multiple trusted CA certificates, you do not have to specify each trusted CA separately. You can load *all* the trusted CA certificates using the following command from configuration mode.

```
[edit]
user@host# set services ssl proxy profile ssl-proxy-profile-name trusted-ca all
```

**NOTE:** Alternatively, you can import a set of trusted CAs from your browser into the SRX Series device. See [Knowledge Base article KB23144](#).

## Importing a Root CA Certificate into a Browser

In order to have your browser or system automatically trust all certificates signed by the root CA configured in the SSL proxy profile, you must instruct your platform or browser to trust the CA root certificate.

To import a root CA certificate:

1. Generate a PEM format file for the configured root CA.

```
request security pki local-certificate export certificate-id root-ca type pem filename
path/file-name.pem
```

2. Import a root CA certificate into a browser.

From Internet Explorer (version 8.0):

- a. From the Tools menu, choose **Internet Options**.
- b. On the Content tab, click **Certificates**.
- c. Select the **Trusted Root Certification Authorities** tab and click **Import**.
- d. In the Certificate Import Wizard, navigate to the required root CA certificate and select it.

From Firefox (version 39.0):

- a. From the Tools menu, choose **Options**.
- b. From the Advanced menu, select the **Certificates** tab and click **View Certificate**.
- c. In the Certificate Manager window, select the **Authorities** tab and click **Import**.
- d. Navigate to the required root CA certificate and select it.

From Google Chrome (45.0):

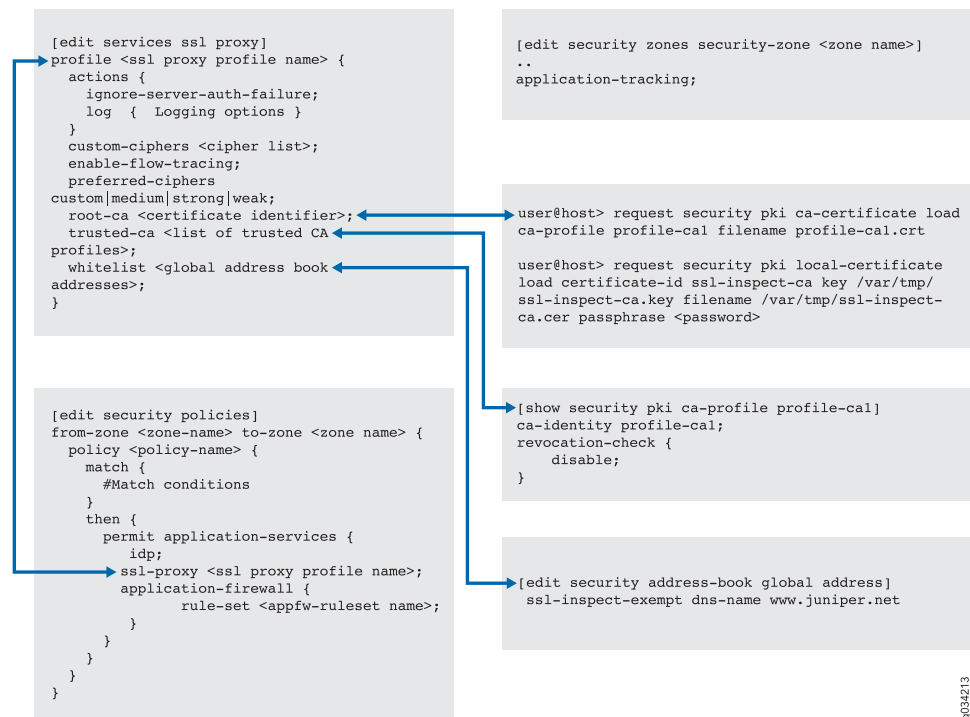

- a. From the Settings menu, choose **Show Advanced Settings**.
- b. From the Advanced menu, select the **Certificates** tab and click **View Certificate**.
- c. Under HTTPS/SSL, click **Manage Certificates**.

- d. In the Certificate window, select **Trusted Root Certification Authorities** and click **Import**.
- e. In the Certificate Import Wizard, navigate to the required root CA certificate and select it.

## Applying an SSL Proxy Profile to a Security Policy

SSL proxy is enabled as an application service within a security policy. In a security policy, you specify the traffic that you want the SSL proxy enabled on as match criteria and then specify the SSL proxy CA profile to be applied to the traffic. [Figure 32](#) displays a graphical view of SSL proxy profile and security policy configuration.

**Figure 32: Applying an SSL Proxy Profile to a Security Policy**

9034213

To enable SSL proxy in a security policy:

1. Create a security policy and specify the match criteria for the policy. As match criteria, specify the traffic for which you want to enable SSL proxy.

```
[edit]
user@host# set security policies from-zone trust to-zone untrust policy policy-name
match source-address source-address
user@host# set security policies from-zone trust to-zone untrust policy policy-name
match destination-address destination-address
user@host# set security policies from-zone trust to-zone untrust policy policy-name
match application application
```

2. Apply the SSL proxy profile to the security policy.

```
[edit]
```

```
user@host# set security policies from-zone trust to-zone untrust policy policy-name
then permit application-services ssl-proxy profile-name profile-name
```

## Creating a Whitelist of Exempted Destinations

SSL encryption and decryption are complicated and expensive procedures. You can selectively bypass SSL proxy processing for some sessions by configuring a whitelist. Typically, you would configure the whitelist to include trusted servers or domains with which you are very familiar. You might also include financial and banking sites that you are legally required to include.

Whitelists include addresses that you want to exempt from undergoing SSL proxy processing. For example, if you want to exempt all sessions to `www.example.net` then you would include it in the whitelist. To configure the whitelist, you specify the domain that you want to exempt in an address book and then configure the address in the SSL proxy profile.

1. Configure the domain in the address book.

```
[edit]
user@host# set security address-book global address address dns-name
www.example.net
```

2. Specify the global address book address in the SSL proxy profile.

```
[edit]
user@host# set services ssl proxy profile profile-name whitelist address
```

Whitelist addresses and address sets are created under the global address book. The following type of addresses (from the global address book) are supported:

- IPv4 addresses (plain text). For example:

```
[edit]
user@host# set security address-book global address address-name ipv4-prefix
```

- IPv4 address range. For example:

```
[edit]
user@host# set security address-book global address address-name range-address
range-low to range-high
```

- IPv4 wildcard. For example:

```
[edit]
user@host# set security address-book global address address-name wildcard-address
a.d.r/netmask
```

Noncontiguous netmasks are not supported. For example:

- 5.0.0.1/255.255.0.0 is supported.
- 5.0.0.1/255.255.0.255 is NOT supported.
- IPv6 address (plain text). For example:

```
[edit]
user@host# set security address-book global address address-name ipv6-prefix
```

- DNS name. For example:

```
[edit]
user@host# set security address-book global address address-name dns-name
domain-name
```

- Translated IP addresses. Sessions are whitelisted based on the actual IP address and not on the translated IP address. Because of this, in the whitelist configuration of the SSL proxy profile, the actual IP address should be provided and not the translated IP addresses.

For example, consider a destination NAT rule that translates destination IP address 20.20.20.20 to 5.0.0.1 using the following commands:

```
[edit]
user@host# set security nat destination pool d1 address 5.0.0.1/32
user@host# set security nat destination rule-set dst-nat rule r1 match
destination-address 20.20.20.20/32
user@host# set security nat destination rule-set dst-nat rule r1 then destination-nat
pool d1
```

In this scenario, to exempt a session from SSL proxy inspection, the following IP address should be added to the whitelist:

```
[edit]
user@host# set security address-book global address ssl-proxy-exempted-addr
20.20.20.20/32
user@host# set services ssl proxy profile ssl-inspect-profile whitelist
ssl-proxy-exempted-addr
```

## Configuring SSL Proxy Logging

When configuring SSL proxy, you can choose to set the option to receive some or all of the logs. SSL proxy logs contain the logical system name, SSL proxy whitelists, policy information, SSL proxy information, and other information that helps you troubleshoot when there is an error.

You can configure logging of *all* or specific events, such as error, warning, and information events. You can also configure logging of sessions that are whitelisted, dropped, ignored, or allowed after an error occurs.

```
[edit]
user@host# set services ssl proxy profile profile-name actions log all
user@host# set services ssl proxy profile profile-name actions log sessions-whitelisted
user@host# set services ssl proxy profile profile-name actions log sessions-allowed
user@host# set services ssl proxy profile profile-name actions log errors
```

You can use **enable-flow-tracing** option to enable debug tracing.

## Configuring Ciphers

You can configure the following ciphers for an SSL proxy profile:

- **preferred-ciphers**—Preferred ciphers allow you to define an SSL cipher that can be used with acceptable key strength. Ciphers are divided in three categories depending on their key strength: strong, medium, or weak.

- **custom-ciphers**—Custom ciphers allow you to define your own cipher list. If you do not want to use one of the three categories, you can select ciphers from each of the categories to form a custom cipher set. To configure custom ciphers, you must set **preferred-ciphers** to custom.

The following example shows how to create a custom cipher. In this example, you set **preferred-cipher** to custom and add the cipher list (rsa-with-3des-ede-cbc-sha and rsa-with-aes-256-cbc-sha):

```
set services ssl proxy profile profile-name preferred-ciphers custom
set services ssl proxy profile profile-name custom-ciphers rsa-with-3des-ede-cbc-sha
set services ssl proxy profile profile-name custom-ciphers rsa-with-aes-256-cbc-sha
```

## Exporting Certificates to a Specified Location

When a self-signed certificate is generated using a PKI command, the newly generated certificate is stored in a predefined location (**var/db/certs/common/local**).

Use the following command to export the certificate to a specific location (within the device). You can specify the certificate ID, the filename, and the type of file format (DER/PEM):

```
user@host> request security pki local-certificate export certificate-id certificate-id
user@host> request security pki local-certificate export filename filename
user@host> request security pki local-certificate export type der
```

## Ignoring Server Authentication

Junos OS allows you to configure an option to ignore server authentication completely. If you configure your system to ignore authentication, then any errors encountered during server certificate verification at the time of the SSL handshake are ignored. Commonly ignored errors include the inability to verify CA signature, incorrect certificate expiration dates, and so forth. If this option is not set, all the sessions where the server sends self-signed certificates are dropped when errors are encountered.

We do not recommend using this option for authentication because configuring it results in websites not being authenticated at all. However, you can use this option to effectively identify the root cause of dropped SSL sessions.

From configuration mode, specify to ignore server authentication:

```
[edit]
user@host# set services ssl proxy profile profile-name actions ignore-server-auth-failure
```

## Enabling Debugging and Tracing for SSL Proxy

Debug tracing on both Routing Engine and the Packet Forwarding Engine can be enabled for SSL proxy by setting the following configuration:

```
user@host# set services ssl traceoptions
```

Table 37 shows the supported levels for trace options.

**Table 37: Trace Levels**

| Cause Type | Description                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Brief      | Only error traces on both the Routing Engine and the Packet Forwarding Engine.                                                                                                               |
| Detail     | Packet Forwarding Engine—Only event details up to the handshake should be traced.<br><br>Routing Engine—Traces related to commit. No periodic traces on the Routing Engine will be available |
| Extensive  | Packet Forwarding Engine—Data transfer summary available.<br><br>Routing Engine—Traces related to commit (more extensive). No periodic traces on the Routing Engine will be available.       |
| Verbose    | All traces are available.                                                                                                                                                                    |

Table 38 shows the flags that are supported.

**Table 38: Supported Flags in Trace**

| Cause Type        | Description                                                                |
|-------------------|----------------------------------------------------------------------------|
| cli-configuration | Configuration-related traces only.                                         |
| initiation        | Enable tracing on the SSL-I plug-in.                                       |
| proxy             | Enable tracing on the SSL-Proxy-Policy plug-in.                            |
| termination       | Enable tracing on the SSL-T plug-in.                                       |
| selected-profile  | Enable tracing only for profiles that have <b>enable-flow-tracing</b> set. |

You can enable logs in the SSL proxy profile to get to the root cause for the drop. The following errors are some of the most common:

- Server certification validation error. Check the trusted CA configuration to verify your configuration.
- System failures such as memory allocation failures.
- Ciphers do not match.
- SSL versions do not match.

- SSL options are not supported.
- Root CA has expired. You need to load a new root CA.

You can enable the **ignore-server-auth-failure** option in the SSL proxy profile to ensure that certificate validation, root CA expiration dates, and other such issues are ignored. If sessions are inspected after the **ignore-server-auth-failure** option is enabled, the problem is localized.

## Application Firewall Overview

---

Traditionally, applications such as HTTP, SMTP, and DNS use well-known standard ports and are easily controlled by a stateful firewall. However, it is possible to run these applications on any port as long as the client and server are using the same protocol as the well-known ports.

Evasive applications could remain undetected with a standard firewall that functions at Layer 3 or Layer 4 by transmitting other protocols over these well-known ports that are usually open by a firewall. AppFW enforces protocol and policy control at Layer 7. It inspects the actual content of the payload and ensures that it conforms to the policy, rather than identifying the application based on Layer 3 and Layer 4 information.

Because of the growing popularity and pervasiveness of Web-based applications and the movement away from traditional, full client-based applications, more and more traffic is being transmitted over HTTP. An application firewall identifies not only the HTTP protocol but also any application running on top of it, letting you enforce security policy at the application level. For example, an application firewall rule set could block HTTP traffic from Facebook but allow Web access to HTTP traffic from MS Outlook.

As a security administrator, you implement an application firewall by:

- Defining an application firewall rule set.
- Creating rules for the rule set that permit, reject, or deny traffic based on the application ID.
- Configuring a security policy that invokes the application firewall service and specifies the rule set to be applied to permitted traffic that matches the security policy.

If the traffic issues from a dynamic application for which there is a rule in the rule set, the matching rule's action is applied to the traffic.

**NOTE:** You can define multiple application firewall rule sets as part of your overall application firewall. However, for each individual security policy that you configure to invoke the AppSecure application firewall service, you can refer to only one rule set.

This topic includes the following sections:

- [Understanding Application Firewall Rule Sets on page 548](#)
- [Configuring an Application Firewall Within a Security Policy on page 549](#)
- [Application Group Support for Application Firewall on page 549](#)
- [Redirecting Users on page 550](#)
- [Session Logging for Application Firewalls on page 551](#)
- [Application Firewall Support in Chassis Cluster on page 551](#)

## Understanding Application Firewall Rule Sets

An application firewall permits, rejects, or denies traffic based on the application of the traffic. The firewall consists of one or more rule sets with rules that specify match criteria, including dynamic applications, and the action to be taken for matching traffic.

An application firewall rule set consists of:

- The name of the rule set
- One or more rules
- A single default rule

Each rule defines dynamic applications to permit, reject, or deny. Each rule consists of:

- The name of the rule
- A list of dynamic applications to be used as match criteria
- The action to take for any traffic that matches one of the specified applications
  - Reject—Notify the client, drop the traffic, close the session, and log the event.
  - Deny—Drop the traffic, close the session, and log the event.
  - Permit—Permit the traffic.

The default rule defines the action to be taken for any traffic that does not match one of the rules. An application firewall rule set must contain a default rule.

There is no limit to the number of dynamic applications in a rule or to the number of rules in a rule set. However, there is a limit to the overall number of rule sets and rules.

The `junos:UNKNOWN` keyword is reserved for unknown dynamic applications. In the following cases, the application ID is set to `junos:UNKNOWN`:

- The traffic does not match an application signature in the database.

- The system encounters an error when identifying the application.
- The session fails over to another device.

Traffic with an application ID of `junos:UNKNOWN` matches a rule with a dynamic application of `junos:UNKNOWN`. If there is no rule defined for `junos:UNKNOWN`, the default rule is applied.

## Configuring an Application Firewall Within a Security Policy

An application firewall is invoked using the **then permit** statement of the security policy.

Any traffic denied or rejected by the security policy based on Layer 3 or Layer 4 criteria is dropped immediately. Traffic permitted by the security policy is further assessed by the application firewall at Layer 7 based on its application ID.

The following sample policy, `outbound-traffic`, permits matching HTTP traffic, and invokes application services and an application firewall. The rule set, `unknown-traffic`, permits, denies, or rejects, traffic based on its match criteria.

```
[edit security policies from-zone trust to-zone untrust outbound-traffic]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application junos-http
user@host# set then permit application-services application-firewall rule-set
unknown-traffic
```

Traffic is processed in the following sequence:

1. Match the zone pair specified in the policy.
2. When specified, match the source and destination IP addresses, ports, and application type.
3. Apply the security policy action to matching traffic.
  - Reject—Notify the client, drop the traffic, and log the event.
  - Deny—Drop the traffic, and log the event.
  - Permit—Open a session, log the event, and apply services as specified.
    - Invoke application services to retrieve the application ID for the traffic.
    - Apply the specified application firewall rule set.

**NOTE:** All IP fragmented packets received on the SRX Series device must be reassembled before forwarding.

## Application Group Support for Application Firewall

Application group support associates related applications under a single name for simplified, consistent reuse when using any application services. As the predefined signature database changes, the content of a predefined application group can be

modified to include new signatures without affecting existing firewall rules. When you define application firewall rules, you can specify dynamic application groups as match criteria.

**NOTE:** An application group can contain applications and groups simultaneously. It is possible to assign one application to multiple groups. There is no limit to the number of dynamic application groups contained in one rule.

For information on creating or listing application groups, see [“Customizing Application Groups for Junos OS Application Identification” on page 509](#).

**NOTE:** On all SRX Series devices, when ALG is enabled, application identification includes the ALG result to identify the application of the control sessions. Application firewall permits ALG data sessions whenever control sessions are permitted. If the control session is denied, there will be no data sessions. When ALG is disabled, application identification relies on its signatures to identify the application of the control and data sessions. If a signature match is not found, the application is considered unknown. Application firewall handles applications based on the application identification result.

## Redirecting Users

Although drop and reject actions are logged, application firewall does not notify clients when either action is taken. Clients are not aware that the webpage is not available and might keep trying to access the page. To provide an explanation for the action or to redirect the client to an informative webpage, use the **block-message** option with the **reject** or **deny** action in an application firewall rule.

```
...
then reject block-message
```

When traffic is rejected by the application firewall rule, a splash screen with the following default message is displayed to the user:

```
user-name, Application Firewall has blocked your request to application application-name
at dst-ip:dst-port accessed from src-ip:src-port.
```

To help the user fully understand which request has been rejected or denied, the default message includes traffic-specific details, such as the username, application, and address information.

You can customize the redirect action by including additional text on the splash screen or by specifying a URL to which the user is redirected. To customize the block message, define the type and content in a block message profile defined in the rule set:

```
[edit security application-firewall profile deny-profile-1]
set block-message type custom-redirect-url content http://abc.company.com/information
```

The block message profile is identified for the rule set, and applied to one or more of the rules using the **block-message** option.

```
[edit security application-firewall rule-sets application-firewall-3]
set profile deny-profile-1
set rule redirect-on-deny
set match dynamic-application [junos:KAZZA junos:EDONKEY junos:YSMG]
set then deny block-message
```

In this example, any traffic matching one of the specified dynamic applications is denied, and the block message defined for rule set, deny-profile-1, is applied. Based on the profile for deny-profile-1, the user is redirected to the URL <http://abc.company.com/information> for further details.

## Session Logging for Application Firewalls

With security policies, the permit action of the matched policy rule creates a session and logs a session create message. A reject or deny action logs a reject or deny message, but does not create a session.

When an application firewall is implemented, the permit action of the security policy creates a session before the application firewall rules are applied. If the dynamic application have been retrieved from the cache, this information is added to the session create message. If the application is in the process of being identified, the dynamic application fields specify UNKNOWN.

If traffic is rejected or denied by the application firewall, application firewall also closes the session. The reject or deny message actions are logged with the reason field containing one of the following phrases:

- **appfw deny** or **appfw deny redirect**
- **appfw reject** or **appfw reject redirect**
- **policy deny**
- **policy reject**

## Application Firewall Support in Chassis Cluster

When the application ID is not identified during failover sessions, the ID is considered an unknown application ID. During this session, the traffic is processed based on the action defined in a rule specified for unknown. If there is no rule defined for unknown, then the default rule is applied.

**NOTE:** When an SRX Series device is operating in chassis cluster mode and application identification is enabled, pre-match state application IDs are not synced to other node. If there are any failover sessions, which were still under classification, will not have any application IDs assigned. This could result in application statistics and counters mismatch.

When the application ID is identified before sessions fail over, the same action taken before the failover is effective after the failover. The application firewall action taken before and after the failover depends on the application ID state, as shown in [Table 39](#).

**Table 39: Application Firewall Actions**

| Before Failover      |                             | After Failover       |                                                          |
|----------------------|-----------------------------|----------------------|----------------------------------------------------------|
| Application ID State | Application Firewall Action | Application ID State | Application Firewall Action                              |
| Success              | Deny                        | Success              | Deny                                                     |
| Success              | Permit                      | Success              | Permit                                                   |
| Pending              | —                           | UNKNOWN              | Action based on the rule defined for unknown application |

**NOTE:** In-service software upgrade (unified ISSU) is not supported due to lack of chassis cluster infrastructure support. Thus, the failover event is controlled through the application firewall policy by allowing or denying the unknown dynamic applications.

## Example: Configuring Application Firewall Rule Sets Within a Security Policy

This example shows how to configure application firewall rule sets within the security policy.

- [Requirements on page 552](#)
- [Overview on page 552](#)
- [Configuration on page 553](#)
- [Verification on page 556](#)

### Requirements

- Create zones. See “[Example: Creating Security Zones](#)” on page 1031.
- Configure an address book with addresses for the policy. See “[Example: Configuring Address Books and Address Sets](#)” on page 1056.

### Overview

In Junos OS, the security policies provide firewall security functionality by enforcing rules for the traffic so that traffic passing through the device is permitted or denied based on

the action defined in the rules. The application firewall support in the policies provides additional security control for dynamic applications.

The application firewall is defined by a collection of rule sets. These rule sets can be defined independently and shared across network security policies. A rule set defines the rules that match the application ID detected, based on the application signature.

This configuration example shows how to:

- Permit or deny selected traffic from the untrust zone to the trust zone, based on the application firewall rule sets defined with the rules matching the dynamic applications.

**NOTE:** On all SRX Series devices, J-Web pages for AppSecure Services are preliminary. We recommend using CLI for configuration of AppSecure features.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security policies from-zone untrust to-zone trust policy policy1 match source-address
1.1.1.0
set security policies from-zone untrust to-zone trust policy policy1 match
destination-address 2.2.2.0
set security policies from-zone untrust to-zone trust policy policy1 match application
junos-http
set security policies from-zone untrust to-zone trust policy policy1 then permit
application-services application-firewall rule-set rs1
set security policies from-zone untrust to-zone trust policy policy2 match source-address
1.1.1.0
set security policies from-zone untrust to-zone trust policy policy2 match
destination-address 2.2.2.0
set security policies from-zone untrust to-zone trust policy policy2 match application any
set security policies from-zone untrust to-zone trust policy policy2 then permit
application-services application-firewall rule-set rs2
set security application-firewall rule-sets rs1 rule r1 match dynamic-application
[junos:KAZZA junos:EDONKEY junos:YSMG]
set security application-firewall rule-sets rs1 rule r1 then deny
set security application-firewall rule-sets rs1 default-rule permit
set security application-firewall rule-sets rs2 rule r1 match dynamic-application
[junos:FACEBOOK-ACCESS junos:GOOGLE-TALK junos:MEEBO junos:UNKNOWN]
set security application-firewall rule-sets rs2 rule r1 then permit
set security application-firewall rule-sets rs2 default-rule deny
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure two security policies with application firewall rule sets that permit or deny traffic from different dynamic applications:

1. Configure a policy to process the traffic that goes to the HTTP static ports with the application firewall rule set rs1.

```
[edit security policies from-zone untrust to-zone trust policy policy1]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application junos-http
user@host# set then permit application-services application-firewall rule-set rs1
```

2. Configure another policy to process any traffic that does not go to the HTTP static ports with the application firewall rule set rs2.

```
[edit security policies from-zone untrust to-zone trust policy policy2]
user@host# set match source-address 1.1.1.0
user@host# set match destination-address 2.2.2.0
user@host# set match application any
user@host# set then permit application-services application-firewall rule-set rs2
```

3. Define the application firewall rule set rs1 to deny traffic from selected dynamic applications.

```
[edit security application-firewall rule-sets rs1]
user@host# set rule r1 match dynamic-application [junos:KAZZA junos:EDONKEY
junos:YSMG]
user@host# set rule r1 then deny
user@host# set default-rule permit
```

4. Define the application firewall rule set rs2 to permit traffic from selected dynamic applications.

```
[edit security application-firewall rule-sets rs2]
user@host# set rule r1 match dynamic-application [junos:FACEBOOK-ACCESS
junos:GOOGLE-TALK junos:MEEBO junos:UNKNOWN]
user@host# set rule r1 then permit
user@host# set default-rule deny
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** and **show security application-firewall** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security policies
from-zone untrust to-zone trust {
 policy 1 {
 match {
 source-address 1.1.1.0;
 destination-address 2.2.2.0;
 application junos-http;
 }
 }
}
```

```

 then {
 permit {
 application-services {
 application-firewall {
 rule-set rs1;
 }
 }
 }
 }
}
policy 2 {
 match {
 source-address 1.1.1.0;
 destination-address 2.2.2.0;
 application any;
 }
 then {
 permit {
 application-services {
 application-firewall {
 rule-set rs2;
 }
 }
 }
 }
}
}
}
user@host# show security application-firewall
rule-sets rs1 {
 rule r1 {
 match {
 dynamic-application [junos:KAZZA junos:EDONKEY junos:YSMG];
 }
 then {
 deny;
 }
 }
 default-rule {
 permit;
 }
}
rule-sets rs2 {
 rule r1 {
 match {
 dynamic-application [junos:FACEBOOK-ACCESS junos:GOOGLE-TALK
 junos:MEEBO junos:UNKNOWN];
 }
 then {
 permit;
 }
 }
 default-rule {
 deny;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying Application Firewall Configuration on page 556](#)

---

### Verifying Application Firewall Configuration

## Example: Configuring an Application Group for Application Firewall

With application identification, multiple applications can be configured in a dynamic application groups for consistent reuse. AppFW rules permit and deny traffic by specifying application names, dynamic application group names, or both. By using predefined application groups, AppFW rules require no updating when new applications are added to common groups.

**NOTE:** The application group is managed by the application identification module.

---

This example shows how to configure application groups within the application firewall rule-set.

- [Requirements on page 557](#)
- [Overview on page 557](#)

- [Configuration on page 557](#)
- [Verification on page 559](#)

## Requirements

Before you begin:

- Create zones. See [“Example: Creating Security Zones” on page 1031](#).

## Overview

The following example configures network policies to control outbound traffic from the trust zone to the untrust zone. All traffic permitted by the policy is processed further with the specified application firewall. The application firewall denies outbound traffic from unknown applications. Outbound Google-Talk traffic is allowed, but all other known social networking traffic is denied. All other traffic is permitted.

The junos:GOOGLE-TALK application is included in the predefined group junos:social-networking. To allow junos:GOOGLE-TALK traffic and deny the rest of the group, the rule permitting junos:GOOGLE-TALK traffic must come before the rule denying traffic from the rest of the applications in the group.

This configuration example shows how to:

- Configure dynamic application groups in an application firewall.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security application-firewall rule-sets social-network
set rule google-rule match dynamic-application junos:GOOGLE-TALK
set rule google-rule then permit
set rule denied-sites match dynamic-application-groups junos:social-networking
set rule denied-sites match dynamic-application junos:UNKNOWN
set rule denied-sites then deny
set default-rule permit
edit security policies from-zone trust to-zone untrust policy outbound-traffic
set match source-address any
set match destination-address any
set match application junos:HTTP
set then permit application-services application-firewall rule-set social-network
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [Using the CLI Editor in Configuration Mode](#).

To configure application firewall rule-sets and security policies for outbound traffic:

1. Create the rule-set social-network.

```
[edit]
user@host# set security application-firewall rule-sets social-network
```

2. Define a rule to permit Google-Talk traffic.

```
[edit security application-firewall rule-sets social-network]
user@host# set rule google-rule match dynamic-application junos:GOOGLE-TALK
user@host# set rule google-rule then permit
```

3. Define a second rule that denies all other social-networking traffic and traffic from an unknown application.

```
[edit security application-firewall rule-sets social-network]
user@host# set rule denied-sites match dynamic-application-groups
 junos:social-networking
user@host# set rule denied-sites match dynamic-application junos:UNKNOWN
user@host# set rule denied-sites then deny
```

Note that rule sequence is important. If the rules google-rule and denied-sites are reversed, Google-Talk traffic would never be permitted. The denied-sites rule would shadow google-rule.

4. Define the default-rule that permits all other traffic.

```
[edit security application-firewall rule-sets social-network]
user@host# user@host# set default-rule permit
```

5. Configure the outbound-traffic policy to apply the social-network rule-set to all outbound traffic.

```
[edit security policies from-zone trust to-zone untrust policy outbound-traffic]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos:HTTP
user@host# set then permit application-services application-firewall rule-set
 social-network
```

**Results** From configuration mode, confirm your configuration by entering the **show security application-firewall** and **show security policies** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show security application-firewall
...
rule-sets social-network {
 rule google-rule {
 match {
 dynamic-application junos:GOOGLE-TALK;
 }
 }
 then {
 permit ;
 }
 rule denied-sites {
 match {
 dynamic-application-groups junos:social-networking
 dynamic-application junos:UNKNOWN;
 }
 }
}
```

```

 }
 then {
 deny;
 }
}
default-rule {
 permit;
}
}
...

[edit]
user@host# show security policies
from-zone untrust to-zone trust {
 ...
 policy outbound-traffic {
 match {
 source-address any;
 destination-address any;
 application junos-http;
 }
 then {
 permit {
 application-services {
 application-firewall {
 rule-set social-network
 }
 }
 }
 }
 }
}
...
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying Application Firewall Configuration

- |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify information about application grouping support under the application firewall policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Example: Configuring Application Firewall When SSL Proxy Is Enabled

**NOTE:** If none of the services (AppFW, IDP, or AppTrack) are configured, then SSL proxy services are bypassed even if an SSL proxy profile is attached to a firewall policy.

This example describes how AppFW supports this AppID functionality when SSL proxy is enabled.

- [Requirements on page 560](#)
- [Overview on page 560](#)
- [Configuration on page 560](#)

### Requirements

Before you begin:

- Create zones. See [“Example: Creating Security Zones” on page 1031](#).
- Configure an address book with addresses for the policy. See [“Example: Configuring Address Books and Address Sets” on page 1056](#).
- Create an application (or application set) that indicates that the policy applies to traffic of that type. See [“Example: Configuring Applications and Application Sets” on page 1152](#).
- Create a SSL proxy profile that enables SSL proxy by means of a policy. See [“Configuring SSL Proxy” on page 534](#).

### Overview

This example shows how to verify the functionality of AppFW when SSL proxy is enabled and a different action, deny or permit, is performed on plain text and encrypted traffic.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security policies from-zone Z_1 to-zone Z_2 policy policy1 match source-address any
set security policies from-zone Z_1 to-zone Z_2 policy policy1 match destination-address any
```

```

set security policies from-zone Z_1 to-zone Z_2 policy policy1 match application junos-https
set security policies from-zone Z_1 to-zone Z_2 policy policy1 then permit
 application-services application-firewall rule-set appfw-rs-1
set security policies from-zone Z_1 to-zone Z_2 policy policy1 then permit
 application-services ssl-proxy profile-name ssl-profile-1
set security policies from-zone Z_1 to-zone Z_2 policy policy2 match source-address any
set security policies from-zone Z_1 to-zone Z_2 policy policy2 match destination-address
 any
set security policies from-zone Z_1 to-zone Z_2 policy policy2 match application junos-http
set security policies from-zone Z_1 to-zone Z_2 policy policy2 then permit
 application-services application-firewall rule-set appfw-rs-2
set security application-firewall rule-sets appfw-rs-1 rule rule1 match dynamic-application
[junos:ORACLE]
user@host# set security application-firewall rule-sets appfw-rs-1 rule rule1 then permit
user@host# set security application-firewall rule-sets appfw-rs-1 default-rule deny
user@host# set security application-firewall rule-sets appfw-rs-2 rule rule1 match
 dynamic-application [junos:HULU]
user@host# set security application-firewall rule-sets appfw-rs-2 rule rule1 then deny
user@host# set security application-firewall rule-sets appfw-rs-2 default-rule permit

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

In this example, you configure two security policies with AppFW rule sets that permit or deny traffic from plain text or encrypted traffic:

- Allow the encrypted version of Oracle and deny any other encrypted traffic.
  - Allow all HTTP traffic, except Hulu.
1. Configure a policy to process the traffic with AppFW rule set appfw-rs-1 and SSL proxy profile ssl-profile-1.
 

