    address-set address-set-name;
    description text;
  }
  attach {
    zone zone-name;
  }
  description text;
}
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OSRelease 11.1. Statement moved under the security hierarchy in Junos OS Release 11.2. Support for address range added in Junos OS Release 12.1. The **description** option added in Junos OS Release 12.1.

Description Define entries in the address book. Address book entries can include any combination of IPv4 addresses, IPv6 addresses, DNS names, wildcard addresses, and address range. You define addresses and address sets in an address book and then use them when configuring different features, such as security policies and NAT.

NOTE: IPv6 wildcard address configuration is not supported in this release.

Options

- **address-book *book-name*—**Name of the address book.
- **global—**An address book that is available by default. You can add any combination of IPv4 addresses, IPv6 addresses, wildcard addresses, DNS names, or address range to the global address book. You do not need to attach the global address book to a security zone; entries in the global address book are available to all security zones that are not attached to address books.

The remaining statements are explained separately. See CLI Explorer.

address-book (System)

Syntax

```
address-book {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level
[edit system security-profile *security-profile-name*]

Release Information
Statement introduced in Junos OS Release 11.2.

Description
Specify the number of address books that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options
- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level
system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

appfw-profile (System)

Syntax

```
appfw-profile {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the application firewall profile quota of a logical system.

Options

- **maximum *amount***—Specify the maximum allowed quota value.

  Range: 0 through 1024

- **reserved *amount***—Specify a reserved quota value that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

appfw-rule

Syntax

```
appfw-rule {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the number of application firewall rule configurations that a master administrator can configure for a master logical system or user logical system when the security profile is bound to the logical systems.

The master administrator:

- Uses security profiles to provision logical systems with resources
- Binds security profiles to the master logical system and the user logical systems
- Can configure more than one security profile, allocating different numbers of resources in various profiles

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can use resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

application-tracking

Syntax

```
application-tracking {
  disable;
  (first-update | first-update-interval first-update-interval);
  session-update-interval session-update-interval;
}
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 10.2. Support for **disable** added in Junos OS Release 11.4.

Description AppTrack, an application tracking tool, is a form of statistical profiling. Enabling this feature for a zone logs flow statistics (the byte count, packet count, and start and end times for a session) at session end. You can modify the logging time and log frequency with command options. Periodically, a network management tool, such as STRM, collects the logged statistics sent by each network device for bandwidth usage analysis of the network.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

cluster (Chassis)

Syntax

```
cluster {
  configuration-synchronize {
    no-secondary-bootup-auto;
  }
  control-link-recovery;
  heartbeat-interval milliseconds;
  heartbeat-threshold number;
  network-management {
    cluster-master;
  }
  redundancy-group  group-number {
    gratuitous-arp-count number;
    hold-down-interval number;
    interface-monitor interface-name {
      weight number;
    }
    ip-monitoring {
      family {
        inet {
          ipv4-address {
            interface {
              logical-interface-name;
              secondary-ip-address ip-address;
            }
            weight number;
          }
        }
      }
      global-threshold number;
      global-weight number;
      retry-count number;
      retry-interval seconds;
    }
    node (0 | 1 ) {
      priority number;
    }
    preempt;
  }
  reth-count number;
  traceoptions {
    file {
      filename;
      files number;
      match regular-expression;
      (world-readable | no-world-readable);
      size maximum-file-size;
    }
    flag flag;
    level {
      (alert | all | critical | debug | emergency | error | info | notice | warning);
    }
    no-remote-trace;
```

cpu

Syntax

```
cpu {
  reserved percent;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the percentage of CPU utilization that is always available to a logical system. This value is configured in a security profile that is bound to a logical system.

Only the master administrator can create security profiles and bind them to logical systems.

NOTE: The cpu-control option at the [edit system security-profile resources] hierarchy level must be specified for the reserved value to take effect.

Options

reserved *percent*—A reserved quota that guarantees that the percentage of CPU specified is always available to the logical system.

Range: 0 through 100 percent (decimal point allowed).

Default: 1 percent for the master logical system and 0 percent for user logical systems.

CAUTION: The master logical system must not be bound to a security profile that is configured with a 0 percent reserved CPU quota as traffic loss could occur.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

datapath-debug

Syntax

```
datapath-debug {
  action-profile profile-name {
    event (jexec | lbt | lt-enter | lt-leave | mac-egress | mac-ingress | np-egress | np-ingress
      | pot) {
      count;
      packet-dump;
      packet-summary;
      trace;
    }
    module {
      flow {
        flag {
          all;
        }
      }
    }
    preserve-trace-order;
    record-pic-history;
  }
  capture-file {
    filename;
    files number;
    format pacp-format;
    size maximum-file-size;
    (world-readable | no-world-readable);
  }
  maximum-capture-size value;
  packet-filter packet-filter-name {
    action-profile (profile-name | default);
    destination-port (port-range | protocol-name);
    destination-prefix destination-prefix;
    interface logical-interface-name;
    protocol (protocol-number | protocol-name;
    source-port (port-range | protocol- name);
    source-prefix source-prefix;
    }
  traceoptions {
    file {
      filename;
      files number;
      match regular-expression;
      size maximum-file-size;
      (world-readable | no-world-readable);
    }
    no-remote-trace;
  }
}
```

Hierarchy Level [edit security]

Release Information Command introduced in Junos OS Release 10.0.

dslite-softwire-initiator

Syntax

```
dslite-softwire-initiator {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 12.1.

Description Specify the number of IPv6 dual-stack lite (DS-Lite) softwire initiators that can connect to the softwire concentrator configured in either a user logical system or the master logical system. This statement is configured in the security profile that is bound to the logical system.

Only the master administrator can create security profiles and bind them to logical systems. The master administrator:

- Uses security profiles to provision logical systems with resources
- Binds security profiles to user logical systems and the master logical system
- Configures more than one security profile, specifying different amounts of resource allocations in various profiles

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources. The default is the system maximum.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system. The default is 0.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

file (System Logging)

Syntax

```
file filename {
  allow-duplicates;
  any (alert | any | critical | emergency | error | info | none | notice | warning);
  archive {
    archive-sites {
      url password;
    }
    (binary-data | no-binary-data);
    files number;
    size size;
    start-time start-time;
    transfer-interval transfer-interval;
    (world-readable | no-world-readable);
  }
  authorization (alert | any | critical | emergency | error | info | none | notice | warning);
  change-log (alert | any | critical | emergency | error | info | none | notice | warning);
  conflict-log (alert | any | critical | emergency | error | info | none | notice | warning);
  daemon (alert | any | critical | emergency | error | info | none | notice | warning);
  dfc (alert | any | critical | emergency | error | info | none | notice | warning);
  explicit-priority;
  external (alert | any | critical | emergency | error | info | none | notice | warning);
  firewall (alert | any | critical | emergency | error | info | none | notice | warning);
  ftp (alert | any | critical | emergency | error | info | none | notice | warning);
  interactive-commands (alert | any | critical | emergency | error | info | none | notice | warning);
  kernel (alert | any | critical | emergency | error | info | none | notice | warning);
  match "regular-expression";
  ntp (alert | any | critical | emergency | error | info | none | notice | warning);
  pfe (alert | any | critical | emergency | error | info | none | notice | warning);
  security (alert | any | critical | emergency | error | info | none | notice | warning);
  structured-data {
    brief;
  }
  user (alert | any | critical | emergency | error | info | none | notice | warning);
}
```

Hierarchy Level [edit system syslog]

Release Information Statement introduced before Junos OS Release 12.1X47 for SRX Series.

Description Specify the file in which to log data.

Options

- *filename*—Specify the name of the file in which to log data.
- *allow-duplicates*—Do not suppress the repeated messages.
- *any*—Specify all facilities information.
  - *alert*—Specify the conditions that should be corrected immediately.
  - *critical*—Specify the critical conditions.
  - *emergency*—Specify the conditions that cause security functions to stop.
  - *error*—Specify the general error conditions.

Copyright © 2016, Juniper Networks, Inc.

    - *info*—Specify the information about normal security operations.
    - *none*—Do not specify any messages.
    - *notice*—Specify the conditions that should be handled specifically.
    - *warning*—Specify the general warning conditions.
- *archive*—Specify the archive file information.
    - *archive-sites*—Specify a list of destination URLs for the archived log files.
        - *url*—Specify the primary and failover URLs to receive archive files.
    - *binary-data*—Mark file such that it contains binary data.
    - *no-binary-data*—Do not mark the file such that it contains binary data.
    - *files*—Specify the number of files to be archived. Range: 1 through 1000 files.
    - *size*—Specify the size of files to be archived. Range: 65,536 through 1,073,741,824 bytes.
    - *world-readable*—Allow any user to read the log file.
    - *no-world-readable*—Do not allow any user to read the log file.
    - *start-time*—Specify the start time for file transmission. Enter the start time in the yyyy-mm-dd.hh:mm format.
    - *transfer-interval*—Specify the frequency at which to transfer the files to archive sites.
- *authorization*—Specify the authorization system.
- *change-log*—Specify the configuration change log.
- *conflict-log*—Specify the configuration conflict log.
- *daemon*—Specify the various system processes.
- *dfc*—Specify the dynamic flow capture.
- *explicit-priority*—Include the priority and facility in messages.
- *external*—Specify the local external applications.
- *firewall*—Specify the firewall filtering system.
- *ftp*—Specify the FTP process.
- *interactive-commands*—Specify the commands executed by the UI.
- *kernel*—Specify the kernel information.
- *match*—Specify the regular expression for lines to be logged.
- *ntp*—Specify the NTP process.
- *pfe*—Specify the Packet Forwarding Engine.
- *security*—Specify the security-related information.

Copyright © 2016, Juniper Networks, Inc.

- *structured-data*—Log the messages in structured log format.
  - *brief*—Omit English language text from the end of the logged message.
- *user*—Specify the user processes.
  - *info*—Specify the informational messages.

Required Privilege Level
system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

firewall-authentication (Security)

Syntax

```
firewall-authentication {
  traceoptions {
    flag flag;
  }
}
```

Hierarchy Level
[edit security]

Release Information
Statement introduced in Junos OS Release 8.5.

Description
Define data-plane firewall authentication tracing options.

Options
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple flag statements.
  - **all**—Enable all tracing operations.
  - **authentication**—Trace data-plane firewall authentication events.
  - **proxy**—Trace data-plane firewall authentication proxy events.
- **detail**—Display moderate amount of data.
- **extensive**—Display extensive amount of data.
- **terse**—Display minimum amount of data.

Required Privilege Level
security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

```
        match regular-expression;
        size maximum-file-size;
        (world-readable | no-world-readable);
      }
      flag flag;
      no-remote-trace;
      packet-filter filter-name {
        destination-port port-identifier;
        destination-prefix address;
        interface interface-name;
        protocol protocol-identifier;
        source-port port-identifier;
        source-prefix address;
      }
      rate-limit messages-per-second;
    }
}
```

Hierarchy Level [edit security]

Release Information Statement modified in Junos OS Release 9.5.

Description Determine how the device manages packet flow. The device can regulate packet flow in the following ways:

- Enable or disable DNS replies when there is no matching DNS request.
- Set the initial session-timeout values.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

flow-gate

Syntax

```
flow-gate {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of flow gates, also known as **pinholes**, that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

flow-session

Syntax

```
flow-session {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Release 11.2 of Junos OS.

Description Specify the number of flow sessions that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

NOTE: An IPv6 session consumes twice the memory of an IPv4 session. Therefore the number of sessions available for IPv6 is half the reserved and maximum quotas configured for the flow session resource in a security profile. Use the vty command **show usp flow resource usage cp-session** to check flow session usage.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

idp-policy

Syntax idp-policy *idp-policy-name*;

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the IDP policy for the security profile.

Options *idp-policy-name*—Name of the IDP policy.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 9.2.

Description You can set the mode of logging (event for traditional system logging or stream for streaming security logs through a revenue port to a server). You can also specify all the other parameters for security logging.

Options

- **disable**—Disable the security logging for the device.
- **event-rate** *rate*—Limits the rate (0 through 1500) at which logs will be streamed per second.
- **rate-cap** *rate-cap-value*—Works with event mode only. Limits the rate (0 through 5000) at which data plane logs will be generated per second.
- **source-address** *source-address*—Specify a source IP address or IP address used when exporting security logs.
- **source-interface** *interface-name*—Specify a source interface name, which is mandatory to configure **stream**.

NOTE: The **source-address** and **source-interface** are alternate values. Using one of the options is mandatory.

- **utc-time-stamp**—Specify to use UTC time for security log timestamps.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

logical-system (System Security Profile)

Syntax logical-system *logical-system-name*;

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the user logical system to bind the security profile to.

The master administrator uses security profiles to provision logical systems with resources. You can bind security profiles to user logical systems and the master logical system. The master administrator can configure more than one security profile allocating different amounts of a resource in various ones.

Only the master administrator can create security profiles and bind them to logical systems.

Options ***logical-system-name***—Name of the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

logical-systems (All)

Syntax

```
logical-systems logical-system-name {
    ...
}
```

Hierarchy Level [edit]

Release Information Statement introduced in Junos OS Release 11.2.

Description Configure a logical system. Only the master administrator can configure a logical system at this hierarchy level.

At this hierarchy level, you can include several of the hierarchies that can be included at the [**edit**] hierarchy level. For descriptions of the applicable statements, see the appropriate hierarchies.

NOTE: The logical-systems configuration statement can only be used by the master administrator.

Options *logical-system-name*—Name of the logical system.

Required Privilege Level
all—To view this statement in the configuration.
all—To add this statement to the configuration.

Hierarchy Level [edit security]

Release Information Statement modified in Junos OS Release 9.6. The **description** option added in Junos OS Release 12.1.

Description Configure Network Address Translation (NAT) for SRX Series devices.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

nat-cone-binding

Syntax

```
nat-cone-binding {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT cone binding configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-destination-pool

Syntax

```
nat-destination-pool {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT destination pool configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

nat-destination-rule

Syntax

```
nat-destination-rule {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT destination rule configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-interface-port-ol (System)

Syntax

```
nat-interface-port-ol {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the security NAT interface port overloading the quota of a logical system.

Options

- **maximum *amount***—Specify the maximum allowed quota value.

  Range: 0 through 64

- **reserved *amount***—Specify a reserved quota value that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-nopat-address

Syntax

```
nat-nopat-address {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT without port address translation configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-pat-address

Syntax

```
nat-pat-address {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT with port address translation (PAT) configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-pat-portnum

Syntax

```
nat-pat-portnum {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the maximum quantity and the reserved quantity of ports for the logical system as part of its security profile. The total number of PAT pools must not exceed the configured maximum ports for the logical system.

Options

maximum *amount*—Specify the maximum number of ports allowed for a logical system. The maximum quantity is not guaranteed and is shared among multiple logical systems.

reserved *amount*—Specify the number of resources guaranteed for a logical system.

Range: For SRX5600 and SRX5800 devices, up to 402,653,184 ports are supported. Pool specifications for logical systems can be viewed using the **show security nat source summary logical-system all** command.

Required Privilege Level

system—To view this statement in the configuration.
system—To add this statement to the configuration.

nat-port-ol-ipnumber

Syntax

```
nat-port-ol-ipnumber {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT port overloading IP number configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

nat-rule-referenced-prefix (System)

Syntax

```
nat-rule-referenced-prefix {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *profile-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Specify the security NAT rule referenced IP prefix quota of a logical system.

Options

- **maximum *amount*** —Specify the maximum allowed quota value.

  Range: 0 through 1,048,576

- **reserved *amount*** —Specify a reserved quota value that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

nat-source-pool

Syntax

```
nat-source-pool {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the NAT source pool configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

nat-source-rule

Syntax

```
nat-source-rule {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the NAT source rule configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

nat-static-rule

Syntax

```
nat-static-rule {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of NAT static rule configurations that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.
Support for the **services-offload** option added in Junos OS Release 11.4.
Support for the **source-identitiy** option added in Junos OS Release 12.1.
Support for the **description** option added in Junos OS Release 12.1.
Support for the **ssl-termination-profile** and **web-redirect-to-https** options added on high-end SRX Series Services Gateways starting from Junos OS Release 12.1X44-D10 and on vSRX, SRX300, SRX320, SRX340, SRX345, SRX550, and SRX1500 Services Gateways starting from Junos OS Release 15.1X49-D40.
Support for the **user-firewall** option added in Junos OS Release 12.1X45-D10.
Support for the **domain** option, and for the **from-zone** and **to-zone** global policy match options, added in Junos OS Release 12.1X47-D10.
Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20. Support for the **extensive** option for **policy-rematch** added in Junos OS Release 15.1X49-D20.

Description

Configure network security policies.

Required Privilege Level

security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

policy (System Security Profile)

Syntax

```
policy {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of security policies that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

policy-with-count

Syntax

```
policy-with-count {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of security policies with a count that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Hierarchy Level [edit access]

Release Information Statement introduced in Junos OS Release 10.4.

 Copyright © 2016, Juniper Networks, Inc.

Description Create a profile containing a set of attributes that define device management access.

Required Privilege Level access—To view this statement in the configuration.
access-control—To add this statement to the configuration.

Related Documentation

purging

Syntax purging;

Hierarchy Level [edit system arp]

Release Information Statement introduced in Junos OS Release 9.6.

Description Purge obsolete ARP entries from the cache when an interface or link goes offline.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Copyright © 2016, Juniper Networks, Inc.

root-authentication

Syntax

```
root-authentication {
    encrypted-password password;
    load-key-file URL;
    plain-text-password;
    ssh-dsa public-key {
    <from pattern-list>;
    }
    ssh-rsa public-key {
    <from pattern-list>;
    }
}
```

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 8.5.

Description Specify authentication information for the root login.

Options

- **encrypted-password *password***—Specify the encrypted authentication password. You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.
- **plain-text-password**—The CLI prompts you for a password encrypts it, and stores the encrypted version in its user database.
- **load-key-file*URL***—File URL containing one or more SSH keys.
- **ssh-dsa *public-key***—SSH DSA public key string.
  - **from *pattern-list***—Pattern list of allowed hosts.
- **ssh-rsa *public-key***—SSH RSA public key string.
  - **from *pattern-list***—Pattern list of allowed hosts.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

root-logical-system

Syntax root-logical-system;

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify root-logical-system to bind the security profile to the master logical system.

The master administrator uses security profiles to provision logical systems with resources. The security profile containing this statement must be bound to root-logical-system only.

Only the master administrator can create security profiles and bind them to logical systems.

Options none

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

scheduler (System Security Profile)

Syntax

```
scheduler {
    maximum amount;
    reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the number of schedulers that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 11.2. The **dslite-softwire-initiator** option introduced in Junos OS Release 12.1.

Description Create a security profile and specify the kinds and amounts of resources to allocate to a logical system to which the security profile is bound.

As a master administrator, you can create a security profile and bind it to more than one logical system if you want to allocate the same kinds and amounts of resources to them. For details on how many security profiles you can create, see "Understanding Logical System Security Profiles (Master Administrators Only)" on page 3253. When you reach the limit, you must delete a security profile and commit the configuration before you can create and commit the configuration for another security profile.

Only the master administrator can create security profiles.

Options

- ***security-profile-name***—Name of the security profile.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

- Understanding Logical System Security Profiles (Master Administrators Only) on page 3253
- Example: Configuring Logical Systems Security Profiles (Master Administrators Only) on page 3258

security-profile-resources

Syntax

```
security-profile-resources {
    cpu-control;
    cpu-control-target percent;
}
```

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 11.4.

Description Configure global settings that apply to all logical systems in the device.

Options

cpu-control—Enable CPU utilization control.

cpu-control-target ***percent***—Specify the upper limit for CPU utilization on the device under normal operating conditions.

Range: 0 through 100 percent (decimal point allowed).

Default: 80 percent.

NOTE: **The cpu-control option must be specified for the cpu-control-target value to take effect.**

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

softwires

Syntax

```
softwires {
  softwire-name name {
    softwire-concentrator ipv6-address;
    softwire-type IPv4-in-IPv6;
  }
  traceoptions {
    file {
      filename;
      files number;
      match regular-expression;
      size maximum-file-size;
      (world-readable | no-world-readable);
    }
    flag (all | configuration | flow);
    no-remote-trace;
  }
}
```

Hierarchy Level [edit security]

Release Information Statement introduced before Junos OS Release 12.1.

Description Configure softwires for IPv6 dual-stack lite (DS-Lite). DS-Lite allows migration to an IPv6 access network without changing end-user software. IPv4 users can continue to access IPv4 internet content using their current hardware, while IPv6 users are able to access IPv6 content.

Options

- **softwire-name *name***—Name of the softwire configuration.
  - **softwire-concentrator *ipv6-address***—IPv6 address of the concentrator.
  - **softwire-type**—Must be IPv4-in-IPv6.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation

zone (System Security Profile)

Syntax

```
zone {
  maximum amount;
  reserved amount;
}
```

Hierarchy Level [edit system security-profile *security-profile-name*]

Release Information Statement introduced in Junos OS Release 11.2.

Description Specify the zones that user logical system administrators and master logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The master administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the master logical system.
- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the master administrator can create security profiles and bind them to logical systems.

Options

- **maximum *amount***—A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.
- **reserved *amount***—A reserved quota that guarantees that the resource amount specified is always available to the logical system.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

        address-set address-set-name;
        description text;
      }
    }
    application-tracking;
    description text;
    host-inbound-traffic {
      protocols protocol-name {
        except;
      }
      system-services service-name {
```