```

[edit security policies from-zone Z_1 to-zone Z_2 policy policy1]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos-https
user@host# set then permit application-services application-firewall rule-set
 appfw-rs-1
user@host# set then permit application-services ssl-proxy profile-name ssl-profile-1

```
  2. Configure another policy with rule set appfw-rs-2.
 

```

[edit security policies from-zone Z_1 to-zone Z_2 policy policy2]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application junos-http
user@host# set then permit application-services application-firewall rule-set
 appfw-rs-2

```
  3. Define the AppFW rule set appfw-rs-1 to permit an encrypted version of Oracle and to deny any other encrypted traffic.
 

```

[edit security application-firewall rule-sets appfw-rs1]
user@host# set rule rule1 match dynamic-application [junos:ORACLE]
user@host# set rule rule1 then permit

```

```
user@host# set default-rule deny
```

4. Define the AppFW rule set appfw-rs-2 to allow all plain text traffic except Hulu.

```
[edit security application-firewall rule-sets appfw-rs2]
user@host# set rule rule1 match dynamic-application [junos:HULU]
user@host# set rule rule1 then deny
user@host# set default-rule permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** and **show security application-firewall** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

**NOTE:** For application junos-https, SSL proxy detects an SSL session based on the dynamic application identified for that session. If you know any web servers that are running nonstandard ports, you can use a custom Junos OS application to identify the application. However, if the web servers are not known, for example on the Internet, use application **any**. Non-SSL sessions that come across the policy rule are ignored by SSL proxy. A syslog **SSL\_PROXY\_SESSION\_IGNORE** is sent out for these sessions. Juniper Networks recommends that you use application “any” with caution because this can result in a lot of traffic, incurring initial SSL proxy processing and thereby impacting performance.

### Verifying Application Firewall In an SSL Proxy Enabled Policy

**Purpose** Verify that the application is configured correctly when SSL proxy is enabled in a policy.

**Action** From operational mode, enter the **show security policies** command.

The following output shows the options for the **show security flow session** command.

```
user@host> show security flow session ?
```

```
Possible completions:
<[Enter]> Execute this command
application Application protocol name
application-firewall Show application-firewall sessions
application-firewall-rule-set Show application firewall sessions matching
rule-set name
 brief Show brief output (default)
 destination-port Destination port (1..65535)
 destination-prefix Destination IP prefix or address
 dynamic-application Dynamic application name
 extensive Show detailed output
+ encrypted Show encrypted traffic
 family Show session by family
 idp Show idp sessions
 interface Name of incoming or outgoing interface
 nat Show sessions with network address translation
```

|                                 |                                                |
|---------------------------------|------------------------------------------------|
| <code>protocol</code>           | IP protocol number                             |
| <code>resource-manager</code>   | Show sessions with resource manager            |
| <code>session-identifier</code> | Show session with specified session identifier |
| <code>source-port</code>        | Source port (1..65535)                         |
| <code>source-prefix</code>      | Source IP prefix or address                    |
| <code>summary</code>            | Show output summary                            |
| <code>tunnel</code>             | Show tunnel sessions                           |
| <code> </code>                  | Pipe through a command                         |

To display SSL encrypted UNKNOWN sessions, use the **show security flow session application-firewall dynamic-application junos:SSL extensive** command.

To display all HTTPS sessions, use the **show security flow session application-firewall dynamic-application junos:HTTP encrypted extensive** command.

## Understanding AppTrack

---

AppTrack, an application tracking tool, provides statistics for analyzing bandwidth usage of your network. When enabled, AppTrack collects byte, packet, and duration statistics for application flows in the specified zone. By default, when each session closes, AppTrack generates a message that provides the byte and packet counts and duration of the session, and sends it to the host device. The Security Threat Response Manager (STRM) retrieves the data and provides flow-based application visibility.

AppTrack messages are similar to session logs and use syslog or structured syslog formats. The message also includes an application field for the session. If AppTrack identifies a custom-defined application and returns an appropriate name, the custom application name is included in the log message. (If the application identification process fails or has not yet completed when an update message is triggered, the message specifies **none** in the application field.)

AppTrack supports both IPv4 and IPv6 addressing. Related messages display addresses in the appropriate IPv4 or IPv6 format.

User identity details such as user name and user role have been added to the AppTrack session create, session close, and volume update logs. These fields will contain the user name and role associated with the policy match. The logging of user name and roles is enabled only for security policies that provide UAC enforcement. For security policies without UAC enforcement, the user name and user role fields are displayed as N/A. The user name is displayed as unauthenticated user and user role is displayed as N/A, if the device cannot retrieve information for that session because there is no authentication table entry for that session or because logging of this information is disabled. The user role field in the log contains the list of all the roles performed by the user if match criteria is specific, authenticated user, or any, and the user name field in the log contains the correct user name. The user role field in the log will contain N/A if the match criteria and the user name field in the log contain unauthenticated user or unknown user.

If you enable AppTrack for a zone and specify a **session-update-interval** time, whenever a packet is received, AppTrack checks whether the time since the start of the session or since the last update is greater than the update interval. If so, AppTrack updates the counts and sends an update message to the host. If a short-lived session starts and ends within the update interval, AppTrack generates a message only at session close.

When you want the initial update message to be sent earlier than the specified update interval, use the **first-update-interval**. The **first-update-interval** lets you enter a shorter interval for the first update only. Alternatively, you can generate the initial update message at session start by using the **first-update** option.

The close message updates the statistics for the last time and provides an explanation for the session closure. The following codes are used:

**TCP RST**—RST received from either end.

**TCP FIN**—FIN received from either end.

**Response received**—Response received for a packet request (such as **icmp req-reply**).

**ICMP error**—ICMP error received (such as **dest unreachable**).

**Aged out**—Session aged out.

**ALG**—ALG closed the session.

**IDP**—IDP closed the session.

**Parent closed**—Parent session closed.

**CLI**—Session cleared by a CLI statement.

**Policy delete**—Policy marked for deletion.

---

## Example: Configuring AppTrack

This example shows how to configure the AppTrack tracking tool so you can analyze the bandwidth usage of your network.

- [Requirements on page 567](#)
- [Overview on page 567](#)
- [Configuration on page 567](#)
- [Verification on page 569](#)

## Requirements

Before you configure AppTrack, it is important that you understand conceptual information about AppTrack and Junos OS application identification. See [“Understanding AppTrack” on page 565](#) and [“Understanding the Junos OS Application Identification Database” on page 488](#).

## Overview

Application identification is enabled by default and is automatically turned on when you configure the AppTrack, AppFW, or IDP service. The Security Threat Response Manager (STRM) retrieves the data and provides flow-based application visibility. STRM includes the support for AppTrack Reporting and includes several predefined search templates and reports.

## Configuration

This example shows how to enable application tracking for the security zone named trust. The first log message is to be generated when the session starts, and update messages should be sent every 4 minutes after that. A final message should be sent at session end.

The example also shows how to add the remote syslog device configuration to receive AppTrack log messages in sd-syslog format. The source IP address that is used when exporting security logs is 5.0.0.254, and the security logs are sent to the host located at address 5.0.0.1.

**NOTE:** On all SRX Series devices, J-Web pages for AppSecure Services are preliminary. We recommend using CLI for configuration of AppSecure features.

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**NOTE:** Changing the `session-update-interval` and the `first-update-interval` is not necessary in most situations. The commands are included in this example to demonstrate their use.

```
user@host# set security log mode stream
user@host# set security log format sd-syslog
user@host# set security log source-address 5.0.0.254
user@host# set security log stream app-track-logs host 5.0.0.1
user@host# set security zones security-zone trust application-tracking
user@host# set security application-tracking session-update-interval 4
user@host# set security application-tracking first-update
```

**NOTE:** On SRX5600, and SRX5800 devices, if the syslog configuration does not specify a destination port, the default destination port will be the syslog port. If you specify a destination port in the syslog configuration, then that port will be used instead.

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure AppTrack:

1. Add the remote syslog device configuration to receive Apptrack messages in sd-syslog format.

```
[edit]
user@host# set security log mode stream
user@host# set security log format sd-syslog
user@host# set security log source-address 5.0.0.254
user@host# set security log stream app-track-logs host 5.0.0.1
```

2. Enable AppTrack for the security zone trust.

```
[edit]
user@host# set security zones security-zone trust application-tracking
```

3. (Optional) For this example, generate update messages every 4 minutes.

```
[edit]
user@host# set security application-tracking session-update-interval 4
```

The default interval between messages is 5 minutes. If a session starts and ends within this update interval, AppTrack generates one message at session close. However, if the session is long-lived, an update message is sent every 5 minutes. The **session-update-interval** *minutes* is configurable as shown in this step.

4. (Optional) For this example, generate the first message when the session starts.

```
[edit]
user@host# set security application-tracking first-update
```

By default, the first message is generated after the first session update interval elapses. To generate the first message at a different time than this, use the **first-update** option (generate the first message at session start) or the **first-update-interval** *minutes* option (generate the first message after the specified minutes). For example, enter the following command to generate the first message one minute after session start.

```
[edit]
user@host# set security application-tracking first-update-interval 1
```

**NOTE:** The `first-update` option and the `first-update-interval minutes` option are mutually exclusive. If you specify both, the `first-update-interval` value is ignored.

Once the first message has been generated, an update message is generated each time the session update interval is reached.

**Results** From configuration mode, confirm your configuration by entering the **show security** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security

...
application-tracking {
 first-update;
 session-update-interval 4;
}
log {
 mode stream;
 format sd-syslog;
 source-address 5.0.0.254;
 stream app-track-logs {
 host {
 5.0.0.1;
 }
 }
}
...

[edit]
user@host# show security zones

...
security-zone trust {
 ...
 application-tracking;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Use the STRM product on the remote logging device to view the AppTrack log messages.

To confirm that the configuration is working properly, you can also perform these tasks on the SRX Series device:

- [Reviewing AppTrack Statistics on page 570](#)
- [Verifying AppTrack Counter Values on page 570](#)
- [Verifying Security Flow Session Statistics on page 570](#)
- [Verifying Application System Cache Statistics on page 571](#)
- [Verifying the Status of Application Identification Counter Values on page 571](#)

### Reviewing AppTrack Statistics

**Purpose** Review AppTrack statistics to view characteristics of the traffic being tracked.

**Action** From operational mode, enter the **show services application-identification statistics applications** command.

```
user@host> show services application-identification statistics applications
```

```
Last Reset: 2012-02-14 21:23:45 UTC
```

| Application | Sessions | Bytes | Encrypted |
|-------------|----------|-------|-----------|
| HTTP        | 1        | 2291  | Yes       |
| HTTP        | 1        | 942   | No        |
| SSL         | 1        | 2291  | Yes       |
| unknown     | 1        | 100   | No        |
| unknown     | 1        | 100   | Yes       |

**NOTE:** For more information on the **show services application-identification statistics applications** command, see [show services application-identification statistics applications](#).

### Verifying AppTrack Counter Values

**Purpose** View the AppTrack counters periodically to monitor logging activity.

**Action** From operational mode, enter the **show security application-tracking counters** command.

```
user@host> show security application-tracking counters
```

| AVT counters:           | Value |
|-------------------------|-------|
| Session create messages | 1     |
| Session close messages  | 1     |
| Session volume updates  | 0     |
| Failed messages         | 0     |

### Verifying Security Flow Session Statistics

**Purpose** Compare byte and packet counts in logged messages with the session statistics from the **show security flow session** command output.

**Action** From operational mode, enter the **show security flow session** command.

```
user@host> show security flow session
```

Flow Sessions on FPC6 PIC0:

```
Session ID: 120000044, Policy name: policy-in-out/4, Timeout: 1796, Valid
In: 4.0.0.1/39075 --> 5.0.0.1/21;tcp, If: ge-0/0/0.0, Pkts: 22, Bytes: 1032
Out: 5.0.0.1/21 --> 4.0.0.1/39075;tcp, If: ge-0/0/1.0, Pkts: 24, Bytes: 1442
```

```
Valid sessions: 1
Pending sessions: 0
Invalidated sessions: 0
Sessions in other states: 0
Total sessions: 1
```

Byte and packet totals in the session statistics should approximate the counts logged by AppTrack but might not be exactly the same. AppTrack counts only incoming bytes and packets. System-generated packets are not included in the total, and dropped packets are not deducted.

---

### Verifying Application System Cache Statistics

**Purpose** Compare cache statistics such as IP address, port, protocol, and service for an application from the **show services application-identification application-system-cache** command output.

**Action** From operational mode, enter the **show services application-identification application-system-cache** command.

---

### Verifying the Status of Application Identification Counter Values

**Purpose** Compare session statistics for application identification counter values from the **show services application-identification counter** command output.

**Action** From operational mode, enter the **show services application-identification counter** command.

## Example: Configuring AppTrack When SSL Proxy Is Enabled

---

This example describes how AppTrack supports AppID functionality when SSL proxy is enabled.

- [Requirements on page 572](#)
- [Overview on page 572](#)
- [Configuration on page 572](#)

### Requirements

Before you begin:

- Create zones. See [“Example: Creating Security Zones” on page 1031](#).
- Create an SSL proxy profile that enables SSL proxy by means of a policy. See [“Configuring SSL Proxy” on page 534](#).

### Overview

You can configure AppTrack either in the to or from zones. This example shows how to configure AppTrack in a to zone in a policy rule when SSL proxy is enabled.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security zones security-zone Z_1 application-tracking
set security policies from-zone Z_1 to-zone Z_2 policy policy1 match source-address any
set security policies from-zone Z_1 to-zone Z_2 policy policy1 match destination-address any
set security policies from-zone Z_1 to-zone Z_2 policy policy1 then permit application-services ssl-proxy profile-name ssl-profile-1
set security policies from-zone Z_1 to-zone Z_2 policy policy1 then permit
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

In this example, you configure application tracking and permit application services in an SSL proxy profile configuration.

1. Configure application tracking in a to-zone (you can also configure using a from-zone).

```
[edit security policies]
user@host# set security zones security-zone Z_1 application-tracking
```

2. Configure SSL proxy profile.

```
[edit security policies from-zone Z_1 to-zone Z_2 policy policy1]
set match source-address any
set match destination-address any
set match application junos-https
set then permit application-services ssl-proxy profile-name ssl-profile-1
set then permit
```

**Results** From configuration mode, confirm your configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
from-zone Z_1 to-zone Z_2 {
 policy policy1 {
 match {
 source-address any;
 destination-address any;
 }
 then {
 permit {
 application-services {
 ssl-proxy {
 profile-name ssl-profile-1;
 }
 }
 }
 }
 }
}
```

**NOTE:** Verify that the configuration is working properly. Verification in AppTrack works similarly to verification in AppFW. See the verification section of “[Example: Configuring Application Firewall When SSL Proxy Is Enabled](#)” on page 560.

#### Related Documentation

- [Security Policies Configuration Overview on page 1073](#)
- [Example: Configuring AppTrack on page 566](#)

## Disabling AppTrack

Application tracking is enabled by default. You can disable application tracking without deleting the zone configuration.

To disable application tracking:

**user@host# set security application-tracking disable**

If application tracking has been previously disabled and you want to reenable it, delete the configuration statement that specifies disabling of application tracking:

**user@host# delete security application-tracking disable**

If you are finished configuring the device, commit the configuration.

To verify the configuration, enter the **show security application-tracking** command.

# Configuring Application QoS

- [Understanding Application QoS \(AppQoS\) on page 575](#)
- [Example: Configuring AppQoS on page 581](#)

## Understanding Application QoS (AppQoS)

---

The application quality of service (AppQoS) feature expands the capability of Junos OS class of service (CoS) to include marking DSCP values based on Layer-7 application types, honoring application-based traffic through loss priority settings, and controlling transfer rates on egress PICs based on Layer-7 application types.

There are four ways to mark DSCP values on SRX Series devices:

- IDP attack action-based DSCP rewriters
- Layer 7 application-based DSCP rewriters
- ALG-based DSCP rewriters
- Firewall filter-based DSCP rewriters

IDP remarking is conducted at the ingress port based on IDP rules. Application remarking is conducted at the egress port based on application rules. Interface-based remarking also occurs at the egress port based on firewall filter rules. (See the [Class of Service Feature Guide for Security Devices](#) for a detailed description of Junos OS CoS features.)

The remarking decisions of these three rewriters can be different. If a packet triggers all three, the method that takes precedence is based on how deep into the packet content the match is conducted. IDP remarking has precedence over application remarking which has precedence over interface-based remarking.

If a packet triggers both AppQoS and ALG-based DSCP rewriters, then AppQoS takes precedence over ALG-based DSCP rewriters.

The AppQoS DSCP rewriter conveys a packet's quality of service through both the forwarding class and a loss priority. The AppQoS rate-limiting parameters control the transmission speed and volume for its associated queues.

- [Unique Forwarding Classes and Queue Assignments on page 576](#)
- [Application-Aware DSCP Code-Point and Loss Priority Settings on page 576](#)

- [Rate Limiters and Profiles on page 578](#)
- [Rate-Limiter Assignment on page 579](#)
- [Rate-Limiter Action on page 581](#)
- [AppQoS Security Policy Configuration on page 581](#)

## Unique Forwarding Classes and Queue Assignments

The forwarding class provides three functions:

- Groups packets with like characteristics
- Assigns output queues
- Resolves conflicts with existing Junos OS firewall filter-based rewriters

Unique forwarding class names protect AppQoS remarking from being overwritten by interface-based rewrite rules. A firewall filter-based rewriter remarks a packet's DSCP value if the packet's forwarding class matches a class defined specifically for this rewriter. If the packet's forwarding class does not match any of the firewall filter-based rewriter's classes, the DSCP value is not remarked. To protect AppQoS values from being overwritten, therefore, use forwarding class names that are unknown to the firewall filter-based rewriter.

Each forwarding class is assigned to an egress queue that provides the appropriate degree of enhanced or standard processing. Many forwarding classes can be assigned to a single queue. Therefore, any queues defined for the device can be used by IDP, AppQoS, and firewall filter-based rewriters. It is the forwarding class name, not the queue, that distinguishes the transmission priority. (See the [Class of Service Feature Guide for Security Devices](#) for information about configuring queues and schedulers.)

For SRX5400, SRX5600, and SRX5800 devices, the AppQoS forwarding class names and queue assignments are defined with the **class-of-service** CLI configuration command:

```
[edit class-of-service]
user@host# forwarding-classes class forwarding-class-name queue-num queue-number
```

For SRX100, SRX210, SRX220, SRX240, SRX550, and SRX1500 devices, the AppQoS forwarding class names and queue assignments are defined with the **class-of-service** CLI configuration command:

```
[edit class-of-service]
user@host# forwarding-classes queue queue-number forwarding-class-name
```

## Application-Aware DSCP Code-Point and Loss Priority Settings

For AppQoS, traffic is grouped based on rules that associate a defined forwarding class with selected applications. The match criteria for the rule includes one or more applications. When traffic from a matching application encounters the rule, the rule action sets the forwarding class, and remarks the DSCP value and loss priority to values appropriate for the application.

A Differentiated Services (DiffServ) code point (DSCP) value is specified in the rule either by a 6-bit bitmap value or by a user-defined or default alias. [Table 40](#) provides a list of Junos OS default DSCP alias names and bitmap values.

**Table 40: Standard CoS Aliases and Bit Values**

| CoS Value Type       | Alias   | Bit Value |
|----------------------|---------|-----------|
| Expedited forwarding | ef      | 101110    |
| Assured forwarding   | af11    | 001010    |
| Assured forwarding   | af12    | 001100    |
| Assured forwarding   | af13    | 001110    |
| Assured forwarding   | af21    | 010010    |
| Assured forwarding   | af22    | 010100    |
| Assured forwarding   | af23    | 010110    |
| Assured forwarding   | af31    | 011010    |
| Assured forwarding   | af32    | 011100    |
| Assured forwarding   | af33    | 011110    |
| Assured forwarding   | af41    | 100010    |
| Assured forwarding   | af42    | 100100    |
| Assured forwarding   | af43    | 100110    |
| Best effort          | be      | 000000    |
|                      | cs1     | 001000    |
|                      | cs2     | 010000    |
|                      | cs3     | 011000    |
|                      | cs4     | 100000    |
|                      | cs5     | 101000    |
| Network control      | nc1/cs6 | 110000    |
| Network control      | nc2/cs7 | 111000    |

The queue's scheduler uses the loss priority to control packet discard during periods of congestion by associating drop profiles with particular loss priority values. (See the [Class of Service Feature Guide for Security Devices](#) for information about configuring queues and schedulers.)

The rule applies a loss priority to the traffic groups. A high loss priority means a high probability that the packet could be dropped during a period of congestion. Four levels of loss priority are available:

- **high**
- **medium-high**
- **medium-low**
- **low**

The rule set is defined in the **class-of-service application-traffic-control** configuration command:

```
[edit class-of-service]
user@host# application-traffic-control rule-sets ruleset-name rule rule-name1 match
 application application-name application-name ...
user@host# application-traffic-control rule-sets ruleset-name rule rule-name1 match
 application-group application-group-name application-group-name ...
user@host# application-traffic-control rule-sets ruleset-name rule rule-name1 then
 forwarding-class fc-name
user@host# application-traffic-control rule-sets ruleset-name rule rule-name1 then
 dscp-code-point bitmap
user@host# application-traffic-control rule-sets ruleset-name rule rule-name1 then
 loss-priority loss-pri-value
```

## Rate Limiters and Profiles

When congestion occurs, AppQoS implements rate limiting on all egress PICs on the device. If packets exceed the assigned limitations, they are dropped. *Rate limiters* maintain a consistent level of throughput and packet loss sensitivity for different classes of traffic. All egress PICs employ the same rate-limiting scheme.

The total bandwidth of a PIC is about 10 Gbps. Rate-limiter hardware for the PIC can provision up to 2 Gbps. Therefore, the upper bandwidth limit for rate limiting is  $2^{31}$  bps.

A rate-limiter profile defines the limitations. It is a unique combination of **bandwidth-limit** and **burst-size-limit** specifications. The **bandwidth-limit** defines the maximum number of kilobits per second that can traverse the port. The **burst-size-limit** defines the maximum number of bytes that can traverse the port in a single burst. The **burst-size-limit** reduces starvation of lower priority traffic by ensuring a finite size for each burst.

AppQoS allows up to 16 profiles and up to 1000 rate limiters per device. Multiple rate limiters can use the same profile. In the following example, five rate limiters are defined using two profiles:

| Rate Limiter Name | Profile         |                  |
|-------------------|-----------------|------------------|
|                   | bandwidth-limit | burst-size-limit |
| limiter-1         | 200             | 26000            |
| limiter-2         | 200             | 26000            |
| limiter-3         | 200             | 26000            |
| limiter-4         | 400             | 52000            |
| limiter-5         | 400             | 52000            |

Rate limiters are defined with the **class-of-service application-traffic-control** configuration command.

```
[edit class-of-service]
user@host# application-traffic-control rate-limiters rate-limiter-name bandwidth-limit
value-in-Kbps burst-rate-limit value-in-bytes
```

## Rate-Limiter Assignment

Rate limiters are applied in rules based on the application of the traffic. Two rate limiters are applied for each session: **client-to-server** and **server-to-client**. This usage allows traffic in each direction to be provisioned separately.

Different AppQoS rules within the same rule set can share a rate limiter. In this case, the applications of those rules share the same bandwidth. There are no limitations on the number of rules in one rule set that can assign the same rate limiter.

The following examples show how the rate limiters defined in the preceding section could be assigned. For instance, a rule set could reuse a rate limiter in several rules and in one or both flow directions:

- rule-set-1
  - rule-1A
    - client-to-server limiter-1
    - server-to-client limiter-1
  - rule-1B
    - client-to-server limiter-1

- server-to-client limiter-1

If the same profiles are needed in several rule sets, a sufficient number of rate limiters needs to be defined specifying the same **bandwidth-limit** and **burst-size-limit**. The two rule sets in the following example implement the same profiles by assigning different, but comparable, rate limiters.

- rule-set-2
  - rule-2A
    - client-to-server limiter-2
    - server-to-client limiter-2
  - rule-2B
    - client-to-server limiter-2
    - server-to-client limiter-4
- rule-set-3
  - rule-3A
    - client-to-server limiter-3
    - server-to-client limiter-3
  - rule-3B
    - client-to-server limiter-3
    - server-to-client limiter-5

A rate limiter is applied using the **class-of-service application-traffic-control rule-sets** command in the same way that a forwarding class, DSCP value, and loss priority are set.

[edit class-of-service]

```
user@host# application-traffic-control rule-sets rule-set-name rule rule-name1 then
rate-limit client-to-server rate-limiter1 server-to-client rate-limiter2
```

If AppQoS and firewall filter-based rate limiting are both implemented on the egress PIC, both are taken into consideration. AppQoS rate limiting is considered first. Firewall filter-based rate limiting occurs after that.

**NOTE:** If packets are dropped from a PIC, the SRX Series device does not send notifications to the client or the server. The upper-level applications on the client and the server devices are responsible for retransmission and error handling.

## Rate-Limiter Action

Based on the type of SRX Series device, AppQoS rules can be configured with different rate-limiter actions:

- Discard
  - When this option is selected, the out-of-profile packets are just dropped.
  - This is the default action type and need not be configured.
  - This option is supported on all SRX Series devices.
- Loss-priority-high
  - When this option is selected, it elevates the loss priority to maximum. In other words, it is a delayed drop; that is, the discard decision is taken at the egress output queue level. If there is no congestion, it allows the traffic even with maximum loss priority. But if congestion occurs, it drop these maximum loss priority packets first.
  - This option must be configured within the AppQoS rule (to override the default action) using the following command:

[edit]

```
user@host# set class-of-service application-traffic-control rule-sets rset-01 rule r1
then rate-limit loss-priority-high
```

- This option is supported only on branch SRX Series devices.

## AppQoS Security Policy Configuration

The AppQoS rule set can be implemented in an existing policy or a specific application policy.

[edit]

```
user@host# security policies from-zone zone-name to-zone zone-name
```

```
[edit security policies from-zone zone-name to-zone zone-name]
```

```
user@host# policy policy-name match source-address IP-address
```

```
user@host# policy policy-name match destination-address IP-address
```

```
user@host# policy policy-name match application application-name application-name
```

```
user@host# policy policy-name then permit application-services application-traffic-control
rule-set app-rule-set-name
```

## Example: Configuring AppQoS

This example shows how to enable AppQoS prioritization and rate limiting within a policy.

- [Requirements on page 582](#)
- [Overview on page 582](#)

- [Configuration on page 582](#)
- [Verification on page 584](#)

## Requirements

No special configuration beyond device initialization is required before configuring this feature.

## Overview

In this example, AppQoS is implemented so that FTP applications are restricted to a level below the specified throughput while other applications are transmitted at a more conventional speed and loss priority level.

**NOTE:** On all SRX Series devices, J-Web pages for AppSecure Services are preliminary. We recommend using CLI for configuration of AppSecure features.

## Configuration

### Step-by-Step Procedure

To configure an AppQoS implementation:

1. Define one or more forwarding classes dedicated to AppQoS marking. In this example, a single forwarding class, my-app-fc, is defined and assigned to queue 0.

For SRX5400, SRX5600, and SRX5800 devices, use the following command:

```
[edit]
user@host# set class-of-service forwarding-classes class my-app-fc queue-num
0
```

For SRX100, SRX210, SRX220, SRX240, SRX1500, and SRX550 devices, use the following command:

```
[edit]
user@host# set class-of-service forwarding-classes queue-num 0 my-app-fc
```

2. Define rate limiters. In this example, two rate limiters are defined.

**NOTE:** For high-end SRX Series devices, you can define up to 1000 rate limiters for a device, but only 16 profiles (unique bandwidth-limit and burst-size-limit combinations).

- test-r1 with a bandwidth of 100 Kbps and a burst limit of 13,000 bytes
- test-r2 with a bandwidth of 200 Kbps and a burst limit of 26,000 bytes

```
[edit]
user@host# set class-of-service application-traffic-control rate-limiters test-r1
bandwidth-limit 100
user@host# set class-of-service application-traffic-control rate-limiters test-r1
burst-size-limit 13000
```

```

user@host# set class-of-service application-traffic-control rate-limiters test-r2
bandwidth-limit 200
user@host# set class-of-service application-traffic-control rate-limiters test-r2
burst-size-limit 26000

```

3. Define AppQoS rules and application match criteria. For this example, rule 0 in rule set ftp-test1 is applied to junos:FTP packets.

```

[edit]
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 match application junos:FTP

```

4. Define the action for rule 0 when it encounters a junos:FTP packet. In this example, when a match is made, the packet is marked with the forwarding class my-app-fc, the DSCP value of af22, and a loss priority of low.

```

[edit]
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then forwarding-class my-app-fc
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then dscp-code-point af22
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then loss-priority low

```

5. Assign rate limiters for rule 0 to traffic in each direction. In this case, the rate limiter test-r1 is set in both directions.

**NOTE:** Rate limiter test-r1 can be assigned to one or both traffic directions in rule 0. It could also be assigned in other rules within rule set ftp-test1. However, once test-r1 is assigned to rule set ftp-test1, it cannot be assigned in any other rule set.

```

[edit]
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then rate-limit client-to-server test-r1
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then rate-limit server-to-client test-r1

```

6. Log the AppQoS event whenever this action is triggered:

```

[edit]
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
0 then log

```

7. Define other rules to handle application packets that did not match the previous rule. In this example, a second and final rule applies to all remaining applications.

```

[edit]
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
1 match application-any

```

8. Assign rate limiters for the second rule. In this example, any traffic that is not from FTP is assigned rate limiter test-r2 in both directions.

```

[edit]

```

```

user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
1 then rate-limit client-to-server test-r2
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
1 then rate-limit server-to-client test-r2
user@host# set class-of-service application-traffic-control rule-sets ftp-test1 rule
1 then log

```

9. Add the AppQoS implementation to a policy. In this example, policy p1 applies the rule set ftp-test1 to all traffic from the trust zone to the untrust zone.

```

[edit]
user@host# set security policies from-zone trust to-zone untrust policy p1
[edit security policies from-zone trust to-zone untrust policy p1]
user@host# set match source-address any
user@host# set match destination-address any
user@host# set match application any
user@host# set then permit application-services application-traffic-control rule-set
ftp-test1

```

**Results** From configuration mode, confirm your policy configuration by entering the **show security policies** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```

...
policy p1 {
 match {
 source-address any;
 destination-address any;
 application any;
 }
 then {
 permit {
 application-services {
 application-traffic-control {
 rule-set ftp-test1
 }
 }
 }
 }
}
...

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Flow Session Configuration on page 585](#)
- [Verifying Session Statistics on page 585](#)

- [Verifying Rate-Limiter Statistics on page 586](#)
- [Verifying Rule Statistics on page 586](#)

### Verifying Flow Session Configuration

- Purpose** Verify that AppQoS is enabled.
- Action** From operational mode, enter the **show security flow session application-traffic-control extensive** command.
- ```
user@host> show security flow session application-traffic-control extensive
Session ID: 3729, Status: Normal, State: Active
Flag: 0x40
Policy name: p1
Source NAT pool: Null
Dynamic application: junos:FTP
Application traffic control rule-set: ftp-test1, Rule: rule0
Maximum timeout: 300, Current timeout: 276
Session State: Valid
Start time: 18292, Duration: 603536
  In: 201.34.0.4/1 --> 224.0.0.13/1;pim,
    Interface: reth1.0,
    Session token: 0x1c0, Flag: 0x0x21
    Route: 0x0, Gateway: 201.34.0.4, Tunnel: 0
    Port sequence: 0, FIN sequence: 0,
    FIN state: 0,
    Pkts: 21043, Bytes: 1136322
  Out: 224.0.0.13/1 --> 201.34.0.4/1;pim,
    Interface: .local..0,
    Session token: 0x80, Flag: 0x0x30
    Route: 0xffffd0000, Gateway: 224.0.0.13, Tunnel: 0
    Port sequence: 0, FIN sequence: 0,
    FIN state: 0,
    Pkts: 0, Bytes: 0
```
- Meaning** The entry for application traffic control identifies the rule set and rule of the current session.

Verifying Session Statistics

- Purpose** Verify that AppQoS session statistics are being accumulated at each egress node.
- Action** From operational mode, enter the **show class-of-service application-traffic-control counter** command.

NOTE: The PIC number is always displayed as 0 for branch SRX Series devices.

```
user@host> show class-of-service application-traffic-control counter
pic: 2/1
Counter type                               Value
Sessions processed                         300
Sessions marked                           200
```

Sessions honored	0
Sessions rate limited	100
Client-to-server flows rate limited	100
Server-to-client flows rate limited	100
pic: 2/0	
Counter type	Value
Sessions processed	400
Sessions marked	300
Sessions honored	0
Sessions rate limited	200
Client-to-server flows rate limited	200
Server-to-client flows rate limited	200

Meaning The AppQoS statistics are maintained only if application-traffic-control service is enabled. The number of sessions processed, marked, and honored show that sessions are being directed based on configured AppQoS features. The rate-limiting statistics count the number of directional session flows that have been rate limited.

Verifying Rate-Limiter Statistics

Purpose Verify that bandwidth is being limited as expected when the FTP application is encountered.

Action From operational mode, enter the **show class-of-service application-traffic-control statistics rate-limiter** command.

NOTE: The PIC number is always displayed as 0 for branch SRX Series devices.

```

user@host> show class-of-service application-traffic-control statistics
rate-limiter
pic: 2/1
  Ruleset   Application  Client-to-server Rate(kbps)  Server-to-client Rate(kbps)
-----
ftp-test1   HTTP         test-r2             200          test-r2             200
ftp-test1   HTTP         test-r2             200          test-r2             200
ftp-test1   FTP          test-r1             100          test-r1             100

```

Meaning Real-time application bandwidth-limit information for each PIC is displayed by rule set. This command provides an indication of the applications being rate limited and the profile being applied.

Verifying Rule Statistics

Purpose Verify that the rule matches the rule statistics.

Action From operational mode, enter the **show class-of-service application-traffic-control statistics rule** command.

NOTE: The PIC number is always displayed as 0 for branch SRX Series devices.

```
user@host>show class-of-service application-traffic-control statistics rule
pic: 2/1
```

Ruleset	Rule	Hits
ftp-test1	0	100
ftp-test1	1	200
...		

```
pic: 2/0
```

Ruleset	Rule	Hits
ftp-test1	0	100
ftp-test1	1	200

Meaning This command provides information on the number of (session) hits for a rule under each rule set.

Class-of-Service Configuration Statement Hierarchy

Use the statements in the **class-of-service** configuration hierarchy to configure class-of-services (CoS) features.

```
class-of-service {
  adaptive-shapers adaptive-shaper-name {
    trigger becn {
      shaping-rate (absolute-rate | percent percent);
    }
  }
  application-traffic-control {
    rate-limiters rate-limiter-name {
      bandwidth-limit kbps;
      burst-size-limit bytes;
    }
  }
  rule-sets rule-set-name {
    rule rule-name {
      match {
        application [application-name];
        application-any;
        application-group [application-group-name];
        application-known;
        application-unknown;
      }
    }
  }
}
```

```

        then {
            dscp-code-point dscp-value;
            forwarding-class class-name;
            log;
            loss-priority (high | low | medium-high | medium-low);
            rate-limit {
                loss-priority-high;
                client-to-server rate-limiter;
                server-to-client rate-limiter;
            }
        }
    }
}

traceoptions {
    file {
        filename;
        files number;
        match regular-expression;
        size maximum-file-size;
        (world-readable | no-world-readable);
    }
    flag flag;
    level (all | error | info | notice | verbose | warning);
    no-remote-trace;
}

}

classifiers {
    (dscp | dscp-ipv6 | exp | ieee-802.1 | ieee-802.1ad | inet-precedence) classifier name
    {
        forwarding-class class-name {

Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, Unified Threat Management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

System Configuration Statement Hierarchy

Use the statements in the **system** configuration hierarchy to configure system management functions including addresses of the Domain Name System (DNS) servers; device's hostname, address, and domain name; health monitoring; interface filtering; properties of the device's auxiliary and console ports; security profiles for logical systems; time zones and Network Time Protocol (NTP) properties; trace options; and user login accounts, including user authentication and the root-level user account. Statement

descriptions that are exclusive to the SRX Series devices running Junos OS are described in this section.

}
```

Hierarchy Level [edit services ssl proxy profile *profile-name*]

Release Information Statement introduced in Junos OS Release 12.1X44-D10.

Description Specify the logging and traffic related actions.

- Options**
- **crl**—Specify the certificate revocation actions.
 - **disable**—Disable CRL verification.
 - **if-not-present**—Specify actions for sessions.
 - **allow**—Allow sessions when CRL information is not available.
 - **drop**—Drop sessions when CRL information is not available.
 - **ignore-hold-instruction-code**—Ignore the unconfirmed (on hold) revocation status, and accept a certificate.
 - **disable-session-resumption**—Disable session resumption.
 - **ignore-server-auth-failure**—Ignore server authentication failure.
 - **log**—Specify the logging actions.
 - **all**—Log all events.
 - **errors**—Log all error events.
 - **info**—Log all information events.
 - **sessions-allowed**—Log SSL session allowed events after an error.

	<ul style="list-style-type: none">• sessions-dropped—Log only SSL session dropped events.• sessions-ignored—Log session ignored events.• sessions-whitelisted—Log SSL session whitelisted events.• warning—Log all warning events.• renegotiation—Specify the renegotiation options.<ul style="list-style-type: none">• allow—Allow secure and nonsecure renegotiation.• allow-secure—Allow secure negotiation only.• drop—Drop session on renegotiation request.
Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.

application-services (Security Policies)

Syntax	<pre>application-services { application-firewall { rule-set <i>rule-set-name</i>; } application-traffic-control { rule-set <i>rule-set-name</i>; } gprs-gtp-profile <i>profile-name</i>; gprs-sctp-profile <i>profile-name</i>; idp; redirect-wx reverse-redirect-wx; ssl-proxy { profile-name <i>profile-name</i>; } uac-policy { captive-portal <i>captive-portal</i>; } utm-policy <i>policy-name</i>; }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit]
Release Information	Statement modified in Junos OS Release 11.1.
Description	Enable application services within a security policy.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Application Firewall Overview on page 547

application-system-cache

Syntax	application-system-cache;
Hierarchy Level	[edit services application-identification]
Release Information	Statement introduced in Junos OS Release 9.2.
Description	When a session is created, specify an application ID to match the application properties of transiting network traffic. The application port mappings are saved in the application system cache.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Understanding the Application System Cache on page 515

application-system-cache-timeout (Services)

Syntax	application-system-cache-timeout <i>value</i> ;
Hierarchy Level	[edit services application-identification]
Release Information	Statement introduced in Junos OS Release 9.2. Support for application identification in the services hierarchy added in Junos OS Release 10.2.
Description	Specify the timeout value in seconds for the application system cache entries. Note the cache is not cleared when IDP policy is loaded. Users need to manually clear or wait for the cache entries to expire.

NOTE: On SRX Series devices, when you change the timeout value for the application system cache entries using the command `set services application-identification application-system-cache-timeout`, the cache entries need to be cleared to avoid inconsistency in timeout values of existing entries.

Options	<i>value</i> —Timeout value for the application system cache entries. Range: 0 through 1,000,000 seconds Default: 3600 seconds
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Understanding the Application System Cache on page 515

application-tracking

Syntax	<pre>application-tracking { disable; (first-update first-update-interval <i>first-update-interval</i>); session-update-interval <i>session-update-interval</i>; }</pre>
Hierarchy Level	[edit security]
Release Information	Statement introduced in Junos OS Release 10.2. Support for disable added in Junos OS Release 11.4.
Description	AppTrack, an application tracking tool, is a form of statistical profiling. Enabling this feature for a zone logs flow statistics (the byte count, packet count, and start and end times for a session) at session end. You can modify the logging time and log frequency with command options. Periodically, a network management tool, such as STRM, collects the logged statistics sent by each network device for bandwidth usage analysis of the network.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring AppTrack on page 566

application-tracking (Security Zones)

Syntax	<pre>application-tracking;</pre>
Hierarchy Level	[edit security zones security-zone <i>zone-name</i>]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	Enable application tracking support for the zone.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• [edit security zones] Hierarchy Level on page 324

application-traffic-control

block-message (Application Firewall)

Syntax	block-message type { custom-text content <i>custom-html-text</i> ; custom-redirect-url content <i>custom-redirect-url</i> ; }
Hierarchy Level	[edit security application-firewall profile <i>profile-name</i>]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Defines the profile of the notification to be sent to clients when HTTP or HTTPS traffic is blocked by a reject or deny action from an application firewall.

NOTE: The block message option is not supported for non-HTTP traffic. In these instances, if the action is drop or reject, the traffic is silently dropped or rejected. The user is not informed of the action and no redirection occurs. The associated system log message identifies the action taken for this traffic.

When the **block-message** option is specified, a splash screen and message inform the client that the traffic has been blocked. The default message text is:

“username, Application Firewall has blocked your request to application application-name at dest-ip:dest-port accessed from src-ip:source-port ”

The variables in the message are replaced with specific traffic values. For clarity, the prefix **junos:** is truncated from the application name.

Options Use the following option pairs to customize the default message or to redirect the client to a custom webpage instead of the default splash screen.

NOTE: Both the **type** and **content** fields must be used to add custom text or redirect the client to a URL.

- **type**—(Optional) The message type to be displayed after a reject or deny action.
 - **custom-text**—Text message in HTML to be added to the default text. If **custom-text** is specified, the splash screen displays both the default block message and the custom-defined block message.

When specified, the user is redirected when a reject or deny action is taken during one of the following HTTP methods: GET, POST, OPTIONS, HEAD, PUT, DELETE, TRACE, CONNECT, PROPFIND, PROPPATCH, LOCK, UNLOCK, COPY, MOVE, MKCOL, BCOPY, BDELETE, BCOPY, BMOVE, BPROPFIND, BPROPPATCH, POLL, SEARCH, SUBSCRIBE, and UNSUBSCRIBE. If the reject or deny action occurs during a different HTTP method, the traffic is silently dropped.

- **custom-redirect-url**—URL redirection.
- **content**—(Optional) Message content for the selected message type.

NOTE: The **content** value must match the **type** option selected: **custom-text** requires text, and **custom-redirect-url** requires a URL value.

- **custom-text**—Custom text to be added to the splash screen. Custom text is inserted below the default message. Add the characters \n to insert a line break in the displayed text.
- **custom-redirect-url**—The URL of the webpage to which the client is directed. When traffic is rejected or denied, the client is redirected to the specified webpage for further action. The URL can be hosted on either the SRX Series device or an external server.

Enter the redirect URL in quotation marks for an HTTP or HTTPS site, as shown in the following examples:

```
"http://custom-redirect-url"
"https://custom-redirect-url"
```

Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

default-rule

Syntax	<pre>default-rule { (deny [block-message] permit reject [block-message]); }</pre>
Hierarchy Level	[edit security application-firewall rule-sets <i>rule-set-name</i>]
Release Information	Statement introduced in Junos OS Release 11.1. Statement updated in Junos OS Release 12.1X44-D10 with the reject option. The block-message option added in Junos OS Release 12.1X45-D10.
Description	<p>Configure the default rule that defines the actions to be performed on a packet that does not match any defined rule.</p> <p>Note that an application firewall is applied after a session has already been created by the security firewall. When traffic is rejected or denied by an application firewall, therefore, logs contain a session open message, a session reject or deny message, and a session close message.</p>
Options	<ul style="list-style-type: none"> • deny—Block the traffic at the firewall. The device drops the packet. No message is returned to the sender. • block-message—(Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the profile option for this rule set, including the block-message option displays a default message or customized message, or redirects the user for denied HTTP or HTTPS traffic. All other traffic is dropped silently. • permit—Permit traffic at the firewall. • reject—Block the traffic at the firewall. For TCP traffic, by default the device drops the packet and returns a TCP reset (RST) message to the source host and to the server in some cases. For UDP and other protocol traffic, by default the device drops the packet and returns an ICMP "destination unreachable, port unreachable" message to both the client and the server. • block-message—(Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the profile option for this rule set, including the block-message option displays a default message or customized message, or redirects the user for rejected HTTP or HTTPS traffic. All other traffic is dropped as specified in the default action for the reject option.

Hierarchy Level [edit system syslog]

Release Information Statement introduced before Junos OS Release 12.1X47 for SRX Series.

Description Specify the file in which to log data.

- Options**
- *filename*—Specify the name of the file in which to log data.
 - *allow-duplicates*—Do not suppress the repeated messages.
 - *any*—Specify all facilities information.
 - *alert*—Specify the conditions that should be corrected immediately.
 - *critical*—Specify the critical conditions.
 - *emergency*—Specify the conditions that cause security functions to stop.
 - *error*—Specify the general error conditions.

- *info*—Specify the information about normal security operations.
- *none*—Do not specify any messages.
- *notice*—Specify the conditions that should be handled specifically.
- *warning*—Specify the general warning conditions.
- *archive*—Specify the archive file information.
 - *archive-sites*—Specify a list of destination URLs for the archived log files.
 - *url*—Specify the primary and failover URLs to receive archive files.
 - *binary-data*—Mark file such that it contains binary data.
 - *no-binary-data*—Do not mark the file such that it contains binary data.
 - *files*—Specify the number of files to be archived. Range: 1 through 1000 files.
 - *size*—Specify the size of files to be archived. Range: 65,536 through 1,073,741,824 bytes.
 - *world-readable*—Allow any user to read the log file.
 - *no-world-readable*—Do not allow any user to read the log file.
 - *start-time*—Specify the start time for file transmission. Enter the start time in the yyyy-mm-dd.hh:mm format.
 - *transfer-interval*—Specify the frequency at which to transfer the files to archive sites.
- *authorization*—Specify the authorization system.
- *change-log*—Specify the configuration change log.
- *conflict-log*—Specify the configuration conflict log.
- *daemon*—Specify the various system processes.
- *dfc*—Specify the dynamic flow capture.
- *explicit-priority*—Include the priority and facility in messages.
- *external*—Specify the local external applications.
- *firewall*—Specify the firewall filtering system.
- *ftp*—Specify the FTP process.
- *interactive-commands*—Specify the commands executed by the UI.
- *kernel*—Specify the kernel information.
- *match*—Specify the regular expression for lines to be logged.
- *ntp*—Specify the NTP process.
- *pfe*—Specify the Packet Forwarding Engine.
- *security*—Specify the security-related information.

- *structured-data*—Log the messages in structured log format.
 - *brief*—Omit English language text from the end of the logged message.
- *user*—Specify the user processes.
 - *info*—Specify the informational messages.

Required Privilege Level system—To view this statement in the configuration.
 system-control—To add this statement to the configuration.

- *syslog (System)*

first-update

Syntax first-update;

Hierarchy Level [edit security application-tracking]

Release Information Statement introduced in Junos OS Release 10.2.

Description Generate an AppTrack start message when a new session begins. (A final message is produced at session end with any option.) This option overrides the **first-update-interval** option if both are specified.

Required Privilege Level security—To view this statement in the configuration.
 security-control—To add this statement to the configuration.

Related Documentation

- [Example: Configuring AppTrack on page 566](#)

first-update-interval

Syntax	first-update-interval <i>first-update-interval</i> ;
Hierarchy Level	[edit security application-tracking]
Release Information	Statement introduced in Junos OS Release 10.2.
Description	For long-lived sessions being monitored by AppTrack, configure this value to issue the first update message after a specified number of minutes.

NOTE: The **first-update-interval** setting is disregarded if the **first-update** option is set to log the first message at session start.

Options	minutes —Maximum number of minutes after session start for the first update message to be sent. This value must be smaller than the session-update-interval setting. Default: 1
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring AppTrack on page 566

flag (Services)

Syntax	<code>flag (all cli-configuration initiation proxy selected-profile termination);</code>
Hierarchy Level	[edit services ssl traceoptions]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the tracing flag parameters.
Options	<ul style="list-style-type: none"> • <i>all</i>—Trace all the parameters. • <i>cli-configuration</i>—Trace CLI configuration events. • <i>initiation</i>—Trace initiation service events. • <i>proxy</i>—Trace proxy service events. • <i>selected-profile</i>—Trace events for profiles with enable-flow-tracing set. • <i>termination</i>—Trace termination service events.
Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring SSL Proxy on page 534

format (Security Log)

Syntax	<code>format (binary sd-syslog syslog)</code>
Hierarchy Level	[edit security log]
Release Information	Statement introduced prior to Junos OS Release 10.0. Statement updated in Junos OS Release 12.1.
Description	Set the default log format for event mode security logging on the device.
Options	<ul style="list-style-type: none"> • <i>binary</i>—Binary encoded text to conserve resources. • <i>sd-syslog</i>—Structured system log file. • <i>syslog</i>—Traditional system log file. <p>Default: syslog.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • System Log Messages

forwarding-classes (CoS)

Syntax	<pre> forwarding-classes { class <i>class-name</i> { priority (high low); queue-num <i>number</i>; spu-priority (high low); } queue <i>queue-number</i> { <i>class-name</i> { priority (high low); } } } </pre>
Hierarchy Level	[edit class-of-service]
Release Information	Statement introduced in Junos OS Release 8.5. Statement updated in Junos OS Release 11.4. The spu-priority option introduced in Junos OS Release 11.4R2.
Description	Configure forwarding classes and assign queue numbers.
Options	<ul style="list-style-type: none"> <i>class-name</i>—Display the forwarding class name assigned to the internal queue number.

NOTE: This option is supported only on high-end SRX Series devices, including the SRX1500, SRX5400, SRX5600, and SRX5800.

NOTE: AppQoS forwarding classes must be different from those defined for interface-based rewriters.

- **policing-priority**—Layer 2 policing. One forwarding class can be configured as **premium** and others are configured as **normal**.
- **priority**—Fabric priority value:
 - **high**—Forwarding class's fabric queuing has high priority.
 - **low**—Forwarding class's fabric queuing has low priority.
- *queue-number*—Specify the internal queue number to which a forwarding class is assigned.
- **spu-priority**—Services Processing Unit (SPU) priority queue, either **high** or **low**.

NOTE: The **spu-priority** option is only supported on SRX1500, SRX3000 line, and SRX5000 line devices.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

global-config (Services)

Syntax

```
global-config {  
    session-cache-timeout seconds;  
}
```

Hierarchy Level [edit services ssl proxy]

Release Information Statement introduced in Junos OS Release 12.1X44-D10.

Description Specify the global proxy configuration.

Options *session-cache-timeout*—Specify the session cache timeout.

Range: 300 to 3600 seconds

Required Privilege Level services—To view this statement in the configuration.
services-control—To add this statement to the configuration.

Related Documentation

- [Enabling Debugging and Tracing for SSL Proxy on page 544](#)

initiation (Services)

Syntax

```
initiation {  
  profile profile-name {  
    actions {  
      ignore-server-auth-failure;  
    }  
    client-certificate;  
    custom-ciphers [cipher];  
    enable-flow-tracing;  
    enable-session-cache;  
    preferred-ciphers (custom | medium | strong | weak);  
    protocol-version (all | tls1 | tls11 | tls12);  
    trusted-ca (all | [ca-profile] );  
  }  
}
```

Hierarchy Level [edit services ssl]

Release Information Statement introduced in Junos OS Release 12.1X44-D10.

Description Specify the configuration for Secure Socket Layer (SSL) initiation support service.

Options

- **client-certificate**—Local certificate.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level

services	—To view this statement in the configuration.
services-control	—To add this statement to the configuration.

level (Services)

Syntax	<code>level [<i>brief</i> <i>detail</i> <i>extensive</i> <i>verbose</i>];</code>
Hierarchy Level	[edit services ssl traceoptions]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the level of debugging the output.
Options	<ul style="list-style-type: none">• <i>brief</i>—Specify brief debugging output.• <i>detail</i>—Specify detailed debugging output.• <i>extensive</i>—Specify extensive debugging output.• <i>verbose</i>—Specify verbose debugging output.
Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring SSL Proxy on page 534

log (Security)

```

Syntax  log {
        cache {
            exclude exclude-name {
                destination-address destination-address;
                destination-port destination-port;

    }
    utc-time-stamp;
}

```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 9.2.

Description You can set the mode of logging (event for traditional system logging or stream for streaming security logs through a revenue port to a server). You can also specify all the other parameters for security logging.

- Options**
- **disable**—Disable the security logging for the device.
 - **event-rate** *rate*—Limits the rate (0 through 1500) at which logs will be streamed per second.
 - **rate-cap** *rate-cap-value*—Works with event mode only. Limits the rate (0 through 5000) at which data plane logs will be generated per second.
 - **source-address** *source-address*—Specify a source IP address or IP address used when exporting security logs.
 - **source-interface** *interface-name*—Specify a source interface name, which is mandatory to configure **stream**.

NOTE: The **source-address** and **source-interface** are alternate values. Using one of the options is mandatory.

- **utc-time-stamp**—Specify to use UTC time for security log timestamps.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Hierarchy Level [edit security]

Release Information	Statement introduced in Junos OS Release 8.5. Support for the services-offload option added in Junos OS Release 11.4. Support for the source-identity option added in Junos OS Release 12.1. Support for the description option added in Junos OS Release 12.1. Support for the ssl-termination-profile and web-redirect-to-https options added in Junos OS Release 12.1X44-D10. Support for the user-firewall option added in Junos OS Release 12.1X45-D10. Support for the domain option, and for the from-zone and to-zone global policy match options added in Junos OS Release 12.1X47-D10. Support for the initial-tcp-mss and reverse-tcp-mss options added in Junos OS Release 12.3X48-D20. Support for the extensive option for policy-rematch added in Junos OS Release 15.1X49-D20.
Description	Configure network security policies.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

Hierarchy Level [edit security policies from-zone *zone-name* to-zone *zone-name*]

Release Information Statement introduced in Junos OS Release 8.5. The **services-offload** option added in Junos OS Release 11.4. Statement updated with the **source-identity** option and the **description** option added in Junos OS Release 12.1. Support for the **user-firewall** option added in Junos OS Release 12.1X45-D10. Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20.

Description Define a security policy.

Options *policy-name*—Name of the security policy.

The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

preferred-ciphers

Syntax preferred-ciphers (custom | medium | strong | weak);

Hierarchy Level [edit services ssl proxy profile *profile-name*]
[edit services ssl termination profile *profile-name*]
[edit services ssl initiation profile *profile-name*]

Release Information Statement introduced in Junos OS Release 12.1X44-D10.

Description Select the preferred ciphers.

Options

- **custom**—Configure custom cipher suite and order of preference.
- **medium**—Use ciphers with key strength of 128 bits or greater.
- **strong**—Use ciphers with key strength of 168 bits or greater.
- **weak**—Use ciphers with key strength of 40 bits or greater.

Required Privilege Level services—To view this statement in the configuration.
services-control—To add this statement to the configuration.

profile (Application Firewall)

Syntax	<pre>profile <i>profile-name</i> { block-message type { custom-text content <i>custom-html-text</i>; custom-redirect-url content <i>custom-redirect-url</i>; } }</pre>
Hierarchy Level	[edit security application-firewall]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	<p>Define the profile of the response to be issued when an application firewall rule set blocks HTTP or HTTPS traffic with a deny or reject action. You can display a default or custom message, or redirect traffic to a URL where an explanation or further action is provided.</p> <p>The remaining statements are explained separately. See CLI Explorer.</p>
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Application Firewall Overview on page 547

profile (Rule Sets)

Syntax	<pre>profile <i>profile-name</i>;</pre>
Hierarchy Level	[edit security application-firewall rule-sets <i>rule-set-name</i>]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Specifies the profile of the block message to be used for any deny or reject action in the rule set that specifies the block-message option.
Options	<i>profile-name</i> —Name of the block-message profile to be used for this rule set.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Application Firewall Overview on page 547

profile (Services)

Syntax	<pre> profile <i>profile-name</i> { actions { crt { disable; if-not-present (allow drop); ignore-hold-instruction-code; } disable-session-resumption; ignore-server-auth-failure; logs { all; errors; info; sessions-allowed; sessions-dropped; sessions-ignored; sessions-whitelisted; warning; } renegotiation { (allow allow-secure drop); } } custom-ciphers [<i>cipher</i>]; enable-flow-tracing; preferred-ciphers (custom medium strong weak); root-ca <i>root-certificate</i>; trusted-ca (all [<i>ca-profile</i>]); whitelist [<i>global-address-book-addresses</i>]; } </pre>
Hierarchy Level	[edit services ssl proxy]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the SSL server profile.
Options	<p><i>profile-name</i>—Specify the profile identifier.</p> <p>The remaining statements are explained separately. See CLI Explorer.</p>
Required Privilege Level	<p>services—To view this statement in the configuration.</p> <p>services-control—To add this statement to the configuration.</p>

rate-limiters

Syntax	<pre>rate-limiters { rate-limiter-name { bandwidth-limit <i>value-in-kbps</i>; burst-size-limit <i>value-in-bytes</i>; } }</pre>
Hierarchy Level	[edit class-of-service application-traffic-control]
Release Information	Statement introduced in Junos OS Release 11.4.
Description	Share the available bandwidth and burst size of a device's PICs by defining rate limiter profiles and applying them in AppQoS rules.
Options	<ul style="list-style-type: none"> • <i>rate-limiter-name</i>—Name of the rate limiter. It is applied in AppQoS rules to share device resources based on quality of service requirements. <p>The combination of rate limiting parameters, namely bandwidth- limit and burst-size-limit rate limit, make up the rate limiter profile. A maximum of 16 profiles are allowed per device. The same profile can be used by multiple rate limiters. For example, a profile with a bandwidth-limit of 200 Kbps and a burst-limit of 130,000 bytes, could be used in several rate limiters.</p> <p>A maximum of 1000 rate limiters can be created. Rate limiters are defined for the device, and are assigned in rules in a rule set. A single rate limiter can be used multiple times within the same rule set. However, the rate limiter cannot be used in another rule set.</p> <ul style="list-style-type: none"> • <i>bandwidth-limit value-in-Kbps</i>—Maximum number of kilobits to be transmitted per second for this rate limiter. Up to 2 GB of bandwidth can be provisioned among multiple rate limiters to share the resource proportionally. • <i>burst-size-limit value-in-bytes</i>—Maximum number of bytes to be transferred in a single burst or time-slice. This limit ensures that a high-priority transmission does not keep a lower priority transmission from transmitting.
<div>  <p>NOTE: The number of bandwidth-limit and burst-size-limit combinations cannot exceed 16.</p> </div>	
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.

                        server-to-client rate-limiter-name;
                    }
                }
            }
        }
    }
```

Hierarchy Level [edit class-of-service application-traffic-control]

Release Information Statement introduced in Junos OS Release 11.4.

Description Defines AppQoS rule sets and the rules that establish priorities based on quality of service requirements for the associated applications. AppQoS rules can be included in policy statements to implement application-aware quality of service control.

- Options**
- **rule-set-name**—Name used to refer to a collection of AppQoS rules.
 - **rule rule-name**—Name applied to the match criteria and resulting actions that control the quality of service provided to any matching applications.
 - **application application-name**—Name of the application to be used as match criteria for the rule.
 - **application-any**—Any application encountering this rule. Note that when you use this specification, all application matching ends. Any application rule following this one will never be encountered.
 - **application-group application-group-name**—Group of applications to be used as match criteria for the rule. Both applications and application groups can be match criteria for a single rule.
 - **application-known**—Match criteria specifying any session that is identified, but its corresponding application is not specified.

- **application-unknown**—Match criteria specifying any session that is not identified.
- **forwarding-class *forwarding-class-name***—The AppQoS class with which matching applications will be marked. This field identifies the rewriter that has marked the DSCP value. Therefore, the AppQoS forwarding class must be different from those used by IDP or firewall filters. With this class specified, firewall filter class will not overwrite the existing DSCP value.
- **dscp-code-point**—DSCP alias or bit map with which matching applications will be marked to establish the output queue. This value can be marked by rewriters from IDP, AppQoS, or a firewall filter. The forwarding-class value identifies which rewriter has re-marked the packet with the current DSCP value. If a packet triggers all three rewriters, IDP takes precedence over AppQoS, which takes precedence over a firewall filter.
- **loss-priority**—Loss priority with which matching applications will be marked. This value is used to determine the likelihood that a packet would be dropped when encountering congestion. A high loss priority means that there is an 80% chance of packet loss in congestion. Possible values are high, medium-high, medium-low and low.
- **rate-limit**—Rate limiters to be associated with client-to-server and with server-to-client traffic for this application. The rate limiter profile defines maximum speed and volume limits for matching applications.
- **log**—AppQoS event logging.

Required Privilege	security—To view this statement in the configuration.
Level	security-control—To add this statement to the configuration.

Hierarchy Level	[edit services]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the configuration for Secure Socket Layer (SSL) support service.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring SSL Proxy on page 534 • Firewall User Authentication Overview on page 5505

ssl-encryption

Syntax	ssl-encryption (any no yes);
Hierarchy Level	[edit security application-firewall rule-sets <i>rule-set-name</i> rule <i>rule-name</i> match]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Distinguishes between encrypted and unencrypted SSL traffic as match criteria for the rule. In application firewall usage, this option lets you specify different actions for encrypted and unencrypted SSL traffic.
Options	<ul style="list-style-type: none"> • any—Matches both encrypted and unencrypted SSL traffic. • no—Matches unencrypted SSL traffic only. • yes—Matches encrypted SSL traffic only.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring SSL Proxy on page 534

ssl-proxy (Application Services)

Syntax	<pre>ssl-proxy { profile-name <i>profile-name</i> }</pre>
Hierarchy Level	[edit security policies from-zone <i>zone-name</i> to-zone <i>zone-name</i> policy <i>policy-name</i> then permit application-services]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	Enable SSL proxy and identify the name of the SSL proxy profile to be used.
Options	<i>profile-name</i> —SSL proxy profile.
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring SSL Proxy on page 534

statistics (Services)

Syntax	statistics { interval <i>interval-number</i> ; }
Hierarchy Level	[edit services application-identification]
Release Information	Statement introduced in Junos OS Release 11.4.
Description	Specify the interval, in minutes, for statistics collection.
Options	interval <i>interval-number</i> —Length of time, in minutes, that application statistics are collected. Range: 1 through 1440 minutes Default: 1 minute

NOTE: For SRX Series devices, the maximum number of interval periods for which statistics are stored is 8.

Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Onbox Application Identification Statistics on page 519

stream (Security Log)

Syntax	<pre>stream <i>stream-name</i> { category (all content-security) format (binary sd-syslog syslog welf) host { <ipaddr> <i>ip-address</i>; port <i>port-number</i>; } severity (alert critical debug emergency error info notice warning); }</pre>
Hierarchy Level	[edit security log]
Release Information	Statement modified in Junos OS Release 9.2.
Description	Set stream settings for a security log. You can set a maximum of three streams.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege	security—To view this statement in the configuration.
Level	security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring AppTrack on page 566

termination (Services)

Syntax	<pre>termination { profile <i>profile-name</i> { custom-ciphers [<i>cipher</i>]; enable-flow-tracing; enable-session-cache; preferred-ciphers (custom medium strong weak); protocol-version (all tls1 tls11 tls12); server-certificate <i>certificate-identifier</i>; } }</pre>
Hierarchy Level	[edit services ssl]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the configuration for Secure Socket Layer (SSL) termination support service.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	services—To view this statement in the configuration. services-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Configuring SSL Proxy on page 534• Firewall User Authentication Overview on page 5505

then (Security Application Firewall)

Syntax	<pre>then { (deny [block-message] permit reject [block-message]); }</pre>
Hierarchy Level	[edit security application-firewall rule-set <i>rule-set-name</i> rule <i>rule-name</i>]
Release Information	Statement introduced in Junos OS Release 11.1. Statement updated in Junos OS Release 12.1X44-D10 with the reject option. The block-message option added in Junos OS Release 12.1X45-D10.
Description	<p>Specify the action to be performed when traffic matches the associated match criteria.</p> <p>Note that an application firewall is applied after a session has already been created by the security firewall. When traffic is rejected or denied by an application firewall, therefore, logs contain a session open message, a session reject or deny message, and a session close message.</p>
Options	<ul style="list-style-type: none"> • deny—Block the traffic at the firewall. The device drops the packet. By default, no message is returned to the sender. • block-message—(Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the profile option for this rule set, including the block-message option displays a default message or customized message, or redirects the user for denied HTTP or HTTPS traffic. All other traffic is dropped silently. • permit—Permit traffic at the firewall. • reject—Block the traffic at the firewall. For TCP traffic, by default the device drops the packet and returns a TCP reset (RST) message to the source host. For UDP and other protocol traffic, by default the device drops the packet and returns an ICMP “destination unreachable, port unreachable” message to both the client and the server. • block-message—(Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the profile option for this rule set, including the block-message option displays a default message or customized message, or redirects the user for rejected HTTP or HTTPS traffic. All other traffic is dropped as specified in the default action for the reject option.
Required Privilege Level	<p>security—To view this statement in the configuration.</p> <p>security-control—To add this statement to the configuration.</p>

traceoptions (Security Application Firewall)

Syntax	<pre> traceoptions { file { filename; files number; match regular-expression; size maximum-file-size; (world-readable no-world-readable); } flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit security application-firewall]
Release Information	Statement introduced in Junos OS Release 11.1.
Description	Configure trace options for the application firewall.
Options	<ul style="list-style-type: none"> • file—Configure the trace file options. <ul style="list-style-type: none"> • filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <code>/var/log</code>. By default, the name of the file is the name of the process being traced. • files number—Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed to trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> • match regular-expression—Refine the output to include lines that contain the regular expression. • size maximum-file-size—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When the trace-file again reaches its maximum size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p> <p>Range: 10 KB through 1 GB</p>

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
 - **all**—Trace with all flags enabled
 - **compilation**—Trace rule set compilation events
 - **configuration**—Trace configuration events
 - **ipc**—Trace process inter communication events
 - **lookup**—Trace rule set lookup events
- **no-remote-trace**—Set remote tracing as disabled.

Required Privilege	trace—To view this statement in the configuration.
Level	trace-control—To add this statement to the configuration.

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OS Release 11.1. The **description** option added in Junos OS Release 12.1.

Description A zone is a collection of interfaces for security purposes. All interfaces in a zone are equivalent from a security point of view. Configure the following zones:

- Functional zone—Special-purpose zone, such as a management zone that can host dedicated management interfaces.
- Security zone—Most common type of zone that is used as a building block in policies.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

clear security application-firewall rule-set statistics

Syntax	clear security application-firewall rule-set statistics
Release Information	Command introduced in Junos OS Release 11.1.
Description	Clear all the security application firewall rule set statistics information.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show security application-firewall rule-set on page 752
Output Fields	This command produces no output.

clear security application-firewall rule-set statistics logical-system

Syntax The master, or root, administrator can issue the following statements:

```
clear security application-firewall rule-set statistics [logical-system logical-system-name |
all | root-logical-system]
```

The user logical system administrator can issue the following statement:

```
clear security application-firewall rule-set statistics all
```

Release Information Command introduced in Junos OS Release 11.4.

Description Clear all security application firewall rule set statistics.

NOTE: User logical system administrators can clear statistics only for the logical systems they can access. For information about master and user administrator roles in logical systems, see [“Understanding the Master Logical System and the Master Administrator Role” on page 3543](#).

Options *logical-system-name*—Name of a specific logical system.

all—(default) Clear all rule set statistics for a specific logical system or all logical systems.

root-logical-system—Clear application firewall rule set statistics on the root logical system (master administrator only).

Required Privilege Level clear

clear services application-identification counter (Values)

Syntax	clear services application-identification counter <ssl-encrypted-sessions>
Release Information	Command introduced in Junos OS Release 10.2. Command updated in Junos OS Release 12.1-X47-D15.
Description	Reset all the Junos OS application identification counter values.
Options	ssl-encrypted-sessions —Reset application identification counter values for SSL encrypted sessions.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none"> • show services application-identification counter (AppSecure) on page 793
List of Sample Output	clear services application-identification counter on page 729
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

clear services application-identification counter

```
user@host> clear services application-identification counter
clear_counter_class: counters cleared, status = 0
```

clear services ssl proxy statistics

Syntax	clear services ssl proxy statistics
Release Information	Command introduced in Junos OS Release 12.1.
Description	Clear services SSL proxy statistics.
Options	none—Clear the ssl proxy statistics.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show services ssl proxy statistics on page 806
Output Fields	This command produces no output.

request security pki ca-certificate ca-profile-group load

Syntax	<code>request security pki ca-certificate ca-profile-group load ca-group-name <i>ca-group-name</i> filename [<i>path/filename</i> default]</code>
Release Information	Command introduced in Junos OS Release 12.1; default option added in Junos OS Release 12.1X47-D10.
Description	<p>For SSL forward proxy, you need to load trusted CA certificates on your system. By default, Junos OS provides a list of trusted CA certificates that include default certificates used by common browsers. Alternatively, you can define your own list of trusted CA certificates and import them on to your system.</p> <p>Use this command to load the default certificates or to specify a path and filename of trusted CA certificates that you define.</p>
Options	<p>ca-group-name <i>ca-group-name</i>—Load the specified CA group profile.</p> <p>filename <i>path/filename</i>—Directory location and filename of the trusted CA certificates defined by you.</p> <p>filename default—Load the trusted CA certificates available by default.</p>
Required Privilege Level	maintenance

```
user@host> request security pki local-certificate generate-self-signed certificate-id self-cert
subject cn=abc domain-name example.net email user@example.net
Self-signed certificate generated and loaded successfully
```

request security pki local-certificate load

Syntax	<code>request security pki local-certificate load certificate-id <i>certificate-id-name</i> filename <i>path</i></code>
Release Information	Command introduced in Junos OS Release 7.5.
Description	Manually load a local digital certificate from a specified location.
Options	<p>certificate-id <i>certificate-id-name</i>—Name of the public/private key pair mapped to the local digital certificate.</p> <p>filename <i>path/filename</i>—Directory location and filename of the local digital certificate provided by the CA.</p>
Required Privilege Level	maintenance
List of Sample Output	request security pki local-certificate load on page 735
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request security pki local-certificate load

```
user@host> request security pki local-certificate load filename /tmp/router2-cert certificate-id
local-entrust2
Local certificate local-entrust2 loaded successfully
```

request services application-identification application

Syntax	<pre>request services application-identification application copy <i>predefined-application-name</i> request services application-identification application [disable enable] <i>predefined-application-name</i> <no-commit></pre>
Release Information	Command introduced in Junos OS Release 11.4.
Description	Copy, disable, or enable a predefined application signature.
Options	<p>copy—(Optional) Copy a predefined application signature from the database to the configuration and change the name (for example, my:FTP). The ID and order will be generated automatically. Do not name your custom application signature with the “junos” prefix; this prefix is reserved for predefined application signatures. You can copy the same predefined application signature only once; duplicate custom signatures are not allowed. The copy command does not initiate signature recompilation.</p> <hr/> <div style="display: flex; align-items: flex-start;"> <div style="margin-right: 10px;">  </div> <div> <p>NOTE: In configuration mode, if an uncommitted action is pending, the request services application-identification application copy command will fail. Uncompiled application signatures are shown as uncommitted in the show services application-identification application [summary detail] command.</p> </div> </div> <hr/> <p>disable—(Optional) Disable a predefined application signature, initiate signature recompilation, and commit all pending uncompiled signatures to the configuration. Include the <no-commit> keyword to defer signature recompilation.</p> <p>The following conditions apply:</p> <ul style="list-style-type: none"> • You cannot disable a predefined application signature that is referenced by an active security policy or custom application signature. First modify or deactivate the policy or custom application signature. • If you disable an application signature, for example, junos:HTTP, that has nested applications, the nested applications will not be recognized. <p>enable—(Optional) Enable a predefined application signature, initiate signature recompilation, and commit all pending uncompiled signatures to the configuration. Include the <no-commit> keyword to defer signature recompilation.</p> <p>no-commit—(Optional) Enables you to enter multiple enable and disable commands before initiating signature recompilation (which takes some time) and committing the configuration. Uncompiled application signatures are shown as uncommitted in the show services application-identification application [summary detail] command.</p>
Required Privilege Level	maintenance

    Number of sessions matched: 0
    Number of sessions redirected: 0
  Number of sessions with appid pending: 0

```

show security application-firewall rule-set logical-system

Syntax The master, or root, administrator can issue the following statements:

```
show security application-firewall rule-set all
show security application-firewall rule-set rule-set-name | all | logical-system
logical-system-name | all | root-logical-system [logical-system-name | all ]
```

The user logical system administrator can issue the following statement:

```
show security application-firewall rule-set all
```

Release Information Command introduced in Junos OS Release 11.4.

Description Display information about application firewall rule set(s) associated with a specific logical system, all logical systems, or the root logical system configured on a device.

NOTE: The master administrator can configure and view application firewall rule sets for the root logical system and all user logical systems configured on the device. User logical system administrators can configure and view application firewall rule set information only for the user logical systems for which they have access. For information about master and user administrator roles in logical systems, see [“Understanding Logical Systems for SRX Series Services Gateways” on page 3527](#).

Options *rule-set-name*—Name of a specific rule set.

logical-system-name—Name of a specific logical system.

all—(default) Display all rule sets for all logical systems. The user logical system administrator can display all rule sets only for the logical system they can access.

root-logical-system—Display application firewall rule set information for the root logical system (master administrator only).

Required Privilege Level view

Output Fields [Table 45](#) lists the output fields for the **show security application-firewall rule-set logical-system** command. Output fields are listed in the approximate order in which they appear.

Table 45: show security application-firewall rule-set logical-system Output Fields

Field Name	Field Description
Rule-set	Name of the rule set.
Logical system	Name of the logical system.
Rule	Name of the rule. <ul style="list-style-type: none"> • Dynamic applications—Name of the applications. • Dynamic application groups—Name of the application groups. • Action—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following: <ul style="list-style-type: none"> • permit • deny • Number of sessions matched—Number of sessions matched with the application firewall rule.
Default rule	The default rule applied when the identified application is not specified in any rules of the rule set. <ul style="list-style-type: none"> • Number of sessions matched—Number of sessions matched with the application firewall default rule.
Number of sessions with appid pending	Number of sessions that are pending with the application ID processing.

Sample Output

show security application-firewall rule-set logical-system all

```

root@host> show security application-firewall rule-set logical-system all

Rule-set: root_rs1
  Logical system: root-logical-system
  Rule: r1
    Dynamic Applications: junos:FTP
    Action: permit
    Number of sessions matched: 10
  Default rule: deny
    Number of sessions matched: 100

  Default rule:deny
    Number of sessions matched: 200
  Number of sessions with appid pending: 4

Rule-set: ls-product-design-rs2
  Logical system: ls-product-design
  Rule: r1
    Dynamic Applications: junos:FACEBOOK
    Action:deny
    Number of sessions matched: 40
  Default rule:permit
    Number of sessions matched: 400
  Number of sessions with appid pending: 10
```

show security application-tracking counters

Syntax	show security application-tracking counters
Release Information	Command introduced in Junos OS Release 10.2.
Description	Display the status of AppTrack counters.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring AppTrack on page 566
Output Fields	Table 46 lists the output fields for the show security application-tracking counters command. Output fields are listed in the approximate order in which they appear.

Table 46: show security application-tracking counters

Field Name	Field Description
Session create messages	The number of log messages generated when a session was created.
Session close messages	The number of log messages generated when a session was closed.
Session volume updates	The number of log messages generated when an update interval was exceeded.
Failed messages	The number of messages that were not generated due to memory or session constraints.

Sample Output

show security application-tracking counters

```

user@host> show security application-tracking counters
AVT counters:
Session create messages      0
Session close messages      0
Session volume updates      0
Failed messages              0

```

show security flow session

Syntax	show security flow session [<i>filter</i>] [brief extensive summary]
Release Information	Command introduced in Junos OS Release 8.5. Support for filter and view options added in Junos OS Release 10.2. Application firewall, dynamic application, and logical system filters added in Junos OS Release 11.2. Policy ID filter added in Junos OS Release 12.3X48-D10.
Description	Display information about all currently active security sessions on the device.
Options	<ul style="list-style-type: none"> • <i>filter</i>—Filter the display by the specified criteria. <p>The following filters reduce the display to those sessions that match the criteria specified by the filter. Refer to the specific show command for examples of the filtered output.</p> <p>application—Predefined application name</p> <p>application-firewall—Application firewall enabled</p> <p>application-firewall-rule-set—Application firewall enabled with the specified rule set</p> <p>application-traffic-control—Application traffic control session</p> <p>application-traffic-control-rule-set—Application traffic control rule set name and rule name</p> <p>destination-port—Destination port</p> <p>destination-prefix—Destination IP prefix or address</p> <p>dynamic-application—Dynamic application</p> <p>dynamic-application-group—Dynamic application</p> <p>encrypted—Encrypted traffic</p> <p>extensive—Display detailed output</p> <p>family—Display session by family</p> <p>idp—IDP enabled sessions</p> <p>interface—Name of incoming or outgoing interface</p> <p>logical-system (all <i>logical-system-name</i>)—Name of a specific logical system or all to display all logical systems</p> <p>nat—Display sessions with network address translation</p> <p>policy-id—Display session information based on policy ID; the range is 1 through 4,294,967,295</p>

protocol—IP protocol number

resource-manager—Resource manager

root-logical-system—Display root logical system as default

security-intelligence—Display security intelligence sessions

services-offload—Display services offload sessions

session-identifier—Display session with specified session identifier

source-port—Source port

source-prefix—Source IP prefix

summary—Display output summary

tunnel—Tunnel sessions

- **brief | extensive | summary**—Display the specified level of output.
- **none**—Display information about all active sessions.

Required Privilege Level view

Output Fields [Table 26](#) lists the output fields for the **show security flow session** command. Output fields are listed in the approximate order in which they appear.

Table 47: show security flow session Output Fields

Field Name	Field Description
Session ID	Number that identifies the session. Use this ID to get more information about the session.
CP Session ID	Number that identifies the central point session. Use this ID to get more information about the central point session.
Policy name	Policy that permitted the traffic.
Timeout	Idle timeout after which the session expires.

Table 47: show security flow session Output Fields (*continued*)

Field Name	Field Description
In	Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Out	Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Total sessions	Total number of sessions.
Status	Session status.
Flag	Internal flag depicting the state of the session, used for debugging purposes. The three available flags are: <ul style="list-style-type: none"> • flag • natflag • natflag2
Policy name	Name and ID of the policy that the first packet of the session matched.
Source NAT pool	The name of the source pool where NAT is used.
Dynamic application	Name of the application.
Application traffic control rule-set	AppQoS rule set for this session.
Rule	AppQoS rule for this session.
Forwarding class	The AppQoS forwarding class name for this session that distinguishes the transmission priority
DSCP code point	Differentiated Services (DiffServ) code point (DSCP) value remarked by the matching rule for this session.
Loss priority	One of four priority levels set by the matching rule to control discarding a packet during periods of congestion. A high loss priority means a high probability that the packet could be dropped during a period of congestion.
Rate limiter client to server	The rate-limiter profile assigned to the client-to-server traffic defining a unique combination of bandwidth-limit and burst-size-limit specifications.
Rate limiter server to client	The rate-limiter profile assigned to the server-to-client traffic defining a unique combination of bandwidth-limit and burst-size-limit specifications.
Maximum timeout	Maximum session timeout.
Current timeout	Remaining time for the session unless traffic exists in the session.

Table 47: show security flow session Output Fields (*continued*)

Field Name	Field Description
Session State	Session state.
Start time	Time when the session was created, offset from the system start time.
Unicast-sessions	Number of unicast sessions.
Multicast-sessions	Number of multicast sessions.
Failed-sessions	Number of failed sessions.
Sessions-in-use	Number of sessions in use. <ul style="list-style-type: none"> Valid sessions Pending sessions Invalidated sessions Sessions in other states
Maximum-sessions	Maximum number of sessions permitted.

List of Sample Output	<p>show security flow session application-firewall extensive on page 767</p> <p>show security flow session application-firewall dynamic-application junos:FTP extensive on page 767</p> <p>show security flow session application-firewall dynamic-application junos:UNKNOWN extensive on page 768</p> <p>show security flow session application-firewall dynamic-application-group junos:WEB extensive on page 769</p> <p>show security flow session application-firewall application-firewall-rule-set rule-set1 extensive on page 769</p>

Output Fields Table 48 lists the output fields for the **show security flow session application-firewall extensive** command. Output fields are listed in the approximate order in which they appear in the extensive display.

Table 48: show security flow session application-firewall extensive Output Fields

Field Name	Field Description
Session ID	Number that identifies the session. Use this ID to display more information about a session.
Status	Session status.
State	Current state of the session: Active, Pending, Closed, Unknown.
Flag	Internal flag depicting the state of the session. It is used for debugging purposes.
Policy name	The name of the policy that permitted the traffic.
Source NAT pool	The name of the source pool where NAT is used.
Dynamic application	Name of the dynamic application of the session. If the dynamic application has yet to be determined, the output indicates Pending. If the dynamic application cannot be determined, the output indicates junos:UNKNOWN.
Dynamic application group	Name of the dynamic application group of the session. If the dynamic application cannot be determined, the output indicates junos:UNASSIGNED.
Dynamic nested application	Name of the dynamic nested application of the session if one exists. If the dynamic nested application is yet to be determined, the output indicates Pending. If the dynamic nested application cannot be determined, the output indicates junos:UNKNOWN.
Application firewall rule-set	Name of the rule set that the session matched.
Rule	Name of the rule that the session matched. If the match has not yet been made, the output indicates Pending. If the rule has been deleted since the match was made, the output indicates the rule is invalid.
Maximum timeout	Maximum amount of idle time allowed for the session.
Current timeout	Number of seconds that the current session has been idle.
Session State	Session state.
Start time	Time when the session was created. Start time is indicated as an offset from the system start time.
In	Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets, and bytes).

Table 48: show security flow session application-firewall extensive Output Fields (*continued*)

Field Name	Field Description
Out	Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Total sessions	Total number of sessions per PIC that fit the display criteria.

Sample Output

show security flow session application-firewall extensive

The displayed information is similar to the **show security flow session** output but includes dynamic application and application firewall details for the session.

```
user@host> show security flow session application-firewall extensive
Flow Sessions on FPC9 PIC0:

show security pki ca-certificate

Syntax	show security pki ca-certificate <brief detail> <ca-profile <i>ca-profile-name</i> >
Release Information	Command introduced in Junos OS Release 7.5.
Description	Display information about certificate authority (CA) digital certificates installed in the router.
Options	<p>none—(Same as brief) Display information about all CA digital certificates.</p> <p>brief detail—(Optional) Display the specified level of output.</p> <p>ca-profile <i>ca-profile-name</i>—(Optional) Display information about only the specified CA profile.</p>
Required Privilege Level	view
List of Sample Output	show security pki ca-certificate on page 772 show security pki ca-certificate detail on page 773
Output Fields	Table 49 lists the output fields for the show security pki ca-certificate command. Output fields are listed in the approximate order in which they appear.

Table 49: show security pki ca-certificate Output Fields

Field Name	Field Description	Level of Output
Certificate identifier	Name of the digital certificate.	All levels
Certificate version	Revision number of the digital certificate.	detail
Serial number	Unique serial number of the digital certificate.	detail
Issued by	Authority that issued the digital certificate.	none brief
Issued to	Device that was issued the digital certificate.	none brief
Issuer	<p>Authority that issued the digital certificate, including details of the authority organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> • Common name—Name of the authority. • Organization—Organization of origin. • Organizational unit—Department within an organization. • State—State of origin. • Country—Country of origin. 	detail

Table 49: show security pki ca-certificate Output Fields (*continued*)

Field Name	Field Description	Level of Output
Subject	Details of the digital certificate holder organized using the distinguished name format. Possible subfields are: <ul style="list-style-type: none"> • Common name—Name of the requestor. • Organization—Organization of origin. • Organizational unit—Department within an organization. • State—State of origin. • Country—Country of origin. 	detail
Validity	Time period when the digital certificate is valid. Values are: <ul style="list-style-type: none"> • Not before—Start time when the digital certificate becomes valid. • Not after—End time when the digital certificate becomes invalid. 	All levels
Public key algorithm	Encryption algorithm used with the private key, such as rsaEncryption(1024 bits) .	All levels
Signature algorithm	Encryption algorithm that the CA used to sign the digital certificate, such as sha1WithRSAEncryption .	detail
Fingerprint	Secure Hash Algorithm (SHA1) and Message Digest 5 (MD5) hashes used to identify the digital certificate.	detail
Distribution CRL	Distinguished name information and the URL for the certificate revocation list (CRL) server.	detail
Use for key	Use of the public key, such as Certificate signing , CRL signing , Digital signature , or Key encipherment .	detail

Sample Output

show security pki ca-certificate

```

user@host> show security pki ca-certificate

show security pki local-certificate (View)

Syntax	show security pki local-certificate < brief detail > < certificate-id <i>certificate-id-name</i> > <system-generated>
Release Information	Command modified in Junos OS Release 9.1. Subject string output field added in Junos OS Release 12.1X44-D10.
Description	Display information about the local digital certificates, corresponding public keys, and the automatically generated self-signed certificate configured on the device.
Options	<ul style="list-style-type: none"> • none—Display basic information about all configured local digital certificates, corresponding public keys, and the automatically generated self-signed certificate. • brief detail—(Optional) Display the specified level of output. • certificate-id <i>certificate-id-name</i> —(Optional) Display information about only the specified local digital certificates and corresponding public keys. • system-generated—Display information about the automatically generated self-signed certificate.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear security pki local-certificate (Device) on page 7102 • request security pki local-certificate generate-self-signed (Security) on page 7115
List of Sample Output	show security pki local-certificate certificate-id hello on page 777 show security pki local-certificate certificate-id hello detail on page 777 show security pki local-certificate system-generated on page 778 show security pki local-certificate system-generated detail on page 778 show security pki local-certificate certificate-id mycert - (local certificate enrolled online using SCEP) on page 778 show security pki local-certificate certificate-id mycert detail - (local certificate enrolled online using SCEP) on page 779
Output Fields	Table 50 lists the output fields for the show security pki local-certificate command. Output fields are listed in the approximate order in which they appear.

Table 50: show security pki local-certificate Output Fields

Field Name	Field Description
Certificate identifier	Name of the digital certificate.
Certificate version	Revision number of the digital certificate.
Serial number	Unique serial number of the digital certificate.

Table 50: show security pki local-certificate Output Fields (*continued*)

Field Name	Field Description
Issued to	Device that was issued the digital certificate.
Issued by	Authority that issued the digital certificate.
Issuer	<p>Authority that issued the digital certificate, including details of the authority organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> • Organization—Organization of origin. • Organizational unit—Department within an organization. • Country—Country of origin. • Locality—Locality of origin. • Common name—Name of the authority.
Subject	<p>Details of the digital certificate holder organized using the distinguished name format. Possible subfields are:</p> <ul style="list-style-type: none"> • Organization—Organization of origin. • Organizational unit—Department within an organization. • Country—Country of origin. • Locality—Locality of origin. • Common name—Name of the authority. • Serial number—Serial number of the device. <p>If the certificate contains multiple subfield entries, all entries are displayed.</p>
Subject string	Subject field as it appears in the certificate.
Alternate subject	Domain name or IP address of the device related to the digital certificate.
Validity	<p>Time period when the digital certificate is valid. Values are:</p> <ul style="list-style-type: none"> • Not before—Start time when the digital certificate becomes valid. • Not after—End time when the digital certificate becomes invalid.
Public key algorithm	Encryption algorithm used with the private key, such as rsaEncryption(1024 bits) .
Public key verification status	Public key verification status: Failed or Passed . The detail output also provides the verification hash.
Signature algorithm	Encryption algorithm that the CA used to sign the digital certificate, such as sha1WithRSAEncryption .
Fingerprint	Secure Hash Algorithm (SHA1) and Message Digest 5 (MD5) hashes used to identify the digital certificate.
Distribution CRL	Distinguished name information and URL for the certificate revocation list (CRL) server.
Use for key	Use of the public key, such as Certificate signing , CRL signing , Digital signature , or Data encipherment .

show security policies

Syntax	<pre>show security policies <detail> <none> policy-name <i>policy-name</i> <detail> <global></pre>
Release Information	<p>Command modified in Junos OS Release 9.2. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations in addition to the existing support of active/passive chassis cluster configurations added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1. Support for global policy added in Junos OS Release 11.4. Support for services offloading added in Junos OS Release 11.4. Support for source-identities added in Junos OS Release 12.1. The Description output field added in Junos OS Release 12.1. Support for negated address added in Junos OS Release 12.1X45-D10. The output fields for Policy Statistics expanded, and the output fields for the global and policy-name options expanded to include from-zone and to-zone global match criteria in Junos OS Release 12.1X47-D10. Support for the initial-tcp-mss and reverse-tcp-mss options added in Junos OS Release 12.3X48-D20.</p>
Description	<p>Display a summary of all security policies configured on the device. If a particular policy is specified, display information particular to that policy.</p>
Options	<ul style="list-style-type: none"> • none—Display basic information about all configured policies. • detail—(Optional) Display a detailed view of all of the policies configured on the device. • policy-name <i>policy-name</i>—(Optional) Display information about the specified policy. • global—Display information about global policies.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • Security Policies Overview on page 1065 • Understanding Security Policy Rules on page 1067 • Understanding Security Policy Elements on page 1071

Output Fields Table 51 lists the output fields for the **show security policies** command. Output fields are listed in the approximate order in which they appear.

Table 51: show security policies Output Fields

Field Name	Field Description
From zone	Name of the source zone.
To zone	Name of the destination zone.
Policy	Name of the applicable policy.
Description	Description of the applicable policy.
State	Status of the policy: <ul style="list-style-type: none"> • enabled: The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it. • disabled: The policy cannot be used in the policy lookup process, and therefore it is not available for access control.
Index	Internal number associated with the policy.
Sequence number	Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, 4.
Source addresses	For standard display mode, the names of the source addresses for a policy. Address sets are resolved to their individual names. For detail display mode, the names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.
Destination addresses	Name of the destination address (or address set) as it was entered in the destination zone's address book. A packet's destination address must match this value for the policy to apply to it.
Source addresses (excluded)	Name of the source address excluded from the policy.
Destination addresses (excluded)	Name of the destination address excluded from the policy.
Source identities	One or more user roles specified for a policy.

Table 51: show security policies Output Fields (*continued*)

Field Name	Field Description
Applications	<p>Name of a preconfigured or custom application whose type the packet matches, as specified at configuration time.</p> <ul style="list-style-type: none"> • IP protocol: The Internet protocol used by the application—for example, TCP, UDP, ICMP. • ALG: If an ALG is explicitly associated with the policy, the name of the ALG is displayed. If application-protocol ignore is configured, ignore is displayed. Otherwise, 0 is displayed. However, even if this command shows ALG: 0, ALGs might be triggered for packets destined to well-known ports on which ALGs are listening, unless ALGs are explicitly disabled or when application-protocol ignore is not configured for custom applications. • Inactivity timeout: Elapsed time without activity after which the application is terminated. • Source port range: The low-high source port range for the session application.
Destination Address Translation	<p>Status of the destination address translation traffic:</p> <ul style="list-style-type: none"> • drop translated—Drop the packets with translated destination addresses. • drop untranslated—Drop the packets without translated destination addresses.
Application Firewall	<p>An application firewall includes the following:</p> <ul style="list-style-type: none"> • Rule-set—Name of the rule set. • Rule—Name of the rule. <ul style="list-style-type: none"> • Dynamic applications—Name of the applications. • Dynamic application groups—Name of the application groups. • Action—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following: <ul style="list-style-type: none"> • permit • deny • Default rule—The default rule applied when the identified application is not specified in any rules of the rule set.
Action or Action-type	<ul style="list-style-type: none"> • The action taken in regard to a packet that matches the policy's tuples. Actions include the following: <ul style="list-style-type: none"> • permit • firewall-authentication • tunnel ipsec-vpn <i>vpn-name</i> • pair-policy <i>pair-policy-name</i> • source-nat pool <i>pool-name</i> • pool-set <i>pool-set-name</i> • interface • destination-nat <i>name</i> • deny • reject • services-offload
Session log	<p>Session log entry that indicates whether the at-create and at-close flags were set at configuration time to log session information.</p>

Table 51: show security policies Output Fields (*continued*)

Field Name	Field Description
Scheduler name	Name of a preconfigured scheduler whose schedule determines when the policy is active and can be used as a possible match for traffic.
Policy statistics	<ul style="list-style-type: none"> • Input bytes—The total number of bytes presented for processing by the device. <ul style="list-style-type: none"> • Initial direction—The number of bytes presented for processing by the device from the initial direction. • Reply direction—The number of bytes presented for processing by the device from the reply direction. • Output bytes—The total number of bytes actually processed by the device. <ul style="list-style-type: none"> • Initial direction—The number of bytes from the initial direction actually processed by the device. • Reply direction—The number of bytes from the reply direction actually processed by the device. • Input packets—The total number of packets presented for processing by the device. <ul style="list-style-type: none"> • Initial direction—The number of packets presented for processing by the device from the initial direction. • Reply direction—The number of packets presented for processing by the device from the reply direction. • Output packets—The total number of packets actually processed by the device. <ul style="list-style-type: none"> • Initial direction—The number of packets actually processed by the device from the initial direction. • Reply direction—The number of packets actually processed by the device from the reply direction. • Session rate—The total number of active and deleted sessions. • Active sessions—The number of sessions currently present because of access control lookups that used this policy. • Session deletions—The number of sessions deleted since system startup. • Policy lookups—The number of times the policy was accessed to check for a match. <p>NOTE: Configure the Policy P1 with the count option to display policy statistics.</p>
Per policy TCP Options	Configured sync and sequence checks, and the configured TCP MSS value for the initial direction and /or the reverse direction.

show services application-identification application

Syntax	show services application-identification application [detail <i>application-name</i>] summary]
Release Information	Command introduced in Junos OS Release 11.4.
Description	Display detailed information about a specified application signature, all application signatures, or a summary of the existing application signatures and nested application signatures. Both custom and predefined application signatures and nested application signatures can be displayed.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • request services application-identification application on page 736
List of Sample Output	show services application-identification application summary on page 789 show services application-identification application detail on page 789
Output Fields	Table 52 lists the output fields for the show services application-identification application command. Output fields are listed in the approximate order in which they appear.

Table 52: show services application-identification application Output Fields

Field Name	Field Description
Application(s)	The number of application signatures present.
Nested Application(s)	The number of nested application signatures present.
Application Name	Name of the predefined or custom application signature. Must be a unique name with a maximum length of 32 characters.
Application Group	Name of the application signature group associated with this application signature/nested application signature. Must be a unique name with a maximum length of 32 characters.
Disabled	The status of the application signature or nested application signature and whether the signature method is currently used to identify this application. The default is No.
ID	The unique ID number of an application signature or nested application signature. ID numbers 1 through 32,767 are automatically generated for predefined application signatures and nested application signatures; these IDs do not change. ID numbers for custom application signatures and nested application signatures use ID numbers 32,768 to 65,534.
Order	A unique number used to specify priority when multiple patterns are matched for the same session. The lowest order number takes the highest priority.

Table 52: show services application-identification application Output Fields (*continued*)

Field Name	Field Description
Application Tags	General information about this application type, for example, associated risk factors, technology, type of traffic, and so on. Support of application signature tags is dependent on the version of the loaded signature database. Please refer to the Juniper Networks security portal for further information.
Port Mapping: Default ports	The default port for this application type.
Signature: Port range	Default ranges: TCP/0 through 65,535; UDP/0 through 65,535 (optional).
Client-to-server: DFA Pattern	Pattern-matching scheme used for client-to-server traffic. Maximum length is 1023 (optional).
Client-to-server: Regex Pattern	A compatible regular expression used to match client-to-server traffic.
Server to-client: DFA Pattern	Pattern-matching scheme used for server-to-client traffic. Maximum length is 1023 (optional).
Server-to-client: Regex Pattern	A compatible regular expression used to match server-to-client traffic.
Minimum Data	The minimum number of bytes or packets to apply to the DFA pattern. Default is 10; range is 4 through 1024.

Sample Output

show services application-identification application-system-cache (View)

Syntax	show services application-identification application-system-cache
Release Information	Command introduced in Junos OS Release 10.2. Command updated in Junos OS Release 12.1X47-D10. Output updated in Junos OS Release 12.1X47-D15.
Description	Display application ID from default port/protocol binding or from the application system cache.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> clear services application-identification application-system-cache (Junos OS) on page 728
List of Sample Output	show services application-identification application-system-cache on page 792
Output Fields	Table 53 lists the output fields for the show services application-identification application-system-cache command. Output fields are listed in the approximate order in which they appear.

Table 53: show services application-identification application-system-cache Output Fields

Field Name	Field Description
application-cache	On or Off status of the application cache.
nested-application-cache	On or Off status of the nested application cache.
cache-unknown-result	On or Off status for caching unknown results.
cache-entry-timeout	The number of seconds the mapping information is saved.
pic	PIC number of the accumulated statistics. NOTE: The PIC number is always displayed as 0 for branch SRX Series devices.
Logical system name	Name of a specific logical system.
IP address	IP address.
Port	Port number.
Protocol	Type of protocol.
Application	Name of the application.
Encrypted	Yes or No to identify the traffic as encrypted or not.

Sample Output

show services application-identification application-system-cache