Copyright © 2016, Juniper Networks, Inc.

```
            except;
          }
        }
        interfaces interface-name {
          host-inbound-traffic {
            protocols protocol-name {
              except;
            }
            system-services service-name {
              except;
            }
          }
        }
        screen screen-name;
        tcp-rst;
      }
    }
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5. Support for wildcard addresses added in Junos OS Release 11.1. The **description** option added in Junos OS Release 12.1.

Description A zone is a collection of interfaces for security purposes. All interfaces in a zone are equivalent from a security point of view. Configure the following zones:

- Functional zone—Special-purpose zone, such as a management zone that can host dedicated management interfaces.
- Security zone—Most common type of zone that is used as a building block in policies.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

clear security application-firewall rule-set statistics logical-system

Syntax The master, or root, administrator can issue the following statements:

clear security application-firewall rule-set statistics [logical-system *logical-system-name* | all | root-logical-system]

The user logical system administrator can issue the following statement:

clear security application-firewall rule-set statistics all

Release Information Command introduced in Junos OS Release 11.4.

Description Clear all security application firewall rule set statistics.

NOTE: User logical system administrators can clear statistics only for the logical systems they can access. For information about master and user administrator roles in logical systems, see "Understanding the Master Logical System and the Master Administrator Role" on page 3221.

Options ***logical-system-name***—Name of a specific logical system.

all—(default) Clear all rule set statistics for a specific logical system or all logical systems.

root-logical-system—Clear application firewall rule set statistics on the root logical system (master administrator only).

Required Privilege Level clear

Related Documentation

- show security application-firewall rule-set logical-system on page 777

Output Fields This command produces no output.

Copyright © 2016, Juniper Networks, Inc.

clear security dns-cache

Syntax clear security dns-cache <dns-name *dns-name*>

Release Information Command introduced in Junos OS Release 12.1X44-D10.

Description Reset DNS cache information.

NOTE: This command is only available to the master administrator on devices that are configured for logical systems. This command is not available in user logical systems or on devices that are not configured for logical systems.

Options

- **dns-name**—Clear DNS cache information for the specified name.

Required Privilege Level clear

request security datapath-debug capture start

Syntax request security datapath-debug capture start

Release Information Command introduced in Junos OS Release 10.0.

Description Start the data path debugging capture.

Required Privilege Level maintenance

Related Documentation
- Understanding Data Path Debugging for Logical Systems on page 3476

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

request security datapath-debug capture start

```
user@host> request security datapath-debug capture start
datapath-debug capture started on file
```

Copyright © 2016, Juniper Networks, Inc.

request security datapath-debug capture stop

Syntax request security datapath-debug capture stop

Release Information Command introduced in Junos OS Release 10.0.

Description Stop the data path debugging capture.

Required Privilege Level maintenance

Related Documentation
- Understanding Data Path Debugging for Logical Systems on page 3476

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

request security datapath-debug capture stop

```
user@host> request security datapath-debug capture stop
datapath-debug capture successfully stopped, use show security datapath-debug
capture to view
```

Copyright © 2016, Juniper Networks, Inc.

set chassis cluster cluster-id node reboot

Syntax set chassis cluster cluster-id *cluster-id* node *node* reboot

Release Information Support for extended cluster identifiers (more than 15 identifiers) added in Junos OS Release 12.1X45-D10.

Description This operational mode command sets the chassis cluster identifier (ID) and node ID on each device, and reboots the devices to enable clustering. The system uses the chassis cluster ID and chassis cluster node ID to apply the correct configuration for each node (for example, when you use the **apply-groups** command to configure the chassis cluster management interface). The chassis cluster ID and node ID statements are written to the EPROM, and the statements take effect when the system is rebooted.

Setting a cluster ID to 0 is equivalent to disabling a cluster. A cluster ID greater than 15 can only be set when the fabric and control link interfaces are connected back-to-back.

NOTE: If you have a cluster set up and running with an earlier release of Junos OS, you can upgrade to Junos OS Release 12.1X45-D10 or later and re-create a cluster with cluster IDs greater than 16. If for any reason you decide to revert to the previous version of Junos OS that did not support extended cluster IDs, the system comes up with standalone devices after you reboot. If the cluster ID set is less than 16 and you roll back to a previous release, the system comes back with the previous setup.

Options **cluster-id *cluster-id*** —Identifies the cluster within the Layer 2 domain.

Range: 0 through 255

node *node* —Identifies a node within a cluster.

Range: 0 to 1

Required Privilege Level maintenance

show chassis cluster status

Syntax **show chassis cluster status**
<redundancy-group *group-number* >

Release Information Command modified in Junos OS Release 9.2. Support for dual control ports added in Junos OS Release 10.0. Support for monitoring failures added in Junos OS Release 12.1X47-D10.

Description Display the failover status of a chassis cluster.

Options
- none—Display the status of all redundancy groups in the chassis cluster.
- **redundancy-group *group-number*** —(Optional) Display the status of the specified redundancy group.

Required Privilege Level view

Related Documentation
- *redundancy-group (Chassis Cluster)*
- *clear chassis cluster failover-count*
- *request chassis cluster failover node*
- *request chassis cluster failover reset*

List of Sample Output
show chassis cluster status on page 3645
show chassis cluster status redundancy-group 1 on page 3646

Output Fields Table 353 lists the output fields for the **show chassis cluster status** command. Output fields are listed in the approximate order in which they appear.

Table 353: show chassis cluster status Output Fields

Field Name	Field Description
Cluster ID	ID number (1-15) of a cluster is applicable for releases upto 12.1X45-D10. ID number (1-255) is applicable for releases 12.1X45-D10 and later. Setting a cluster ID to 0 is equivalent to disabling a cluster.
Redundancy-Group	ID number (1-128) of a redundancy group in the chassis cluster.
Node name	Node (device) in the chassis cluster (**node0** or **node1**).
Priority	Assigned priority for the redundancy group on that node.

Copyright © 2016, Juniper Networks, Inc.

Table 353: show chassis cluster status Output Fields *(continued)*

Field Name	Field Description
Status	State of the redundancy group (**Primary**, **Secondary**, **Lost**, or **Unavailable**). • **Primary**—Redundancy group is active and passing traffic. • **Secondary**—Redundancy group is passive and not passing traffic. • **Lost**—Node loses contact with the other node through the control link. Most likely to occur when both nodes are in a cluster and due to control link failure, one node cannot exchange heartbeats, or when the other node is rebooted. • **Unavailable**—Node has not received a single heartbeat over the control link from the other node since the other node booted up. Most likely to occur when one node boots up before the other node, or if only one node is present in the cluster.
Preempt	• **Yes**: Mastership can be preempted based on priority. • **No**: Change in priority will not preempt the mastership.
Manual failover	• **Yes**: If the Mastership is set manually through the CLI with the **request chassis cluster failover node** or **request chassis cluster failover redundancy-group** command. This overrides **Priority** and **Preempt**. • **No**: Mastership is not set manually through the CLI.
Monitor-failures	• **None**: Cluster working properly. • **Monitor Failure code**: Cluster is not working properly and the respective failure code is displayed.

Sample Output

Displays chassis cluster status with all redundancy groups.

show chassis cluster status

```
user@host> show chassis cluster status

Monitor Failure codes:
  CS  Cold Sync monitoring        FL  Fabric Connection monitoring
    GR  GRES monitoring             HW  Hardware monitoring
    IF  Interface monitoring        IP  IP monitoring
    LB  Loopback monitoring         MB  Mbuf monitoring
    NH  Nexthop monitoring          NP  NPC monitoring

<*filename* | user <*username*>>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.1 for the QFX Series.
Option *device-type (device-id* | *device-alias*) is introduced in Junos OS Release 13.1 for the QFX Series.
Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

List log files, display log file contents, or display information about users who have logged in to the router or switch.

NOTE: On MX Series routers, modifying a configuration to replace a service interface with another service interface is treated as a catastrophic event. When you modify a configuration, the entire configuration associated with the service interface—including NAT pools, rules, and service sets—is deleted and then re-created for the newly specified service interface. If there are active sessions associated with the service interface that is being replaced, these sessions are deleted and the NAT pools are then released, which leads to the generation of the NAT_POOL_RELEASE system log messages. However, because NAT pools are already deleted as a result of the catastrophic configuration change and no longer exist, the NAT_POOL_RELEASE system log messages are not generated for the changed configuration.

Options

none—List all log files.

<all-lcc | lcc *number* | scc>—(Routing matrix only)(Optional) Display logging information about all T640 routers (or line-card chassis) or a specific T640 router (replace ***number*** with a value from 0 through 3) connected to a TX Matrix router. Or, display logging information about the TX Matrix router (or switch-card chassis).

device-type—(QFabric system only) (Optional) Display log messages for only one of the following device types:

Copyright © 2016, Juniper Networks, Inc.

- **director-device**—Display logs for Director devices.
- **infrastructure-device**—Display logs for the logical components of the QFabric system infrastructure, including the diagnostic Routing Engine, fabric control Routing Engine, fabric manager Routing Engine, and the default network Node group and its backup (NW-NG-0 and NW-NG-0-backup).
- **interconnect-device**—Display logs for Interconnect devices.
- **node-device**—Display logs for Node devices.

NOTE: If you specify the device-type optional parameter, you must also specify either the device-id or device-alias optional parameter.

(***device-id*** **|** ***device-alias***)—If a device type is specified, display logs for a device of that type. Specify either the device ID or the device alias (if configured).

filename—(Optional) Display the log messages in the specified log file. For the routing matrix, the filename must include the chassis information.

user <*username*>—(Optional) Display logging information about users who have recently logged in to the router or switch. If you include ***username***, display logging information about the specified user.

show security application-firewall rule-set

Syntax show security application-firewall rule-set (*<rule-set-name>* | all)

Release Information Command introduced in Junos OS Release 11.1. Updated in Junos OS Release 12.1X44-D10 with output format changes. Updated in Junos OS Release 12.1X45-D10 with redirection counters.

Description Display information about the specified rule set defined in the application firewall.

Options ***rule-set-name***—Name of the rule set.

all—Display information about all the application firewall rule sets.

Required Privilege Level view

Related Documentation
- clear security application-firewall rule-set statistics on page 745

List of Sample Output
show security application-firewall rule-set my_ruleset1 on page 3652
show security application-firewall rule-set all on page 3652

Output Fields Table 44 lists the output fields for the **show security application-firewall rule-set** command. Output fields are listed in the approximate order in which they appear.

Table 354: show security application-firewall rule-set Output Fields

Field Name	Field Description
Rule-set	Name of the rule set.
Logical system	Name of the logical system of the rule set.
Profile	The redirect profile to be used for rules requiring redirection for reject or deny actions.

Rule	Name of the rule
	• **Dynamic applications**—Name of the applications.
	• **Dynamic application groups**—Name of the application groups.
	• **SSL-Encryption**—Setting for SSL traffic.
	• **Action**—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following:
	  ◦ **permit**
	  ◦ **deny**
	  ◦ **reject**
	  ◦ **redirect**
	• **Number of sessions matched**—Number of sessions matched with the application firewall rule.
	• **Number of sessions redirected**—Number of sessions redirected by the application firewall rule.

Copyright © 2016, Juniper Networks, Inc.

Table 354: show security application-firewall rule-set Output Fields *(continued)*

Field Name	Field Description
Default rule	The default rule applied when the identified application is not specified in any rules of the rule set. • **Number of sessions matched**—Number of sessions matched with the application firewall default rule. • **Number of sessions redirected**—Number of sessions redirected by the application firewall rule.
Number of sessions with appid pending	Number of sessions that are pending application identification processing

Sample Output

show security application-firewall rule-set my_ruleset1

```
user@host>show security application-firewall rule-set my_ruleset1
Rule-set: my_ruleset1
     Rule: rule1
         Dynamic Applications: junos:facebook, junos:messenger
         Dynamic Application Groups: junos:web, junos:chat
         SSL-Encryption: any
         Action: deny or redirect
         Number of sessions matched: 10
         Number of sessions redirected: 10
     Default rule: permit
         Number of sessions matched: 200
         Number of sessions redirected: 0
     Number of sessions with appid pending: 2
```

Sample Output

show security application-firewall rule-set all

```
user@host> show security application-firewall rule-set all
Rule-set: appfw
    Logical system: root-logical-system
    Profile: lsy2_pf555
    Rule: 2
        Dynamic Applications: junos:HTTP
        SSL-Encryption: any
        Action:deny or redirect
        Number of sessions matched: 2
        Number of sessions redirected: 2
    Rule: 1
        Dynamic Applications: junos:FTP
        SSL-Encryption: any
        Action:permit
        Number of sessions matched: 0
        Number of sessions redirected: 0
    Default rule:permit
        Number of sessions matched: 0
        Number of sessions redirected: 0
    Number of sessions with appid pending: 0
```

show security application-firewall rule-set logical-system

Syntax

The master, or root, administrator can issue the following statements:

show security application-firewall rule-set all
show security application-firewall rule-set *rule-set-name* | all | logical-system *logical-system-name* | all | root-logical-system [*logical-system-name* | all]

The user logical system administrator can issue the following statement:

show security application-firewall rule-set all

Release Information

Command introduced in Junos OS Release 11.4.

Description

Display information about application firewall rule set(s) associated with a specific logical system, all logical systems, or the root logical system configured on a device.

NOTE: The master administrator can configure and view application firewall rule sets for the root logical system and all user logical systems configured on the device. User logical system administrators can configure and view application firewall rule set information only for the user logical systems for which they have access. For information about master and user administrator roles in logical systems, see "Understanding Logical Systems for SRX Series Services Gateways" on page 3205.

Options

rule-set-name—Name of a specific rule set.

logical-system-name—Name of a specific logical system.

all—(default) Display all rule sets for all logical systems. The user logical system administrator can display all rule sets only for the logical system they can access.

root-logical-system—Display application firewall rule set information for the root logical system (master administrator only).

Required Privilege Level

Table 355: show security application-firewall rule-set logical-system Output Fields

Field Name	Field Description
Rule-set	Name of the rule set.
Logical system	Name of the logical system.

Rule	Name of the rule.
	• **Dynamic applications**—Name of the applications.
	• **Dynamic application groups**—Name of the application groups.
	• **Action**—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following:
	  ◦ **permit**
	  ◦ **deny**
	• **Number of sessions matched**—Number of sessions matched with the application firewall rule.

Default rule	The default rule applied when the identified application is not specified in any rules of the rule set. • **Number of sessions matched**—Number of sessions matched with the application firewall default rule.
Number of sessions with appid pending	Number of sessions that are pending with the application ID processing.

Sample Output

show security application-firewall rule-set logical-system all

```
root@host> show security application-firewall rule-set logical-system all

Rule-set: root_rs1
    Logical system: root-logical-system
    Rule: r1
        Dynamic Applications: junos:FTP
        Action:permit
        Number of sessions matched: 10
Default rule:deny
        Number of sessions matched: 100
Number of sessions with appid pending: 4

Rule-set: root-rs2
    Logical system: root-logical-system
    Rule: r1
        Dynamic Application Groups: junos:web
        Action:permit
        Number of sessions matched: 20
Default rule:deny
        Number of sessions matched: 100
Number of sessions with appid pending: 10
```

show security application-tracking counters

Syntax show security application-tracking counters

Release Information Command introduced in Junos OS Release 10.2.

Description Display the status of AppTrack counters.

Required Privilege Level view

Related Documentation
- Example: Configuring AppTrack on page 574

Output Fields Table 46 lists the output fields for the **show security application-tracking counters** command. Output fields are listed in the approximate order in which they appear.

Table 356: show security application-tracking counters

Field Name	Field Description
Session create messages	The number of log messages generated when a session was created.
Session close messages	The number of log messages generated when a session was closed.
Session volume updates	The number of log messages generated when an update interval was exceeded.
Failed messages	The number of messages that were not generated due to memory or session constraints.

Sample Output

show security application-tracking counters

```
user@host> show security application-tracking counters
AVT counters:                       Value
 Session create messages              0
 Session close messages               0
 Session volume updates               0
 Failed messages                      0
```

Table 357: show security dns-cache Output Fields

Field Name	Field Description
DNS Name	DNS name.
Address Family	IPv4 or IPv6.
TTL	Time-to-live value.
IP Address	IP address for the DNS name.

Sample Output

show security dns-cache

```
user@host> show security dns-cache
DNS Name: dns1.test.com:
  Address Family: IPv4, TTL: 10
    IP Address: 1.1.1.1
  Address Family: IPv6: TTL = 15
    IP Address: 2001:1.1.1.1
DNS Name: dns2.test.com:
  Address Family: IPv4, TTL: 20
```

Copyright © 2016, Juniper Networks, Inc.

```
    IP Address: 2.2.2.2
    IP Address: 2.2.2.3
```

Sample Output

show security dns-cache dns-name dns2.test.com

```
user@host> show security dns-cache dns-name dns2.test.com
DNS Name: dns2.test.com:
  Address Family: IPv4, TTL: 20
    IP Address: 2.2.2.2
    IP Address: 2.2.2.3
```

show security firewall-authentication history

Syntax **show security firewall-authentication history**
<node (*node-id* | all | local | primary)>

Release Information Command introduced in Junos OS Release 8.5. The **node** options added in Junos OS Release 9.0.

Description Display security firewall authentication history information.

Options
- none—Display history of firewall authentication information.
- **node**—(Optional) For chassis cluster configurations, display all firewall authentication history on a specific node (device) in the cluster.
  - ***node-id*** —Identification number of the node. It can be 0 or 1.
  - **all**—Display information about all nodes.
  - **local**—Display information about the local node.
  - **primary**—Display information about the primary node.

Required Privilege Level view

List of Sample Output
show security firewall-authentication history on page 3663
show security firewall-authentication history node all on page 3663

Output Fields Table 358 lists the output fields for the **show security firewall-authentication history** command. Output fields are listed in the approximate order in which they appear.

Table 358: show security firewall-authentication history Output Fields

Field Name	Field Description
Authentications	Number of authentications.
Id	Identification number.
Source IP	IP address of the authentication source.
Date	Authentication date.
Time	Authentication time.
Duration	Authentication duration.
Status	Authentication status success or failure.

Copyright © 2016, Juniper Networks, Inc.

Table 358: show security firewall-authentication history Output Fields *(continued)*

Field Name	Field Description
User	Name of the user.

Sample Output

show security firewall-authentication history

```
user@host> show security firewall-authentication history
History of firewall authentication data:
  Authentications: 1
          Id Source Ip       Date       Time     Duration   Status   User
           1 211.0.0.6       2007-04-03 11:43:06 00:00:45   Success  hello
```

Sample Output

show security firewall-authentication history node all

```
user@host> show security firewall-authentication history node all
node0:
--------------------------------------------------------------------------
History of firewall authentication data:
Authentications: 2
Id Source Ip       Date       Time     Duration   Status   User
1 100.0.0.1       2008-01-04 12:00:10 0:05:49    Success  local1
2 100.0.0.1       2008-01-04 14:36:52 0:01:03    Success  local1
node1:
--------------------------------------------------------------------------
History of firewall authentication data:
  Authentications: 1
          Id Source Ip       Date       Time     Duration   Status   User
           1 100.0.0.1       2008-01-04 14:59:43 1193046:06: Success local1
```

show security firewall-authentication users

Syntax

show security firewall-authentication users
<node (*node-id* | all | local | primary)>

Release Information

Command introduced in Junos OS Release 8.5. The **node** options added in Junos OS Release 9.0.

Description

Display firewall authentication details about all users.

Options

- none—Display details about all firewall authentication users.
- **node**—(Optional) For chassis cluster configurations, display firewall authentication details for all users on a specific node.
  - *node-id*—Identification number of the node. It can be 0 or 1.
  - **all**—Display information about all nodes.
  - **local**—Display information about the local node.
  - **primary**—Display information about the primary node.

Output Fields

Table 359 lists the output fields for the **show security firewall-authentication users** command. Output fields are listed in the approximate order in which they appear.

Table 359: show security firewall-authentication users Output Fields

Field Name	Field Description
Total users in table	Gives count of how many entries/users the command will display.
Id	Identification number.
Source IP	IP address of the authentication source.
Src zone	User traffic received from the zone.
Dst zone	User traffic destined to the zone.
Profile	Name of profile used for authentication.
Age	Idle timeout for the user.

Copyright © 2016, Juniper Networks, Inc.

Table 359: show security firewall-authentication users Output Fields *(continued)*

Field Name	Field Description
Status	Authentication status success or failure.
User	Name of the user.

Sample Output

show security firewall-authentication users

```
user@host> show security firewall-authentication users
Firewall authentication data:
  Total users in table: 1
          Id Source Ip       Src zone Dst zone Profile    Age Status   User
           1 1111:1212/64        z1       z2       p1       0 Success  local1
```

Sample Output

show security firewall-authentication users node 0

```
user@host> show security firewall-authentication users node 0
node0:
--------------------------------------------------------------------------
Firewall authentication data:
  Total users in table: 1
          Id Source Ip       Src zone Dst zone Profile    Age Status   User

           3 100.0.0.1       z1       z2       p1           1 Success  local1
```

Sample Output

show security firewall-authentication users node all

```
user@host> show security firewall-authentication users node all
node0:
--------------------------------------------------------------------------
Firewall authentication data:
  Total users in table: 1
          Id Source Ip       Src zone Dst zone Profile    Age Status   User
           3 100.0.0.1       z1       z2       p1           1 Success  local1

node1:
--------------------------------------------------------------------------
Firewall authentication data:
  Total users in table: 1
          Id Source Ip       Src zone Dst zone Profile    Age Status   User
           2 100.0.0.1       z1       z2       p1           1 Success  local1
```

show security flow session

Syntax **show security flow session**
[*filter*] **[brief | extensive | summary]**

Release Information Command introduced in Junos OS Release 8.5. Support for filter and view options added in Junos OS Release 10.2. Application firewall, dynamic application, and logical system filters added in Junos OS Release 11.2. Policy ID filter added in Junos OS Release 12.3X48-D10. Support for connection tag added in Junos OS Release 15.1X49-D40.

Description Display information about all currently active security sessions on the device.