```
user@host> show services application-identification application-system-cache

```

show services application-identification counter (AppSecure)

Syntax	show services application-identification counter <ssl-encrypted-sessions>
Release Information	Command introduced in Junos OS Release 10.2. Output updated in Junos OS Release 12.1X47-D10. Command and output updated in Junos OS Release 12.1X47-D15.
Description	Display the status of all Junos OS application identification counter values per SPU.
Options	ssl-encrypted-sessions —Display counters for SSL encrypted sessions.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear services application-identification counter (Values) on page 729
List of Sample Output	show services application-identification counter on page 794 show services application-identification counter ssl-encrypted-sessions on page 795
Output Fields	Table 54 lists the output fields for the show services application-identification counter command. Output fields are listed in an approximate order in which they appear.

Table 54: show services application-identification counter Output Fields

Field Name	Field Description
PIC	PIC number of the accumulated statistics. <i>NOTE:</i> The PIC number is always displayed as 0 for branch SRX Series devices.
Unknown applications	Number of unknown applications.
Encrypted unknown applications	Number of encrypted unknown applications.
Cache hits	Number of sessions that matched the application in the AI cache.
Cache misses	Number of sessions that did not find the application in the AI cache.
Client-to-server packets processed	Number of client-to-server packets processed.
Server-to-client packets processed	Number of server-to-client packets processed.
Client-to-server bytes processed	Number of client-to-server payload bytes processed.
Server-to-client layer bytes processed	Number of server-to-client payload bytes processed.
Client-to-server packets processed	Number of client-to-server packets processed.
Server-to-client packets processed	Number of server-to-client packets processed.

Table 54: show services application-identification counter Output Fields (*continued*)

Field Name	Field Description
Client-to-server bytes processed	Number of client-to-server payload bytes processed.
Server-to-client layer bytes processed	Number of server-to-client payload bytes processed.
Client-to-server encrypted packets processed	Number of client-to-server encrypted packets processed.
Server-to-client encrypted packets processed	Number of server-to-client encrypted packets processed.
Client-to-server encrypted bytes processed	Number of client-to-server encrypted payload bytes processed.
Server-to-client layer encrypted bytes processed	Number of server-to-client encrypted payload bytes processed.
Sessions bypassed due to resource allocation failure	Number of sessions bypassed due to resource allocation failure.
Segment case 1 - New segment to left	TCP segments contained before the previous segment.
Segment case 2 - New segment overlap right	TCP segments that start before the previous segment and are contained in it.
Segment case 3 - Old segment overlapped	TCP segments that start before the previous segment and extend beyond it.
Segment case 4 - New segment overlapped	TCP segments that start and end within the previous segment.
Segment case 5 - New segment overlap left	TCP segments that start within the previous segments and extend beyond it.
Segment case 6 - New segment overlap left	TCP segments that start after the previous segment. This is the normal case.

Sample Output

show services application-identification group

Syntax	show services application-identification group [detail <i>application-group name</i>] summary]
Release Information	Command introduced in Junos OS Release 11.4.
Description	Display detailed or summary information about a specified application signature group or all application signature groups. Both custom and predefined application signature groups can be displayed.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • request services application-identification group on page 740
List of Sample Output	show services application-identification group summary on page 796 show services application-identification group detail on page 797
Output Fields	Table 55 lists the output fields for the show services application-identification group command. Output fields are listed in the approximate order in which they appear.

Table 55: show services application-identification group Output Fields

Field Name	Field Description
Description	Description of the specified application in the detailed display.
Group ID or ID	The unique ID number of an application signature or application signature group. ID numbers 1 through 32,767 are automatically generated for predefined application signatures and application signature groups; these IDs do not change. ID numbers for custom application signatures and application signature groups use ID numbers 32,768 to 65,534.
Disabled	The status of the application signature group and whether the signature method is currently used to identify this application. The default is No.
Application Group(s)	The application signature groups present.
Applications	The application signatures associated with this application signature group.

Sample Output

show services application-identification group summary

```

user@host> show services application-identification group summary
Application Group(s): 24
Application Groups                                Disabled  ID

Attack Detection and Prevention Overview

Attack detection and prevention, also known as stateful firewall, detects and prevents attacks in network traffic. An exploit can be either an information-gathering probe or an attack to compromise, disable, or harm a network or network resource. In some cases, the distinction between the two objectives of an exploit can be unclear. For example, a barrage of TCP SYN segments might be an IP address sweep with the intent of triggering responses from active hosts, or it might be a SYN flood attack with the intent of overwhelming a network so that it can no longer function properly. Furthermore, because an attacker usually precedes an attack by performing reconnaissance on the target, we can consider information-gathering efforts as a precursor to an impending attack—that is, they constitute the first stage of an attack. Thus, the term *exploit* encompasses both reconnaissance and attack activities, and the distinction between the two is not always clear.

Juniper Networks provides various detection and defense mechanisms at the zone and policy levels to combat exploits at all stages of their execution:

- Screen options at the zone level.
- Firewall policies at the inter-, intra-, and super-zone policy levels (*super-zone* here means in global policies, where no security zones are referenced).

To secure all connection attempts, Junos OS uses a dynamic packet-filtering method known as stateful inspection. Using this method, Junos OS identifies various components in the IP packet and TCP segment headers—source and destination IP addresses, source and destination port numbers, and packet sequence numbers—and maintains the state

of each TCP session and pseudo UDP session traversing the firewall. (Junos OS also modifies session states based on changing elements such as dynamic port changes or session termination.) When a responding TCP packet arrives, Junos OS compares the information reported in its header with the state of its associated session stored in the inspection table. If they match, the responding packet is allowed to pass the firewall. If the two do not match, the packet is dropped.

Junos OS screen options secure a zone by inspecting, then allowing or denying, all connection attempts that require crossing an interface bound to that zone.

Understanding IPv6 Support for Screens

Juniper Networks provides various detection and defense mechanisms at the zone and policy levels to combat exploits at all stages of their execution. Screen options are at the zone level. Junos OS screen options secure a zone by inspecting it, and then allowing or denying all connection attempts that require crossing an interface bound to that zone.

By default, IPv6 packets bypass the screen module. However, you can configure screen options to check and filter packets based on IPv6 extension headers, packet headers, and ICMPv6 traffic. Based on your configuration, the screen can drop packets, create logs, and provide increased statistics for IPv6 traffic.

- [IPv6 Extension Header Checking and Filtering on page 814](#)
- [Maximum Number of Extension Headers on page 815](#)
- [Bad Option Extension Headers on page 816](#)
- [ICMPv6 Checking and Filtering on page 816](#)
- [IPv6 Packet Header Checking and Filtering on page 817](#)

IPv6 Extension Header Checking and Filtering

You can use the **ipv6-extension-header** statement to selectively screen one or more extension headers. [Table 60](#) lists common IPv6 extension headers and their type values.

Table 60: IPv6 Extension Headers and Type Values

Header Name	Header Type Value	Internet Standards
Authentication	51	RFC 2460
Encapsulating Security Payload	50	RFC 2460
Host Identify Protocol	139	RFC 5201

Table 60: IPv6 Extension Headers and Type Values (*continued*)

Header Name	Header Type Value	Internet Standards
Destination Options <ul style="list-style-type: none"> • ILNP nonce option • Home address option • Line identification option • Tunnel encapsulation limit option 	60	RFC 2460
Fragment	44	RFC 2460
Hop-by-Hop Options <ul style="list-style-type: none"> • CALIPSO option • RPL option • SFM DPD option • Jumbo payload option • Quick start option • Router alert option 	0	RFC 2460
Mobility	135	RFC 6275
No next	59	RFC 2460
Routing	43	RFC 2460
Shim6	140	RFC 5533

Maximum Number of Extension Headers

You can specify the maximum number of permitted extension headers in a packet by using the **ipv6-extension-header-limit** statement. Although the maximum number of extension headers in a packet is not explicitly specified, the order of extension headers is recommended in RFC 2460:

1. Hop-by-Hop Options header
2. Destination Options header
3. Routing header
4. Fragment extension header
5. Authentication header
6. Encapsulating Security Payload header
7. Destination Options header

Each extension header should occur at most once, except for the destination options header, which should occur at most twice (once before a routing header and once before the upper-layer protocol header).

The maximum extension header number based on RFC 2460 is 7. Other extension headers have been defined by subsequent RFCs. We recommend the maximum extension header number to be in the range of 0 through 32.

Bad Option Extension Headers

You can configure screens to detect and drop any packet with an incorrectly formatted IP option in the IP packet header (IPv4 or IPv6). The device records the event in the screen counters list for the ingress interface. [Table 61](#) lists key criteria that the device uses to screen packets for bad options.

Table 61: Bad Option Extension Header Screening Criteria

Screening Criteria	Internet Standards	Description
Routing extension header is after fragment header	RFC 2460	The order of extension headers in a packet is defined; accordingly, the fragment extension header must be after the routing header.
Wrong router alert parameter	RFC 2711	This option is located in the hop-by-hop header and in the Junos OS implementation: <ul style="list-style-type: none"> There can be only one option of this type per hop-by-hop header The header length must be 2. There can be only one router alert option in one extension header.
More than one back-to-back pad option	draft-krishnan-ipv6-hopbyhop-00	This type of traffic is screened as error packets.
Non-zero payload in PadN option	RFC 4942	The system checks that the PadN only has zero octets in its payload.
Padding beyond the next eight-octet boundary	RFC 4942	The system checks for padding beyond the next eight octet boundary. There is no legitimate reason for padding beyond the next eight octet boundary.
Jumbo payload with non-zero IPv6 header payload	RFC 2675	The payload length field in the IPv6 header must be set to zero in every packet that carries the jumbo payload option.

ICMPv6 Checking and Filtering

You can enable ICMPv6 checking and filtering. The system then checks whether the ICMPv6 packet received matches the defined criteria and performs the specified action on matching packets. Some of the key defined criteria are as follows:

- Information message of unknown type—Many types of ICMPv6 information messages are defined, such as echo request (value 128), echo reply (value 129), and router solicitation (value 133). The maximum type definition is 149. Any value higher than 149 is treated as an unknown type and screened accordingly.

- Does not meet the ICMPv6 ND packet format rules (RFC 4861)—There are standard rules, such as the IP Hop limit field has a value of 255, ICMP checksum must be valid, the ICMP code must be 0, and so on.
- Malformed ICMPv6 packet filtering—For instance, the ICMPv6 packet is too big (message type 2), the next header is set to routing (43), and routing header is set to hop-by-hop.

IPv6 Packet Header Checking and Filtering

You can enable the checking and filtering of IPv6 packet headers using the **ipv6-malformed-header** statement. Once enabled, the system verifies any incoming IPv6 packet to check if it matches any of the defined criteria. The system then performs the specified action (drop or alarm-without-drop) on matching packets. [Table 62](#) lists key criteria that the device uses to screen packets.

Table 62: IPv6 Packet Header Screening Criteria

Screening Criteria	Internet Standards	Description
Deprecated site-local source and destination addresses	RFC 3879	The IPv6 site-local unicast prefix (1111111011 binary or FEC0::/10) is not supported.
Illegal multicast address scope values	RFC 4291	The unassigned multicast address scope values are treated as illegal.
Documentation-only prefix (2001:DB8::/32)	RFC 3849	IANA is to record the allocation of the IPv6 global unicast address prefix (2001:DB8::/32) as a documentation-only prefix in the IPv6 address registry. No end party is to be assigned this address.
Deprecated IPv4-compatible IPv6 source and destination addresses (::/96)	RFC 4291	The IPv4-compatible IPv6 address has been deprecated and is not supported.
ORCHID source and destination addresses (2001:10::/28)	RFC 5156	Addresses of the Overlay Routable Cryptographic Hash Identifiers (2001:10::/28) are used as identifiers and cannot be used for routing at the IP layer. Addresses within this block must not appear on the public Internet.
An IPv4 address embedded inside the IPv6 address (64:ff9b::/96) is an illegal, unacceptable IPv4 address	RFC 6052	The IPv6 address, 64:ff9b::/96, is reserved as "Well-known Prefix" for use in algorithmic mapping.

Understanding Screens Options on SRX Series Devices

On all SRX Series devices, the screens are divided into two categories:

- Statistics-based screens
- Signature-based screens

Table 63 lists all the statistics-based screen options.

Table 63: Statistics-Based Screen Options

Screen Option Name	Description
ICMP flood	<p>Use the ICMP flood IDS option to protect against ICMP flood attacks. An ICMP flood attack typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.</p> <p>The threshold value defines the number of ICMP packets per second (pps) allowed to ping the same destination address before the device rejects further ICMP packets.</p>
UDP flood	<p>Use the UDP flood IDS option to protect against UDP flood attacks. A UDP flood attack occurs when an attacker sends IP packets containing a UDP datagram with the purpose of slowing down the resources, such that valid connections can no longer be handled.</p> <p>The threshold value defines the number of UDP packets per second allowed to ping the same destination IP address. When the number of packets exceeds this value within any 1-second period, the device generates an alarm and drops subsequent packets for the remainder of that second.</p>
TCP SYN flood source	<p>Use the TCP SYN flood source IDS option to set the source threshold value. The threshold value defines the number of SYN segments to be received per second before the device begins dropping connection requests.</p> <p>The applicable range is 4 through 500,000 SYN pps.</p>
TCP SYN flood destination	<p>Use the SYN flood destination IDS option to set the destination threshold value. The threshold value defines the number of SYN segments received per second before the device begins dropping connection requests.</p> <p>The applicable range is 4 through 500,000 SYN pps.</p>
TCP SYN flood	<p>Use the TCP SYN flood IDS option to detect and prevent SYN flood attacks. Such attacks occur when the connecting host continuously sends TCP SYN requests without replying to the corresponding ACK responses.</p>
TCP port scan	<p>Use the TCP port scan IDS option to prevent the port scan attacks. The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.</p>
TCP SYN-ACK-ACK proxy	<p>Use the TCP SYN-ACK-ACK proxy screen option to prevent SYN-ACK-ACK attack. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold, SRX Series devices running Junos OS reject further connection requests from that IP address.</p>

Table 63: Statistics-Based Screen Options (*continued*)

Screen Option Name	Description
ICMP IP sweep	<p>Use the ICMP IP sweep IDS option to detect and prevent an IP sweep attack. An IP sweep attack occurs when an attacker sends ICMP echo requests (pings) to multiple destination addresses. If a target host replies, the reply reveals the target's IP address to the attacker. If the device receives 10 ICMP echo requests within the number of microseconds specified in this statement, it flags this as an IP sweep attack, and rejects the eleventh and all further ICMP packets from that host for the remainder of the second.</p> <p>The threshold value defines the maximum number of microseconds during which up to 10 ICMP echo requests from the same host are allowed into the device.</p>
TCP SYN flood alarm	<p>Use the TCP SYN flood alarm IDS option to set the alarm threshold value. The threshold value defines the number of half-complete proxy connections per second at which the device makes entries in the event alarm log. The range is 1 through 500,000 requests per second.</p>
TCP SYN flood attack	<p>Use the TCP SYN flood attack IDS option to set the attack threshold value. The threshold value defines the number of SYN packets per second required to trigger the SYN proxy response. The range is 1 through 500,000 proxied pps.</p>
UDP udp sweep	<p>Use the UDP udp sweep IDS option to detect and prevent UDP sweep attacks. In a UDP sweep attack, an attacker sends UDP packets to the target device. If the device responds to those packets, the attacker gets an indication that a port in the target device is open, which makes the port vulnerable to attack. If a remote host sends UDP packets to 10 addresses in 0.005 seconds (5000 microseconds), then the device flags this as a UDP sweep attack.</p> <p>If the alarm-without-drop option is not set, the device rejects the eleventh and all further UDP packets from that host for the remainder of the specified threshold period.</p> <p>The threshold value defines the number of microseconds for which the device accepts 10 UDP packets from the same remote source to different destination addresses.</p>

Table 64 lists all the signature-based screen options.

Table 64: Signature-Based Screen Options

Screen Option Name	Description
TCP Winnuke	<p>Enable or disable the TCP WinNuke attacks IDS option. WinNuke is a denial-of-service (DoS) attack targeting any computer on the Internet running Windows.</p>
TCP SYN fragment	<p>Use the TCP SYN fragment attack IDS option to drop any packet fragments used for the attack. A SYN fragment attack floods the target host with SYN packet fragments. The host caches these fragments, waiting for the remaining fragments to arrive so it can reassemble them. The flood of connections that cannot be completed eventually fills the host's memory buffer. No further connections are possible, and damage to the host's operating system can occur.</p>
TCP no flag	<p>Use the TCP tcp no flag IDS option to drop illegal TCP packets with a missing or malformed flag field. The threshold value defines the number of TCP headers without flags set. A normal TCP segment header has at least one control flag set.</p>
TCP SYN FIN	<p>Use the TCP SYN FIN IDS option to detect an illegal combination of flags that attackers can use to consume sessions on the target device, thus resulting in a denial-of-service (DoS) condition.</p>

Table 64: Signature-Based Screen Options (*continued*)

Screen Option Name	Description
TCP land	Enable or disable the TCP land attack IDS option. Land attacks occur when an attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and the source IP address.
TCP FIN no ACK	Use the FIN bit with no ACK bit IDS option to detect an illegal combination of flags, and reject packets that have this combination.
ICMP ping of death	<p>Use the ping of death IDS option to detect and reject oversized and irregular ICMP packets. Although the TCP/IP specification requires a specific packet size, many ping implementations allow larger packet sizes. Larger packets can trigger a range of adverse system reactions, including crashing, freezing, and restarting.</p> <p>Ping of death occurs when IP packets are sent that exceed the maximum legal length (65,535 bytes).</p>
ICMP fragment	Use the ICMP fragment IDS option to detect and drop any ICMP frame with the More Fragments flag set or with an offset indicated in the offset field.
ICMP large	Use the ICMP large IDS option to detect and drop any ICMP frame with an IP length greater than 1024 bytes.
IP unknown protocol	Use the IP unknown protocol IDS option to discard all received IP frames with protocol numbers greater than 137 for IPv4 and 139 for IPv6. Such protocol numbers are undefined or reserved.
IP bad option	Use the IP bad IDS option to detect and drop any packet with an incorrectly formatted IP option in the IP packet header. The device records the event in the screen counters list for the ingress interface. This screen option is applicable to IPv4 and IPv6.
IP strict source route option	Use the IP strict source route IDS option to detect packets where the IP option is 9 (strict source routing), and record the event in the screen counters list for the ingress interface. This option specifies the complete route list for a packet to take on its journey from source to destination. The last address in the list replaces the address in the destination field. Currently, this screen option is applicable only to IPv4.
IP loose source route option	Use the IP loose source route IDS option to detect packets where the IP option is 3 (loose source routing), and record the event in the screen counters list for the ingress interface. This option specifies a partial route list for a packet to take on its journey from source to destination. The packet must proceed in the order of addresses specified, but it is allowed to pass through other devices in between those specified. The type 0 routing header of the loose source route option is the only related header defined in IPv6.
IP source route option	Use the IP source route IDS option to detect packets and record the event in the screen counters list for the ingress interface.
IP stream option	Use the IP stream IDS option to detect packets where the IP option is 8 (stream ID), and record the event in the screen counters list for the ingress interface. This option provides a way for the 16-bit SATNET stream identifier to be carried through networks that do not support streams. Currently, this screen option is applicable only to IPv4.
IP block fragment	Enable or disable the IP packet fragmentation blocking. When this feature is enabled, Junos OS denies IP fragments on a security zone and blocks all IP packet fragments that are received at interfaces bound to that zone.

Table 64: Signature-Based Screen Options (*continued*)

Screen Option Name	Description
IP record route option	Use the IP record route IDS option to detect packets where the IP option is 7 (record route), and record the event in the screen counters list for the ingress interface. This option records the IP addresses of the network devices along the path that the IP packet travels. Currently, this screen option is applicable only to IPv4.
IP timestamp option	Use the IP timestamp IDS option to detect packets where the IP option list includes option 4 (Internet timestamp), and record the event in the screen counters list for the ingress interface. This option records the time (in Universal Time) when each network device receives the packet during its trip from the point of origin to its destination. Currently, this screen option is applicable only to IPv4.
IP security option	Use the IP security IDS option to detect packets where the IP option is 2 (security), and record the event in the screen counters list for the ingress interface. Currently, this screen option is applicable only to IPv4.
IP spoofing	Use the IP address spoofing IDS option to prevent spoofing attacks. IP spoofing occurs when an invalid source address is inserted in the packet header to make the packet appear to come from a trusted source.
IP tear drop	Use the IP tear drop IDS option to block teardrop attacks. Teardrop attacks occur when fragmented IP packets overlap and cause the host attempting to reassemble the packets to crash. The tear drop option directs the device to drop any packets that have such a discrepancy. Teardrop attacks exploit the reassembly of fragmented IP packets.

Understanding Screen Options on the SRX5000 Module Port Concentrator

The SRX5000 line Module Port Concentrator (SRX5K-MPC) supports Junos OS screen options. Screen options secure a zone by inspecting, then allowing or denying, all connection attempts that require crossing an interface bound to that zone.

Using screen options, your security device can protect against different internal and external attacks, including SYN flood attacks, UDP flood attacks, and port scan attacks. Junos OS applies screen checks to traffic prior to the security policy processing, resulting in less resource utilization.

The screen options are divided into the following two categories:

- Statistics-based screens
- Signature-based screens

Statistics-Based Screens

All screen features implemented on an SRX5K-MPC are independent of Layer 2 or Layer 3 mode. The flood protections are used to defend against SYN flood attacks, session table flood attacks, firewall denial-of-service (DoS) attacks, and network DoS attacks.

The following four types of threshold-based flood protection are performed on each processor for both IPv4 and IPv6:

- UDP-based flood protection
- ICMP-based flood protection
- TCP source-based SYN flood protection
- TCP destination-based SYN flood protection

NOTE: If one of the two types of TCP SYN flood protections is configured on a zone, the second type of TCP SYN flood protection is automatically enabled on the same zone. These two types of protections always work together.

Each type of flood protection is threshold-based, and the threshold is calculated per zone on each microprocessor. If the flood is detected on a microprocessor chip, that particular microprocessor takes action against the offending packets based on the configuration:

- Default action (report and drop)—Screen logging and reporting are done on an SPU, so offending packets need to be forwarded to the central point or SPU for this purpose. To protect SPUs from flooding, only the first offending packet for each screen in a zone is sent to the SPU for logging and reporting in each second. The rest of the offending packets are counted and dropped in a microprocessor.

For example, assume UDP flooding is configured at a logical interface with a threshold set to 5000 packets per second. If UDP packets come in at the rate of 20,000 per second, then about 5000 UDP packets are forwarded to the central point or SPU each second, and the remaining packets are detected as flooding. However, only one UDP flooding packet is sent to the SPU for logging and reporting in each second. The remaining packets are dropped in the microprocessor.

- Alarm only (alarm-without-drop)—An offending packet detected by screen protection is not dropped. It skips the rest of the screen checks and is forwarded to the central point or SPU with the screen result copied to its meta-header. It is not counted as a dropped packet.

Differences Between IOC1 and IOC2

The behavior of screens is the same whether the device has either IOC1 or an IOC2 card. However, there are differences in the threshold values for the statistics-based screens. [Table 65](#) lists the statistics-based screen options and the behavior of the screens depending on whether the device has either IOC1 or an IOC2 card.

Table 65: Statistics-Based Screen Options

Screen Option Name	Description	IOC1	IOC2
ICMP flood	<p>Sets the ICMP flood threshold value. The ICMP flood screen option is used to protect against ICMP flood attacks. An ICMP flood attack typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.</p> <p>The threshold value defines the number of ICMP packets per second allowed to ping the same destination address before the device rejects further ICMP packets.</p>	If the Incoming traffic exceeds the threshold pps, either the packets are dropped or an alarm is raised.	<p>On SRX5000 line devices with IOC2 card, there is a change in the screen configuration for lookup (LU) chips. There are four LU chips in each IOC2 card. If the incoming traffic exceeds the threshold value pps, the packets are dropped. For example, if the user specify the threshold value of 1000 pps, we configure 250 pps on each LU chip internally, so that the threshold value of 1000 pps gets distributed equally among the 4 LU chips. As an expected result, the user gets the overall threshold value of 1000 pps.</p> <p>On SRX5000 line devices, when the IOC2 card is in start of file (SOF) mode, only one LU chip will function. If the incoming traffic rate exceeds the threshold value, the packets are dropped as a result of the expected behavior.</p>

Table 65: Statistics-Based Screen Options (*continued*)

Screen Option Name	Description	IOC1	IOC2
UDP flood	<p>Sets the UDP flood threshold value. The UDP flood screen option is used to protect against UDP flood attacks. UDP flood attack occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the resources, such that valid connections can no longer be handled.</p> <p>The threshold value defines the number of UDP pps allowed to ping the same destination IP address/port pair. When the number of packets exceeds this value within any 1-second period, the device generates an alarm and drops subsequent packets for the remainder of that second.</p>	If the Incoming traffic exceeds the threshold pps, either the packets are dropped or an alarm is raised.	<p>On SRX5000 line devices with IOC2 card, there is a change in the screen configuration for lookup (LU) chips. There are four LU chips in each IOC2 card. If the incoming traffic exceeds the threshold value pps, the packets are dropped. For example, if the user specify the threshold value of 1000 pps, we configure 250 pps on each LU chip internally, so that the threshold value of 1000 pps gets distributed equally among the 4 LU chips. As an expected result, the user gets the overall threshold value of 1000 pps.</p> <p>On SRX5000 line devices, when the IOC2 card is in start of file (SOF) mode, only one LU chip will function. If the incoming traffic rate exceeds the threshold value, the packets are dropped as a result of the expected behavior.</p>

Table 65: Statistics-Based Screen Options (*continued*)

Screen Option Name	Description	IOC1	IOC2
TCP SYN flood source	<p>Sets the TCP SYN flood source threshold value. The threshold value defines the number of SYN segments to be received per second before the device begins dropping connection requests.</p> <p>The applicable range is 4 through 500,000 SYN pps.</p>	<p>If the Incoming traffic exceeds the threshold pps, either the packets are dropped or an alarm is raised..</p>	<p>On SRX5000 line devices with IOC2 card, there is a change in the screen configuration for lookup (LU) chips. There are four LU chips in each IOC2 card. If the incoming traffic exceeds the threshold value pps, the packets are dropped. For example, if the user specify the threshold value of 1000 pps, we configure 250 pps on each LU chip internally, so that the threshold value of 1000 pps gets distributed equally among the 4 LU chips. As an expected result, the user gets the overall threshold value of 1000 pps.</p> <p>On SRX5000 line devices, when the IOC2 card is in start of file (SOF) mode, only one LU chip will function. If the incoming traffic rate exceeds the threshold value, the packets are dropped as a result of the expected behavior.</p>

Table 65: Statistics-Based Screen Options (*continued*)

Screen Option Name	Description	IOC1	IOC2
TCP SYN flood destination	<p>Sets the TCP SYN flood destination threshold value. The threshold value defines the number of SYN segments received per second before the device begins dropping connection requests.</p> <p>The applicable range is 4 through 500,000 SYN pps.</p>	If the Incoming traffic exceeds the threshold pps, either the packets are dropped or an alarm is raised.	<p>On SRX5000 line devices with IOC2 card, there is a change in the screen configuration for lookup (LU) chips. There are four LU chips in each IOC2 card. If the incoming traffic exceeds the threshold value pps, the packets are dropped. For example, if the user specify the threshold value of 1000 pps, we configure 250 pps on each LU chip internally, so that the threshold value of 1000 pps gets distributed equally among the 4 LU chips. As an expected result, the user gets the overall threshold value of 1000 pps.</p> <p>On SRX5000 line devices, when the IOC2 card is in start of file (SOF) mode, only one LU chip will function. If the incoming traffic rate exceeds the threshold value, the packets are dropped as a result of the expected behavior.</p>

NOTE: On SRX5400, SRX5600, and SRX5800 line devices, the screen threshold value is set for each IOC in the DUT for the LAG/LACP and RLAG/RETH child links. When you have cross-IOC child interfaces as a part of LAG/LACP or RETH/RLAG interfaces and the ingress traffic is also traversing multiple child links across IOCs, set the threshold value to match the total number of packets passed by the screen from multiple IOCs with the expected total number of packets per second (pps) at the egress interface.

Signature-Based Screens

The SRX5K-MPC provides signature-based screen options along with sanity checks on the received packet.

Sometimes packets received by the device are malformed or invalid, and they might cause damage to the device and network. These packets must be dropped during initial stages of processing.

For both signature-based screen options and sanity checks, the packet contents, including packet header, status and control bits, and extension headers (for IPv6), are examined.

You can configure the screens according to your requirements, whereas packet sanity checks are performed by default.

The packet sanity checks and screen options are performed on packets received on ingress interfaces.

The processor does sanity checks and runs some screen features to detect the malformed and malicious ingress packets received from physical interfaces. Packets that fail a sanity check are counted and dropped.

The following packet sanity checks are supported:

- IPv4 sanity check
- IPv6 sanity check

The following screen features are supported:

- IP-based screen
- UDP-based screen
- TCP-based screen
- ICMP-based screen

The screen features are applicable to both IPv4 and IPv6 packets, with the exception of IP options screens, which only apply to IPv4 packets. If a packet is detected by one screen option, it skips the rest of the screen checks and is forwarded to the central point or Services Processing Unit (SPU) for logging and statistics collection.

- [Example: Configuring Multiple Screening Options on page 827](#)

Example: Configuring Multiple Screening Options

This example shows how to create one intrusion detection service (IDS) profile for multiple screening options.

- [Requirements on page 827](#)
- [Overview on page 828](#)
- [Configuration on page 828](#)
- [Verification on page 830](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In a security zone, you can apply one IDS profile to multiple screening options. In this example we are configuring the following screening options:

- ICMP screening
- IP screening
- TCP screening
- UDP screening

These screening options are assigned to an untrust zone.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option screen-config icmp ip-sweep threshold 1000
set security screen ids-option screen-config icmp fragment
set security screen ids-option screen-config icmp large
set security screen ids-option screen-config icmp flood threshold 200
set security screen ids-option screen-config icmp ping-death
set security screen ids-option screen-config ip bad-option
set security screen ids-option screen-config ip stream-option
set security screen ids-option screen-config ip spoofing
set security screen ids-option screen-config ip strict-source-route-option
set security screen ids-option screen-config ip unknown-protocol
set security screen ids-option screen-config ip tear-drop
set security screen ids-option screen-config tcp syn-fin
set security screen ids-option screen-config tcp tcp-no-flag
set security screen ids-option screen-config tcp syn-frag
set security screen ids-option screen-config tcp port-scan threshold 1000
set security screen ids-option screen-config tcp syn-ack-ack-proxy threshold 500
set security screen ids-option screen-config tcp syn-flood alarm-threshold 500
set security screen ids-option screen-config tcp syn-flood attack-threshold 500
set security screen ids-option screen-config tcp syn-flood source-threshold 50
set security screen ids-option screen-config tcp syn-flood destination-threshold 1000
set security screen ids-option screen-config tcp syn-flood timeout 10
set security screen ids-option screen-config tcp land
set security screen ids-option screen-config tcp winnuke
set security screen ids-option screen-config tcp tcp-sweep threshold 1000
set security screen ids-option screen-config udp flood threshold 500
set security screen ids-option screen-config udp udp-sweep threshold 1000
set security zones security-zone untrust screen screen-config
```

Enter **commit** from configuration mode.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an IDS profile for multiple screening options:

1. Configure the ICMP screening options.

```
[edit security screen ids-option screen-config]
user@host# set icmp ip-sweep threshold 1000
user@host# set icmp fragment
user@host# set icmp large
user@host# set icmp flood threshold 200
user@host# set icmp ping-death
```

2. Configure the IP screening options.

```
[edit security screen ids-option screen-config]
user@host# set ip bad-option
user@host# set ip stream-option
user@host# set ip spoofing
user@host# set ip strict-source-route-option
user@host# set ip unknown-protocol
user@host# set ip tear-drop
```

3. Configure the TCP screening options.

```
[edit security screen ids-option screen-config]
user@host# set tcp syn-fin
user@host# set tcp tcp-no-flag
user@host# set tcp syn-frag
user@host# set tcp port-scan threshold 1000
user@host# set tcp syn-ack-ack-proxy threshold 500
user@host# set tcp syn-flood alarm-threshold 500
user@host# set tcp syn-flood attack-threshold 500
user@host# set tcp syn-flood source-threshold 50
user@host# set tcp syn-flood destination-threshold 1000
user@host# set tcp syn-flood timeout 10
user@host# set tcp land
user@host# set tcp winnuke
user@host# set tcp tcp-sweep threshold 1000
```

4. Configure the UDP screening options.

```
[edit security screen ids-option screen-config]
user@host# set udp flood threshold 500
user@host# set udp udp-sweep threshold 1000
```

5. Attach the IDS profile to the zone.

```
[edit]
user@host# set security zones security-zone untrust screen screen-config
```

Results From configuration mode, confirm your configuration by entering the **show security screen ids-option screen-config** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen ids-option screen-config
icmp {
  ip-sweep threshold 1000;
  fragment;
  large;
  flood threshold 200;
  ping-death;
}
ip {
  bad-option;
  stream-option;
  spoofing;
  strict-source-route-option;
  unknown-protocol;
  tear-drop;
}
tcp {
  syn-fin;
  tcp-no-flag;
  syn-frag;
  port-scan threshold 1000;
  syn-ack-ack-proxy threshold 500;
  syn-flood {
    alarm-threshold 500;
    attack-threshold 500;
    source-threshold 50;
    destination-threshold 1000;
    timeout 10;
  }
  land;
  winnuke;
  tcp-sweep threshold 1000;
}
udp {
  flood threshold 500;
  udp-sweep threshold 1000;
}

[edit]
user@host# show security zones
security-zone untrust {
  screen screen-config;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying the IDS Profile for Multiple Screening Options

Purpose Verify that the IDS profile for multiple screening options is configured properly.

Action Enter the **show security screen ids-option screen-config Screen object status** and **show security zones** command from operational mode.

```
user@host> show security screen ids-option screen-config
Screen object status:
```

Name	Value
ICMP flood threshold	200
UDP flood threshold	500
TCP winnuke	enabled
TCP port scan threshold	1000
ICMP address sweep threshold	1000
TCP sweep threshold	1000
UDP sweep threshold	1000
IP tear drop	enabled
TCP SYN flood attack threshold	500
TCP SYN flood alarm threshold	500
TCP SYN flood source threshold	50
TCP SYN flood destination threshold	1000
TCP SYN flood timeout	10
IP spoofing	enabled
ICMP ping of death	enabled
TCP land attack	enabled
TCP SYN fragment	enabled
TCP no flag	enabled
IP unknown protocol	enabled
IP bad options	enabled
IP strict source route option	enabled
IP stream option	enabled
ICMP fragmentation	enabled
ICMP large packet	enabled
TCP SYN FIN	enabled
TCP SYN-ACK-ACK proxy threshold	500

```
user@host> show security zones
```

```
Security zone: untrust
Send reset for non-SYN session TCP packets: Off
Policy configurable: Yes
Screen: screen-config
Interfaces bound: 0
Interfaces:
```

NOTE: On all SRX Series devices, the TCP synchronization flood alarm threshold value does not indicate the number of packets dropped, however the value does show the packet information after the alarm threshold has been reached.

The synchronization cookie or proxy never drops packets; therefore the alarm-without-drop (not drop) action is shown in the system log.

Understanding Central Point Architecture Enhancements for Screens

The central point architecture is enhanced to achieve a higher number of connections per second (CPS) and due to the enhancements, the central point session and central point packet processing have been moved from the central point to the Services Processing Unit (SPU).

Previously, the central point had a session limit and if no resources (session limit entries) were available, then the packet was always permitted by the session limit. Now, both the central point and the SPU have session limits. If there are no resources available in the central point, but resources are available in the SPU, then the central point cannot limit the sessions but the SPU can limit the sessions. So, the SPU drops the packet SPU session limit checking and only if both the central point and the SPU have no resources will the packet *always* be permitted.

The following scenarios describe when the central point and the SPU determine whether to permit or drop a packet.

- When the central point has no session limit entry and the SPU has a session limit entry:
 - a. If the session limit counter of the SPU is larger than the threshold value, the packet is dropped.
 - b. If the session limit counter of the SPU is not larger than the threshold value, the packet is permitted.
- When the SPU does not have a session limit entry:
 - a. If the session limit counter of the SPU is larger than the threshold value, the packet is permitted.
 - b. If the session limit counter of the SPU is not larger than threshold, the packet is permitted.

NOTE: An extra message is sent to the central point to maintain accurate session counts might impact the number of connections per second (CPS) for screens. This impacts the source or destination session limit.

Global traffic statistics lacking a central point might impact some global view screens. Only the SYN cookie has no global view, and the global traffic statistics are handled by the SPU, so the counter might be not accurate as before. For other statistics-based screens, handled by both the central point and the SPU, the counters are accurate.

Previously, statistics-based screens were handled only by the central point and the log and the SNMP trap could be rate-limited strictly. Now both the central point and the SPU can generate the log and the SNMP trap independently. Therefore, the log and the SNMP trap might be larger than before.

DoS Attack Overview

The intent of a denial-of-service (DoS) attack is to overwhelm the targeted victim with a tremendous amount of bogus traffic so that the victim becomes so preoccupied processing the bogus traffic that legitimate traffic cannot be processed. The target can be the firewall, the network resources to which the firewall controls access, or the specific hardware platform or operating system of an individual host.

If a DoS attack originates from multiple source addresses, it is known as a distributed denial-of-service (DDoS) attack. Typically, the source address of a DoS attack is spoofed. The source addresses in a DDoS attack might be spoofed, or the actual addresses of compromised hosts might be used as “zombie agents” to launch the attack.

The device can defend itself and the resources it protects from DoS and DDoS attacks.

Firewall DoS Attacks Overview

The intent of a denial-of-service (DoS) attack is to overwhelm the targeted victim with a tremendous amount of bogus traffic so that the victim becomes so preoccupied processing the bogus traffic that legitimate traffic cannot be processed.

If attackers discover the presence of the Juniper Networks firewall, they might launch a DoS attack against it instead of the network behind it. A successful DoS attack against a firewall amounts to a successful DoS attack against the protected network in that it thwarts attempts of legitimate traffic to traverse the firewall.

An attacker might use session table floods and SYN-ACK-ACK proxy floods to fill up the session table of Junos OS and thereby produce a DoS.

Understanding Firewall Filters on the SRX5000 Module Port Concentrator

The SRX5000 line Module Port Concentrator (SRX5K-MPC) for the SRX5400, SRX5600, and SRX5800 supports a firewall filter to provide filter based forwarding and packet

filtering at logical interfaces including the chassis loopback interface. A firewall filter is used to secure networks, to protect Routing Engines and Packet Forwarding Engines, and to ensure class of service (CoS).

The firewall filter provides:

- Filter-based forwarding at logical interfaces
- Protection of a Routing Engine from DoS attacks
- Blocking of certain types of packets to reach a Routing Engine and packet counter

The firewall filter examines packets and performs actions according to the configured filter policy. The policy is composed of match conditions and actions. The match conditions cover various fields of Layer 3 packet and Layer 4 header information. In association with the match conditions, various actions are defined in the firewall filter policy, and these actions include **accept**, **discard**, **log** counter, and so on.

After configuring the firewall filter, you can apply a logical interface to the firewall filter in the ingress or egress, or in both directions. All packets passing through the logical interface are checked by the firewall filter. As part of the firewall filter configuration, a policer is defined and applied to the logical interface. A policer restricts the traffic bandwidth at the logical interface.

NOTE: Firewall filtering on an SRX5K-MPC does not support aggregated Ethernet interfaces.

NOTE: On SRX5400, SRX5600 and SRX5800 devices with an SRX5K-MPC, applying a policer at the loopback (lo0) interface ensures that the Packet Forwarding Engine discards certain types of packets and prevents them from reaching the Routing Engine.

Understanding Session Table Flood Attacks

A successful DoS attack overwhelms its victim with such a massive barrage of false simulated traffic that it becomes unable to process legitimate connection requests. DoS attacks can take many forms—SYN flood, SYN-ACK-ACK flood, UDP flood, ICMP flood, and so on—but they all seek the same objective, which is to fill up their victim's session table.

When the session table is full, that host cannot create any new sessions and begins rejecting new connection requests. The source-based session limits screen option and the destination-based session limit screen option help mitigate such attacks.

Understanding Source-Based Session Limits

In addition to limiting the number of concurrent sessions from the same source IP address, you can also limit the number of concurrent sessions to the same destination IP address. One benefit of setting a source-based session limit is that it can stem an attack such as the Nimda virus (which is actually both a virus and a worm) that infects a server and then begins generating massive amounts of traffic from that server. Because all the virus-generated traffic originates from the same IP address, a source-based session limit ensures that the firewall can curb such excessive amounts of traffic. See [Figure 33](#).

Figure 33: Limiting Sessions Based on Source IP Address

Another benefit of source-based session limiting is that it can mitigate attempts to fill up the firewall's session table if all the connection attempts originate from the same source IP address.

Determining what constitutes an acceptable number of connection requests requires a period of observation and analysis to establish a baseline for typical traffic flows. You also need to consider the maximum number of concurrent sessions required to fill up the session table of the particular Juniper Networks platform you are using. To see the maximum number of sessions that your session table supports, use the CLI command **show security flow session summary**, and then look at the last line in the output, which lists the number of current (allocated) sessions, the maximum number of sessions, and the number of failed session allocations:

```
Maximum-sessions: 32768
```

The default maximum for source-based session limits is 128 concurrent sessions, a value that might need adjustment to suit the needs of your network environment and the platform.

NOTE: Junos OS supports source-based session limits for both IPv4 and IPv6 traffic.

Example: Setting Source-Based Session Limits

This example shows how to limit the amount of sessions based on source IP.

- [Requirements on page 842](#)
- [Overview on page 842](#)
- [Configuration on page 842](#)
- [Verification on page 843](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

The following example shows how to limit the number of sessions that any one server in the DMZ and in zone a can initiate. Because the DMZ contains only web servers, none of which should initiate traffic, you set the source-session limit at the lowest possible value, which is one session. On the other hand, zone a contains personal computers, servers, printers, and so on, many of which do initiate traffic. For zone a, you set the source-session limit to a maximum of 80 concurrent sessions.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 1-limit-session limit-session source-ip-based 1
set security zones security-zone dmz screen 1-limit-session
set security screen ids-option 80-limit-session limit-session source-ip-based 80
set security zones security-zone zone_a screen 80-limit-session
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To configure the source-based session limits:

1. Specify the number of concurrent sessions based on source IP for the DMZ zone.

```
[edit security]
user@host# set screen ids-option 1-limit-session limit-session source-ip-based 1
```

2. Set the security zone for the DMZ to the configuration limit.

```
[edit security]
user@host# set zones security-zone dmz screen 1-limit-session
```
3. Specify the number of concurrent sessions based on source IP for the zone a zone.

```
[edit security]
user@host# set screen ids-option 80-limit-session limit-session source-ip-based
80
```
4. Set the security zone for zone a to the configuration limit.

```
[edit security]
user@host# set zones security-zone zone_a screen 80-limit-session
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option 1-limit-session {
  limit-session {
    source-ip-based 1;
  }
}
ids-option 80-limit-session {
  limit-session {
    source-ip-based 1;
  }
}

[edit]
user@host# show security zones
security-zone dmz {
  screen 1-limit-session;
}
security-zone zone_a {
  screen 80-limit-session;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Source-Based Session Limits

Purpose Verify source-based session limits.

Action Enter the **show security screen ids-option 1-limit-session**, **show security screen ids-option 80-limit-session**, and **show security zones** commands from operational mode.

```
user@host> show security screen ids-option 1-limit-session
Screen object status:
Name                                     Value
Session source limit threshold         1
```

```
user@host> show security screen ids-option 80-limit-session
Screen object status:
Name                               Value
  Session source limit threshold    80

user@host> show security zones
Security zone: dmz
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: 1-limit-session
  Interfaces bound: 0
  Interfaces:
```

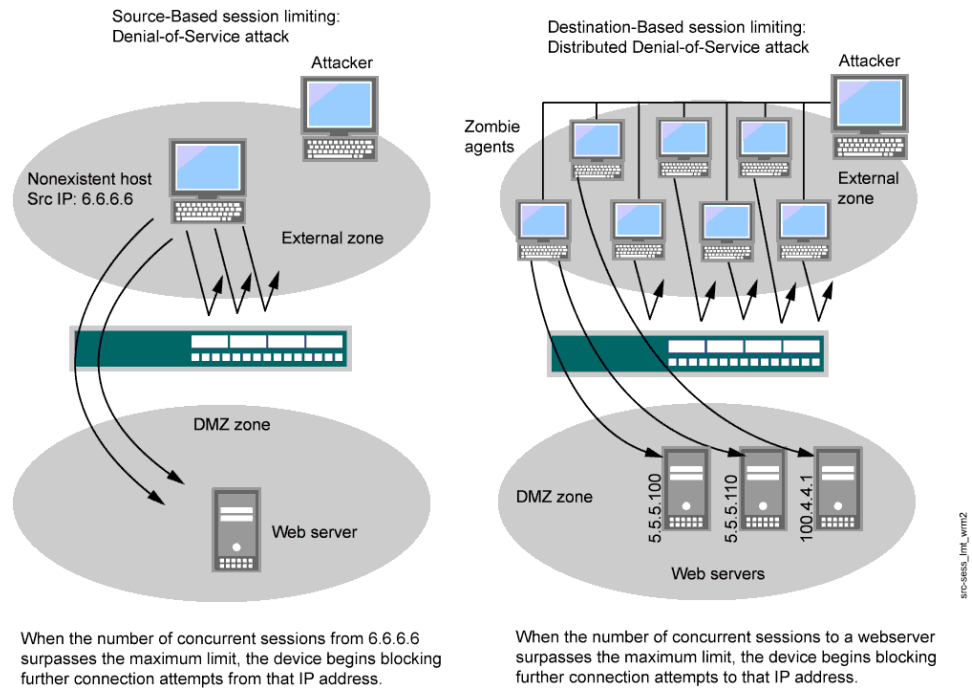

Meaning The sample output shows the source session limit values for DMZ zone and zone a.

Understanding Destination-Based Session Limits

In addition to limiting the number of concurrent sessions from the same source IP address, you can also limit the number of concurrent sessions to the same destination IP address. A wily attacker can launch a distributed denial-of-service (DDoS) attack. In a DDoS attack, the malicious traffic can come from hundreds of hosts, known as “zombie agents,” that are surreptitiously under the control of an attacker. In addition to the SYN, UDP, and ICMP flood detection and prevention screen options, setting a destination-based session limit can ensure that Junos OS allows only an acceptable number of concurrent connection requests—no matter what the source—to reach any one host. See [Figure 34](#).

Figure 34: Distributed DOS Attack

The default maximum for destination-based session limits is 128 concurrent sessions, a value that might need adjustment to suit the needs of your network environment and the platform.

Example: Setting Destination-Based Session Limits

This example shows how to set the destination-based session limits.

- [Requirements on page 845](#)
- [Overview on page 846](#)
- [Configuration on page 846](#)
- [Verification on page 847](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you limit the amount of traffic to a webserver at 1.2.2.5. The server is in the DMZ. The example assumes that after observing the traffic flow from the external zone to this server for a month, you have determined that the average number of concurrent sessions it receives is 2000. Also, you set the new session limit at 2000 concurrent sessions. Although traffic spikes might sometimes exceed that limit, the example assumes that you are opting for firewall security over occasional server inaccessibility.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 2000-limit-session limit-session destination-ip-based
2000
set security zones security-zone external_zone screen 2000-limit-session
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To set the destination-based session limits:

1. Specify the number of concurrent sessions.

```
[edit]
user@host# set security screen ids-option 2000-limit-session limit-session
destination-ip-based 2000
```

2. Set the security zone for the external zone.

```
[edit]
user@host# set security zones security-zone external_zone screen
2000-limit-session
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option 2000-limit-session {
  limit-session {
    destination-ip-based 2000;
  }
}

[edit]
user@host# show security zones
security-zone external_zone {
  screen 2000-limit-session;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Destination-Based Session Limits

Understanding SYN-ACK-ACK Proxy Flood Attacks

When an authentication user initiates a Telnet or an FTP connection, the user sends a SYN segment to the Telnet or FTP server. Junos OS intercepts the SYN segment, creates an entry in its session table, and proxies a SYN-ACK segment to the user. The user then replies with an ACK segment. At this point, the initial three-way handshake is complete. Junos OS sends a login prompt to the user. If the user, with malicious intent, does not log in but instead continues initiating SYN-ACK-ACK sessions, the firewall session table can fill up to the point where the device begins rejecting legitimate connection requests.

To prevent such an attack, you can enable the SYN-ACK-ACK proxy protection screen option. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold, Junos OS rejects further connection requests from that IP address. By default, the threshold is 512 connections from any single IP address. You can change this threshold (to any number between 1 and 250,000) to better suit the requirements of your network environment.

NOTE: Junos OS supports SYN-ACK-ACK proxy protection for both IPv4 and IPv6 addresses.

Protecting Your Network Against a SYN-ACK-ACK Proxy Flood Attack

This example shows how to protect your network against a SYN-ACK-ACK proxy flood attack.

- [Requirements on page 848](#)
- [Overview on page 848](#)
- [Configuration on page 848](#)
- [Verification on page 849](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you enable protection against a SYN-ACK-ACK proxy flood. The value unit is connections per source address. The default value is 512 connections from any single address.

Configuration

**CLI Quick
Configuration**

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 1000-syn-ack-ack-proxy tcp syn-ack-ack-proxy threshold
1000
set security zones security-zone zone screen 1000-syn-ack-ack-proxy
```

**Step-by-Step
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To protect against a SYN-ACK-ACK proxy flood attack:

1. Specify the source session limits.

```
[edit]
user@host# set security screen ids-option 1000-syn-ack-ack-proxy tcp
syn-ack-ack-proxy threshold 1000
```
2. Set the security zone for zone screen.

```
[edit]
user@host# set security zones security-zone zone screen 1000-syn-ack-ack-proxy
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option 1000-syn-ack-ack-proxy {
    tcp {
        syn-ack-ack-proxy threshold 1000;
    }
}

[edit]
user@host# show security zones
security-zone zone {
    screen 1000-syn-ack-ack-proxy;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying SYN-ACK-ACK Proxy Flood Attack

Purpose Verify SYN-ACK-ACK proxy flood attack.

Action Enter the **show security screen ids-option 1000-syn-ack-ack-proxy** and **show security zones** commands from operational mode.

```
user@host> show security screen ids-option 1000-syn-ack-ack-proxy
node0:
```

```
-----
Screen object status:
Name                                     Value
TCP SYN-ACK-ACK proxy threshold        1000
```

```
user@host> show security zones
Security zone: zone
Send reset for non-SYN session TCP packets: Off
Policy configurable: Yes
Screen: 1000-syn-ack-ack-proxy
Interfaces bound: 0
Interfaces:
```

Meaning The sample output shows that there is no attack from SYN-ACK-ACK-proxy flood.

Network DoS Attacks Overview

A denial-of-service (DoS) attack directed against one or more network resources floods the target with an overwhelming number of SYN, ICMP, or UDP packets or with an overwhelming number of SYN fragments.

Depending on the attackers' purpose and the extent and success of previous intelligence gathering efforts, the attackers might single out a specific host, such as a device or server or they might aim at random hosts across the targeted network. Either approach has the potential of upsetting service to a single host or to the entire network, depending on how critical the role of the victim is to the rest of the network.

Understanding SYN Flood Attacks

A SYN flood occurs when a host becomes so overwhelmed by SYN segments initiating incomplete connection requests that it can no longer process legitimate connection requests.

Two hosts establish a TCP connection with a triple exchange of packets known as a *three-way handshake*: A sends a SYN segment to B; B responds with a SYN/ACK segment; and A responds with an ACK segment. A SYN flood attack inundates a site with SYN segments containing forged (spoofed) IP source addresses with nonexistent or unreachable addresses. B responds with SYN/ACK segments to these addresses and then waits for responding ACK segments. Because the SYN/ACK segments are sent to nonexistent or unreachable IP addresses, they never elicit responses and eventually time out. See [Figure 35](#).

Figure 35: SYN Flood Attack

By flooding a host with incomplete TCP connections, the attacker eventually fills the memory buffer of the victim. Once this buffer is full, the host can no longer process new TCP connection requests. The flood might even damage the victim's operating system. Either way, the attack disables the victim and its normal operations.

This topic includes the following sections:

- [SYN Flood Protection on page 853](#)
- [SYN Flood Options on page 854](#)

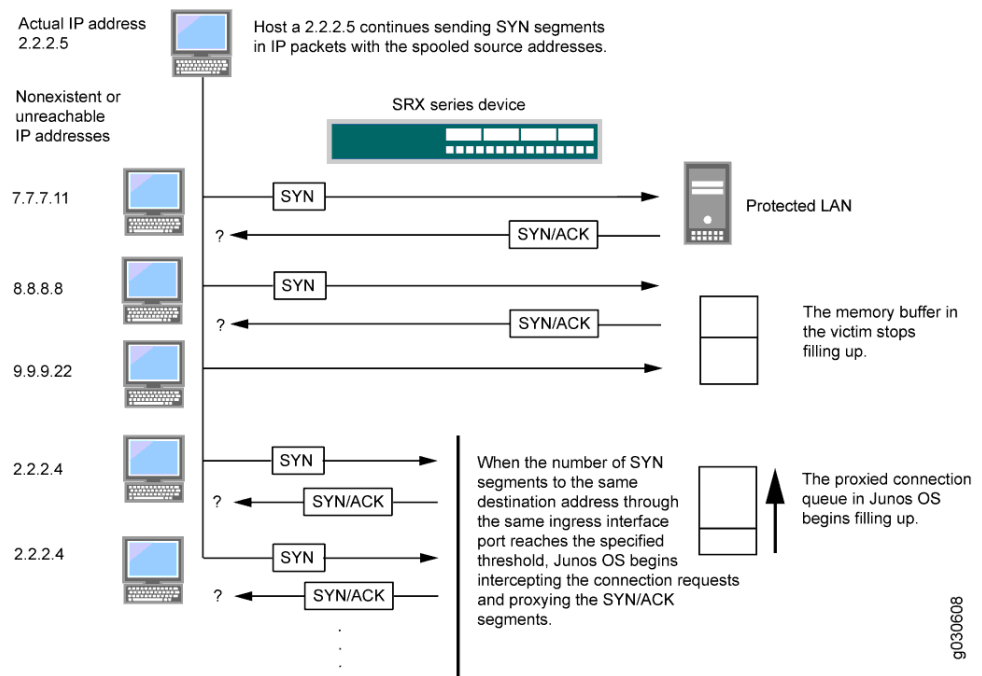

SYN Flood Protection

Junos OS can impose a limit on the number of SYN segments permitted to pass through the firewall per second. You can base the attack threshold on the destination address and ingress interface port, the destination address only, or the source address only. When the number of SYN segments per second exceeds the set threshold, Junos OS will either start proxying incoming SYN segments, replying with SYN/ACK segments and storing the incomplete connection requests in a connection queue, or it will drop the packets.

SYN proxying only happens when a destination address and ingress interface port attack threshold is exceeded. If a destination address or source address threshold is exceeded, additional packets are simply dropped.

In [Figure 36](#), the SYN attack threshold for a destination address and ingress interface port has been exceeded and Junos OS has started proxying incoming SYN segments. The incomplete connection requests remain in the queue until the connection is completed or the request times out.

Figure 36: Proxying SYN Segments

SYN Flood Options

You can set the following parameters for proxying uncompleted TCP connection requests:

- **Attack Threshold**—This option allows you to set the number of SYN segments (that is, TCP segments with the SYN flag set) to the same destination address per second required to activate the SYN proxying mechanism. Although you can set the threshold to any number, you need to know the normal traffic patterns at your site to set an appropriate threshold for it. For example, if it is an e-business site that normally gets 20,000 SYN segments per second, you might want to set the threshold to 30,000 per second. If a smaller site normally gets 20 SYN segments per second, you might consider setting the threshold to 40.
- **Alarm Threshold**—This option allows you to set the number of proxied, half-complete TCP connection requests per second after which Junos OS enters an alarm in the event log. The value you set for an alarm threshold triggers an alarm when the number of proxied, half-completed connection requests to the same destination address per second exceeds that value. For example, if you set the SYN attack threshold at 2000 SYN segments per second and the alarm at 1000, then a total of 3000 SYN segments to the same destination address per second is required to trigger an alarm entry in the log.

For each SYN segment to the same destination address in excess of the alarm threshold, the attack detection module generates a message. At the end of the second, the logging module compresses all similar messages into a single log entry that indicates how many SYN segments to the same destination address and port number arrived after exceeding the alarm threshold. If the attack persists beyond the first second, the event log enters an alarm every second until the attack stops.

- **Source Threshold**—This option allows you to specify the number of SYN segments received per second from a single source IP address—regardless of the destination IP address—before Junos OS begins dropping connection requests from that source.

Tracking a SYN flood by source address uses different detection parameters from tracking a SYN flood by destination address. When you set a SYN attack threshold and a source threshold, you put both the basic SYN flood protection mechanism and the source-based SYN flood tracking mechanism in effect.

- **Destination Threshold**—This option allows you to specify the number of SYN segments received per second for a single destination IP address before Junos OS begins dropping connection requests to that destination. If a protected host runs multiple services, you might want to set a threshold based on destination IP address only—regardless of the destination port number.

When you set a SYN attack threshold and a destination threshold, you put both the basic SYN flood protection mechanism and the destination-based SYN flood tracking mechanism in effect.

Consider a case where Junos OS has policies permitting FTP requests and HTTP requests to the same IP address. If the SYN flood attack threshold is 1000 packets per second (pps) and an attacker sends 999 FTP packets and 999 HTTP pps, Junos OS

treats both FTP and HTTP packets with the same destination address as members of a single set and rejects the 1001st packet—FTP or HTTP—to that destination.

- **Timeout**—This option allows you to set the maximum length of time before a half-completed connection is dropped from the queue. The default is 20 seconds, and you can set the timeout from 1–50 seconds. You might try decreasing the timeout value to a shorter length until you begin to see any dropped connections during normal traffic conditions. Twenty seconds is a very conservative timeout for a three-way handshake ACK response.

NOTE: Junos OS supports SYN flood protection for both IPv4 and IPv6 traffic.

Protecting Your Network Against SYN Flood Attacks by Enabling SYN Flood Protection

This example shows how to protect your network against SYN flood attacks by enabling SYN flood protection.

- [Requirements on page 855](#)
- [Overview on page 855](#)
- [Configuration on page 855](#)
- [Verification on page 856](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you enable the zone-syn-flood protection screen option and set the timeout value to 20. You also specify the zone where the flood might originate.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option zone-syn-flood tcp syn-flood source-threshold 10000
```

```
set security screen ids-option zone-syn-flood tcp syn-flood destination-threshold 10000
set security zones security-zone untrust screen zone-syn-flood
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To enable SYN flood protection:

1. Specify the screen object name.

```
[edit]
user@host# set security screen ids-option zone-syn-flood tcp syn-flood
source-threshold 10000
user@host# set security screen ids-option zone-syn-flood tcp syn-flood
destination-threshold 10000
```

2. Set the security zone for the zone screen.

```
[edit]
user@host# set security zones security-zone untrust screen zone-syn-flood
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option zone-syn-flood {
  tcp {
    syn-flood {
      source-threshold 10000;
      destination-threshold 10000;
      timeout 20;
    }
  }
}

[edit]
user@host# show security zones
security-zone untrust {
  screen zone-syn-flood;
  interfaces {
    ge-0/0/1.0;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying SYN Flood Protection

Purpose Verify SYN flood protection.

Action Enter the `show security screen ids-option zone-syn-flood` and `show security zones` commands from operational mode.

```
user@host> show security screen ids-option zone-syn-flood
node0:
```

```
-----
Screen object status:
```

Name	Value
TCP SYN flood attack threshold	200
TCP SYN flood alarm threshold	512
TCP SYN flood source threshold	10000
TCP SYN flood destination threshold	10000
TCP SYN flood timeout	20

```
user@host> show security zones
```

```
Security zone: untrust
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: zone-syn-flood
  Interfaces bound: 1
  Interfaces:
    ge-0/0/1.0
```

Meaning The sample output shows that SYN flood protection is enabled with source and destination threshold.

Example: Enabling SYN Flood Protection for Webserver in the DMZ

This example shows how to enable SYN flood protection for webserver in the DMZ.

- [Requirements on page 857](#)
- [Overview on page 857](#)
- [Configuration on page 860](#)
- [Verification on page 863](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

This example shows how to protect four webserver in the DMZ from SYN flood attacks originating in the external zone, by enabling the SYN flood protection screen option for the external zone. See [Figure 37](#).

NOTE: We recommend that you augment the SYN flood protection that Junos OS provides with device-level SYN flood protection on each webserver. In this example, the web servers are running UNIX, which also provides some SYN flood defenses, such as adjusting the length of the connection request queue and changing the timeout period for incomplete connection requests.

Figure 37: Device-Level SYN Flood Protection

To configure the SYN flood protection parameters with appropriate values for your network, you must first establish a baseline of typical traffic flows. For example, for one week, you run a sniffer on ethernet3—the interface bound to zone_external—to monitor the number of new TCP connection requests arriving every second for the four web servers in the DMZ. Your analysis of the data accumulated from one week of monitoring produces the following statistics:

- Average number of new connection requests per server: 250 per second
- Average peak number of new connection requests per server: 500 per second

NOTE: A sniffer is a network-analyzing device that captures packets on the network segment to which you attach it. Most sniffers allow you to define filters to collect only the type of traffic that interests you. Later, you can view and evaluate the accumulated information. In this example, you want the sniffer to collect all TCP packets with the SYN flag set arriving at ethernet3 and destined for one of the four web servers in the DMZ. You might want to continue running the sniffer at regular intervals to see whether there are traffic patterns based on the time of day, day of the week, time of the month, or season of the year. For example, in some organizations, traffic might increase dramatically during a critical event. Significant changes probably warrant adjusting the various thresholds.