NOTE: For the normal flow sessions, the **show security flow session** command displays bytes counters based on IP header length. However for sessions in Express Path mode, the statistics is collected from IOC2 and IOC3 ASIC hardware engine, and includes full packet length with L2 headers. Because of this, the output displays slightly larger bytes counters for sessions in Express Path mode than the normal flow session.

Options

- *filter*—Filter the display by the specified criteria.

  The following filters reduce the display to those sessions that match the criteria specified by the filter. Refer to the specific **show** command for examples of the filtered output.

  application—Predefined application name

  application-firewall—Application firewall enabled

  application-firewall-rule-set—Application firewall enabled with the specified rule set

  application-traffic-control—Application traffic control session

  application-traffic-control-rule-set—Application traffic control rule set name and rule name

  conn-tag—Session connection tag

  destination-port—Destination port

  destination-prefix—Destination IP prefix or address

  dynamic-application—Dynamic application

  dynamic-application-group—Dynamic application

  encrypted—Encrypted traffic

  extensive—Display detailed output

Copyright © 2016, Juniper Networks, Inc.

family—Display session by family

idp—IDP enabled sessions

interface—Name of incoming or outgoing interface

logical-system (all | *logical-system-name*)—Name of a specific logical system or **all** to display all logical systems

nat—Display sessions with network address translation

policy-id—Display session information based on policy ID; the range is 1 through 4,294,967,295

protocol—IP protocol number

resource-manager—Resource manager

root-logical-system—Display root logical system as default

security-intelligence—Display security intelligence sessions

services-offload—Display services offload sessions

session-identifier—Display session with specified session identifier

source-port—Source port

source-prefix—Source IP prefix

summary—Display output summary

tunnel—Tunnel sessions

- brief | extensive | summary—Display the specified level of output.
- none—Display information about all active sessions.

Required Privilege Level view

Output Fields Table 26 lists the output fields for the **show security flow session** command. Output fields are listed in the approximate order in which they appear.

Copyright © 2016, Juniper Networks, Inc.

Table 360: show security flow session Output Fields

Field Name	Field Description
Session ID	Number that identifies the session. Use this ID to get more information about the session.
Conn Tag	A 32-bit connection tag that uniquely identifies the GPRS tunneling protocol, user plane (GTP-U) and the Stream Control Transmission Protocol (STCP) sessions. The connection tag for GTP-U is the tunnel endpoint identifier (TEID) and for SCTP is the vTag. The connection ID remains 0 if the connection tag is not used by the sessions.
CP Session ID	Number that identifies the central point session. Use this ID to get more information about the central point session.
Policy name	Policy that permitted the traffic.
Timeout	Idle timeout after which the session expires.
In	Incoming flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Out	Reverse flow (source and destination IP addresses, application protocol, interface, session token, route, gateway, tunnel, port sequence, FIN sequence, FIN state, packets and bytes).
Total sessions	Total number of sessions.
Status	Session status.
Flag	Internal flag depicting the state of the session, used for debugging purposes. The three available flags are: • flag • natflag • natflag2
Policy name	Name and ID of the policy that the first packet of the session matched.
Source NAT pool	The name of the source pool where NAT is used.
Dynamic application	Name of the application.
Application traffic control rule-set	AppQoS rule set for this session.
Rule	AppQoS rule for this session.
Forwarding class	The AppQoS forwarding class name for this session that distinguishes the transmission priority
DSCP code point	Differentiated Services (DiffServ) code point (DSCP) value remarked by the matching rule for this session.

Copyright © 2016, Juniper Networks, Inc.

Table 360: show security flow session Output Fields *(continued)*

Field Name	Field Description
Loss priority	One of four priority levels set by the matching rule to control discarding a packet during periods of congestion. A high loss priority means a high probability that the packet could be dropped during a period of congestion.
Rate limiter client to server	The rate-limiter profile assigned to the client-to-server traffic defining a unique combination of **bandwidth-limit** and **burst-size-limit** specifications.
Rate limiter server to client	The rate-limiter profile assigned to the server-to-client traffic defining a unique combination of **bandwidth-limit** and **burst-size-limit** specifications.
Maximum timeout	Maximum session timeout.
Current timeout	Remaining time for the session unless traffic exists in the session.
Session State	Session state.
Start time	Time when the session was created, offset from the system start time.
Unicast-sessions	Number of unicast sessions.
Multicast-sessions	Number of multicast sessions.
Failed-sessions	Number of failed sessions.
Sessions-in-use	Number of sessions in use. • Valid sessions • Pending sessions • Invalidated sessions • Sessions in other states
Maximum-sessions	Maximum number of sessions permitted.

Sample Output

show security flow session

show security idp logical-system policy-association

Syntax show security idp logical-system policy-association

Release Information Command introduced in Junos OS Release 11.3.

Description Display the IDP policy assigned to a logical system. The IDP policy is assigned to a logical system through the security profile.

Required Privilege Level view

Related Documentation
- security-profile on page 3628

List of Sample Output show security idp logical-system policy-association on page 3672

Output Fields Table 361 lists the output fields for the **show security idp logical-system policy-association** command.

Table 361: show security idp logical-system policy-association Output Fields

Field Name	Field Description
Logical system	Name of the logical system to which an IDP policy is assigned.
IDP policy	Name of the IDP policy that is specified in the security profile that is bound to the logical system.

Sample Output

show security idp logical-system policy-association

```
user@host> show security idp logical-system policy-association
Logical system          IDP policy
root-logical-system     idp-policy1
lsys1                   idp-policy2
```

show security ike security-associations

Syntax

show security ike security-associations
peer-address
brief | detail
family (inet | inet6)
fpc *slot-number*
index *SA-index-number*
kmd-instance (all | *kmd-instance-name*)
pic *slot-number*
sa-type shortcut <detail>

Release Information

Command introduced in Junos OS Release 8.5 . Support for the **fpc**, **pic**, and **kmd-instance** options added in Junos OS Release 9.3. Support for the **family** option added in Junos OS Release 11.1. Support for Auto Discovery VPN added in Junos OS Release 12.3X48-D10.

Description

Display information about Internet Key Exchange security associations (IKE SAs).

Options

- none—Display standard information about existing IKE SAs, including index numbers.
- ***peer-address***—(Optional) Display details about a particular SA based on the IPv4 or IPv6 address of the destination peer. This option and **index** provide the same level of output.
- **brief**—(Optional) Display standard information about all existing IKE SAs. (Default)
- **detail**—(Optional) Display detailed information about all existing IKE SAs.
- **family**—(Optional) Display IKE SAs by family. This option is used to filter the output.
  - **inet**—IPv4 address family.
  - **inet6**—IPv6 address family.
- **fpc *slot-number***—(Optional) Display information about existing IKE SAs in this Flexible PIC Concentrator (FPC) slot. This option is used to filter the output.
- **index *SA-index-number***—(Optional) Display information for a particular SA based on the index number of the SA. For a particular SA, display the list of existing SAs by using the command with no options. This option and ***peer-address*** provide the same level of output.
- **kmd-instance** —(Optional) Display information about existing IKE SAs in the key management process (in this case, it is KMD) identified by FPC *slot-number* and PIC *slot-number*. This option is used to filter the output.
  - **all**—All KMD instances running on the Services Processing Unit (SPU).
  - ***kmd-instance-name***—Name of the KMD instance running on the SPU.
- **pic *slot-number*** —(Optional) Display information about existing IKE SAs in this PIC slot. This option is used to filter the output.
- **sa-type**—(Optional for ADVPN) Type of SA. **shortcut** is the only option for this release.

Output Fields Table 362 lists the output fields for the **show security ike security-associations** command. Output fields are listed in the approximate order in which they appear.

Table 362: show security ike security-associations Output Fields

Field Name	Field Description
IKE Peer or Remote Address	IP address of the destination peer with which the local peer communicates.
Index	Index number of an SA. This number is an internally generated number you can use to display information about a single SA.
Gateway Name	Name of the IKE gateway.
Location	• **FPC**—Flexible PIC Concentrator (FPC) slot number. • **PIC**—PIC slot number. • **KMD-Instance**—The name of the KMD instance running on the SPU, identified by FPC *slot-number* and PIC *slot-number*. Currently, 4 KMD instances are running on each SPU, and any particular IKE negotiation is carried out by a single KMD instance.
Role	Part played in the IKE session. The device triggering the IKE negotiation is the initiator, and the device accepting the first IKE exchange packets is the responder.
State	State of the IKE SAs: • **DOWN**—SA has not been negotiated with the peer. • **UP**—SA has been negotiated with the peer.
Initiator cookie	Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.

Copyright © 2016, Juniper Networks, Inc.

Table 362: show security ike security-associations Output Fields *(continued)*

Field Name	Field Description
Responder cookie	Random number generated by the remote node and sent back to the initiator as a verification that the packets were received. A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity.
Mode or Exchange type	Negotiation method agreed on by the two IPsec endpoints, or peers, used to exchange information between one another. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are: • **main**—The exchange is done with six messages. This mode or exchange type encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate. • **aggressive**—The exchange is done with three messages. This mode or exchange type does not encrypt the payload, leaving the identity of the neighbor unprotected. NOTE: IKEv2 protocol does not use the mode configuration for negotiation. Therefore, mode displays the version number of the security association.
Local	Address of the local peer.
Remote	Address of the remote peer.
Lifetime	Number of seconds remaining until the IKE SA expires.

Algorithms	IKE algorithms used to encrypt and secure exchanges between the peers during the IPsec Phase 2 process:
	
	• **Authentication**—Type of authentication algorithm used:
	  ◦ **sha1**—Secure Hash Algorithm 1 authentication.
	  ◦ **md5**—MD5 authentication.
	• **Encryption**—Type of encryption algorithm used:
	  ◦ **aes-256-cbc**—Advanced Encryption Standard (AES) 256-bit encryption.
	  ◦ **aes-192-cbc**— AES192-bit encryption.
	  ◦ **aes-128-cbc**—AES 128-bit encryption.
	  ◦ **3des-cbc**—3 Data Encryption Standard (DES) encryption.
	  ◦ **des-cbc**—DES encryption.

Diffie-Hellman group	Specifies the IKE Diffie-Hellman group.
Traffic statistics	• **Input bytes**—Number of bytes received. • **Output bytes**—Number of bytes transmitted. • **Input packets**—Number of packets received. • **Output packets**—Number of packets transmitted.

Copyright © 2016, Juniper Networks, Inc.

Table 362: show security ike security-associations Output Fields *(continued)*

Field Name	Field Description
Flags	Notification to the key management process of the status of the IKE negotiation: • **caller notification sent**—Caller program notified about the completion of the IKE negotiation. • **waiting for done**—Negotiation is done. The library is waiting for the remote end retransmission timers to expire. • **waiting for remove**—Negotiation has failed. The library is waiting for the remote end retransmission timers to expire before removing this negotiation. • **waiting for policy manager**—Negotiation is waiting for a response from the policy manager.
IPSec security associations	• ***number* created:** The number of SAs created. • ***number* deleted**: The number of SAs deleted.

Phase 2 negotiations in progress	Number of Phase 2 IKE negotiations in progress and status information:
	• **Negotiation type**—Type of Phase 2 negotiation. Junos OS currently supports quick mode.
	• **Message ID**—Unique identifier for a Phase 2 negotiation.
	• **Local identity**—Identity of the local Phase 2 negotiation. The format is *id-type-name (proto-name:port-number,[0..id-data-len] = iddata-presentation)*.
	• **Remote identity**—Identity of the remote Phase 2 negotiation. The format is *id-type-name (proto-name:port-number,[0..id-data-len] = iddata-presentation)*.
	• **Flags**—Notification to the key management process of the status of the IKE negotiation:
	  ◦ **caller notification sent**—Caller program notified about the completion of the IKE negotiation.
	  ◦ **waiting for done**—Negotiation is done. The library is waiting for the remote end retransmission timers to expire.
	  ◦ **waiting for remove**—Negotiation has failed. The library is waiting for the remote end retransmission timers to expire before removing this negotiation.
	  ◦ **waiting for policy manager**—Negotiation is waiting for a response from the policy manager.

Sample Output

show security ike security-associations (IPv4)

```

show security ipsec security-associations

Syntax

show security ipsec security-associations
brief | detail
family (inet | inet6)
fpc *slot-number*
index *SA-index-number*
kmd-instance (all | *kmd-instance-name*)
pic *slot-number>*
sa-type shortcut
vpn-name *vpn-name* <traffic-selector *traffic-selector-name*>

Release Information

Command introduced in Junos OS Release 8.5. Support for the **fpc**, **pic**, and **kmd-instance** options added in Junos OS Release 9.3. Support for the **family** option added in Junos OS Release 11.1. Support for the **vpn-name** option added in Junos OS Release 11.4R3. Support for the **traffic-selector** option and traffic selector field added in Junos OS Release 12.1X46-D10. Support for Auto Discovery VPN (ADVPN) added in Junos OS Release 12.3X48-D10.

Description

Display information about the IPsec security associations (SAs).

Options

- none—Display information about all SAs.
- **brief** | **detail**—(Optional) Display the specified level of output.
- **family**—(Optional) Display SAs by family. This option is used to filter the output.
  - **inet**—IPv4 address family.
  - **inet6**—IPv6 address family.
- **fpc** ***slot-number***—(Optional) Display information about existing IPsec SAs in this Flexible PIC Concentrator (FPC) slot. This option is used to filter the output.
- **index** ***SA-index-number***—(Optional) Display detailed information about the specified SA identified by this index number. To obtain a list of all SAs that includes their index numbers, use the command with no options.
- **kmd-instance**—(Optional) Display information about existing IPsec SAs in the key management process (in this case, it is KMD) identified by the FPC *slot-number* and PIC *slot-number*. This option is used to filter the output.
  - **all**—All KMD instances running on the Services Processing Unit (SPU).
  - ***kmd-instance-name***—Name of the KMD instance running on the SPU.
- **pic** ***slot-number***—(Optional) Display information about existing IPsec SAs in this PIC slot. This option is used to filter the output.
- **sa-type**—(Optional for ADVPN) Type of SA. **shortcut** is the only option for this release.
- **vpn-name** ***vpn-name***—Name of the VPN. If configured, **traffic-selector** ***traffic-selector-name*** can optionally be specified.

Output Fields Table 363 lists the output fields for the **show security ipsec security-associations** command. Output fields are listed in the approximate order in which they appear.

Table 363: show security ipsec security-associations

Field Name	Field Description
Total active tunnels	Total number of active IPsec tunnels.
ID	Index number of the SA. You can use this number to get additional information about the SA.
VPN name	IPsec name for VPN.
Gateway	IP address of the remote gateway.
Port	If Network Address Translation (NAT) is used, this value is 4500. Otherwise, it is the standard IKE port, 500.
Algorithm	Cryptography used to secure exchanges between peers during the IKE Phase 2 negotiations includes: • An authentication algorithm used to authenticate exchanges between the peers. Options are **hmac-md5-95**, **hmac-sha1-96,** or **ESP**. • An encryption algorithm used to encrypt data traffic. Options are **3des-cbc, aes-128-cbc, aes-192-cbc**, **aes-256-cbc**, or **des-cbc.**

Copyright © 2016, Juniper Networks, Inc.

Table 363: show security ipsec security-associations *(continued)*

Field Name	Field Description
SPI	Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase 1 and Phase 2.
Life: sec/kb	The lifetime of the SA, after which it expires, expressed either in seconds or kilobytes.
Sta	State has two options, **Installed** and **Not Installed**. • **Installed**—The SA is installed in the SA database. • **Not Installed**—The SA is not installed in the SA database. For transport mode, the value of State is always **Installed**.
Mon	The Mon field refers to VPN monitoring status. If VPN monitoring is enabled, then this field displays **U** (up) or **D** (down). A hyphen (-) means VPN monitoring is not enabled for this SA.
vsys or Virtual-system	The root system.
Tunnel index	Numeric identifier of the specific IPsec tunnel for the SA.
Local gateway	Gateway address of the local system.
Remote gateway	Gateway address of the remote system.
Traffic selector	Name of the traffic selector.
Local identity	Identity of the local peer so that its partner destination gateway can communicate with it. The value is specified as an IP address, fully qualified domain name, e-mail address, or distinguished name (DN).
Remote identity	IP address of the destination peer gateway.
DF-bit	State of the don't fragment bit: **set** or **cleared**.
Policy-name	Name of the applicable policy.
Location	**FPC**—Flexible PIC Concentrator (FPC) slot number. **PIC**—PIC slot number. **KMD-Instance**—The name of the KMD instance running on the SPU, identified by FPC *slot-number* and PIC *slot-number*. Currently, 4 KMD instances running on each SPU, and any particular IPsec negotiation is carried out by a single KMD instance.
Tunnel events	Tunnel event and the number of times the event has occurred. See "Tunnel Events" on page 6797 for descriptions of tunnel events and the action you can take.
Direction	Direction of the SA; it can be inbound or outbound.

Copyright © 2016, Juniper Networks, Inc.

Table 363: show security ipsec security-associations *(continued)*

Field Name	Field Description
AUX-SPI	Value of the auxiliary security parameter index(SPI). • When the value is **AH** or **ESP**, **AUX-SPI** is always 0. • When the value is **AH+ESP**, **AUX-SPI** is always a positive integer.
Mode	Mode of the SA: • **transport**—Protects host-to-host connections. • **tunnel—**Protects connections between security gateways.
Type	Type of the SA: • **manual**—Security parameters require no negotiation. They are static and are configured by the user. • **dynamic**—Security parameters are negotiated by the IKE protocol. Dynamic SAs are not supported in transport mode.
State	State of the SA: • **Installed**—The SA is installed in the SA database. • **Not Installed**—The SA is not installed in the SA database. For transport mode, the value of State is always **Installed**.

Protocol	Protocol supported.
	• Transport mode supports Encapsulation Security Protocol (ESP) and Authentication Header (AH).
	• Tunnel mode supports ESP and AH.
	  ◦ **Authentication**—Type of authentication used.
	  ◦ **Encryption**—Type of encryption used.

Soft lifetime	The soft lifetime informs the IPsec key management system that the SA is about to expire. Each lifetime of an SA has two display options, hard and soft, one of which must be present for a dynamic SA. This allows the key management system to negotiate a new SA before the hard lifetime expires. • **Expires in seconds**—Number of seconds left until the SA expires.
Hard lifetime	The hard lifetime specifies the lifetime of the SA. • **Expires in seconds**—Number of seconds left until the SA expires.
Lifesize Remaining	The lifesize remaining specifies the usage limits in kilobytes. If there is no lifesize specified, it shows unlimited. • **Expires in kilobytes**—Number of kilobytes left until the SA expires.
Anti-replay service	State of the service that prevents packets from being replayed. It can be **Enabled** or **Disabled**.

Copyright © 2016, Juniper Networks, Inc.

Table 363: show security ipsec security-associations *(continued)*

Field Name	Field Description
Replay window size	Configured size of the antireplay service window. It can be 32 or 64 packets. If the replay window size is 0, the antireplay service is disabled. The antireplay window size protects the receiver against replay attacks by rejecting old or duplicate packets.
Bind-interface	The tunnel interface to which the route-based VPN is bound.
Copy-Outer-DSCP	Indicates if copying outer IP header DSCP and ECN to inner IP header is enabled or disabled.

show security match-policies

Syntax

show security match-policies
destination-ip *ip-address*
destination-port *port-number*
from-zone *zone-name*
protocol *protocol-name* | *protocol-number*
result-count *number*
source-identity *role-name*
source-ip *ip-address*
source-port *port-number*
to-zone *zone-name*

Release Information

Command introduced in Junos OS Release 10.3. Command updated in Junos OS Release 10.4 . Command updated in Junos OS Release 12.1. Command updated to include optional from-zone and to-zone global match options in Junos OS Release 12.1X47-D10.

Description

The **show security match-policies** command allows you to troubleshoot traffic problems using the match criteria: source port, destination port, source IP address, destination IP address, and protocol. For example, if your traffic is not passing because either an appropriate policy is not configured or the match criteria is incorrect, then the **show security match-policies** command allows you to work offline and identify where the problem actually exists. It uses the search engine to identify the problem and thus enables you to use the appropriate match policy for the traffic.

The **result-count** option specifies how many policies to display. The first enabled policy in the list is the policy that is applied to all matching traffic. Other policies below it are "shadowed" by the first and are never encountered by matching traffic.

NOTE: **The show security match-policies command is applicable only to security policies; IDP policies are not supported.**

Options

- **destination-ip** ***destination-ip***—Destination IP address of the traffic.
- **destination-port** ***destination-port***—Destination port number of the traffic. Range is 1 through 65,535
- **from-zone** ***from-zone***—Name or ID of the source zone of the traffic.
- **protocol** ***protocol-name*** **|** ***protocol-number***—Protocol name or numeric value of the traffic.
  - **ah** or **51**
  - **egp** or **8**
  - **esp** or **50**
  - **gre** or **47**
  - **icmp** or **1**
  - **igmp** or **2**

Copyright © 2016, Juniper Networks, Inc.

- **igp** or **9**
- **ipip** or **94**
- **ipv6** or **41**
- **ospf** or **89**
- **pgm** or **113**
- **pim** or **103**
- **rdp** or **27**
- **rsvp** or **46**
- **sctp** or **132**
- **tcp** or **6**
- **udp** or **17**
- **vrrp** or **112**

- **result-count** ***number***—(Optional) The number of policy matches to display. Valid range is from 1 through 16. The default value is 1.
- **source-identity** ***role-name***—Source identity of the traffic determined by the user role.
- **source-ip** ***source-ip***—Source IP address of the traffic.
- **source-port** ***source-port***—Source port number of the traffic. Range is 1 through 65,535.
- **to-zone** ***to-zone***—Name or ID of the destination zone of the traffic.

Example 2: show security match policies ... result-count on page 3696
Example 3: show security match policies ... source-identity on page 3697

Output Fields Table 102 lists the output fields for the **show security match-policies** command. Output fields are listed in the approximate order in which they appear.

Table 364: show security match-policies Output Fields

Field Name	Field Description
Policy	Name of the applicable policy.

Copyright © 2016, Juniper Networks, Inc.

Table 364: show security match-policies Output Fields *(continued)*

Field Name	Field Description
Action or **Action-type**	The action to be taken for traffic that matches the policy's match criteria. Actions include the following: • **permit** • **firewall-authentication** • **tunnel ipsec-vpn** *vpn-name* • **pair-policy** *pair-policy-name* • **source-nat pool** *pool-name* • **pool-set** *pool-set-name* • **interface** • **destination-nat** *name* • **deny** • **reject**
State	Status of the policy: • **enabled**: The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it. • **disabled**: The policy cannot be used in the policy lookup process, and therefore it is not available for access control.
Index	An internal number associated with the policy.
Sequence number	Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, and 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, and 4.
From zone	Name of the source zone.
To zone	Name of the destination zone.
Source addresses	The names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.
Destination addresses	The names and corresponding IP addresses of the destination addresses (or address sets) for a policy as entered in the destination zone's address book. A packet's destination address must match one of these addresses for the policy to apply to it.
Application	Name of a preconfigured or custom application, or **any** if no application is specified.
IP protocol	Numeric value for the IP protocol used by the application, such as 6 for TCP or 1 for ICMP.
ALG	If an ALG is associated with the session, the name of the ALG. Otherwise, 0.
Inactivity timeout	Elapsed time without activity after which the application is terminated.
Source-port range	Range of matching source ports defined in the policy.

Copyright © 2016, Juniper Networks, Inc.

Table 364: show security match-policies Output Fields *(continued)*

Field Name	Field Description
Destination-port range	Range of matching destination ports defined in the policy.
Source identities	One or more user roles defined in the matching policy.

Sample Output

Example 1: show security match-policies

```
user@host> show security match-policies from-zone z1 to-zone z2 source-ip 10.10.10.1
destination-ip 192.0.2.1 source-port 1 destination-port 21 protocol tcp
Policy: p1, action-type: permit, State: enabled, Index: 4
  Sequence number: 1
  From zone: z1, To zone: z2
  Source addresses:
    a2: 198.51.100.0/24
    a3: 10.10.10.1/32
  Destination addresses:
    d2: 203.0.113.0/24
    d3: 192.0.2.1/32
  Application: junos-ftp
    IP protocol: tcp, ALG: ftp, Inactivity timeout: 1800
      Source port range: [0-0]
      Destination port range: [21-21]
```

Example 2: show security match policies ... result-count

```
user@host> show security match-policies source-ip 10.10.10.1 destination-ip 192.0.2.5 source_port
1004 destination_port 80 protocol tcp result_count 5
Policy: p1, action-type: permit, State: enabled, Index: 4
  Sequence number: 1
  From zone: zone-A, To zone: zone-B
  Source addresses:
    sa1: 10.10.0.0/16
  Destination addresses:
    da5: 192.0.2.0/24
  Application: any
    IP protocol: 1, ALG: 0, Inactivity timeout: 0
      Source port range: [1000-1030]
    Destination port range: [80-80]

Policy: p15, action-type: deny, State: enabled, Index: 18
  Sequence number: 15
  From zone: zone-A, To zone: zone-B

show security nat destination rule

Syntax

show security nat destination rule
rule-name
all
logical-system (*logical-system-name* | all)
root-logical-system

Release Information

Command introduced in Junos OS Release 9.2. The **Description** output field added in Junos OS Release 12.1. Support for IPv6 logical systems and the **Successful sessions**, **Failed sessions**, and **Number of sessions** output fields added in Junos OS Release 12.1X45-D10. Output for multiple destination ports and the **application** option field added in Junos OS Release 12.1X47-D10.

Description

Display information about the specified destination Network Address Translation (NAT) rule.

Options

rule-name—Display information about the specified destination NAT rule.

all—Display information about all the destination NAT rules.

logical-system (*logical-system-name* | all)—Display information about the destination NAT rules for the specified logical system or for all logical systems.

root-logical-system—Display information about the destination NAT rules for the master (root) logical system.

Required Privilege Level

List of Sample Output

show security nat destination rule dst2-rule on page 3699
show security nat destination rule all on page 3700

Output Fields

Table 365 lists the output fields for the **show security nat destination rule** command. Output fields are listed in the approximate order in which they appear.

Table 365: show security nat destination rule Output Fields

Field Name	Field Description
Total destination-nat rules	Number of destination NAT rules.
Total referenced IPv4/IPv6 ip-prefixes	Number of IP prefixes referenced in source, destination, and static NAT rules. This total includes the IP prefixes configured directly as address names and as address set names in the rule.
Destination NAT rule	Name of the destination NAT rule.

Copyright © 2016, Juniper Networks, Inc.

Table 365: show security nat destination rule Output Fields *(continued)*

Field Name	Field Description
Description	Description of the destination NAT rule.
Rule-Id	Rule identification number.
Rule position	Position of the destination NAT rule.
From routing instance	Name of the routing instance from which the packets flow.
From interface	Name of the interface from which the packets flow.
From zone	Name of the zone from which the packets flow.
Source addresses	Name of the source addresses that match the rule. The default value is any.
Destination addresses	Name of the destination addresses that match the rule. The default value is any.
Action	The action taken when a packet matches the rule's tuples. Actions include the following: • **destination NAT pool**—Use user-defined destination NAT pool to perform destination NAT. • **off**—Do not perform destination NAT.
Destination ports	Destination ports number that match the rule. The default value is any.
Application	Indicates whether the application option is configured.
Translation hits	Number of translation hits.
Successful sessions	Number of successful session installations after the NAT rule is matched.
Failed sessions	Number of unsuccessful session installations after the NAT rule is matched.
Number of sessions	Number of sessions that reference the specified rule.

Sample Output

show security nat destination rule dst2-rule

```
user@host>show security nat destination rule dst2-rule

 Destination NAT rule: dst2-rule           Rule-set: dst2
  Description               : The destination rule dst2-rule is for the sales
team
  Rule-Id                   : 1

Output Fields

Table 366 lists the output fields for the **show security nat destination summary** command. Output fields are listed in the approximate order in which they appear.

Table 366: show security nat destination summary Output Fields

Field Name	Field Description
Total destination nat pool number	Number of destination NAT pools.
Pool name	Name of the destination address pool.
Address range	IP address or IP address range for the pool.
Routing Instance	Name of the routing instance.
Port	Port number.
Total	Number of IP addresses that are in use.
Available	Number of IP addresses that are free for use.
Total destination nat rule number	Number of destination NAT rules.

Copyright © 2016, Juniper Networks, Inc.

Table 366: show security nat destination summary Output Fields *(continued)*

Field Name	Field Description
Total hit times	Number of times a translation in the translation table is used for all the destination NAT rules.
Total fail times	Number of times a translation in the translation table failed to translate for all the destination NAT rules.

Sample Output

show security nat destination summary

```
user@host> show security nat destination summary

Total pools: 2
Pool name           Address                     Routing        Port  Total
                    Range                       Instance             Address

Output Fields

Table 367 lists the output fields for the **show security nat source rule** command. Output fields are listed in the approximate order in which they appear

Table 367: show security nat source rule Output Fields

Field Name	Field Description
Source NAT rule	Name of the source NAT rule.
Total rules	Number of source NAT rules.
Total referenced IPv4/IPv6 ip-prefixes	Number of IP prefixes referenced in source, destination, and static NAT rules. This total includes the IP prefixes configured directly, as address names, and as address set names in the rule.

Copyright © 2016, Juniper Networks, Inc.

Table 367: show security nat source rule Output Fields *(continued)*

Field Name	Field Description
Description	Description of the source NAT rule.
Rule-Id	Rule identification number.
Rule position	Position of the source NAT rule.
From zone	Name of the zone from which the packets flow.
To zone	Name of the zone to which the packets flow.
From routing instance	Name of the routing instance from which the packets flow.
To routing instance	Name of the routing instance to which the packets flow.
From interface	Name of the interface from which the packets flow.
To interface	Name of the interface to which the packets flow.
Source addresses	Name of the source addresses that match the rule.
Source port	Source port numbers that match the rule.
Destination address	Name of the destination addresses that match the rule.
Destination ports	Destination port numbers that match the rule.
Application	Indicates whether the application option is configured.
Action	The action taken in regard to a packet that matches the rule's tuples. Actions include the following: • **off**—Do not perform source NAT. • **source NAT pool**—Use user-defined source NAT pool to perform source NAT • **interface**—Use egress interface's IP address to perform source NAT.
Persistent NAT type	Persistent NAT type.
Persistent NAT mapping type	Persistent NAT mapping type.
Inactivity timeout	Inactivity timeout for persistent NAT binding.
Max session number	Maximum number of sessions.
Translation hits	Number of translation hits.
Successful sessions	Number of successful session installations after the NAT rule is matched.

Copyright © 2016, Juniper Networks, Inc.

Table 367: show security nat source rule Output Fields *(continued)*

Field Name	Field Description
Failed sessions	Number of unsuccessful session installations after the NAT rule is matched.
Number of sessions	Number of sessions that reference the specified rule.

Sample Output

show security nat source rule r2

```
user@host> show security nat source rule r2

Output Fields

Table 368 lists the output fields for the **show security nat source summary** command. Output fields are listed in the approximate order in which they appear.

Table 368: show security nat source summary Output Fields

Field Name	Field Description
Total source nat pool number	Number of source NAT pools.
Pool name	Name of the source address pool.
Address range	IP address or IP address range for the pool.
Routing Instance	Name of the routing instance.
PAT	Whether Port Address Translation (PAT) is enabled (yes or no).
Total Address	Number of IP addresses that are in use.
Total source nat rule number	Number of source NAT rules.

Copyright © 2016, Juniper Networks, Inc.

Table 368: show security nat source summary Output Fields *(continued)*

Field Name	Field Description
Total port number usage for port translation pool	Number of ports assigned to the pool.
Maximum port number for port translation pool	Maximum number of NAT or PAT transactions done at any given time.

Sample Output

show security nat source summary

```
user@host> show security nat source summary logical-system all

Logical system: root-logical-system
Total port number usage for port translation pool: 67108864
Maximum port number for port translation pool: 134217728

show security nat static rule

Syntax

show security nat static rule
rule-name
all
logical-system (*logical-system-name* | all)
root-logical-system

Release Information

Command introduced in Junos OS Release 9.3. The **Description** output field added in Junos OS Release 12.1. Support for IPv6 logical systems and the **Successful sessions**, **Failed sessions**, **Number of sessions**, **Source addresses,** and **Source ports** output fields added in Junos OS Release 12.1X45-D10. The **Destination NPTv6 addr** and **Destination NPTv6 Netmask** output fields added in Junos OS Release 12.3X48-D25.

Description

Display information about the specified static Network Address Translation (NAT) rule.

Options

rule-name—Name of the rule.

all—Display information about all the static NAT rules.

logical-system (*logical-system-name* | all)—Display information about the static NAT rules for the specified logical system or for all logical systems.

root-logical-system—Display information about the static NAT rules for the master (root) logical system.

Output Fields

Table 369 lists the output fields for the **show security nat static rule** command. Output fields are listed in the approximate order in which they appear.

Table 369: show security nat static rule Output Fields

Field Name	Field Description
Static NAT rule	Name of the static NAT rule.
Total referenced IPv4/IPv6 ip-prefixes	Number of IP prefixes referenced in source, destination, and static NAT rules. This total includes the IP prefixes configured directly, as address names, and as address set names in the rule.
Rule-set	Name of the rule set. Currently, you can configure 8 rules within the same rule set.

Copyright © 2016, Juniper Networks, Inc.

Table 369: show security nat static rule Output Fields *(continued)*

Field Name	Field Description
Description	Description of the static NAT rule.
Rule-Id	Rule identification number.
Rule position	Position of the rule that indicates the order in which it applies to traffic.
From interface	Name of the interface from which the packets flow.
From routing instance	Name of the routing instance from which the packets flow.
From zone	Name of the zone from which the packets flow.
Destination addresses	Name of the destination addresses that match the rule.
Destination NPTv6 addr	Destination address that matches the rule.
Source addresses	Name of the source addresses that match the rule.
Host addresses	Name of the host addresses that match the rule.
Netmask	Subnet IP address.
Destination NPTv6 Netmask	Subnet IPv6 address.
Host routing-instance	Name of the host routing instance.
Destination port	Destination port numbers that match the rule. The default value is any.
Source port	Source port numbers that match the rule.
Total static-nat rules	Number of static NAT rules.
Translation hits	Number of times a translation in the translation table is used for a static NAT rule.
Successful sessions	Number of successful session installations after the NAT rule is matched.
Failed sessions	Number of unsuccessful session installations after the NAT rule is matched.
Number of sessions	Number of sessions that reference the specified rule.

Sample Output

show security nat static rule

```
user@host> show security nat static rule sta-r2

 Static NAT rule: sta-r2                  Rule-set: sta-nat
```

show security policies

Syntax

show security policies
<detail>
<none>
policy-name *policy-name*
<detail>
<global>

Release Information

Command modified in Junos OS Release 9.2. Support for IPv6 addresses added in Junos OS Release 10.2. Support for IPv6 addresses in active/active chassis cluster configurations in addition to the existing support of active/passive chassis cluster configurations added in Junos OS Release 10.4. Support for wildcard addresses added in Junos OS Release 11.1. Support for global policy added in Junos OS Release 11.4. Support for services offloading added in Junos OS Release 11.4. Support for source-identities added in Junos OS Release 12.1. The **Description** output field added in Junos OS Release 12.1. Support for negated address added in Junos OS Release 12.1X45-D10. The output fields for Policy Statistics expanded, and the output fields for the **global** and **policy-name** options expanded to include from-zone and to-zone global match criteria in Junos OS Release 12.1X47-D10. Support for the **initial-tcp-mss** and **reverse-tcp-mss** options added in Junos OS Release 12.3X48-D20.

Description

Display a summary of all security policies configured on the device. If a particular policy is specified, display information particular to that policy.

Options

- **none**—Display basic information about all configured policies.
- **detail**—(Optional) Display a detailed view of all of the policies configured on the device.
- **policy-name *policy-name***—(Optional) Display information about the specified policy.
- **global**—Display information about global policies.

Output Fields Table 51 lists the output fields for the **show security policies** command. Output fields are listed in the approximate order in which they appear.

Table 370: show security policies Output Fields

Field Name	Field Description
From zone	Name of the source zone.
To zone	Name of the destination zone.
Policy	Name of the applicable policy.
Description	Description of the applicable policy.
State	Status of the policy: • **enabled**: The policy can be used in the policy lookup process, which determines access rights for a packet and the action taken in regard to it. • **disabled**: The policy cannot be used in the policy lookup process, and therefore it is not available for access control.
Index	Internal number associated with the policy.
Sequence number	Number of the policy within a given context. For example, three policies that are applicable in a from-zoneA-to-zoneB context might be ordered with sequence numbers 1, 2, 3. Also, in a from-zoneC-to-zoneD context, four policies might have sequence numbers 1, 2, 3, 4.
Source addresses	For standard display mode, the names of the source addresses for a policy. Address sets are resolved to their individual names. For detail display mode, the names and corresponding IP addresses of the source addresses for a policy. Address sets are resolved to their individual address name-IP address pairs.
Destination addresses	Name of the destination address (or address set) as it was entered in the destination zone's address book. A packet's destination address must match this value for the policy to apply to it.
Source addresses (excluded)	Name of the source address excluded from the policy.
Destination addresses (excluded)	Name of the destination address excluded from the policy.
Source identities	One or more user roles specified for a policy.

Copyright © 2016, Juniper Networks, Inc.

Table 370: show security policies Output Fields *(continued)*

Field Name	Field Description
Applications	Name of a preconfigured or custom application whose type the packet matches, as specified at configuration time. • **IP protocol**: The Internet protocol used by the application—for example, TCP, UDP, ICMP. • **ALG**: If an ALG is explicitly associated with the policy, the name of the ALG is displayed. If **application-protocol ignore** is configured, ignore is displayed. Otherwise, 0 is displayed. However, even if this command shows ALG: 0, ALGs might be triggered for packets destined to well-known ports on which ALGs are listening, unless ALGs are explicitly disabled or when **application-protocol ignore** is not configured for custom applications. • **Inactivity timeout**: Elapsed time without activity after which the application is terminated. • **Source port range**: The low-high source port range for the session application.
Destination Address Translation	Status of the destination address translation traffic: • **drop translated**—Drop the packets with translated destination addresses. • **drop untranslated**—Drop the packets without translated destination addresses.
Application Firewall	An application firewall includes the following: • **Rule-set**—Name of the rule set. • **Rule**—Name of the rule. ◦ **Dynamic applications**—Name of the applications. ◦ **Dynamic application groups**—Name of the application groups. ◦ **Action**—The action taken with respect to a packet that matches the application firewall rule set. Actions include the following: ▪ **permit** ▪ **deny** • **Default rule**—The default rule applied when the identified application is not specified in any rules of the rule set.
Action or Action-type	• The action taken in regard to a packet that matches the policy's tuples. Actions include the following: ◦ **permit** ◦ **firewall-authentication** ◦ **tunnel ipsec-vpn** *vpn-name* ◦ **pair-policy** *pair-policy-name* ◦ **source-nat pool** *pool-name* ◦ **pool-set** *pool-set-name* ◦ **interface** ◦ **destination-nat** *name* ◦ **deny** ◦ **reject** ◦ **services-offload**
Session log	Session log entry that indicates whether the **at-create** and **at-close** flags were set at configuration time to log session information.

Copyright © 2016, Juniper Networks, Inc.

Table 370: show security policies Output Fields *(continued)*

Field Name	Field Description
Scheduler name	Name of a preconfigured scheduler whose schedule determines when the policy is active and can be used as a possible match for traffic.

Policy statistics	• **Input bytes**—The total number of bytes presented for processing by the device.
	  • **Initial direction**—The number of bytes presented for processing by the device from the initial direction.
	  • **Reply direction**—The number of bytes presented for processing by the device from the reply direction.
	• **Output bytes**—The total number of bytes actually processed by the device.
	  • **Initial direction**—The number of bytes from the initial direction actually processed by the device.
	  • **Reply direction**—The number of bytes from the reply direction actually processed by the device.
	• **Input packets**—The total number of packets presented for processing by the device.
	  • **Initial direction**—The number of packets presented for processing by the device from the initial direction.
	  • **Reply direction**—The number of packets presented for processing by the device from the reply direction.
	• **Output packets**—The total number of packets actually processed by the device.
	  • **Initial direction**—The number of packets actually processed by the device from the initial direction.
	  • **Reply direction**—The number of packets actually processed by the device from the reply direction.
	• **Session rate**—The total number of active and deleted sessions.
	• **Active sessions**—The number of sessions currently present because of access control lookups that used this policy.
	• **Session deletions**—The number of sessions deleted since system startup.
	• **Policy lookups**—The number of times the policy was accessed to check for a match.
	NOTE: Configure the Policy P1 with the **count** option to display policy statistics.

Per policy TCP Options	Configured sync and sequence checks, and the configured TCP MSS value for the initial direction and /or the reverse direction.

show security screen statistics

Syntax

show security screen statistics (zone *zone-name* | interface *interface-name*)
<logical-system (*logical-system-name* | all)>
<node (*node-id* | all | local | primary)>
<root-logical-system>

Release Information

Command introduced in Junos OS Release 8.5. **node** options added in Junos OS Release 9.0. **logical-system all** option added in Junos OS Release 11.2R6. Support for IPv6 extension header screens added in Junos OS Release 12.1X46-D10.

Description

Display intrusion detection service (IDS) security screen statistics.

Options

- **zone** ***zone-name*** —Display screen statistics for this security zone.
- **interface** *interface-name*—Display screen statistics for this interface.
- **logical-system**—(Optional) Display screen statistics for configured logical systems.
  - ***logical-system-name***—Display screen statistics for the named logical system.
  - **all**—Display screen statistics for all logical systems, including the master (root) logical system.
- **node**—(Optional) For chassis cluster configurations, display screen statistics on a specific node.
  - ***node-id***—Identification number of a node. It can be 0 or 1.
  - **all**—Display information about all nodes.
  - **local**—Display information about the local node.
  - **primary**—Display information about the primary node.
- **root-logical-system**—(Optional) Display screen statistics for the master logical system only.

Output Fields Table 69 lists the output fields for the **show security screen statistics** command. Output fields are listed in the approximate order in which they appear.

Table 371: show security screen statistics Output Fields

Field Name	Field Description
ICMP flood	Internet Control Message Protocol (ICMP) flood counter. An ICMP flood typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.
UDP flood	User Datagram Protocol (UDP) flood counter. UDP flooding occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the resources, such that valid connections can no longer be handled.
TCP winnuke	Number of Transport Control Protocol (TCP) WinNuke attacks. WinNuke is a denial-of-service (DoS) attack targeting any computer on the Internet running Windows.
TCP port scan	Number of TCP port scans. The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.
ICMP address sweep	Number of ICMP address sweeps. An IP address sweep can occur with the intent of triggering responses from active hosts.
IP tear drop	Number of teardrop attacks. Teardrop attacks exploit the reassembly of fragmented IP packets.
TCP SYN flood	Number of TCP SYN attacks.
IP spoofing	Number of IP spoofs. IP spoofing occurs when an invalid source address is inserted in the packet header to make the packet appear to come from a trusted source.
ICMP ping of death	ICMP ping of death counter. Ping of death occurs when IP packets are sent that exceed the maximum legal length (65,535 bytes).
IP source route option	Number of IP source route attacks.
TCP address sweep	Number of TCP address sweeps.
TCP land attack	Number of land attacks. Land attacks occur when an attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and source IP address.
TCP SYN fragment	Number of TCP SYN fragments.
TCP no flag	Number of TCP headers without flags set. A normal TCP segment header has at least one control flag set.
IP unknown protocol	Number of IPs.
IP bad options	Number of invalid options.
IP record route option	Number of packets with the IP record route option enabled. This option records the IP addresses of the network devices along the path that the IP packet travels.