Based on this information, you set the following SYN flood protection parameters for zone_external as shown in [Table 66](#).

Table 66: SYN Flood Protection Parameters

Parameter	Value	Reason for Each Value
Attack threshold	625 pps	This is 25% higher than the average peak number of new connection requests per second per server, which is unusual for this network environment. When the number of SYN packets per second for any one of the four web servers exceeds this number, the device begins proxying new connection requests to that server. (In other words, beginning with the 626th SYN packet to the same destination address in one second, the device begins proxying connection requests to that address.)
Alarm threshold	250 pps	When the device proxies 251 new connection requests in one second, it makes an alarm entry in the event log. By setting the alarm threshold somewhat higher than the attack threshold, you can avoid alarm entries for traffic spikes that only slightly exceed the attack threshold.
Source threshold	25 pps	<p>When you set a source threshold, the device tracks the source IP address of SYN packets, regardless of the destination address. (Note that this source-based tracking is separate from the tracking of SYN packets based on destination address, which constitutes the basic SYN flood protection mechanism.)</p> <p>In the one week of monitoring activity, you observed that no more than 1/25 of new connection requests for all servers came from any one source within a one-second interval. Therefore, connection requests exceeding this threshold are unusual and provide sufficient cause for the device to execute its proxying mechanism. (Note that 25 pps is 1/25 of the attack threshold, which is 625 pps.)</p> <p>If the device tracks 25 SYN packets from the same source IP address, then, beginning with the 26th packet, it rejects all further SYN packets from that source for the remainder of that second and for the next second as well.</p>
Destination threshold	4000 pps	When you set a destination threshold, the device runs a separate tracking of only the destination IP address, regardless of the destination port number. Because the four web servers receive only HTTP traffic (destination port 80)—no traffic to any other destination port number reaches them—setting another destination threshold offers no additional advantage.

Table 66: SYN Flood Protection Parameters (*continued*)

Parameter	Value	Reason for Each Value
Timeout	20 seconds	The default value of 20 seconds is a reasonable length of time to hold incomplete connection requests.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family inet address 1.2.2.1/24
set interfaces fe-1/0/0 unit 0 family inet address 1.1.1.1/24
set security zones security-zone zone_dmz interfaces ge-0/0/0.0
set security zones security-zone zone_external interfaces fe-1/0/0.0
set security zones security-zone zone_dmz address-book address ws1 1.2.2.10/32
set security zones security-zone zone_dmz address-book address ws2 1.2.2.20/32
set security zones security-zone zone_dmz address-book address ws3 1.2.2.30/32
set security zones security-zone zone_dmz address-book address ws4 1.2.2.40/32
set security zones security-zone zone_dmz address-book address-set web_servers address
ws1
set security zones security-zone zone_dmz address-book address-set web_servers address
ws2
set security zones security-zone zone_dmz address-book address-set web_servers address
ws3
set security zones security-zone zone_dmz address-book address-set web_servers address
ws4
set security policies from-zone zone_external to-zone zone_dmz policy id_1 match
source-address any destination-address web_servers application junos-http
set security policies from-zone zone_external to-zone zone_dmz policy id_1 then permit
set security screen ids-option zone_external-syn-flood tcp syn-flood alarm-threshold
250 attack-threshold 625 source-threshold 25 timeout 20
set security zones security-zone zone_external screen zone_external-syn-flood
```

Step-by-Step Procedure To configure SYN flood protection parameters:

1. Set interfaces.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet address 1.2.2.1/24
user@host# set interfaces fe-1/0/0 unit 0 family inet address 1.1.1.1/24
user@host# set security zones security-zone zone_dmz interfaces ge-0/0/0.0
user@host# set security zones security-zone zone_external interfaces fe-1/0/0.0
```

2. Define addresses.

```
[edit]
user@host# set security zones security-zone zone_dmz address-book address ws1
1.2.2.10/32
user@host# set security zones security-zone zone_dmz address-book address ws2
1.2.2.20/32
user@host# set security zones security-zone zone_dmz address-book address ws3
1.2.2.30/32
```

```

user@host# set security zones security-zone zone_dmz address-book address ws4
1.2.2.40/32
user@host# set security zones security-zone zone_dmz address-book address-set
web_servers address ws1
user@host# set security zones security-zone zone_dmz address-book address-set
web_servers address ws2
user@host# set security zones security-zone zone_dmz address-book address-set
web_servers address ws3
user@host# set security zones security-zone zone_dmz address-book address-set
web_servers address ws4

```

3. Configure the policy.

```

[edit]
user@host# set security policies from-zone zone_external to-zone zone_dmz policy
id_1 match source-address any
user@host# set security policies from-zone zone_external to-zone zone_dmz policy
id_1 match destination-address web_servers
user@host# set security policies from-zone zone_external to-zone zone_dmz policy
id_1 match application junos-http
user@host# set security policies from-zone zone_external to-zone zone_dmz policy
id_1 then permit

```

4. Configure the screen options.

```

[edit]
user@host# set security screen ids-option zone_external-syn-flood tcp syn-flood
alarm-threshold 250
user@host# set security screen ids-option zone_external-syn-flood tcp syn-flood
attack-threshold 625
user@host# set security screen ids-option zone_external-syn-flood tcp syn-flood
source-threshold 25
user@host# set security screen ids-option zone_external-syn-flood tcp syn-flood
timeout 20
user@host# set security zones security-zone zone_external screen
zone_external-syn-flood

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security zones**, **show security policies**, and **show security screen** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```

[edit]
user@host# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.2.2.1/24;
    }
  }
}
fe-1/0/0 {

```

```
unit 0 {
  family inet {
    address 1.1.1.1/24;
  }
}
...
[edit]
user@host# show security zones
...

  address ws4 1.2.2.40/32;
address-set web_servers {
  address ws1;
  address ws2;
  address ws3;
  address ws4;
}
}
interfaces {
  ge-0/0/0.0;
}
}
security-zone zone_external {
  screen zone_external-syn-flood;
  interfaces {
    fe-1/0/0.0;
  }
}
[edit]
user@host# show security policies
from-zone zone_external to-zone zone_dmz {
  policy id_1 {
match {
source-address any;
  destination-address web_servers;
  application junos-http;
}
then {
permit;
  }
}
}
[edit]
user@host# show security screen
...
ids-option zone_external-syn-flood {
  tcp {
syn-flood {
alarm-threshold 250;
  attack-threshold 625;
  source-threshold 25;
```

```

        timeout 20;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying SYN Flood Protection for Webserver in the DMZ

Purpose	Verify SYN flood protection for webserver in the DMZ.
Action	From operational mode, enter the show interfaces , show security zones , show security policies , and show security screen ids-option zone_external-syn-flood commands.
Related Documentation	<ul style="list-style-type: none"> • Understanding SYN Flood Attacks on page 852 • Protecting Your Network Against SYN Flood Attacks by Enabling SYN Flood Protection on page 855 • Configuring SYN Flood Protection Options (CLI Procedure)

Understanding Whitelists for SYN Flood Screens

Junos OS provides the administrative option to configure a whitelist of trusted IP addresses to which the SYN flood screen will not reply with a SYN/ACK. Instead, the SYN packets from the source addresses or to the destination addresses in the list are allowed to bypass the SYN cookie and SYN proxy mechanisms. This feature is needed when you have a service in your network that cannot tolerate proxied SYN/ACK replies under any condition, including a SYN flood event.

Both IP version 4 (IPv4) and IP version 6 (IPv6) whitelists are supported. Addresses in a whitelist should be all IPv4 or all IPv6. In each whitelist, there can be up to 32 IP address prefixes. You can specify multiple addresses or address prefixes as a sequence of addresses separated by spaces and enclosed in square brackets.

A whitelist can cause high CPU usage on a central point depending on the traffic level. For example, when no screen is enabled, the connections per second (cps) is 492K; when the screen is enabled and the whitelist is disabled, the cps is 373K; and when both the screen and the whitelist are enabled, the cps is 194K. After enabling the whitelist, the cps drops by 40 percent.

Related Documentation	<ul style="list-style-type: none"> • Understanding SYN Flood Attacks on page 852 • Protecting Your Network Against SYN Flood Attacks by Enabling SYN Flood Protection on page 855 • Example: Configuring Whitelists for SYN Flood Screens on page 864
------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Example: Configuring Whitelists for SYN Flood Screens

This example shows how to configure whitelists of IP addresses to be exempted from the SYN cookie and SYN proxy mechanisms that occur during the SYN flood screen protection process.

- [Requirements on page 864](#)
- [Overview on page 864](#)
- [Configuration on page 864](#)
- [Verification on page 865](#)

Requirements

Before you begin, configure a security screen and enable the screen in the security zone. See [“Example: Enabling SYN Flood Protection for Webrowsers in the DMZ” on page 857](#).

Overview

In this example, you configure whitelists named **wlipv4** and **wlipv6**. All addresses are IP version 4 (IPv4) for **wlipv4**, and all addresses are IP version 6 (IPv6) for **wlipv6**. Both whitelists include destination and source IP addresses.

Multiple addresses or address prefixes can be configured as a sequence of addresses separated by spaces and enclosed in square brackets, as shown in the configuration of the destination addresses for **wlipv4**.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option js1 tcp syn-flood white-list wlipv4 source-address 1.1.1.0/24
set security screen ids-option js1 tcp syn-flood white-list wlipv4 destination-address
  2.2.2.2/32
set security screen ids-option js1 tcp syn-flood white-list wlipv4 destination-address
  3.3.3.3/32
set security screen ids-option js1 tcp syn-flood white-list wlipv4 destination-address
  4.4.4.4/32
set security screen ids-option js1 tcp syn-flood white-list wlipv6 source-address 2001::1/64
set security screen ids-option js1 tcp syn-flood white-list wlipv6 destination-address
  2002::1/64
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the whitelists:

1. Specify the name of the whitelist and the IP addresses to be exempted from the SYN/ACK.

```
[edit security screen ids-option js1 tcp syn-flood]
user@host# set white-list wlipv4 source-address 1.1.1.0/24
user@host# set white-list wlipv4 destination-address [2.2.2.2 3.3.3.3 4.4.4.4]
user@host# set white-list wlipv6 source-address 2001::1/64
user@host# set white-list wlipv6 destination-address 2002::1/64
```

Results From configuration mode, confirm your configuration by entering the **show security screen** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option js1 {
  tcp {
    syn-flood {
      white-list wlipv4 {
        source-address 1.1.1.0/24;
        destination-address [ 2.2.2.2/32 3.3.3.3/32 4.4.4.4/32 ];
      }
      white-list wlipv6 {
        source-address 2001::1/64;
        destination-address 2002::1/64;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Whitelist Configuration

Purpose Verify that the whitelist is configured properly.

Action From operational mode, enter the **show security screen ids-option** command.

Understanding SYN Cookie Protection

SYN cookie is a stateless SYN proxy mechanism you can use in conjunction with other defenses against a SYN flood attack.

As with traditional SYN proxying, SYN cookie is activated when the SYN flood attack threshold is exceeded. However, because SYN cookie is stateless, it does not set up a session or policy and route lookups upon receipt of a SYN segment, and it maintains no

connection request queues. This dramatically reduces CPU and memory usage and is the primary advantage of using SYN cookie over the traditional SYN proxying mechanism.

When SYN cookie is enabled on Junos OS and becomes the TCP-negotiating proxy for the destination server, it replies to each incoming SYN segment with a SYN/ACK containing an encrypted cookie as its initial sequence number (ISN). The cookie is an MD5 hash of the original source address and port number, destination address and port number, and ISN from the original SYN packet. After sending the cookie, Junos OS drops the original SYN packet and deletes the calculated cookie from memory. If there is no response to the packet containing the cookie, the attack is noted as an active SYN attack and is effectively stopped.

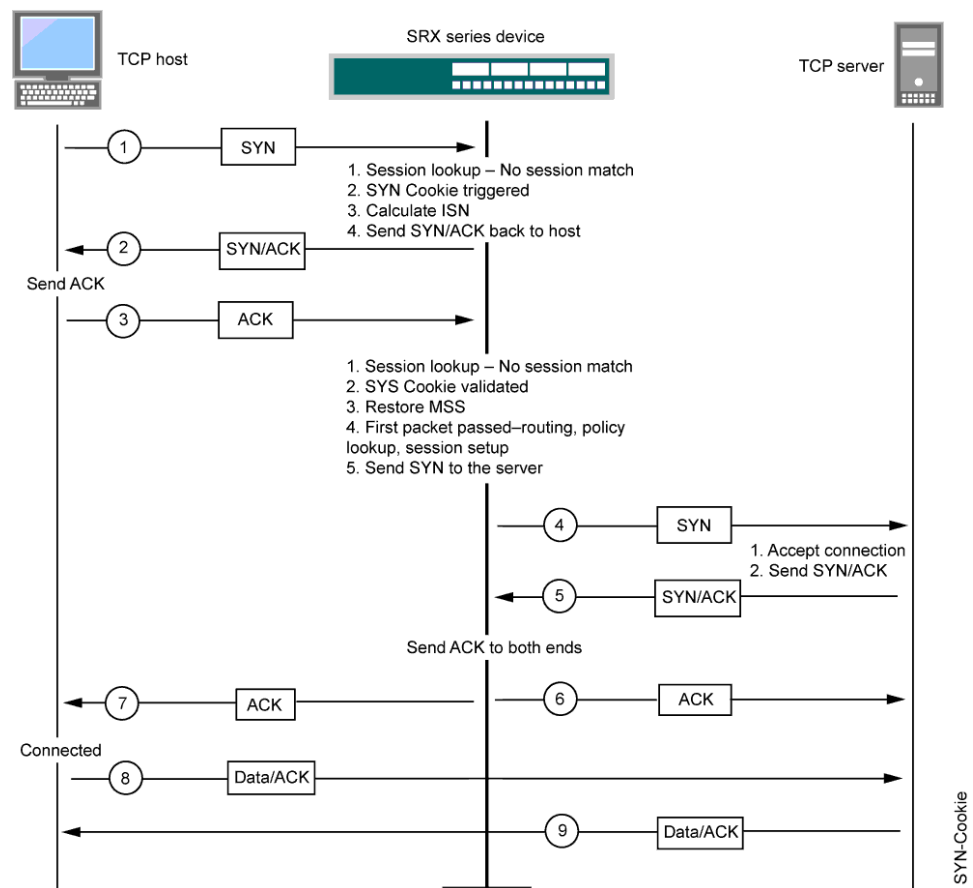

If the initiating host responds with a TCP packet containing the cookie +1 in the TCP ACK field, Junos OS extracts the cookie, subtracts 1 from the value, and recomputes the cookie to validate that it is a legitimate ACK. If it is legitimate, Junos OS starts the TCP proxy process by setting up a session and sending a SYN to the server containing the source information from the original SYN. When Junos OS receives a SYN/ACK from the server, it sends ACKs to the server and to the initiation host. At this point the connection is established and the host and server are able to communicate directly.

NOTE: The use of SYN cookie or SYN proxy enables the SRX Series device to protect the TCP servers behind it from SYN flood attacks in IPv6 flows.

Figure 38 shows how a connection is established between an initiating host and a server when SYN cookie is active on Junos OS.

Figure 38: Establishing a Connection with SYN Cookie Active

SYN Cookie Options

You can set the following parameters for incomplete TCP proxy connection requests:

- **Attack Threshold**—This option allows you to set the number of SYN segments (that is, TCP segments with the SYN flag set) to the same destination address and port number per second required to activate the SYN proxy mechanism. Although you can set the threshold to any number, you need to know the normal traffic patterns at your site to set an appropriate threshold for it. For example, for an e-business site that normally gets 2000 SYN segments per second, you might want to set the threshold to 30,000 SYN segments per second. The valid threshold range is 1 to 1,000,000. For a smaller site that normally gets 20 SYN segments per second, you might consider setting the threshold to 40 SYN segments per second.
- **Alarm Threshold**—This option allows you to set the number of proxied, half-complete TCP connection requests per second after which Junos OS enters an alarm in the event log. The alarm threshold value you set triggers an alarm when the number of proxied, half-completed connection requests to the same destination address and port number per second exceeds that value. For example, if you set the SYN attack threshold at 2000 SYN segments per second and the alarm at 1000, then a total of 3001 SYN segments to the same destination address and port number per second is required to

trigger an alarm entry in the log. The valid threshold range is 1 to 1,000,000 and the default alarm threshold value is 512.

- **Source Threshold**—This option allows you to specify the number of SYN segments received per second from a single source IP address—regardless of the destination IP address and port number—before Junos OS begins dropping connection requests from that source.

When you set a SYN attack threshold and a source threshold, you put both the basic SYN flood protection mechanism and the source-based SYN flood tracking mechanism in effect. The valid threshold range is 4 to 1,000,000 and the default alarm threshold value is 4000.

- **Destination Threshold**—This option allows you to specify the number of SYN segments received per second for a single destination IP address before Junos OS begins dropping connection requests to that destination. If a protected host runs multiple services, you might want to set a threshold based on destination IP address only—regardless of the destination port number. The valid threshold range is 4 to 1,000,000 and the default alarm threshold value is 4000.

When you set a SYN attack threshold and a destination threshold, you put both the basic SYN flood protection mechanism and the destination-based SYN flood tracking mechanism in effect.

- **Timeout**—This option allows you to set the maximum length of time before a half-completed connection is dropped from the queue. The default is 20 seconds, and you can set the timeout from 0 to 50 seconds. You might try decreasing the timeout value to a shorter length until you begin to see dropped connections during normal traffic conditions.

When either a source or destination threshold is not configured, the system will use the default threshold value. The default source and destination threshold value is 4000 pps.

Detecting and Protecting Your Network Against SYN Flood Attacks by Enabling SYN Cookie Protection

This example shows how to detect and protect your network against SYN flood attacks by enabling the SYN cookie protection.

- [Requirements on page 869](#)
- [Overview on page 869](#)
- [Configuration on page 869](#)
- [Verification on page 870](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you set the external-syn-flood timeout value to 20 and set the security zone for external screen to external-syn-flood. Also, you set the protection mode to syn-cookie.

NOTE: The SYN cookie feature can detect and protect only against spoofed SYN flood attacks, minimizing the negative impact on hosts that are secured by Junos OS. If an attacker uses a legitimate IP source address, rather than a spoofed IP source, then the SYN cookie mechanism does not stop the attack.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option external-syn-flood tcp syn-flood timeout 20
set security zones security-zone external screen external-syn-flood
set security flow syn-flood-protection-mode syn-cookie
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To enable the SYN cookie protection:

1. Specify the external-syn-flood timeout value.

```
[edit]
user@host# set security screen ids-option external-syn-flood tcp syn-flood timeout
20
```

2. Set the security-zone for external screen.

```
[edit]
user@host# set security zones security-zone external screen external-syn-flood
```

3. Set the protection mode.

```
[edit]
user@host# set security flow syn-flood-protection-mode syn-cookie
```

Results

From configuration mode, confirm your configuration by entering the **show security screen**, **show security zones**, and **show security flow** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show security screen
  set security flow syn-flood-protection-mode syn-cookie {
    tcp {
      syn-flood {
        source-ip-based 1;
      }
    }
  }

[edit]
user@host# show security zones
  security-zone external {
    screen external-syn-flood;
  }

[edit]
user@host# show security flow
  syn-flood-protection-mode syn-cookie;

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying SYN Cookie Protection

Purpose Verifying SYN cookie protection.

Action Enter the **show security screen ids-option external-syn-flood** and **show security zones** commands from operational mode.

```

user@host> show security screen ids-option external-syn-flood
node0:

```

```

-----
Screen object status:

```

Name	Value

Understanding ICMP Flood Attacks

An ICMP flood typically occurs when ICMP echo requests overload the target of the attack with so many requests that the target expends all its resources responding until it can no longer process valid network traffic.

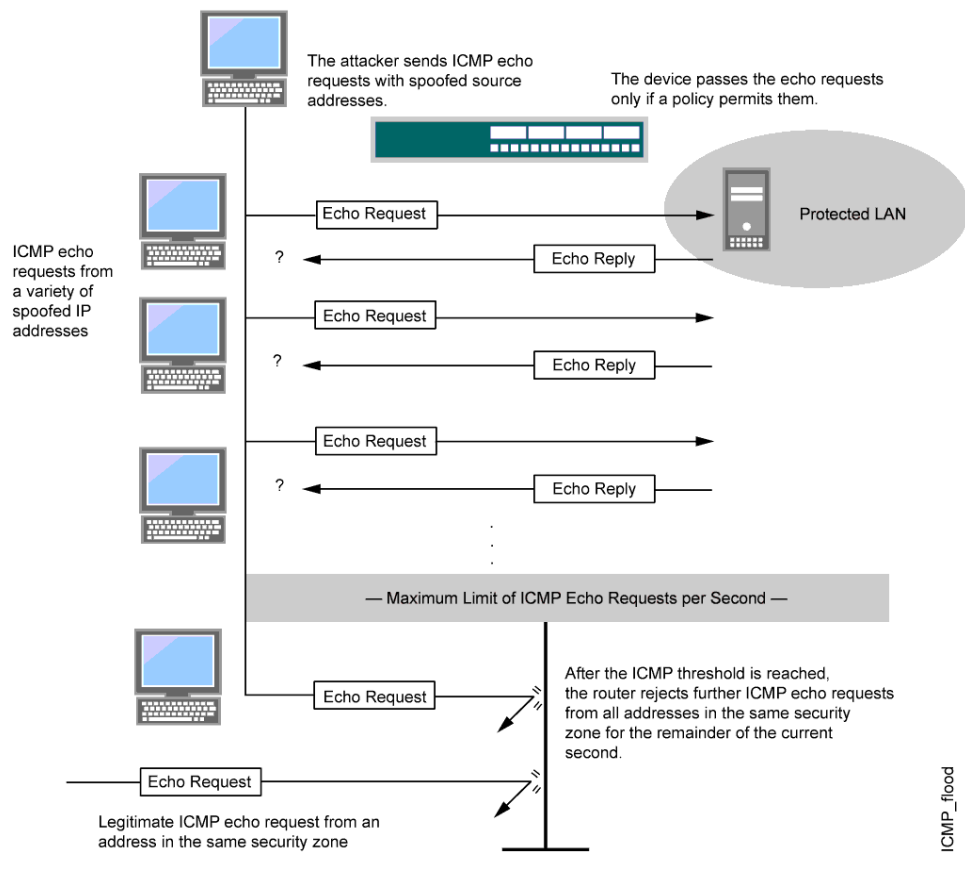

NOTE: ICMP messages generated in flow mode are limited to 12 messages every 10 seconds. This rate limit is calculated on a per-CPU basis. Once the threshold is reached, no further acknowledgement messages are sent to the device.

When enabling the ICMP flood protection feature, you can set a threshold that, once exceeded, invokes the ICMP flood attack protection feature. (The default threshold value is 1000 packets per second.) If the threshold is exceeded, Junos OS ignores further ICMP echo requests for the remainder of that second plus the next second as well. See [Figure 39](#).

NOTE: An ICMP flood can consist of any type of ICMP message. Therefore, Junos OS monitors all ICMP message types, not just echo requests.

Figure 39: ICMP Flooding

NOTE: Junos OS supports ICMP flood protection for both IPv4 and IPv6 traffic.

Protecting Your Network Against ICMP Flood Attacks by Enabling ICMP Flood Protection

This example shows how to protect your network against ICMP flood attacks by enabling ICMP flood protection.

- [Requirements on page 873](#)
- [Overview on page 873](#)
- [Configuration on page 873](#)
- [Verification on page 874](#)

Requirements

No special configuration beyond device initialization is required before enabling ICMP flood protection.

Overview

In this example, you enable ICMP flood protection. The value unit is ICMP packets per second, or pps. The default value is 1000 pps. You specify the zone where a flood might originate.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 1000-icmp-flood icmp flood threshold 1000
set security zones security-zone zone screen 1000-icmp-flood
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To enable ICMP flood protection:

1. Specify the ICMP flood threshold value.

```
[edit]
user@host# set security screen ids-option 1000-icmp-flood icmp flood threshold
1000
```

2. Set the security zone for zone screen.

```
[edit]
user@host# set security zones security-zone zone screen 1000-icmp-flood
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option 1000-icmp-flood {
  icmp {
    flood threshold 1000;
  }
}

[edit]
user@host# show security zones
security-zone zone {
  screen 1000-icmp-flood;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying ICMP Flood Protection

Purpose	Verify ICMP flood protection
Action	<p>Enter the show security screen ids-option 1000-icmp-flood and show security zones commands from operational mode.</p> <pre> user@host> show security screen ids-option 1000-icmp-flood node0: ----- Screen object status: Name Value ICMP flood threshold 1000 user@host> show security zones Security zone: zone Send reset for non-SYN session TCP packets: Off Policy configurable: Yes Screen: 1000-icmp-flood Interfaces bound: 0 Interfaces: </pre>
Meaning	The sample output shows that ICMP flood protection is enabled and threshold is set.

Understanding UDP Flood Attacks

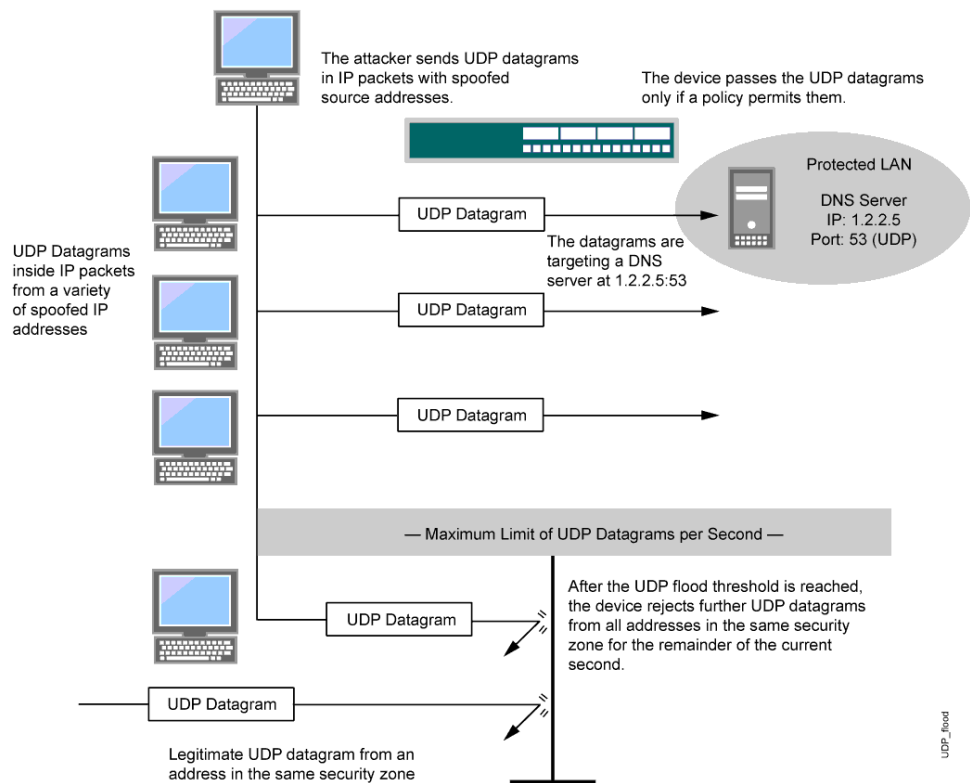

Similar to an ICMP flood, a UDP flood occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the victim to the point that the victim can no longer handle valid connections.

After enabling the UDP flood protection feature, you can set a threshold that, once exceeded, invokes the UDP flood attack protection feature. (The default threshold value is 1000 packets per second, or pps.) If the number of UDP datagrams from one or more sources to a single destination exceeds this threshold, Junos OS ignores further UDP datagrams to that destination for the remainder of that second plus the next second as well. See [Figure 40](#).

NOTE: The high-end SRX Series devices do not drop the packet in the next second.

Figure 40: UDP Flooding

NOTE: Junos OS supports UDP flood protection for IPV4 and IPV6 packets.

Protecting Your Network Against UDP Flood Attacks by Enabling UDP Flood Protection

This example shows how to protect your network against UDP flood attacks by enabling UDP flood protection.

- [Requirements on page 875](#)
- [Overview on page 876](#)
- [Configuration on page 876](#)
- [Verification on page 877](#)

Requirements

No special configuration beyond device initialization is required before enabling UDP flood protection.

Overview

In this example, you enable UDP flood protection. The value unit is UDP packets per second, or pps. The default value is 1000 pps. You specify the zone where a flood might originate.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option 1000-udp-flood udp flood threshold 1000
set security zones security-zone external screen 1000-udp-flood
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To enable UDP flood protection:

1. Specify the UDP flood threshold value.

```
[edit]
user@host# set security screen ids-option 1000-udp-flood udp flood threshold
1000
```

2. Set the security zone for external screen.

```
[edit]
user@host# set security zones security-zone external screen 1000-udp-flood
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option 1000-udp-flood {
  udp {
    flood threshold 1000;
  }
}
```

```
[edit]
user@host# show security zones
security-zone external {
  screen 1000-udp-flood;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying UDP Flood Protection

Purpose	Verify UDP flood protection.
Action	<p>Enter the show security screen ids-option 1000-udp-flood and show security zones commands from operational mode.</p> <pre> user@host> show security screen ids-option 1000-udp-flood node0: ----- Screen object status: Name Value UDP flood threshold 1000 user@host> show security zones Security zone: external Send reset for non-SYN session TCP packets: Off Policy configurable: Yes Screen: 1000-udp-flood Interfaces bound: 0 Interfaces: </pre>
Meaning	The sample output shows that UDP flood protection is enabled and threshold is set.

Understanding Land Attacks

Combining a SYN attack with IP spoofing, a land attack occurs when an attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and the source IP address.

The receiving system responds by sending the SYN-ACK packet to itself, creating an empty connection that lasts until the idle timeout value is reached. Flooding a system with such empty connections can overwhelm the system, causing a denial of service (DoS). See [Figure 41](#).

Figure 41: Land Attack

When you enable the screen option to block land attacks, Junos OS combines elements of the SYN flood defense and IP spoofing protection to detect and block any attempts of this nature.

NOTE: Junos OS supports land attack protection for both IPv4 and IPv6 packets.

Protecting Your Network Against Land Attacks by Enabling Land Attack

This example shows how to protect your network against attacks by enabling land attack.

- [Requirements on page 878](#)
- [Overview on page 879](#)
- [Configuration on page 879](#)
- [Verification on page 879](#)

Requirements

No special configuration beyond device initialization is required before enabling land attack.

Overview

This example shows how to enable protection against a land attack. In this example, you set the security screen object name as `land` and set the security zone as `zone`.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option land tcp land
set security zones security-zone zone screen land
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*. To enable protection against a land attack:

1. Specify the screen object name.

```
[edit]
user@host# set security screen ids-option land tcp land
```

2. Set the security zone.

```
[edit]
user@host# set security zones security-zone zone screen land
```

Results From configuration mode, confirm your configuration by entering the **show security screen** and **show security zones** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security screen
ids-option land {
  tcp {
    land;
  }
}

[edit]
user@host# show security zones
security-zone zone {
  screen land;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying Protection Against a Land Attack

Purpose Verify protection against a land attack.

Action Enter the **show security screen ids-option land** and **show security zones** commands from operational mode.