Copyright © 2016, Juniper Networks, Inc.

Table 371: show security screen statistics Output Fields *(continued)*

Field Name	Field Description
IP timestamp option	Number of IP timestamp option attacks. This option records the time (in Universal Time) when each network device receives the packet during its trip from the point of origin to its destination.
IP security option	Number of IP security option attacks.
IP loose source route option	Number of IP loose source route option attacks. This option specifies a partial route list for a packet to take on its journey from source to destination.
IP strict source route option	Number of IP strict source route option attacks. This option specifies the complete route list for a packet to take on its journey from source to destination.
IP stream option	Number of stream option attacks. This option provides a way for the 16-bit SATNET stream identifier to be carried through networks that do not support streams.
ICMP fragment	Number of ICMP fragments. Because ICMP packets contain very short messages, there is no legitimate reason for ICMP packets to be fragmented. If an ICMP packet is so large that it must be fragmented, something is amiss.
ICMP large packet	Number of large ICMP packets.
TCP SYN FIN	Number of TCP SYN FIN packets.
TCP FIN no ACK	Number of TCP FIN flags without the acknowledge (ACK) flag.
Source session limit	Number of concurrent sessions that can be initiated from a source IP address.
TCP SYN-ACK-ACK proxy	Number of TCP flags enabled with SYN-ACK-ACK. To prevent flooding with SYN-ACK-ACK sessions, you can enable the SYN-ACK-ACK proxy protection screen option. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold and SRX Series devices running Junos OS reject further connection requests from that IP address.
IP block fragment	Number of IP block fragments.
Destination session limit	Number of concurrent sessions that can be directed to a single destination IP address.
UDP address sweep	Number of UDP address sweeps.
IPv6 extension header	Number of packets filtered for the defined IPv6 extension headers.
IPv6 extension hop by hop option	Number of packets filtered for the defined IPv6 hop-by-hop option types.
IPv6 extension destination option	Number of packets filtered for the defined IPv6 destination option types.
IPv6 extension header limit	Number of packets filtered for crossing the defined IPv6 extension header limit.
IPv6 malformed header	Number of IPv6 malformed headers defined for the intrusion detection service (IDS).

Table 371: show security screen statistics Output Fields *(continued)*

ICMPv6 malformed packet	Number of ICMPv6 malformed packets defined for the IDS options.

Sample Output

show security screen statistics zone scrzone

```
user@host> show security screen statistics zone scrzone
Screen statistics:
IDS attack type                              Statistics
  ICMP flood                                 0
  UDP flood                                  0
  TCP winnuke                                0
  TCP port scan                              91
  ICMP address sweep                         0
  TCP sweep                                  0
  UDP sweep                                  0
  IP tear drop                               0
  TCP SYN flood                              0
  IP spoofing                                0
  ICMP ping of death                         0
  IP source route option                     0
  TCP land attack                            0
  TCP SYN fragment                           0
  TCP no flag                                0
  IP unknown protocol                        0
  IP bad options                             0
  IP record route option                     0
  IP timestamp option                        0
  IP security option                         0
  IP loose source route option               0
  IP strict source route option              0
  IP stream option                           0
  ICMP fragment                              0
  ICMP large packet                          0
  TCP SYN FIN                                0
  TCP FIN no ACK                             0
  Source session limit                       0
  TCP SYN-ACK-ACK proxy                      0
  IP block fragment                          0
  Destination session limit                  0
```

Sample Output

show security screen statistics zone untrust (IPv6)

```
user@host>show security screen statistics zone untrust
Screen statistics:

show system security-profile

Syntax show system security-profile (all-resource | *resource*) <detail | terse> <logical-system (all | *logical-system-name*)> <root-logical-system> <summary>

Release Information Command introduced in Junos OS Release 11.2. Support for application firewall added in Junos OS Release 11.3. Option to display all resources for a logical system added in Junos OS Release 11.. Resource information for ports in source NAT pools with port translation added in Release Junos OS 11.4.

Description Display information about a resource allocated to the logical system in a security profile. For each resource specified, the number used by the logical system and the configured maximum and reserved values are displayed.

This command can be used by the master administrator to display resource information for the master logical system or user logical system. This command can also be used by the user logical system administrator to display resource information for a user logical system.

Options Either specify **all-resource** to display information about all resources allocated for the logical system, or specify one of the following resources:

- address-book—Address books.
- appfw-rule-set—Application firewall rule set entries.
- appfw-rule—Application firewall rule entries.
- auth-entry—Firewall authentication entries.
- cpu—CPU utilization.
- flow-gate—Flow gates, also known as pinholes.
- flow-session—Flow sessions.
- nat-cone-binding—Network Address Translation (NAT) cone bindings.
- nat-destination-pool—NAT destination pools.
- nat-destination-rule—NAT destination rules.
- nat-nopat-address—NAT without port address translations.
- nat-pat-address—NAT with port address translations.
- nat-pat-portnum—NAT source port numbers for port translation
- nat-port-ol-ipnumber—NAT port overloading IP numbers.
- nat-rule-referenced-prefix—NAT rule referenced IP-prefixes.
- nat-source-pool—NAT source pools.
- nat-source-rule—NAT source rules.
- nat-static-rule—NAT static rules.

Copyright © 2016, Juniper Networks, Inc.

- policy—Security policies.
- policy-with-count—Security policies with a count.
- scheduler—Schedulers.
- zone—Security zones.

detail | terse—(Optional) Display the specified level of output.

The following options are available only to the master administrator:

- logical-system—Display resource information for a specified user logical system. Specify **all** to display resource information for all logical systems, including the master logical system.
- root-logical-system—Display resource information for the master (root) logical system.
- summary—Display summary information about the resource for all logical systems.

Output Fields Table 372 lists the output fields for the **show system security-profile** command. Output fields are listed in the approximate order in which they appear.

Table 372: show system security-profile Output Fields

Field Name	Field Description
logical system name	Name of the logical system.
security profile name	Name of the security profile bound to the logical system.
usage	Number of resources that are currently being used by the logical system.
reserved	Number of resources that are guaranteed to be available to the logical system.
maximum	Number of resources that the logical system can use. The maximum does not guarantee that the amount specified for the resource in the security profile is available. The maximum is not applicable for CPU resources.
CPU control	**TRUE** if CPU control is enabled or **FALSE** if CPU control is not enabled.

Copyright © 2016, Juniper Networks, Inc.

Table 372: show system security-profile Output Fields *(continued)*

Field Name	Field Description
CPU control target	Upper limit for CPU utilization on the device. The default value is 80 percent.
CPU name	Central point (CP) or services processing unit (SPU). CP utilization and average utilization of all SPUs is shown. The **detail** option shows CPU utilization on each SPU.
drop rate	Packets dropped for CPU control.

Sample Output

show system security-profile all-resource

```
user@host> show system security-profile all-resource

resource                                  usage    reserved     maximum

- Example: Deleting Security Services on page 3748
- Example: Enabling MPLS on page 3750

MPLS Overview

Multiprotocol Label Switching (MPLS) is a method for engineering traffic patterns by assigning short labels to network packets that describe how to forward them through the network. MPLS is independent of routing tables or any routing protocol and can be used for unicast packets.

The MPLS framework supports traffic engineering and the creation of virtual private networks (VPNs). Traffic is engineered (controlled) primarily by the use of signaling protocols to establish label-switched paths (LSPs). VPN support includes Layer 2 and Layer 3 VPNs and Layer 2 circuits.

When you enable your device to allow MPLS traffic, the device performs packet-based processing and functions as a standard Junos router.

CAUTION: When packet forwarding mode is changed to MPLS, all flow-based security features are deactivated, and the device performs packet-based processing only. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device. However, MPLS can be enabled in flow-based packet forwarding mode for selected traffic using firewall filters.

This overview contains the following topics:

- Label Switching on page 3744
- Label-Switched Paths on page 3744
- Label-Switching Routers on page 3745
- Labels on page 3746
- Label Operations on page 3746

- LSP Establishment on page 3747

Label Switching

In a traditional IP network, packets are transmitted with an IP header that includes a source and destination address. When a router receives such a packet, it examines its forwarding tables for the next-hop address associated with the packet's destination address and forwards the packet to the next-hop location.

In an MPLS network, each packet is encapsulated with an MPLS header. When a router receives the packet, it copies the header as an index into a separate MPLS forwarding table. The MPLS forwarding table consists of pairs of inbound interfaces and path information. Each pair includes forwarding information that the router uses to forward the traffic and modify, when necessary, the MPLS header.

Because the MPLS forwarding table has far fewer entries than the more general forwarding table, the lookup consumes less processing time and processing power. The resultant savings in time and processing are a significant benefit for traffic that uses the network to transit between outside destinations only.

Label-Switched Paths

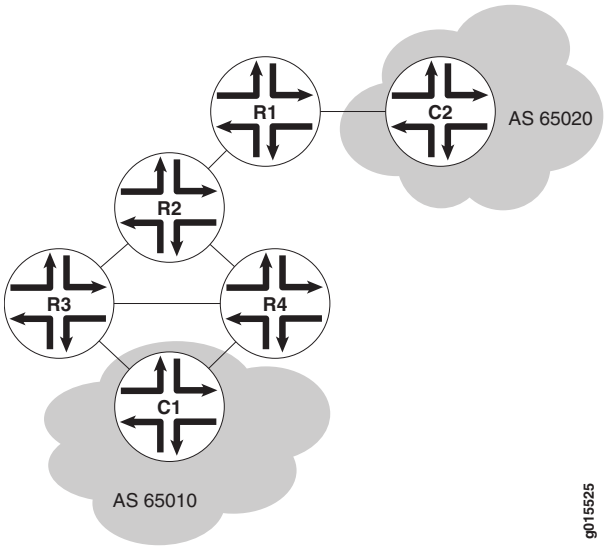
Label-switched paths (LSPs) are unidirectional routes through a network or autonomous system (AS). In normal IP routing, the packet has no predetermined path. Instead, each router forwards a packet to the next-hop address stored in its forwarding table, based only on the packet's destination address. Each subsequent router then forwards the packet using its own forwarding table.

In contrast, MPLS routers within an AS determine paths through a network through the exchange of MPLS traffic engineering information. Using these paths, the routers direct traffic through the network along an established route. Rather than selecting the next hop along the path as in IP routing, each router is responsible for forwarding the packet to a predetermined next-hop address.

Figure 138 shows a typical LSP topology.

Copyright © 2016, Juniper Networks, Inc.

Figure 138: Typical LSP Topology



In the topology shown in Figure 138, traffic is forwarded from Host C1 to the transit network with standard IP forwarding. When the traffic enters the transit network, it is switched across a preestablished LSP through the network. In this example, an LSP might switch the traffic from Router R4 to Router R2 to Router R1. When the traffic exits the network, it is forwarded to its destination by IP routing protocols.

Label-Switching Routers

Routers that are part of the LSP are label-switching routers (LSRs). Each LSR must be configured with MPLS so that it can interpret MPLS headers and perform the MPLS operations required to pass traffic through the network. An LSP can include four types of LSRs:

- Inbound router—The only entry point for traffic into MPLS. Native IPv4 packets are encapsulated into the MPLS protocol by the inbound router. Each LSP can have only one inbound router. Inbound routers are also known as ingress routers.
- Transit router—Any router in the middle of an LSP. An individual LSP can contain between 0 and 253 transit routers. Transit routers forward MPLS traffic along the LSP, using only the MPLS header to determine how the packet is routed.
- Penultimate router—The second-to-last router in the LSP. The penultimate router in an LSP is responsible for stripping the MPLS header from the packet before forwarding it to the outbound router.
- Outbound router—The endpoint for the LSP. The outbound router receives MPLS packets from the penultimate router and performs an IP route lookup. The router then forwards the packet to the next hop of the route. Each LSP can have only one outbound router. Outbound routers are also known as egress routers.

Labels

To forward traffic through an MPLS network, MPLS routers encapsulate packets and assign and manage headers known as *labels*. A label is a 20–bit unsigned integer in the range 0 through 1,048,575. The routers use the labels to index the MPLS forwarding tables that determine how packets are routed through the network.

When a network's inbound router receives traffic, it inserts an MPLS label between the IP packet and the appropriate Layer 2 header for the physical link. The label contains an index value that identifies a next-hop address for the particular LSP. When the next-hop transit router receives the packet, it uses the index in the MPLS label to determine the next-hop address for the packet and forwards the packet to the next router in the LSP.

As each packet travels through the transit network, every router along the way performs a lookup on the MPLS label and forwards the packet accordingly. When the outbound router receives a packet, it examines the header to determine that it is the final router in the LSP. The outbound router then removes the MPLS header, performs a regular IP route lookup, and forwards the packet with its IP header to the next-hop address.

Label Operations

Each LSR along an LSP is responsible for examining the MPLS label, determining the LSP next hop, and performing the required label operations. LSRs can perform five label operations:

- Push—Adds a new label to the top of the packet. For IPv4 packets arriving at the inbound router, the new label is the first label in the label stack. For MPLS packets with an existing label, this operation adds a label to the stack and sets the stacking bit to 0, indicating that more MPLS labels follow the first.

  When it receives the packet, the inbound router performs an IP route lookup on the packet. Because the route lookup yields an LSP next hop, the inbound router performs a label push on the packet, and then forwards the packet to the LSP next hop.

- Swap—Replaces the label at the top of the label stack with a new label.

  When a transit router receives the packet, it performs an MPLS forwarding table lookup. The lookup yields the LSP next hop and the path index of the link between the transit router and the next router in the LSP.

- Pop—Removes the label from the top of the label stack. For IPv4 packets arriving at the penultimate router, the entire MPLS label is removed from the label stack. For MPLS packets with an existing label, this operation removes the top label from the label stack and modifies the stacking bit as necessary—sets it to 1, for example, if only a single label remains in the stack.

  If multiple LSPs terminate at the same outbound router, the router performs MPLS label operations for all outbound traffic on the LSPs. To share the operations among multiple routers, most LSPs use penultimate hop popping (PHP).

- Multiple push—Adds multiple labels to the top of the label stack. This action is equivalent to performing multiple push operations.

Copyright © 2016, Juniper Networks, Inc.

The multiple push operation is used with label stacking, which is beyond the scope of this topic.

- Swap and push—Replaces the top label with a new label and then pushes a new label to the top of the stack.

  The swap and push operation is used with label stacking, which is beyond the scope of this topic.

Penultimate Hop Popping

Multiple LSPs terminating at a single outbound router load the router with MPLS label operations for all their outbound traffic. Penultimate hop popping (PHP) transfers the operation from the outbound router to penultimate routers.

With PHP, the penultimate router is responsible for popping the MPLS label and forwarding the traffic to the outbound router. The outbound router then performs an IP route lookup and forwards the traffic. For example, if four LSPs terminate at the same outbound router and each has a different penultimate router, label operations are shared across four routers.

LSP Establishment

An MPLS LSP is established by one of two methods: static LSPs and dynamic LSPs.

Static LSPs

Like a static route, a static LSP requires each router along the path to be configured explicitly. You must manually configure the path and its associated label values. Static LSPs require less processing by the LSRs because no signaling protocol is used. However, because paths are statically configured, they cannot adapt to network conditions. Topology changes and network outages can create black holes in the LSP that exist until you manually reconfigure the LSP.

Dynamic LSPs

Dynamic LSPs use signaling protocols to establish themselves and propagate LSP information to other LSRs in the network. You configure the inbound router with LSP information that is transmitted throughout the network when you enable the signaling protocols across the LSRs. Because the LSRs must exchange and process signaling packets and instructions, dynamic LSPs consume more resources than static LSPs. However, dynamic LSPs can avoid the network black holes of static LSPs by detecting topology changes and outages and propagating them throughout the network.

MPLS Configuration Overview

When you first install Junos OS on your device, MPLS is disabled by default. You must explicitly configure your device to allow MPLS traffic to pass through. Complete the following steps for all devices in your MPLS network that are running Junos OS.

To enable MPLS:

1. Delete all configured security services from the device. If you do not complete this step, you will get a commit failure. See "Example: Deleting Security Services" on page 3748.
2. Enable MPLS on the device. See "Example: Enabling MPLS" on page 3750.
3. Commit the configuration.
4. Reboot the device.
5. Configure MPLS features such as traffic engineering, VPNs, and VPLS. See:
   - MPLS Traffic Engineering and Signaling Protocols Overview on page 3755
   - MPLS VPN Overview on page 3791
   - CLNS Overview on page 3815
   - VPLS Overview on page 3841

CAUTION: When packet forwarding mode is changed to MPLS, all flow-based security features are deactivated, and the device performs packet-based processing only. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device. However, MPLS can be enabled in flow-based packet forwarding mode for selected traffic using firewall filters.

Example: Deleting Security Services

This example shows how to delete configured services in the security level of the configuration hierarchy.

- Requirements on page 3749
- Overview on page 3749
- Configuration on page 3749
- Verification on page 3749

Copyright © 2016, Juniper Networks, Inc.

Requirements

Before you begin, save your current configuration to a temporary file. Do this prior to removing all configurations from the security level of the configuration hierarchy and deleting the inherited configurations.

Overview

In this example, you save your current configuration in the var/tmp/ directory with an appropriate filename and .cfg extension—for example, *curfeb08.cfg*. Then you remove all configurations from the **security** level of the configuration hierarchy, and delete all global groups and inherited configurations.

Configuration

Step-by-Step Procedure

To delete the configured services in the security level of the configuration hierarchy:

1. Save your current configuration.

   ```
   [edit]
   user@host# save /var/tmp/curfeb08.cfg
   ```

2. Remove all configurations in the **security** level of the configuration hierarchy.

   ```
   [edit]
   user@host# delete security
   ```

3. Remove all inherited configurations in the security level of the configuration hierarchy.

   ```
   [edit]
   user@host# delete groups global security
   ```

CAUTION: Do not commit after deleting the security configurations. A commit without any security configurations leaves the router unreachable through the management port.

Verification

To verify the configuration is working properly, enter the **show groups global security** command.

Example: Enabling MPLS

This example shows how to enable MPLS for packet-based processing. It also shows how to enable the MPLS family and MPLS process on all of the transit interfaces in the network.

NOTE: When MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, IP packets, and IPsec VPNs are unavailable on the device.

Before changing from flow mode to packet mode, you must remove all security policies remaining under flow mode. To prevent management connection loss, you must bind the management interface to zones and enable host-inbound traffic to prevent the device from losing connectivity.

For information about configuring zones, see *Building Blocks Feature Guide for Security Devices*.

Requirements

Before you begin, delete all configured security services. See "Example: Deleting Security Services" on page 3748.

Overview

The instructions in this topic describe how to enable MPLS on the device. You must enable MPLS on the device before including a device running Junos OS in an MPLS network.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security forwarding-options family mpls mode packet-based
set interfaces ge-1/0/0 unit 0 family mpls
set protocols mpls ge-1/0/0 unit 0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable MPLS:

1. Enable MPLS for packet-based processing.

```
[edit security forwarding-options]
user@host# set family mpls mode packet-based
```

Copyright © 2016, Juniper Networks, Inc.

2. Enable the MPLS family on each transit interface that you want to include in the MPLS network.

```
[edit interfaces]
user@host# set interfaces ge-1/0/0 unit 0 family mpls
```

3. Enable the MPLS process on all of the transit interfaces in the MPLS network.

```
[edit protocols mpls]
user@host# set interface ge-1/0/0 unit 0
```

Results From configuration mode, confirm your configuration by entering the **show security forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

NOTE: If you enable MPLS for packet-based processing by using the command **set security forward-option family mpls mode packet**, the mode will not change immediately and the system will display the following messages:

warning: Reboot may required when try reset flow inet mode

warning: Reboot may required when try reset mpls flow mode please check security flow status for detail.

You need to reboot your device for the configuration to take effect.

CAUTION: If you disable MPLS and switch back to using the security services (flow-based processing), the mode will not change immediately and the system will display warning messages instructing you to restart your device. You must reboot your device for the configuration to take effect. This will also result in management sessions being reset and transit traffic getting interrupted.

```
[edit]
user@host# show security forwarding-options
family {
   mpls {
      mode packet-based;
   }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Copyright © 2016, Juniper Networks, Inc.

Verification

Confirm that the configuration is working properly.

- Verifying MPLS Is Enabled at the Protocols Level on page 3752
- Verifying MPLS Is Enabled at the Interfaces Level on page 3752

Verifying MPLS Is Enabled at the Protocols Level

Purpose Verify that MPLS is enabled at the protocols level.

Action From operational mode, enter the **show protocols** command.

Verifying MPLS Is Enabled at the Interfaces Level

Purpose Verify that MPLS is enabled at the interfaces level.

Action From operational mode, enter the **show interfaces** command.

MPLS Traffic Engineering and Signaling Protocols Overview

Traffic engineering facilitates efficient and reliable network operations while simultaneously optimizing network resources and traffic performance. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) to a potentially less congested physical path across a network. To support traffic engineering, besides source routing, the network must do the following:

- Compute a path at the source by taking into account all the constraints, such as bandwidth and administrative requirements.
- Distribute the information about network topology and link attributes throughout the network once the path is computed.
- Reserve network resources and modify link attributes.

When transit traffic is routed through an IP network, MPLS is often used to engineer its passage. Although the exact path through the transit network is of little importance to either the sender or the receiver of the traffic, network administrators often want to route traffic more efficiently between certain source and destination address pairs. By adding a short label with specific routing instructions to each packet, MPLS switches packets from router to router through the network rather than forwarding packets based on next-hop lookups. The resulting routes are called label-switched paths (LSPs). LSPs control the passage of traffic through the network and speed traffic forwarding.

Copyright © 2016, Juniper Networks, Inc.

You can create LSPs manually, or through the use of signaling protocols. Signaling protocols are used within an MPLS environment to establish LSPs for traffic across a transit network. Junos OS supports two signaling protocols—LDP and the Resource Reservation Protocol (RSVP).

MPLS traffic engineering uses the following components:

- MPLS LSPs for packet forwarding
- IGP extensions for distributing information about the network topology and link attributes
- Constrained Shortest Path First (CSPF) for path computation and path selection
- RSVP extensions to establish the forwarding state along the path and to reserve resources along the path

Junos OS also supports traffic engineering across different OSPF regions.

Understanding the LDP Signaling Protocol

LDP is a signaling protocol that runs on a device configured for MPLS support. The successful configuration of both MPLS and LDP initiates the exchange of TCP packets across the LDP interfaces. The packets establish TCP-based LDP sessions for the exchange of MPLS information within the network. Enabling both MPLS and LDP on the appropriate interfaces is sufficient to establish LSPs.

LDP is a simple, fast-acting signaling protocol that automatically establishes LSP adjacencies within an MPLS network. Routers then share LSP updates such as hello packets and LSP advertisements across the adjacencies. Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces. After both are configured, LDP begins transmitting and receiving LDP messages through all LDP-enabled interfaces. Because of LDP's simplicity, it cannot perform the true traffic engineering which RSVP can perform. LDP does not support bandwidth reservation or traffic constraints.

When you configure LDP on a label-switching router (LSR), the router begins sending LDP discovery messages out all LDP-enabled interfaces. When an adjacent LSR receives LDP discovery messages, it establishes an underlying TCP session. An LDP session is then created on top of the TCP session. The TCP three-way handshake ensures that the LDP session has bidirectional connectivity. After they establish the LDP session, the LDP neighbors maintain, and terminate, the session by exchanging messages. LDP advertisement messages allow LSRs to exchange label information to determine the next hops within a particular LSP. Any topology changes, such as a router failure, generate LDP notifications that can terminate the LDP session or generate additional LDP advertisements to propagate an LSP change.

- Example: Configuring LDP-Signaled LSPs on page 3757

Example: Configuring LDP-Signaled LSPs

This example shows how to create and configure LDP instances within an MPLS network.

- Requirements on page 3757
- Overview on page 3757
- Configuration on page 3758
- Verification on page 3759

Requirements

Before you begin:

- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Configure an IGP across your network. (The LDP configuration is added to the existing IGP configuration and included in the MPLS configuration.)
- Configure a network to use LDP for LSP establishment by enabling MPLS on all transit interfaces in the MPLS network.

NOTE: **Because LDP runs on top of an IGP such as IS-IS or OSPF, you must configure LDP and the IGP on the same set of interfaces.**

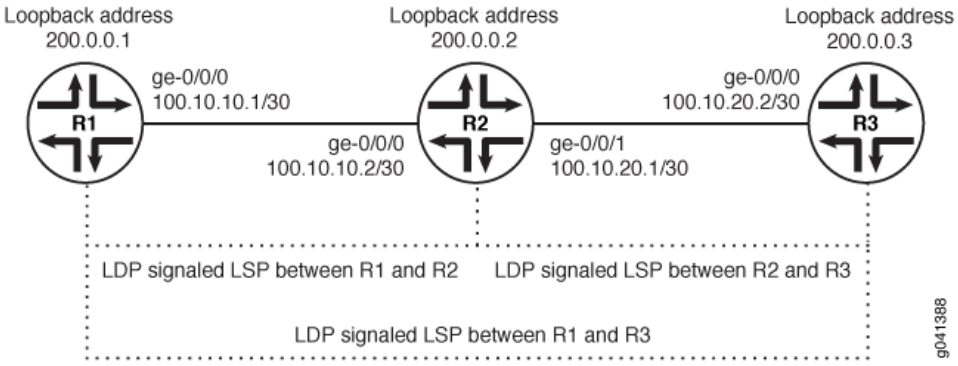
Overview

To configure LDP-signaled LSPs, you must enable the MPLS family on all transit interfaces in the MPLS network and include all the transit interfaces under the [**protocols mpls**] and [**protocols ldp**] hierarchy levels.

In this example, you enable the MPLS family and create an LDP instance on all the transit interfaces. Additionally, you enable the MPLS process on all the transit interfaces in the MPLS network. In this example, you configure a sample network as shown in Figure 139.

Copyright © 2016, Juniper Networks, Inc.

Figure 139: Typical LDP-Signaled LSP



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level and then enter **commit** from configuration mode.

For Router R1, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

For Router R2, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
set interfaces ge-0/0/1 unit 0 family mpls
set protocols mpls ge-0/0/1 unit 0
set protocols ldp interface ge-0/0/0.1 unit 0
```

For Router R3, perform the following:

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols mpls ge-0/0/0 unit 0
set protocols ldp interface ge-0/0/0.0 unit 0
```

Step-by-Step Procedure

To enable LDP instances within an MPLS network:

1. Enable the MPLS family on the transit interface on Router R1.

   ```
   [edit]
   user@R1# set interfaces ge-0/0/0 unit 0 family mpls
   ```

2. Enable the MPLS process on the transit interface.

   ```
   [edit]
   user@R1# set protocols mpls interface ge-0/0/0 unit 0
   ```

3. Create the LDP instance on the transit interface.

Copyright © 2016, Juniper Networks, Inc.

```
[edit]
user@R1# set protocols ldp interface ge-0/0/0 unit 0
```

Results Confirm your configuration by entering the **show** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@R1# show
...
  interfaces {
    ge-0/0/0 {
      unit 0 {
        family inet {
          address 10.100.37.20/24;
        }
        family mpls;
      }
    }
    }
  ...
    protocols {
      mpls {
        interface all;
      }
      ldp {
        interface ge-0/0/0.0;
      }
    }
```

If you are done configuring the device, enter the **commit** command from the configuration mode to activate the configuration.

Verification

Confirm that the configuration is working properly.

- Verifying LDP Neighbors on page 3759
- Verifying LDP Sessions on page 3760
- Verifying the Presence of LDP-Signaled LSPs on page 3761
- Verifying Traffic Forwarding over the LDP-Signaled LSP on page 3761

Verifying LDP Neighbors

Purpose Verify that each device shows the appropriate LDP neighbors.

Action From the CLI, enter the **show ldp neighbor** command.

```
user@r2> show ldp neighbor
```

```
Address     Interface       Label space ID      Hold time
100.10.10.1    ge-0/0/0.0      200.0.0.1:0           11
100.10.20.2   ge-0/0/1.0      200.0.0.2:0           14
```

The output shows the IP addresses of the neighboring interfaces along with the interface through which the neighbor adjacency is established. Verify the following information:

- Each interface on which LDP is enabled is listed.
- Each neighboring LDP interface address is listed with the appropriate corresponding LDP interface.
- Under **Label space ID**, the appropriate loopback address for each neighbor appears.

Verifying LDP Sessions

Purpose Verify that a TCP-based LDP session has been established between all LDP neighbors. Also, verify that the modified keepalive value is active.

Action From the CLI, enter the **show ldp session detail** command.

```
user@r1> show ldp session detail
200.0.0.2, State: Operational, Connection: Open, Hold time: 22
  Session ID: 200.0.0.1:0--200.0.0.2:0
  Next keepalive in 9 seconds
  Active, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
  Neighbor types: discovered
  Keepalive interval: 10, Connect retry interval: 1
  Local address: 200.0.0.1, Remote address: 200.0.0.2
  Up for 01:58:49
  Capabilities advertised: none
  Capabilities received: none
  Protection: disabled
  Local - Restart: disabled, Helper mode: enabled
  Remote - Restart: disabled, Helper mode: enabled
  Local maximum neighbor reconnect time: 120000 msec
  Local maximum neighbor recovery time: 240000 msec
  Nonstop routing state: Not in sync
  Next-hop addresses received:
 100.10.10.2
 100.10.20.1
```

The output shows the detailed information, including session IDs, keepalive interval, and next-hop addresses, for each established LDP session. Verify the following information:

- Each LDP neighbor address has an entry, listed by loopback address.
- The state for each session is **Operational**, and the connection for each session is **Open**. A state of **Nonexistent** or a connection of **Closed** indicates a problem with one of the following:
  - LDP configuration
  - Passage of traffic between the two devices
  - Physical link between the two routers
- For **Keepalive interval**, the appropriate value, **10**, appears.

Copyright © 2016, Juniper Networks, Inc.

Verifying the Presence of LDP-Signaled LSPs

Purpose Verify that each Juniper Networks device's **inet.3** routing table has an LSP for the loopback address on each of the other routers.

Action From the CLI, enter the **show route table inet.3** command.

```
user@r1> run show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
200.0.0.2/32       *[LDP/9] 05:20:20, metric 1
                    > via ge-0/0/0.0, Push 300640
200.0.0.3/32       *[LDP/9] 05:20:20, metric 1
                    > via ge-0/0/0.0, Push 300704
```

The output shows the LDP routes that exist in the **inet.3** routing table. Verify that an LDP-signaled LSP is associated with the loopback addresses of the other routers in the MPLS network.

Verifying Traffic Forwarding over the LDP-Signaled LSP

Purpose Verify that the LDP path between R1 and R3 is complete over the LDP-signaled LSP.

Action From the CLI on R1, enter the **traceroute mpls ldp 200.0.0.3** command.

```
user@r1> traceroute mpls ldp 200.0.0.3
Probe options: ttl 64, retries 3, wait 10, paths 16, exp 7, fanout 16
ttl Label Protocol Address Previous Hop Probe Status
1 300704 LDP 200.0.0.1 (null) Unhelpful
2 200.0.0.2 200.0.0.1 Unhelpful
3 200.0.0.3 200.0.0.2 Egress
Path 1 via ge-0/0/0.0 destination 127.0.0.64
```

The output shows the path between R1 and R3 using an LDP signalled LSP.

Understanding the RSVP Signaling Protocol

RSVP is a signaling protocol that handles bandwidth allocation and true traffic engineering across an MPLS network. Like LDP, RSVP uses discovery messages and advertisements to exchange LSP path information between all hosts. However, RSVP also includes a set of features that control the flow of traffic through an MPLS network. Whereas LDP is restricted to using the configured IGP's shortest path as the transit path through the network, RSVP uses a combination of the Constrained Shortest Path First (CSPF) algorithm and Explicit Route Objects (EROs) to determine how traffic is routed through the network.

Basic RSVP sessions are established in exactly the same way that LDP sessions are established. By configuring both MPLS and RSVP on the appropriate transit interfaces,

Copyright © 2016, Juniper Networks, Inc.

you enable the exchange of RSVP packets and the establishment of LSPs. However, RSVP also lets you configure link authentication, explicit LSP paths, and link coloring.

This topic contains the following sections:

- RSVP Fundamentals on page 3762
- Bandwidth Reservation Requirement on page 3762
- Explicit Route Objects on page 3762
- Constrained Shortest Path First on page 3763
- Link Coloring on page 3764

RSVP Fundamentals

RSVP uses unidirectional and simplex flows through the network to perform its function. The inbound router initiates an RSVP path message and sends it downstream to the outbound router. The path message contains information about the resources needed for the connection. Each router along the path begins to maintain information about a reservation.

When the path message reaches the outbound router, resource reservation begins. The outbound router sends a reservation message upstream to the inbound router. Each router along the path receives the reservation message and sends it upstream, following the path of the original path message. When the inbound router receives the reservation message, the unidirectional network path is established.

The established path remains open as long as the RSVP session is active. The session is maintained by the transmission of additional path and reservation messages that report the session state every 30 seconds. If a router does not receive the maintenance messages for 3 minutes, it terminates the RSVP session and reroutes the LSP through another active router.

Bandwidth Reservation Requirement

When a bandwidth reservation is configured, reservation messages propagate the bandwidth value throughout the LSP. Routers must reserve the bandwidth specified across the link for the particular LSP. If the total bandwidth reservation exceeds the available bandwidth for a particular LSP segment, the LSP is rerouted through another LSR. If no segments can support the bandwidth reservation, LSP setup fails and the RSVP session is not established.

Explicit Route Objects

Explicit Route Objects (EROs) limit LSP routing to a specified list of LSRs. By default, RSVP messages follow a path that is determined by the network IGP's shortest path. However, in the presence of a configured ERO, the RSVP messages follow the path specified.

EROs consist of two types of instructions: loose hops and strict hops. When a loose hop is configured, it identifies one or more transit LSRs through which the LSP must be routed. The network IGP determines the exact route from the inbound router to the first loose

Copyright © 2016, Juniper Networks, Inc.

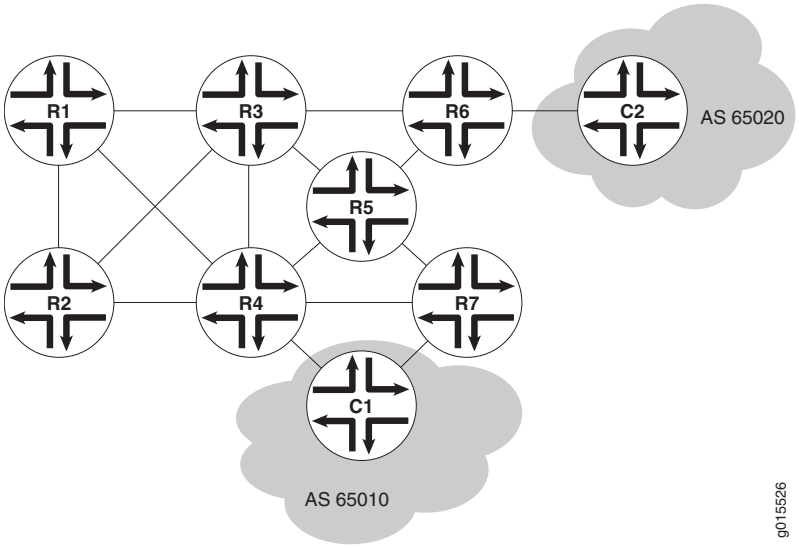
hop, or from one loose hop to the next. The loose hop specifies only that a particular LSR be included in the LSP.

When a strict hop is configured, it identifies an exact path through which the LSP must be routed. Strict-hop EROs specify the exact order of the routers through which the RSVP messages are sent.

You can configure loose-hop and strict-hop EROs simultaneously. In this case, the IGP determines the route between loose hops, and the strict-hop configuration specifies the exact path for particular LSP path segments.

Figure 140 shows a typical RSVP-signaled LSP that uses EROs.

Figure 140: Typical RSVP-Signaled LSP with EROs



In the topology shown in Figure 140, traffic is routed from Host C1 to Host C2. The LSP can pass through Routers R4 or Router R7. To force the LSP to use R4, you can set up either a loose-hop or strict-hop ERO that specifies R4 as a hop in the LSP. To force a specific path through Router R4, R3, and R6, configure a strict-hop ERO through the three LSRs.

Constrained Shortest Path First

Whereas IGPs use the Shortest Path First (SPF) algorithm to determine how traffic is routed within a network, RSVP uses the Constrained Shortest Path First (CSPF) algorithm to calculate traffic paths that are subject to the following constraints:

- LSP attributes—Administrative groups such as link coloring, bandwidth requirements, and EROs
- Link attributes—Colors on a particular link and available bandwidth

These constraints are maintained in the traffic engineering database (TED). The database provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors.

Copyright © 2016, Juniper Networks, Inc.

In determining which path to select, CSPF follows these rules:

- Computes LSPs one at a time, beginning with the highest priority LSP—the one with the lowest setup priority value. Among LSPs of equal priority, CSPF starts with those that have the highest bandwidth requirement.
- Prunes the traffic engineering database of links that are not full duplex and do not have sufficient reservable bandwidth.
- If the LSP configuration includes the **include** statement, prunes all links that do not share any included colors.
- If the LSP configuration includes the **exclude** statement, prunes all links that contain excluded colors. If a link does not have a color, it is accepted.
- Finds the shortest path toward the LSP's outbound router, taking into account any EROs. For example, if the path must pass through Router A, two separate SPF algorithms are computed: one from the inbound router to Router A and one from Router A to the outbound router.
- If several paths have equal cost, chooses the one with a last-hop address the same as the LSP's destination.
- If several equal-cost paths remain, selects the path with the least number of hops.
- If several equal-cost paths remain, applies CSPF load-balancing rules configured on the LSP.

Link Coloring

RSVP allows you to configure administrative groups for CSPF path selection. An administrative group is typically named with a color, assigned a numeric value, and applied to the RSVP interface for the appropriate link. Lower numbers indicate higher priority.

After configuring the administrative group, you can either exclude, include, or ignore links of that color in the TED:

- If you exclude a particular color, all segments with an administrative group of that color are excluded from CSPF path selection.
- If you include a particular color, only those segments with the appropriate color are selected.
- If you neither exclude nor include the color, the metrics associated with the administrative groups and applied on the particular segments determine the path cost for that segment.

The LSP with the lowest total path cost is selected into the TED.

Example: Configuring RSVP-Signaled LSPs

This example shows how to create an LSP between routers in an IP network using RSVP as the signaling protocol.

- Requirements on page 3765
- Overview and Topology on page 3765
- Configuration on page 3766
- Verification on page 3767

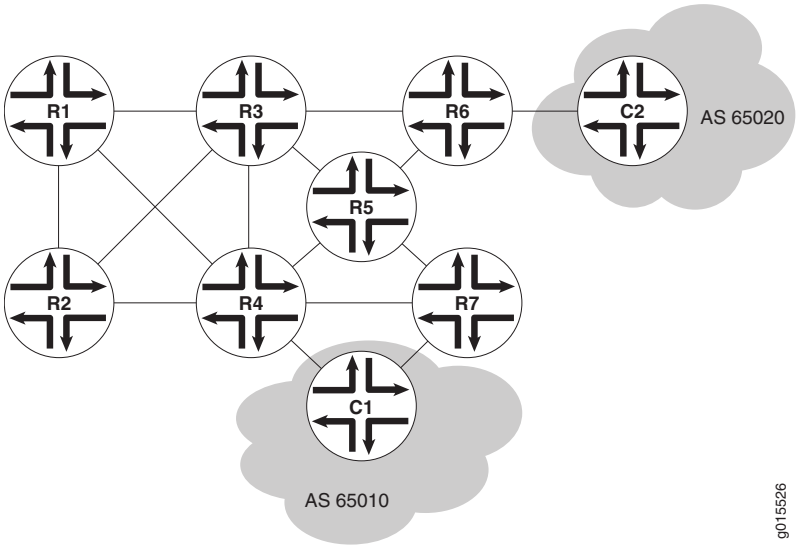
Requirements

Before you begin, delete security services from the device. See "Example: Deleting Security Services" on page 3748.

Overview and Topology

Using RSVP as a signaling protocol, you can create LSPs between routers in an IP network. In this example, you configure a sample network as shown in Figure 141.

Figure 141: Typical RSVP-Signaled LSP



To establish an LSP between routers, you must individually enable the MPLS family and configure RSVP on each of the transit interfaces in the MPLS network. This example shows how to enable MPLS and configure RSVP on the ge-0/0/0 transit interface. Additionally, you must enable the MPLS process on all of the MPLS interfaces in the network.

This example shows how to define an LSP from R1 to R7 on the ingress router (R1) using R7's loopback address (10.0.9.7). The configuration reserves 10 Mbps of bandwidth. Additionally, the configuration disables the CSPF algorithm, ensuring that Hosts C1 and C2 use the RSVP-signaled LSP that correspond to the network IGP's shortest path.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level and then enter **commit** from configuration mode.

```
set interfaces ge-0/0/0 unit 0 family mpls
set protocols rsvp interface ge-0/0/0.0
set protocols mpls label-switched-path r1-r7 to 10.0.9.7
set protocols mpls label-switched-path r1-r7 bandwidth 10m
set protocols mpls interface all
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure RSVP:

1. Enable the MPLS family on all transit interfaces in the MPLS network.

   ```
   [edit]
   user@host# set interfaces ge-0/0/0 unit 0 family mpls
   ```

2. Enable RSVP on each transit interface in the MPLS network.

   ```
   [edit]
   user @host# set protocols rsvp interface ge-0/0/0
   ```

3. Enable the MPLS process on the transit interface in the MPLS network.

   ```
   [edit]
   user@host# set protocols mpls interface ge-0/0/0
   ```

4. Define the LSP on the ingress router.

   ```
   [edit protocols mpls]
   user@host# set label-switched-path r1-r7 to 10.0.9.7
   ```

5. Reserve 10 Mbps of bandwidth on the LSP.

   ```
   [edit protocols mpls]
   user @host# set label-switched-path r1-r7 bandwidth 10m
   ```

Results

Confirm your configuration by entering the **show** command from configuration mode. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
user@host# show
...
  interfaces {
  ge-0/0/0 {
     family mpls;
```

Copyright © 2016, Juniper Networks, Inc.

```
    }
  }
  }
  ...
  protocols {
    rsvp {
      interface ge-0/0/0.0;
    }
    mpls {
      label-switched-path r1-r7 {
        to 10.0.9.7;
        bandwidth 10m;
      }
      interface all;
    }
  }
...
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying RSVP Neighbors on page 3767
- Verifying RSVP Sessions on page 3767
- Verifying the Presence of RSVP-Signaled LSPs on page 3768

Verifying RSVP Neighbors

Purpose Verify that each device shows the appropriate RSVP neighbors—for example, that Router R1 in Figure 141 lists both Router R3 and Router R2 as RSVP neighbors.

Action From the CLI, enter the **show rsvp neighbor** command.