```
user@host> show security screen ids-option land
node0:
-----
Screen object status:
Name                                     Value
TCP land attack                         enabled

user@host> show security zones
Security zone: zone
  Send reset for non-SYN session TCP packets: Off
  Policy configurable: Yes
  Screen: land
  Interfaces bound: 0
  Interfaces:
```

Meaning The sample output shows that protection against a land attack is enabled.

Understanding Screen IPv6 Tunneling Control

Several IPv6 transition methodologies are provided to utilize the tunneling of IPv6 packets over IPv4 networks that do not support IPv6. For this reason, these methods use public gateways and bypass the policies of the operator.

The security of tunneled packets is a major concern for service providers, because tunneled packets are easily accessed by attackers. Numerous IPv6 transition methodologies have evolved for sending tunneled packets through a network; however, because some of them operate on public gateways, they bypass the policies of the operator. This means that packet transmission is exposed to attackers. To overcome and secure transfer of packets, the IPv6 end nodes are required to de-capsulate the encapsulated data packets. Screen is one of the latest available technologies for blocking or allowing tunneling traffic based on user preferences.

You can configure the following screen options to check and filter packets based on IPv6 extension headers, packet headers, and Bad-Header IPv6 or IPv4 address validation. Based on your configuration, the screen can drop packets, create logs, and provide increased statistics for IP tunneling.

- **GRE 4in4 Tunnel:** The GRE 4in4 Tunnel screen matches the following signature: **| IPv4 outer header | GRE header | IPv4 inner header**

An outer IPv4 header must be **Protocol 47 GRE Encapsulation**. A GRE header must have **protocol E-type 0x0800 IPv4**. If these conditions are met, this packet is classified as GRE 4in4 tunnel signature.

- **GRE 4in6 Tunnel:** The GRE 4in6 Tunnel screen matches the following signature: **IPv6 outer main header | IPv6 extension header(s) | GRE header | IPv4 inner header**

An outer IPv6 main header or an IPv6 extension header must have a **Next Header of value 47 for GRE**. A GRE header must have **protocol E-type 0x0800 IPv4**. If these conditions are met, this packet is classified as GRE 4in6 tunnel signature.

- **GRE 6in4 Tunnel:** The GRE 6in4 Tunnel screen matches the following signature: **IPv4 outer header | GRE header | IPv6 inner header**

An outer IPv4 header must be **Protocol 47 GRE Encapsulation**. A GRE header must have **protocol E-type 0x086DD IPv6**. If these conditions are met, this packet is classified as GRE 6in4 tunnel signature.

- **GRE 6in6 Tunnel:** The GRE 6in6 Tunnel screen matches the following signature: **IPv6 outer main header | IPv6 extension header(s) | GRE header | IPv6 inner header**

An outer IPv6 main header or an IPv6 extension header must have a Next Header of **value 47 for GRE**. A GRE header must have **protocol E-type 0x086DD` IPv6**. If these conditions are met, this packet is classified as GRE 6in6 tunnel signature.

- **IPinIP 6to4relay Tunnel :** The IPinIP 6to4relay Tunnel screen matches the following signature: **| IPv4 outer header | IPv6 inner header**

An outer IPv4 header must be **Protocol 41 IPv6 Encapsulation**. An outer header source address or destination address must be in network **192.88.99.0/24**. An inner IPv6 header source address or destination address must be in network **2002::/16**. If these conditions are met, this packet is classified as IPinIP 6to4relay tunnel signature.

- **IPinIP 6in4 Tunnel :** The IPinIP 6in4 Tunnel screen matches the following signature: **| IPv4 outer header | IPv6 inner header**

An outer IPv4 header must be **Protocol 41 IPv6 Encapsulation**. If this condition is met, this packet is classified as IPinIP 6in4 tunnel signature.

NOTE: Typically, when IPv6 packets need to be transported in a complete IPv4 network, the IPv6 packets utilizes a point-to-point 6in4 tunnel.

- **IPinIP 6over4 Tunnel :** The IPinIP 6over4 Tunnel screen matches the following signature: **| IPv4 outer header | IPv6 inner header**

An outer IPv4 header must be **Protocol 41 IPv6 Encapsulation:W**. An inner header source address or destination address must be in **fe80::/64** network. If these conditions are met, this packet is classified as IPinIP 6over4 tunnel signature.

- **IPinIP 4in6 Tunnel :** The IPinIP 4in6 Tunnel screen matches the following signature: **| IPv6 outer main header | IPv6 extension header(s) | IPv4 inner header**

An outer IPv6 header or an IPv6 extension header must have a Next Header of **value 04 for IPv4**. If these conditions are met, this packet is classified as IPinIP 4in6 tunnel signature.

- **IPinIP ISATAP Tunnel:** The IPinIP ISATAP Tunnel screen matches the following signature: **| IPv6 outer main header | IPv6 inner header**

An outer IPv4 header must be **Protocol 41 IPv6 Encapsulation**. An inner IPv6 header source address or destination address must be in **fe80::200:5efe/96** or **fe80::5efe/96**

network. If these conditions are met, this packet is classified as IPinIP ISATAP tunnel signature.

- **IPinIP DS-Lite Tunnel:** The IPinIP DS-Lite Tunnel screen matches the following signature: **| IPv6 outer main header | IPv6 extension header(s) | IPv4 inner header**

An outer IPv6 header or an IPv6 extension header must have a Next Header of **value 04 for IPv4**. An inner IPv4 source address or destination address must be in **192.0.0.0/29** network. If these conditions are met, this packet is classified as IPinIP DS-Lite tunnel signature.

- **IPinIP 6in6 Tunnel:** The IPinIP 6in6 Tunnel screen matches the following signature: **| IPv6 outer main header | IPv6 extension header(s) | IPv6 inner main header**

An outer IPv6 main header or an IPv6 extension header must have a Next Header of **value 41 for IPv6**. An inner IPv6 main header must be **Version 6**. If these two conditions are met, this packet is classified as IPinIP 6in6 tunnel signature.

- **IPinIP 4in4 Tunnel:** The IPinIP 4in4 Tunnel screen matches the following signature: **| IPv6 outer header | IPv4 inner header**. An outer IPv4 header must have a Protocol of **value 04 for IPv4**. An inner IPv4 header must be **Version 4**.

- **IPinUDP Teredo Tunnel:** The IPinUDP Teredo Tunnel matches the following signature: **IPv4 outer header | UDP header | IPv6 inner header**

An outer IPv4 header must have a **Protocol of 17 for UDP payload**. A UDP header source or destination port must be **3544**. An inner IPv6 header source address or destination address must be in network **2001:0000::/32**.

- **IP Tunnel Bad Inner-Header Check:** The Bad Inner Header Tunnel screen checks the tunnel traffic inner header information for consistency. The packet drops when any of the following is detected:

- Inner header does not match outer header.
- Inner header TTL or Hop Limit must not be 0 or 255.
- Inner header IPv6 address checking.
- Inner header IPv4 address checking.
- Outer and Inner header length checks:
- Inner header IPv4 and IPv6 TCP/UDP/ICMP header length check:
TCP/UDP/ICMP header length must fit inside of inner IPv4/IPv6/EH6 header length when inner IP(v4/v6) is not a first, next, or last fragment.
- TCP: The minimum TCP header size must fit in the previous encapsulation length.
- ICMP: The minimum ICMP header size must fit in the previous encapsulation length.
- Fragmented packets: For fragmented packets, if the tunnel information needs to be checked for a screen and is not in the first fragment, then checking is not performed except the parts of the tunnel encapsulation that are included in the first fragment. Length checks are performed on first fragment packets using the actual packet buffer length, but the length checks are ignored because the inner header is larger than the outer header.

- When the outer header is first fragment, do not examine the past physical packet length of the fragment.
- When the inner header is a first fragment, do not examine the past length of the fragment.

For non-first fragment packets, checking is not performed in Bad Inner Header Tunnel screen.

- When outer header is a non-first fragment, examine the packet for screens that only use IP header signatures, because the payload cannot be examined.
- When inner header is a non-first fragment, do not examine the next packet.
- The IPv4 inner header checks that IPv4 header is from 20 to 50 bytes.

Starting with Junos OS Release 12.3X48-D10, the syslog messages **RT_SCREEN_IP** and **RT_SCREEN_IP_LS** for the IP tunneling screen have been updated to include the tunnel screen attacks and log-without-drop criteria. The following list illustrates some examples of these new system log messages for each of the tunnel types:

- **RT_SCREEN_IP:** Tunnel GRE 6in4! source: 12.12.12.1, destination: 11.11.11.1, zone name: untrust, interface name: ge-0/0/1.0, action: alarm-without-drop
- **RT_SCREEN_IP:** Tunnel GRE 6in6! source: 1212::12, destination: 1111::11, zone name: untrust, interface name: ge-0/0/1.0, action: drop
- **RT_SCREEN_IP:** Tunnel GRE 4in4! source: 12.12.12.1, destination: 11.11.11.1, zone name: untrust, interface name: ge-0/0/1.0, action: drop
- **RT_SCREEN_IP_LS:** [lsys: LSYS1] Tunnel GRE 6in4! source: 12.12.12.1, destination: 11.11.11.1, zone name: untrust, interface name: ge-0/0/1.0, action: alarm-without-drop
- **RT_SCREEN_IP_LS:** [lsys: LSYS1] Tunnel GRE 6in6! source: 1212::12, destination: 1111::11, zone name: untrust, interface name: ge-0/0/1.0, action: drop
- **RT_SCREEN_IP_LS:** [lsys: LSYS1] Tunnel GRE 4in4! source: 12.12.12.1, destination: 11.11.11.1, zone name: untrust, interface name: ge-0/0/1.0, action: drop

Example: Improving Tunnel Traffic Security with IP Tunneling Screen Options

This example shows how to configure the tunnel screens to enable the screens to control, allow, or block the transit of tunneled traffic.

- [Requirements on page 884](#)
- [Overview on page 884](#)

- [Configuration on page 885](#)
- [Verification on page 888](#)

Requirements

This example uses the following hardware and software components:

- An SRX Series device
- Junos OS Release 12.3X48-D10 and later

Before you begin:

- Understand the IPv6 Tunneling control. See [“Understanding Screen IPv6 Tunneling Control” on page 880](#).

Overview

You can configure the following IP tunneling screen options to check and filter packets, based on IPv6 extension headers, packet headers, and bad-inner-header IPv6 or IPv4 address validation. Based on your configuration, the screen can drop packets, create logs, and provide increased statistics for IP tunneling. The following tunneling screen options are assigned to an untrust zone.

- GRE 4in4 Tunnel
- GRE 4in6 Tunnel
- GRE 6in4 Tunnel
- GRE 6in6 Tunnel
- IPinUDP Teredo Tunnel
- IPinIP 4in4 Tunnel
- IPinIP 4in6 Tunnel
- IPinIP 6in4 Tunnel
- IPinIP 6in6 Tunnel
- IPinIP 6over4 Tunnel
- IPinIP 6to4relay Tunnel
- IPinIP ISATAP Tunnel
- IPinIP DS-Lite Tunnel
- Bad Inner Header Tunnel

Configuration

To configure the IP tunneling screen options, perform these tasks:

- [Configuring GRE Tunnel Screens on page 885](#)
- [Configuring an IPinUDP Teredo Tunnel Screen on page 885](#)
- [Configuring an IPinIP Tunnel Screen on page 886](#)
- [Configuring a Bad-Header Tunnel Screen on page 887](#)
- [Results on page 887](#)

Configuring GRE Tunnel Screens

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option screen1 ip tunnel gre gre-4in4
set security screen ids-option screen1 ip tunnel gre gre-4in6
set security screen ids-option screen1 ip tunnel gre gre-6in4
set security screen ids-option screen1 ip tunnel gre gre-6in6
set security zones security-zone untrust screen screen1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a GRE tunnel screen:

1. Configure a GRE tunnel screen to check the tunnel traffic inner header information for consistency and validate the signature type screen.

```
[edit security screen ids-option screen1 ip tunnel gre]
user@host# set gre-4in4
user@host# set gre-4in6
user@host# set gre-6in4
user@host# set gre gre-6in6
```

2. Configure the screens in the security zones.

```
user@host#set security zones security-zone untrust screen screen1
```

Configuring an IPinUDP Teredo Tunnel Screen

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option screen1 ip tunnel ip-in-udp teredo
set security zones security-zone untrust screen screen1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an IPinUDP Teredo tunnel screen:

1. Configure an IPinUDP Teredo tunnel screen to check the tunnel traffic inner header information for consistency and validate the signature type screen.

```
[edit security screen ids-option screen1 ip tunnel]
user@host# set ip-in-udp teredo
```

2. Configure the screens in the security zones.

```
user@host# set security zones security-zone untrust screen screen1
```

Configuring an IPinIP Tunnel Screen

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option screen1 ip tunnel ipip dslite
set security screen ids-option screen1 ip tunnel ipip ipip-4in4
set security screen ids-option screen1 ip tunnel ipip ipip-4in6
set security screen ids-option screen1 ip tunnel ipip ipip-6in4
set security screen ids-option screen1 ip tunnel ipip ipip-6in6
set security screen ids-option screen1 ip tunnel ipip ipip-6over4
set security screen ids-option screen1 ip tunnel ipip ipip-6to4relay
set security screen ids-option screen1 ip tunnel ipip isatap
set security zones security-zone untrust screen screen1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an IPinIP tunnel screen:

1. Configure an IPinIP tunnel screen to check the tunnel traffic inner header information for consistency and validate the signature type screen.

```
[edit security screen ids-option screen1 ip tunnel ipip]
user@host# set dslite
user@host# set ipip-4in4
user@host# set ipip-4in6
user@host# set ipip-6in4
user@host# set ipip-6in6
user@host# set ipip-6over4
user@host# set ipip-6to4relay
user@host# set ipip-isatap
```

2. Configure the screens in the security zones.

```
user@host# set security zones security-zone untrust screen screen1
```

Configuring a Bad-Inner-Header Tunnel Screen

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security screen ids-option screen1 ip tunnel bad-inner-header
set security zones security-zone untrust screen screen1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a bad-inner-header tunnel screen:

1. Configure a bad-inner-header tunnel screen to check the tunnel traffic inner header information for consistency.

```
[edit security screen ids-option screen1 ip tunnel]
user@host# set bad-inner-header
```

2. Configure the screens in the security zones.

```
user@host# set security zones security-zone untrust screen screen1
```

Results

From configuration mode, confirm your configuration by entering the **show security screen** and **show security screen statistics zone untrust ip tunnel** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
[edit]
user@host# show security screen
...
ids-option screen1 {
ip {
tunnel {
gre {
gre-4in4;
gre-4in6;
gre-6in4;
gre-6in6;
}
ip-in-udp {
teredo;
}
}
ipip {
ipip-4in4;
ipip-4in6;
}
```

```

        ipip-6in4;
        ipip-6in6;
        ipip-6over4;
        ipip-6to4relay;
        isatap;
        dslite;
    }
    bad-inner-header;
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Security Screen Configuration on page 888](#)
- [Verifying IP Tunnel Screens in the Security Zones on page 888](#)

Verifying the Security Screen Configuration

Purpose Display the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option screen1** command.

```

user@host> show security screen ids-option screen1
show security screen ids-option screen1:
  Name                                     Value
  IP Tunnel Bad Inner Header              enabled
  IP Tunnel GRE 6in4                      enabled
  IP Tunnel GRE 4in6                      enabled
  IP Tunnel GRE 6in6                      enabled
  IP Tunnel GRE 4in4                      enabled
  IP Tunnel IPinUDP Teredo                enabled
  IP Tunnel IPIP 6to4 Relay               enabled
  IP Tunnel IPIP 6in4                     enabled
  IP Tunnel IPIP 6over4                   enabled
  IP Tunnel IPIP 4in6                     enabled
  IP Tunnel IPIP 4in4                     enabled
  IP Tunnel IPIP 6in6                     enabled
  IP Tunnel IPIP ISATAP                   enabled
  IP Tunnel IPIP DS-Lite                   enabled

```

Meaning The **show security screen ids-option screen1** command displays screen object status as enabled.

Verifying IP Tunnel Screens in the Security Zones

Purpose Verify that the IP tunneling screen options are configured properly in the security zones.

Action From operational mode, enter the **show security screen statistics zone untrust ip tunnel** command.

```
user@host> show security screen statistics zone untrust ip tunnel
```

IP Tunnel Screen statistics:

IDS attack type	Statistics
IP tunnel GRE 6in4	0
IP tunnel GRE 4in6	0
IP tunnel GRE 6in6	0
IP tunnel GRE 4in4	0
IP tunnel IPIP 6to4 relay	0
IP tunnel IPIP 6in4	0
IP tunnel IPIP 6over4	0
IP tunnel IPIP 4in6	0
IP tunnel IPIP 4in4	0
IP tunnel IPIP 6in6	0
IP tunnel IPIP ISATAP	0
IP tunnel IPIP DS-Lite	0
IP tunnel IPinUDP Teredo	0
IP tunnel bad inner header	0

Meaning The **show security screen statistics zone untrust ip tunnel** command displays the IP tunnel screen statistics summary.

OS-Specific DoS Attacks Overview

If an attacker not only identifies the IP address and responsive port numbers of an active host but also its operating system (OS), instead of resorting to brute-force attacks, the attacker can launch more elegant attacks that can produce one-packet or two-packet “kills.”

OS-specific denial-of-service (DoS) attacks, including ping of death attacks, teardrop attacks, and WinNuke attacks, can cripple a system with minimal effort. If Junos OS is protecting hosts susceptible to these attacks, you can configure Junos OS to detect these attacks and block them before they reach their target.

Understanding Ping of Death Attacks

OS-specific DoS attacks, such as ping of death attacks, can cripple a system with minimal effort.

The maximum allowable IP packet size is 65,535 bytes, including the packet header, which is typically 20 bytes. An ICMP echo request is an IP packet with a pseudo header, which is 8 bytes. Therefore, the maximum allowable size of the data area of an ICMP echo request is 65,507 bytes (65,535 - 20 - 8 = 65,507).

However, many ping implementations allow the user to specify a packet size larger than 65,507 bytes. A grossly oversized ICMP packet can trigger a range of adverse system reactions such as denial of service (DoS), crashing, freezing, and rebooting.

When you enable the ping of death screen option, Junos OS detects and rejects such oversized and irregular packet sizes even when the attacker hides the total packet size by fragmenting it. See [Figure 42](#).

NOTE: For information about IP specifications, see RFC 791, *Internet Protocol*. For information about ICMP specifications, see RFC 792, *Internet Control Message Protocol*. For information about ping of death attacks, see <http://www.insecure.org/spl0its/ping-o-death.html>.

Figure 42: Ping of Death

The size of this packet is 65,538 bytes. It exceeds the size limit prescribed by RFC 791, *Internet Protocol*, which is 65,535 bytes. As the packet is transmitted, it becomes broken into numerous fragments. The reassembly process might cause the receiving system to crash.

NOTE: Junos OS supports ping of death protection for both IPv4 and IPv6 packets.

Example: Protecting Against a Ping of Death Attack

This example shows how to protect against a ping-of-death attack.

- [Requirements on page 892](#)
- [Overview on page 892](#)
- [Configuration on page 893](#)
- [Verification on page 893](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you enable protection against a ping-of-death attack and specify the zone where the attack originates.

Configuration

- Step-by-Step Procedure** To enable protection against a ping of death:
1. Specify the screen object name.

```
[edit]  
user@host# set security screen ids-option ping-death icmp ping-death
```
 2. Set the security zone for zone screen.

```
[edit]  
user@host# set security zones security-zone zone screen ping-death
```
 3. If you are done configuring the device, commit the configuration.

```
[edit]  
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security screen ids-option ping-death** and **show security zones** commands in operational mode.

- Related Documentation**

 - [DoS Attack Overview on page 837](#)

Understanding Teardrop Attacks

OS-specific denial-of-service (DoS) attacks, such as teardrop attacks, can cripple a system with minimal effort.

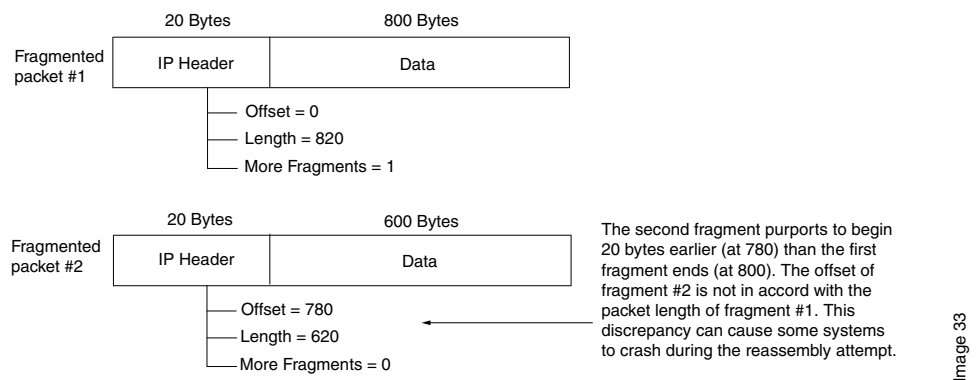

Teardrop attacks exploit the reassembly of fragmented IP packets. In the IP header, one of the fields is the fragment offset field, which indicates the starting position, or offset, of the data contained in a fragmented packet relative to the data of the original unfragmented packet. See [Figure 43](#).

Figure 43: Teardrop Attacks

When the sum of the offset and size of one fragmented packet differ from that of the next fragmented packet, the packets overlap, and the server attempting to reassemble the packet can crash, especially if it is running an older OS that has this vulnerability. See [Figure 44](#).

Figure 44: Fragment Discrepancy

After you enable the teardrop attack screen option, whenever Junos OS detects this discrepancy in a fragmented packet, it drops it.

NOTE: Junos OS supports teardrop attack prevention for both IPv4 and IPv6 packets.

Example: Protecting Against a Teardrop Attack

This example shows how to protect against a teardrop attack.

- [Requirements on page 895](#)
- [Overview on page 895](#)
- [Configuration on page 895](#)
- [Verification on page 895](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you enable protection against a teardrop attack and also specify the zone where the attack originates.

Configuration

Step-by-Step Procedure

To enable protection against teardrop attack:

1. Specify the screen name.

```
[edit]
user@host# set security screen ids-option tear-drop ip tear-drop
```
2. Associate the screen with a security zone.

```
[edit]
user@host# set security zones security-zone zone screen tear-drop
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security screen ids-option tear-drop** and **show security zones** commands in operational mode.

Understanding WinNuke Attacks

OS-specific denial-of-service (DoS) attacks, such as WinNuke attacks, can cripple a system with minimal effort.

WinNuke is a DoS attack targeting any computer on the Internet running Windows. The attacker sends a TCP segment—usually to NetBIOS port 139 with the urgent (URG) flag set—to a host with an established connection (see [Figure 45](#)). This introduces a NetBIOS fragment overlap, which causes many machines running Windows to crash. After the attacked machine is rebooted, the following message appears, indicating that an attack has occurred:

```
An exception OE has occurred at 0028:[address] in VxD MSTCP(01) +
000041AE. This was called from 0028:[address] in VxD NDIS(01) +
00008660. It may be possible to continue normally.
Press any key to attempt to continue.
Press CTRL+ALT+DEL to restart your computer. You will lose any unsaved information in
all applications.
Press any key to continue.
```

Figure 45: WinNuke Attack Indicators

If you enable the WinNuke attack defense screen option, Junos OS scans any incoming Microsoft NetBIOS session service (port 139) packets. If Junos OS observes that the URG flag is set in one of those packets, it unsets the URG flag, clears the URG pointer, forwards the modified packet, and makes an entry in the event log noting that it has blocked an attempted WinNuke attack.

NOTE: Junos OS supports WinNuke attack protection for both IPv4 and IPv6 traffic.

Example: Protecting Against a WinNuke Attack

This example shows how to protect against a WinNuke attack.

- [Requirements on page 897](#)
- [Overview on page 897](#)
- [Configuration on page 897](#)
- [Verification on page 897](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you enable protection against a WinNuke attack and specify the zone where the attack originates.

Configuration

Step-by-Step Procedure

To enable protection against WinNuke attack:

1. Specify the screen name.

```
[edit]
user@host# set security screen ids-option winnuke tcp winnuke
```
2. Associate the screen with a security zone.

```
[edit]
user@host# set security zones security-zone zone screen winnuke
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show security screen ids-option winnuke** and **show security zones** commands in operational mode.

- [Understanding Network Reconnaissance Using IP Options on page 908](#)
- [Example: Detecting Packets That Use IP Screen Options for Reconnaissance on page 911](#)

Reconnaissance Deterrence Overview

Attackers can better plan their attack when they first know the layout of the targeted network (which IP addresses have active hosts), the possible entry points (which port numbers are active on the active hosts), and the constitution of their victims (which operating system the active hosts are running). To gain this information, attackers must perform reconnaissance.

Juniper Networks provides several screen options for deterring attackers' reconnaissance efforts and thereby hindering them from obtaining valuable information about the protected network and network resources.

Related Documentation

- [Understanding Network Reconnaissance Using IP Options on page 908](#)

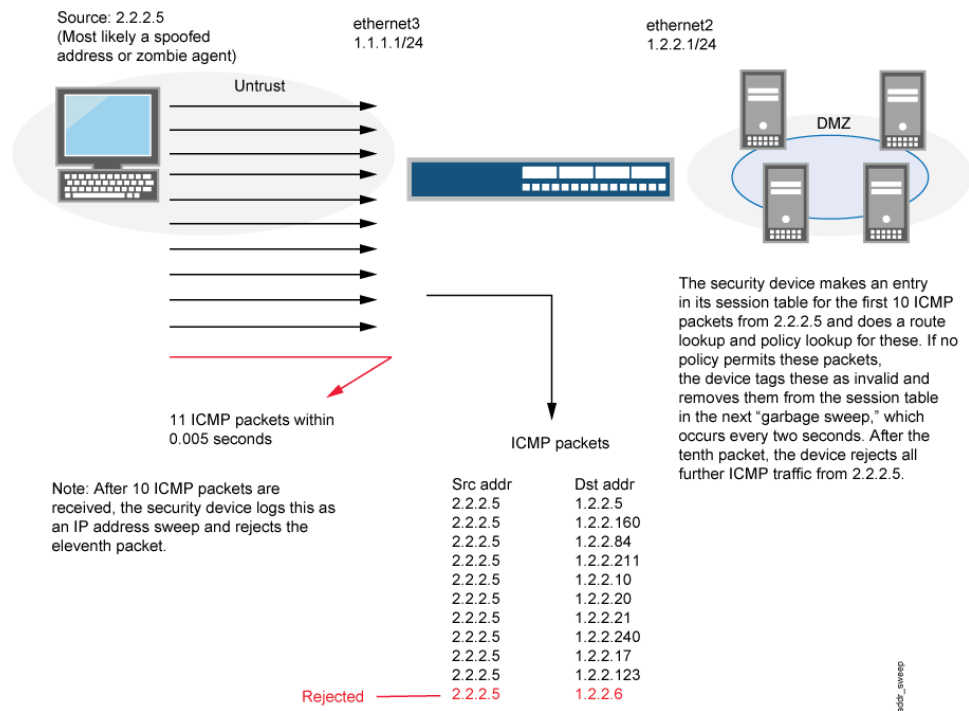

Understanding IP Address Sweeps

An address sweep occurs when one source IP address sends a defined number of ICMP packets sent to different hosts within a defined interval (5000 microseconds is the default). The purpose of this attack is to send ICMP packets—typically echo requests—to various hosts in the hopes that at least one replies, thus uncovering an address to target.

Junos OS internally logs the number of ICMP packets to different addresses from one remote source. Using the default settings, if a remote host sends ICMP traffic to 10

addresses in 0.005 seconds (5000 microseconds), then the device flags this as an address sweep attack and rejects all further ICMP packets from that host for the remainder of the specified threshold time period. See [Figure 46](#).

Figure 46: Address Sweep

Consider enabling this screen option for a security zone only if there is a policy permitting ICMP traffic from that zone. Otherwise, you do not need to enable the screen option. The lack of such a policy denies all ICMP traffic from that zone, precluding an attacker from successfully performing an IP address sweep anyway.

NOTE: Junos OS supports this screen option for ICMPv6 traffic also.

Example: Blocking IP Address Sweeps

This example describes how to configure a screen to block an IP address sweep originating from a security zone.

- [Requirements on page 903](#)
- [Overview on page 903](#)
- [Configuration on page 903](#)
- [Verification on page 903](#)

Requirements

Before you begin:

- Understand how IP address sweeps work. See [“Understanding IP Address Sweeps” on page 901](#).
- Configure security zones. See [“Security Zones and Interfaces Overview” on page 1029](#).

Overview

You need to enable a screen for a security zone if you have configured a policy that permits ICMP traffic from that zone. If you have not configured such a policy, then your system denies all ICMP traffic from that zone, and the attacker cannot perform an IP address sweep successfully anyway.

In this example you configure a **5000-ip-sweep** screen to block IP address sweeps originating in the zone-1 security zone.

Configuration

Step-by-Step Procedure

To configure a screen to block IP address sweeps:

1. Configure a screen.

```
[edit]
user@host# set security screen ids-option 5000-ip-sweep icmp ip-sweep threshold
5000
```

2. Enable the screen in the security zone.

```
[edit]
user@host# set security zones security-zone zone-1 screen 5000-ip-sweep
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- [Verifying the Screens in the Security Zone on page 903](#)
- [Verifying the Security Screen Configuration on page 904](#)

Verifying the Screens in the Security Zone

Purpose Verify that the screen is enabled in the security zone.

Action From operational mode, enter the **show security zones** command.

```
[edit]
user@host> show security zones
Security zone: zone-1
Send reset for non-SYN session TCP packets: Off
```

```
Policy configurable: Yes
Screen: 5000-ip-sweep
  Interfaces bound: 1
  Interfaces:
    ge-1/0/0.0
```

Verifying the Security Screen Configuration

Purpose Display the configuration information about the security screen.

Action From operational mode, enter the **show security screen ids-option *screen-name*** command.

[edit]

```
user@host> show security screen ids-option 5000-ip-sweep
Screen object status:
```

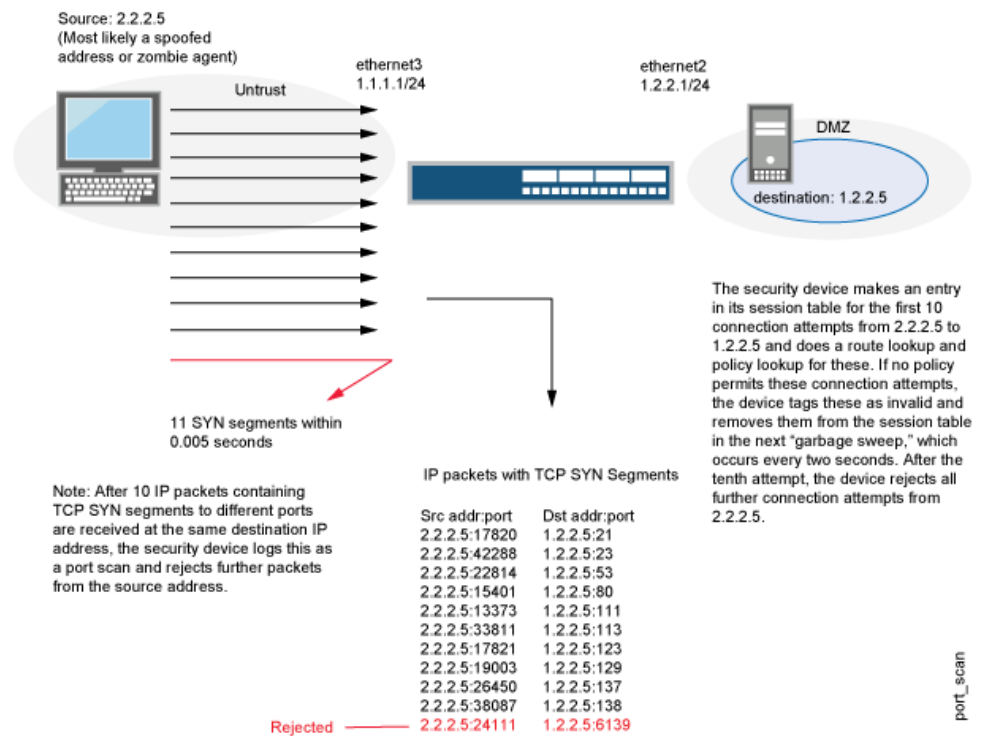

Name	Value
ICMP address sweep threshold	5000