```
user@r1> show rsvp neighbor
RSVP neighbor: 2 learned
Address            Idle Up/Dn LastChange HelloInt HelloTx/Rx
10.0.6.2              0  3/2       13:01        3   366/349
10.0.3.3              0  1/0       22:49        3   448/448
```

The output shows the IP addresses of the neighboring routers. Verify that each neighboring RSVP router loopback address is listed.

Verifying RSVP Sessions

Purpose Verify that an RSVP session has been established between all RSVP neighbors. Also, verify that the bandwidth reservation value is active.

Action From the CLI, enter the **show rsvp session detail** command.

```
user@r1> show rsvp session detail
Ingress RSVP: 1 sessions
```

Copyright © 2016, Juniper Networks, Inc.

```
10.0.9.7
  From: 10.0.6.1, LSPstate: Up, ActiveRoute: 0
  LSPname: r1-r7, LSPpath: Primary
  Bidirectional, Upstream label in: -, Upstream label out: -
  Suggested label received: -, Suggested label sent: -
  Recovery label received: -, Recovery label sent: 100000
  Resv style: 1 FF, Label in: -, Label out: 100000
  Time left:    -,  Since: Thu Jan 26 17:57:45 2002
  Tspec: rate 10Mbps size 10Mbps peak Infbps m 20 M 1500
  Port number: sender 3 receiver 17 protocol 0
  PATH rcvfrom: localclient
  PATH sentto: 10.0.4.13 (ge-0/0/1.0) 1467 pkts
  RESV rcvfrom: 10.0.4.13  (ge-0/0/1.0) 1467 pkts
  Record route: <self> 10.0.4.13  10.0.2.1  10.0.8.10
```

The output shows the detailed information, including session IDs, bandwidth reservation, and next-hop addresses, for each established RSVP session. Verify the following information:

- Each RSVP neighbor address has an entry for each neighbor, listed by loopback address.
- The state for each LSP session is **Up**.
- For **Tspec**, the appropriate bandwidth value, **10Mbps**, appears.

Verifying the Presence of RSVP-Signaled LSPs

Purpose Verify that the routing table of the entry (ingress) router has a configured LSP to the loopback address of the other router. For example, verify that the **inet.3** routing table of the R1 entry router in Figure 141 has a configured LSP to the loopback address of Router R7.

Action From the CLI, enter the **show route table inet.3** command.

```
user@r1> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.9.7/32         *[RSVP/7] 00:05:29, metric 10
                    > to 10.0.4.17 via ge-0/0/0.0, label-switched-path r1-r7
```

The output shows the RSVP routes that exist in the **inet.3** routing table. Verify that an RSVP-signaled LSP is associated with the loopback address of the exit (egress) router, R7, in the MPLS network.

Understanding Point-to-Multipoint LSPs

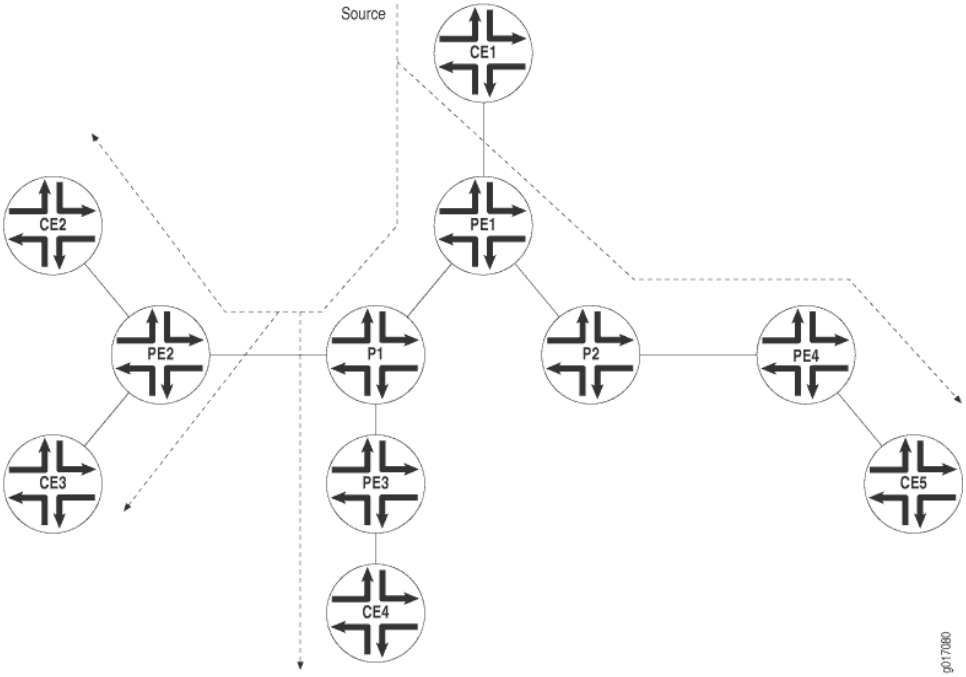
A point-to-multipoint MPLS label-switched path (LSP) is an LDP-signaled or RSVP-signaled LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the inbound (ingress) router. Packet replication takes

Copyright © 2016, Juniper Networks, Inc.

place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in Figure 142. Device PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Device PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Device P1 replicates the packet and forwards it to Routers PE2 and PE3. Device P2 sends the packet to Device PE4.

Figure 142: Point-to-Multipoint LSPs



Following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP allows you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an outbound (egress) router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any primary paths fail, traffic can be quickly switched to the bypass.
- You can configure subpaths either statically or dynamically.
- You can enable graceful restart on point-to-multipoint LSPs.

Copyright © 2016, Juniper Networks, Inc.

- Point-to-Multipoint LSP Configuration Overview on page 3770

Point-to-Multipoint LSP Configuration Overview

To set up a point-to-multipoint LSP:

1. Configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers.
2. Specify a pathname on the primary LSP and this same path name on each branch LSP.

NOTE: By default, the branch LSPs are dynamically signaled by means of Constrained Shortest Path First (CSPF) and require no configuration. You can alternatively configure the branch LSPs as static paths.

Related Documentation

- Understanding Point-to-Multipoint LSPs on page 3768

Example: Configuring an RSVP-Signaled Point-to-Multipoint LSP

This example shows how to configure a collection of paths to create an RSVP-signaled point-to-multipoint label-switched path (LSP).

- Requirements on page 3770
- Overview on page 3770
- Configuration on page 3771
- Verification on page 3786

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

In this example, multiple routing devices serve as the transit, branch, and leaf nodes of a single point-to-multipoint LSP. On the provider edge (PE), Device PE1 is the ingress node. The branches go from PE1 to PE2, PE1 to PE3, and PE1 to PE4. Static unicast routes on the ingress node (PE1) point to the egress nodes.

This example also demonstrates static routes with a next hop that is a point-to-multipoint LSP, using the **p2mp-lsp-next-hop** statement. This is useful when implementing filter-based forwarding.

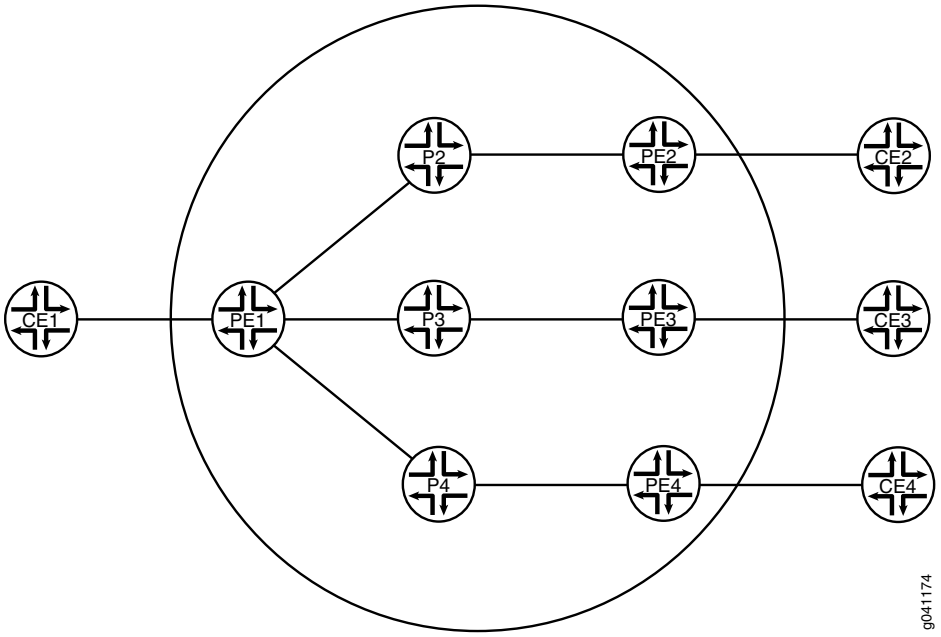
Copyright © 2016, Juniper Networks, Inc.

NOTE: Another option is to use the **lsp-next-hop** statement to configure a regular point-to-point LSP to be the next hop. Though not shown in this example, you can optionally assign an independent preference and metric to the next hop.

Topology Diagram

Figure 143 shows the topology used in this example.

Figure 143: RSVP-Signaled Point-to-Multipoint LSP



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

Configuring the Ingress Label-Switched Router (LSR) (Device PE1)

Step-by-Step Procedure

To configure Device PE1:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit interfaces]
user@PE1# set ge-2/0/2 unit 0 description PE1-to-CE1
user@PE1# set ge-2/0/2 unit 0 family inet address 10.0.244.10/30
```

Copyright © 2016, Juniper Networks, Inc.

```
user@PE1# set fe-2/0/10 unit 1 description PE1-to-P2
user@PE1# set fe-2/0/10 unit 1 family inet address 2.2.2.1/24
user@PE1# set fe-2/0/10 unit 1 family mpls
user@PE1# set fe-2/0/9 unit 8 description PE1-to-P3
user@PE1# set fe-2/0/9 unit 8 family inet address 6.6.6.1/24
user@PE1# set fe-2/0/9 unit 8 family mpls
user@PE1# set fe-2/0/8 unit 9 description PE1-to-P4
user@PE1# set fe-2/0/8 unit 9 family inet address 3.3.3.1/24
user@PE1# set fe-2/0/8 unit 9 family mpls
user@PE1# set lo0 unit 1 family inet address 100.10.10.10/32
```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```
[edit protocols]
user@PE1# set rsvp interface fe-2/0/10.1
user@PE1# set rsvp interface fe-2/0/9.8
user@PE1# set rsvp interface fe-2/0/8.9
user@PE1# set rsvp interface lo0.1
user@PE1# set mpls interface fe-2/0/10.1
user@PE1# set mpls interface fe-2/0/9.8
user@PE1# set mpls interface fe-2/0/8.9
user@PE1# set mpls interface lo0.1
user@PE1# set ospf area 0.0.0.0 interface ge-2/0/2.0
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/10.1
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/9.8
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/8.9
user@PE1# set ospf area 0.0.0.0 interface lo0.1
```

3. Configure the MPLS point-to-multipoint LSPs.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 to 100.50.50.50
user@PE1# set mpls label-switched-path PE1-PE2 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE3 to 100.70.70.70
user@PE1# set mpls label-switched-path PE1-PE3 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE4 to 100.40.40.40
user@PE1# set mpls label-switched-path PE1-PE4 p2mp p2mp1
```

4. (Optional) Enable link protection on the LSPs.

   Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 link-protection
user@PE1# set mpls label-switched-path PE1-PE3 link-protection
user@PE1# set mpls label-switched-path PE1-PE4 link-protection
```

5. Enable MPLS to perform traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set mpls traffic-engineering bgp-igp
```

   This causes the ingress routes to be installed in the **inet.0** routing table. By default, MPLS performs traffic engineering for BGP only. You need to enable MPLS traffic engineering on the ingress LSR only.

Copyright © 2016, Juniper Networks, Inc.

6. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

7. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 100.10.10.10
```

8. Configure static IP unicast routes with the point-to-multipoint LSP name as the next hop for each route.

```
[edit routing-options]
user@PE1# set static route 5.5.5.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
```

9. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4)

Step-by-Step Procedure

To configure the transit and egress LSRs:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit]

```

3. Enable traffic engineering for OSPF.

```
[edit]
user@P2# set protocols ospf traffic-engineering
user@P2# set protocols ospf traffic-engineering
user@P3# set protocols ospf traffic-engineering
user@PE2# set protocols ospf traffic-engineering
user@PE3# set protocols ospf traffic-engineering
user@PE4# set protocols ospf traffic-engineering
```

   This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

4. Configure the router IDs.

```
[edit]
user@P2# set routing-options router-id 100.20.20.20
user@P3# set routing-options router-id 100.60.60.60
user@P4# set routing-options router-id 100.30.30.30
user@PE2# set routing-options router-id 100.50.50.50
user@PE3# set routing-options router-id 100.70.70.70
user@PE4# set routing-options router-id 100.40.40.40
```

5. If you are done configuring the devices, commit the configuration.

```
[edit]
user@host# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Configuring Device CE1

Step-by-Step Procedure

To configure Device CE1:

1. Configure an interface to Device PE1.

```
[edit interfaces]
user@CE1# set ge-1/3/2 unit 0 family inet address 10.0.244.9/30
user@CE1# set ge-1/3/2 unit 0 description CE1-to-PE1
```

2. Configure static routes from Device CE1 to the three other customer networks, with Device PE1 as the next hop.

```
[edit routing-options]
user@CE1# set static route 10.0.104.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.134.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.224.8/30 next-hop 10.0.244.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE1# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/3/2 {
   unit 0 {
      family inet {
         address 10.0.244.9/30;
         description CE1-to-PE1;
      }
   }
}

user@CE1# show routing-options
static {
   route 10.0.104.8/30 next-hop 10.0.244.10;
   route 10.0.134.8/30 next-hop 10.0.244.10;
   route 10.0.224.8/30 next-hop 10.0.244.10;
}
```

Configuring Device CE2

Step-by-Step Procedure

To configure Device CE2:

1. Configure an interface to Device PE2.

```
[edit interfaces]
user@CE2# set ge-1/3/3 unit 0 family inet address 10.0.224.9/30
user@CE2# set ge-1/3/3 unit 0 description CE2-to-PE2
```

2. Configure a static route from Device CE2 to CE1, with Device PE2 as the next hop.

```
[edit routing-options]
```

Copyright © 2016, Juniper Networks, Inc.

```
user@CE2# set static route 10.0.244.8/30 next-hop 10.0.224.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/3/3 {
  unit 0 {
    family inet {
      address 10.0.224.9/30;
      description CE2-to-PE2;
    }
  }
}
```

```
user@CE2# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.224.10;
}
```

Configuring Device CE3

Step-by-Step Procedure To configure Device CE3:

1. Configure an interface to Device PE3.

```
[edit interfaces]
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.134.9/30
user@CE3# set ge-2/0/1 unit 0 description CE3-to-PE3
```

2. Configure a static route from Device CE3 to CE1, with Device PE3 as the next hop.

```
[edit routing-options]
user@CE3# set static route 10.0.244.8/30 next-hop 10.0.134.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE3# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE3# show interfaces
ge-2/0/1 {
  unit 0 {
    family inet {
      address 10.0.134.9/30;
      description CE3-to-PE3;
```

Copyright © 2016, Juniper Networks, Inc.

```
    }
  }
}
user@CE3# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.134.10;
}
```

Configuring Device CE4

Step-by-Step Procedure

To configure Device CE4:

1. Configure an interface to Device PE4.

```
[edit interfaces]
user@CE4# set ge-3/1/3 unit 0 family inet address 10.0.104.10/30
user@CE4# set ge-3/1/3 unit 0 description CE4-to-PE4
```

2. Configure a static route from Device CE4 to CE1, with Device PE4 as the next hop.

```
[edit routing-options]
user@CE4# set static route 10.0.244.8/30 next-hop 10.0.104.9
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE4# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE4# show interfaces
ge-3/1/3 {
  unit 0 {
    family inet {
      address 10.0.104.10/30;
      description CE4-to-PE4;
    }
  }
}
user@CE4# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.104.9;
}
```

Verification

Confirm that the configuration is working properly.

- Verifying Connectivity on page 3787
- Verifying the State of the Point-to-Multipoint LSP on page 3787
- Checking the Forwarding Table on page 3788

Verifying Connectivity

Purpose Make sure that the devices can ping each other.

Action Run the **ping** command from CE1 to the interface on CE2 connecting to PE2.

```
user@CE1> ping 10.0.224.9
PING 10.0.224.9 (10.0.224.9): 56 data bytes
64 bytes from 10.0.224.9: icmp_seq=0 ttl=61 time=1.387 ms
64 bytes from 10.0.224.9: icmp_seq=1 ttl=61 time=1.394 ms
64 bytes from 10.0.224.9: icmp_seq=2 ttl=61 time=1.506 ms
^C
--- 10.0.224.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.387/1.429/1.506/0.055 ms
```

Run the **ping** command from CE1 to the interface on CE3 connecting to PE3.

```
user@CE1> ping 10.0.134.9
PING 10.0.134.9 (10.0.134.9): 56 data bytes

MPLS VPN Overview

Virtual private networks (VPNs) are private networks that use a public network to connect two or more remote sites. Instead of dedicated connections between networks, VPNs use virtual connections routed (tunneled) through public networks that are typically service provider networks. VPNs are a cost-effective alternative to expensive dedicated lines. The type of VPN is determined by the connections it uses and whether the customer network or the provider network performs the virtual tunneling.

You can configure a router running Junos OS to participate in several types of VPNs. This topic discusses MPLS VPNs.

This topic contains the following sections:

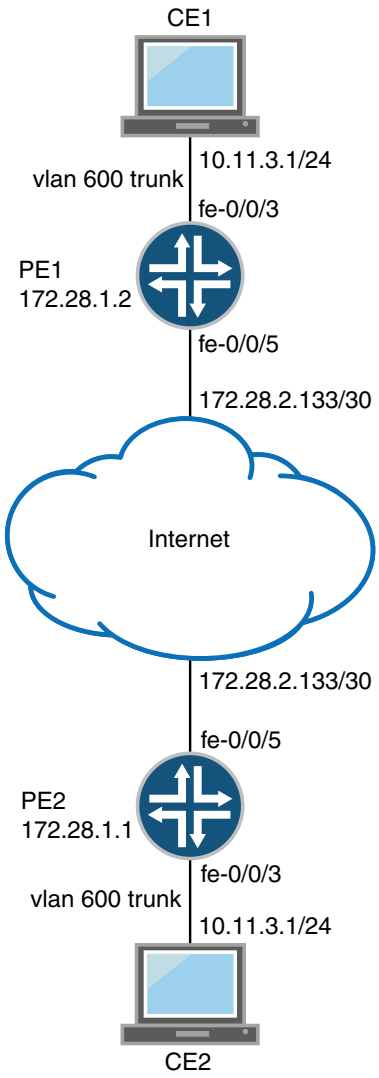
- MPLS VPN Topology on page 3791
- MPLS VPN Routing on page 3793
- VRF Instances on page 3793
- Route Distinguishers on page 3793

MPLS VPN Topology

There are many ways to set up an MPLS VPN and direct traffic through it. Figure 144 shows a typical MPLS VPN topology.

Copyright © 2016, Juniper Networks, Inc.

Figure 144: Typical VPN Topology



There are three primary types of MPLS VPNs: Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. All types of MPLS VPNs share certain components:

- The provider edge (PE) routers in the provider's network connect to the customer edge (CE) routers located at customer sites. PE routers support VPN and MPLS label functionality. Within a single VPN, pairs of PE routers are connected through a virtual tunnel, typically a label-switched path (LSP).
- Provider routers within the core of the provider's network are not connected to any routers at a customer site but are part of the tunnel between pairs of PE routers. Provider routers support LSP functionality as part of the tunnel support, but do not support VPN functionality.
- CE routers are the routers or switches located at the customer site that connect to the provider's network. CE routers are typically IP routers, but they can also be Asynchronous Transfer Mode (ATM), Frame Relay, or Ethernet switches.

Copyright © 2016, Juniper Networks, Inc.

All VPN functions are performed by the PE routers. Neither CE routers nor provider routers are required to perform any VPN functions.

MPLS VPN Routing

VPNs tunnel traffic as follows from one customer site to another customer site, using a public network as a transit network, when certain requirements are met:

1. Traffic is forwarded by standard IP forwarding from the CE routers to the PE routers.
2. The PE routers establish an LSP through the provider network.
3. The inbound PE router receives traffic, and it performs a route lookup. The lookup yields an LSP next hop, and the traffic is forwarded along the LSP.
4. The traffic reaches the outbound PE router, and the PE router pops the MPLS label and forwards the traffic with standard IP routing.

VRF Instances

A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The interfaces belong to the routing tables, and the routing protocol parameters control the information in the routing tables. In the case of MPLS VPNs, each VPN has a VPN routing and forwarding (VRF) instance.

A VRF instance consists of one or more routing tables, a derived forwarding table, the interfaces that use the forwarding table, and the policies and routing protocols that determine what goes into the forwarding table. Because each instance is configured for a particular VPN, each VPN has separate tables, rules, and policies that control its operation.

A separate VRF table is created for each VPN that has a connection to a CE router. The VRF table is populated with routes received from directly connected CE sites associated with the VRF instance, and with routes received from other PE routers in the same VPN.

Route Distinguishers

Because a typical transit network is configured to handle more than one VPN, the provider routers are likely to have multiple VRF instances configured. As a result, depending on the origin of the traffic and any filtering rules applied to the traffic, the BGP routing tables can contain multiple routes for a particular destination address. Because BGP requires that exactly one BGP route per destination be imported into the forwarding table, BGP must have a way to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs.

A route distinguisher is a locally unique number that identifies all route information for a particular VPN. Unique numeric identifiers allow BGP to distinguish between routes that are otherwise identical.

Each routing instance that you configure on a PE router must have a unique route distinguisher. There are two possible formats:

Copyright © 2016, Juniper Networks, Inc.

- ***as-number:number***, where ***as-number*** is an autonomous system (AS) number (a 2–byte value) in the range 1 through 65,535, and ***number*** is any 4–byte value. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the ISP or the customer AS number.
- ***ip-address:number***, where ***ip-address*** is an IP address (a 4–byte value) and ***number*** is any 2–byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a public IP address in your assigned prefix range.

The route target defines which route is part of a VPN. A unique route target helps distinguish between different VPN services on the same router. Each VPN also has a policy that defines how routes are imported into the VRF table on the router. A Layer 2 VPN is configured with import and export policies. A Layer 3 VPN uses a unique route target to distinguish between VPN routes.

The PE router then exports the route in IBGP sessions to the other provider routers. Route export is governed by any routing policy that has been applied to the particular VRF table. To propagate the routes through the provider network, the PE router must also convert the route to VPN format, which includes the route distinguisher.

When the outbound PE router receives the route, it strips off the route distinguisher and advertises the route to the connected CE router, typically through standard BGP IPv4 route advertisements.

Configuring a BGP Session for MPLS VPNs (CLI Procedure)

NOTE: This section is valid for Layer 2 VPNs and Layer 3 VPNs, but not Layer 2 circuits.

To configure an IBGP session, perform the following steps on each PE router:

1. Configure BGP.

   [edit]
   user@host# **edit protocols bgp group *group-name***

2. Set the BGP type to internal.

   [edit protocols bgp group *group-name*]
   user@host# **set type internal**

3. Specify the loopback interface.

   [edit protocols bgp group *group-name*]
   user@host# **set local-address *loopback-interface-ip-address***

Copyright © 2016, Juniper Networks, Inc.

4. Set the Layer 2 or Layer 3 VPN family type to unicast.

   ```
   [edit protocols bgp group group-name]
   user@host# set family family-type unicast
   ```

   Replace ***family-type*** with **l2vpn** for a Layer 2 VPN or **inet–vpn** for a Layer 3 VPN.

5. Enter the loopback address of the neighboring PE router.

   ```
   [edit protocols bgp]
   user@host# set neighbor ip-address
   ```

6. Commit the configuration if you are finished configuring the device.

   ```
   [edit]
   user@host# commit
   ```

Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)

To configure RSVP and OSPF:

1. Configure OSPF with traffic engineering support on the PE routers.

   ```
   [edit]
   user@host# edit protocols ospf traffic-engineering shortcuts
   ```

   NOTE: You must configure the IGP at the **[edit protocols]** level, not within the routing instance at the **[edit routing-instances]** level.

2. Enable RSVP on interfaces that participate in the LSP. For PE routers, enable interfaces on the source and destination points. For provider routers, enable interfaces that connect the LSP between the PE routers.

   ```
   [edit]
   user@host# edit protocols rsvp interface interface-name
   ```

3. Commit the configuration if you are finished configuring the device.

   ```
   [edit]
   user@host# commit
   ```

Configuring a Routing Instance for MPLS VPNs (CLI Procedure)

To configure a VPN routing instance on each PE router:

1. Create the routing instance.

   ```
   [edit]
   user@host# edit routing-instances routing-instance-name
   ```

2. Create a routing instance description. (This text appears in the output of the **show route instance detail** command.)

   ```
   [edit routing-instances routing-instance-name]
   user@host# set description "text"
   ```

3. Specify the instance type, either **l2vpn** for Layer 2 VPNs or **vrf** for Layer 3 VPNs.

   ```
   [edit routing-instances routing-instance-name]
   user@host# set instance-type instance-type
   ```

4. Specify the interface of the remote PE router.

   ```
   [edit routing-instances routing-instance-name]
   user@host# set interface interface-name
   ```

5. Specify the route distinguisher using one of the following commands:

   ```
   [edit routing-instances routing-instance-name]
   user@host# set route-distinguisheras-number:number
   user@host# set route-distinguisher ip-address:number
   ```

6. Specify the policy for the Layer 2 VRF table.

   ```
   [edit routing-instances routing-instance-name]
   user@host# set vrf-import import-policy-name vrf-export export-policy-name
   ```

7. Specify the policy for the Layer 3 VRF table.

   ```
   [edit routing-instances routing-instance-name]
   user@host# set vrf-target target:community-id
   ```

   Where *community-id* is either *as-number:number* or *ip-address:number*.

8. Commit the configuration if you are finished configuring the device.

Copyright © 2016, Juniper Networks, Inc.

```
[edit]
user@host# commit
```

CHAPTER 160

Configuring MPLS Layer 2 VPNs

- Understanding MPLS Layer 2 VPNs on page 3799
- MPLS Layer 2 VPN Configuration Overview on page 3799
- Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure) on page 3801
- Configuring Interfaces for Layer 2 VPNs (CLI Procedure) on page 3802
- Verifying an MPLS Layer 2 VPN Configuration on page 3803

Understanding MPLS Layer 2 VPNs

In an MPLS Layer 2 VPN, traffic is forwarded to the provider edge (PE) router in Layer 2 format, carried by MPLS through an label-switched path (LSP) over the service provider network, and then converted back to Layer 2 format at the receiving customer edge (CE) router.

Routing occurs on the customer routers, typically on the CE router. The CE router connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE router receiving the traffic sends it across the network to the PE router on the outbound side. The PE routers need no information about the customer's routes or routing topology, and need only to determine the virtual tunnel through which to send the traffic.

Implementing a Layer 2 VPN on the router is similar to implementing a VPN using a Layer 2 technology such as Asynchronous Transfer Mode (ATM) or Frame Relay.

Related Documentation

- MPLS VPN Overview on page 3791
- MPLS Layer 2 VPN Configuration Overview on page 3799

MPLS Layer 2 VPN Configuration Overview

To configure MPLS Layer 2 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

Copyright © 2016, Juniper Networks, Inc.

To configure an MPLS Layer 2 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See *Interfaces Feature Guide for Security Devices*.
2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 2 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 3802.
3. For all of the routers in the VPN configuration, configure the appropriate protocols.
   a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 VPN interfaces that communicate with other PE routers and provider routers.
   b. BGP and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See "Configuring a BGP Session for MPLS VPNs (CLI Procedure)" on page 3794.
   c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but you cannot use them for interfaces between PE routers and CE routers.

      In addition, configure an IGP such as OSPF or static routes for PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

      See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 3808 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 3795.
4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the AS number. You must specify it on each router involved in the VPN. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 3795.
5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP distinguish between potentially identical network layer reachable information [NLRI] messages received from different

 Copyright © 2016, Juniper Networks, Inc.

VPNs.) See "Configuring a Routing Instance for MPLS VPNs (CLI Procedure)" on page 3796.

6. For each PE router in the VPN configuration, configure a VPN routing policy if you are not using a route target. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. If the routing instance uses a policy for accepting and rejecting packets instead of a route target, you must specify the import and export routing policies and the community on each PE router. See "Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)" on page 3801.

Related Documentation

- Verifying an MPLS Layer 2 VPN Configuration on page 3803

Configuring a Routing Policy for MPLS Layer 2 VPNs (CLI Procedure)

These instructions show how to configure a Layer 2 VPN routing policy on the PE routers in the VPN.

After configuring an import routing policy for a Layer 2 VPN, configure an export routing policy for the Layer 2 VPN. Configure this export policy on the PE routers in the VPN. The export routing policy defines how routes are exported from the PE router routing table. An export policy is applied to routes sent to other PE routers in the VPN. The export policy must also evaluate all routes received over the routing protocol session with the CE router. The export policy must also contain a second term for rejecting all other routes.

To configure a Layer 2 VPN routing policy on a PE router:

1. Configure the import routing policy.

   ```
   [edit]
   user@host# edit policy-options policy-statement import-policy-name
   ```

2. Define the import policy's term for accepting packets.

   ```
   [edit edit policy-options policy-statement import-policy-name]
   user@host# set term term-name-accept from protocol bgp community
     community-name
   user@host# set term term-name-accept then accept
   ```

3. Define the import policy's term for rejecting packets.

   ```
   [edit edit policy-options policy-statement import-policy-name]
   user@host# set term term-name-reject then reject
   ```

4. Configure the export routing policy.

   ```
   [edit]
   user@host# edit policy-options policy-statement export-policy-name
   ```

5. Define the export policy's term for accepting packets.

   ```
   [edit policy-options policy-statement export-policy-name]
   user@host# set term term-name-accept from community add community-name
   user@host# set termterm-name-accept then accept
   ```

Copyright © 2016, Juniper Networks, Inc.

6. Define the export policy's term for rejecting packets.

   [edit policy-options policy-statement *export-policy-name*]
   user@host# set term *term-name-reject* from community add *community-name*
   user@host# set term *term-name-reject* then reject

7. Define the export policy's community using one of the following commands.

   [edit policy-options policy-statement *export-policy-name*]
   user@host# community *community-name* target: *as-number*
   user@host# community *community-name* target: *ip-address*:*number*

8. Commit the configuration if you are finished configuring the device.

   [edit]
   user@host# commit

Configuring Interfaces for Layer 2 VPNs (CLI Procedure)

Configuring the router interfaces that participate in the VPN is similar to configuring them for other uses, with a few requirements for the VPN. Perform the following tasks for each interface involved in the VPN, except Layer 3 loopback interfaces, which do not require other configuration.

To configure an interface for an MPLS VPN:

1. Configure IPv4 on all of the routers' interfaces.

   - For all interfaces except loopback interfaces and Layer 2 VPN interfaces facing a CE router:

     [edit]
     user@host# edit interfaces *interface-name* unit *logical_interface* family inet address *ipv4_address*

   - For a loopback address on a Layer 2 configuration:

     [edit]
     user@host# edit interfaces lo0 unit *logical_interface* family inet address *ipv4_address* primary

   - For a Layer 2 VPN interface facing a CE router:

     [edit]
     user@host# set interfaces *interface-name* vlan-tagging encapsulation vlan-ccc unit *logical_interface* encapsulation vlan-ccc vlan-id *id-number*

2. Configure the MPLS address family on the PE router or provider router interfaces that communicate with other PE routers or provider routers (and not loopback addresses).

   [edit interfaces *interface*]
   user@host# set unit *logical_interface* family mpls

Copyright © 2016, Juniper Networks, Inc.

3. Configure encapsulation for the interfaces on the PE routers that communicate with the CE routers in Layer 2 VPNs and Layer 2 circuits. If multiple logical units are configured, the encapsulation type is needed at the interface level only. It is always required at the unit level.

   [edit interfaces *interface*]
   user@host# **set encapsulation *encapsulation_type***
   user@host# **set unit *logical_interface* encapsulation *encapsulation_type***

4. Enable protocol mpls on CE facing interface.

   [edit interfaces *interface*]
   user@host# **set protocols mpls interface *interface-name***

5. Commit the configuration if you are finished configuring the device.

   [edit]
   user@host# **commit**

Verifying an MPLS Layer 2 VPN Configuration

Purpose Verify the connectivity of MPLS Layer 2 VPNs using the **ping mpls** command. This command helps to verify that a VPN has been enabled by testing the integrity of the VPN connection between the PE routers. It does not test the connection between a PE router and CE router.

Action

- To ping an interface configured for the Layer 2 VPN on the PE router, use the following command:

  ping mpls l2vpn interface *interface-name*

- To ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier to test the integrity of the Layer 2 VPN connection (specified by identifiers) between the two PE routers, use the following command:

  ping mpls l2vpn instance *l2vpn-instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number*

Understanding MPLS Layer 2 Circuits

An MPLS Layer 2 circuit is a point-to-point Layer 2 connection that transports traffic by means of MPLS or another tunneling technology on the service provider network. The Layer 2 circuit creates a virtual connection to direct traffic between two customer edge (CE) routers across a service provider network. The main difference between a Layer 2 VPN and a Layer 2 circuit is the method of setting up the virtual connection. As with a leased line, a Layer 2 circuit forwards all packets received from the local interface to the remote interface.

Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router to the local CE router. All Layer 2 circuits using a particular remote PE router neighbor is identified by its IP address and is usually the endpoint destination for the label-switched path (LSP) tunnel transporting the Layer 2 circuit.

Each virtual circuit ID uniquely identifies the Layer 2 circuit among all the Layer 2 circuits to a specific neighbor. The key to identifying a particular Layer 2 circuit on a PE router is the neighbor address and the virtual circuit ID. Based on the virtual circuit ID and the neighbor relationship, an LDP label is bound to an LDP circuit. LDP uses the binding for sending traffic on that Layer 2 circuit to the remote CE router.

MPLS Layer 2 Circuit Configuration Overview

To configure an MPLS Layer 2 circuit:

1. Determine all of the routers that you want to participate in the circuit, and then complete the initial configuration of their interfaces. See the *Interfaces Feature Guide for Security Devices*.
2. For all of the routers in the circuit configuration, update the interface configurations to enable participation in the Layer 2 circuit.
   a. On the interface communicating with the other provider edge (PE) router, specify MPLS and IPv4, and include the IP address. For the loopback interface, specify **inet**, and include the IP address. For IPv4, designate the loopback interface as primary so it can receive control packets. (Because it is always operational, the loopback interface is best able to perform the control function.)
   b. On the PE router interface facing the customer edge (CE) router, specify a circuit cross-connect (CCC) encapsulation type. The type of encapsulation depends on the interface type. For example, an Ethernet interface uses **ethernet-ccc**. (The encapsulation type determines how the packet is constructed for that interface.)
   c. On the CE router interface that faces the PE router, specify **inet** (for IPv4), and include the IP address. In addition, specify a routing protocol such as Open Shortest Path First (OSPF), which specifies the area and IP address of the router interface.

   See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 3802.
3. For all of the routers in the circuit configuration, configure the appropriate protocols.
   a. MPLS—For PE routers and provider routers, use MPLS to advertise the Layer 2 circuit interfaces that communicate with other PE routers and provider routers.
   b. BGP—For PE routers, configure a BGP session.
   c. IGP and a signaling protocol—For PE routers, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

      In addition, configure an IGP such as OSPF or static routes on the PE routers to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

Copyright © 2016, Juniper Networks, Inc.

See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 3808 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 3795.

4. For all of the routers in the circuit configuration, configure routing options. The only required routing option for circuits is the autonomous system (AS) number. You must specify it on each router involved in the circuit. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 3795.
5. For PE routers, configure Layer 2 circuits on the appropriate interfaces. See "Configuring an MPLS Layer 2 Circuit (CLI Procedure)" on page 3807.

Related Documentation

- Verifying an MPLS Layer 2 Circuit Configuration on page 3807

Configuring an MPLS Layer 2 Circuit (CLI Procedure)

To configure a Layer 2 circuit on a PE router:

1. Enable a Layer 2 circuit on the appropriate interface.

   ```
   [edit]
   user@host# edit protocols l2circuit neighbor interface-name interface interface-name
   ```

2. Enter the circuit ID number.

   ```
   [edit protocols l2circuit neighbor interface-name interface interface-name]
   user@host# set virtual-circuit-id id-number
   ```

   For **neighbor**, specify the local loopback address, and for **interface**, specify the interface name of the remote PE router.

3. Commit the configuration if you are finished configuring the device.

   ```
   [edit]
   user@host# commit
   ```

- MPLS Layer 2 Circuit Configuration Overview on page 3806

Verifying an MPLS Layer 2 Circuit Configuration

Purpose To verify the connectivity of MPLS Layer 2 circuits, use the **ping mpls** command. This command helps to verify that the circuit has been enabled by testing the integrity of the Layer 2 circuit between the source and destination routers.

Action

- To ping an interface configured for the Layer 2 circuit on the PE router, enter the following command:

  ping mpls l2circuit interface *interface-name*

- To ping a combination of the IPv4 prefix and the virtual circuit ID on the destination PE router, enter the following command:

  ping mpls l2circuit virtual-circuit*prefix virtual-circuit-id*

Related Documentation

- MPLS Layer 2 Circuit Configuration Overview on page 3806

Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)

The following instructions show how to configure LDP and OSPF on PE routers and provider routers. Within the task, you specify which interfaces to enable for LDP. Perform this step on each PE router interface and provider router interface that communicates with other PE routers and provider routers. For OSPF, you configure at least one area on at least one of the router's interfaces. (An AS can be divided into multiple areas.) These instructions use the backbone area **0.0.0.0** and show how to enable traffic engineering for Layer 2 VPN circuits.

To configure LDP and OSPF:

1. Enable the ldp protocol.

   ```
   [edit]
   user@host# edit protocols ldp
   ```

   NOTE: You must configure the IGP at the **[protocols]** level of the configuration hierarchy, not within the routing instance at the **[routing-instances]** level of the configuration hierarchy.

2. Specify which interfaces to enable for LDP.

   ```
   [edit protocols ldp]
   user@host# edit interface interface-name
   ```

3. Configure OSPF for each interface that uses LDP.

   ```
   [edit]
   user@host# edit protocols ospf area 0.0.0.0 interface interface-name
   ```

4. (Layer 2 VPN circuits only) Enable traffic engineering.

   ```
   [edit protocols ospf]
   user@host# set traffic engineering
   ```

5. Commit the configuration if you are finished configuring the device.

   ```
   [edit]
   user@host# commit
   ```

Configuring MPLS Layer 3 VPNs

- Understanding MPLS Layer 3 VPNs on page 3809
- MPLS Layer 3 VPN Configuration Overview on page 3810
- Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure) on page 3811
- Verifying an MPLS Layer 3 VPN Configuration on page 3812

Understanding MPLS Layer 3 VPNs

An MPLS Layer 3 VPN operates at the Layer 3 level of the OSI model, the Network layer. The VPN is composed of a set of sites that are connected over a service provider's existing public Internet backbone. The sites share common routing information and the connectivity of the sites is controlled by a collection of policies.

In an MPLS Layer 3 VPN, routing occurs on the service provider's routers. The provider routers route and forward VPN traffic at the entry and exit points of the transit network. The service provider network must learn the IP addresses of devices sending traffic across the VPN and the routes must be advertised and filtered throughout the provider network. As a result, Layer 3 VPNs require information about customer routes and a more extensive VPN routing and forwarding (VRF) policy configuration than a Layer 2 VPN. This information is used to share and filter routes that originate or terminate in the VPN.

The MPLS Layer 3 VPN requires more processing power on the provider edge (PE) routers than a Layer 2 VPN, because the Layer 3 VPN has larger routing tables for managing network traffic on the customer sites. Route advertisements originate at the customer edge (PE) routers and are shared with the inbound PE routers through standard IP routing protocols, typically BGP. Based on the source address, the PE router filters route advertisements and imports them into the appropriate VRF table.

The provider router uses OSPF and LDP to communicate with the PE routers. For OSPF, the provider router interfaces that communicate with the PE routers are specified, as well as the loopback interface. For the PE routers, the loopback interface is in passive mode, meaning it does not send OSPF packets to perform the control function.

MPLS Layer 3 VPN Configuration Overview

To configure MPLS Layer 3 VPN functionality on a router running Junos OS, you must enable support on the provider edge (PE) router and configure the PE router to distribute routing information to other routers in the VPN, as explained in the following steps. However, because the tunnel information is maintained at both PE routers, neither the provider core routers nor the customer edge (CE) routers need to maintain any VPN information in their configuration databases.

To configure an MPLS Layer 3 VPN:

1. Determine all of the routers that you want to participate in the VPN, and then complete the initial configuration of their interfaces. See the *Interfaces Feature Guide for Security Devices*.
2. For all of the routers in the VPN configuration, update the interface configurations to enable participation in the Layer 3 VPN. As part of the interface configuration, you must configure the MPLS address family for each interface that uses LDP or RSVP. See "Configuring Interfaces for Layer 2 VPNs (CLI Procedure)" on page 3802.
3. For all of the routers in the VPN configuration, configure the appropriate protocols.
   a. MPLS—If you are using RSVP, use MPLS to advertise the Layer 3 VPN interfaces on the PE routers and provider routers that communicate with other PE routers and provider routers.
   b. BGP, EBGP, and internal BGP (IBGP)—For PE routers, configure a BGP session to enable the routers to exchange information about routes originating and terminating in the VPN. (The PE routers use this information to determine which labels to use for traffic destined to the remote sites. The IBGP session for the VPN runs through the loopback address.) In addition, CE routers require a BGP connection to the PE routers. See "Configuring a BGP Session for MPLS VPNs (CLI Procedure)" on page 3794.
   c. IGP and a signaling protocol—For PE routers and provider, configure a signaling protocol (either LDP or RSVP) to dynamically set up label-switched paths (LSPs) through the provider network. (LDP routes traffic using IGP metrics. RSVP has traffic engineering that lets you override IGP metrics as needed.) You must use LDP or RSVP between PE routers and provider routers, but cannot use them for interfaces between PE routers and CE routers.

      In addition, configure an IGP such as OSPF or static routes on the PE routers in order to enable exchanges of routing information between the PE routers and provider routers. Each PE router's loopback address must appear as a separate route. Do not configure any summarization of the PE router's loopback addresses at the area boundary. Configure the provider network to run OSPF or IS-IS as an IGP, as well as IBGP sessions through either a full mesh or route reflector.

Copyright © 2016, Juniper Networks, Inc.

See "Configuring an IGP and the LDP Signaling Protocol (CLI Procedure)" on page 3808 and "Configuring an IGP and the RSVP Signaling Protocol (CLI Procedure)" on page 3795.

4. For all of the routers in the VPN configuration, configure routing options. The only required routing option for VPNs is the autonomous system (AS) number. You must specify it on each router involved in the VPN. See "Configuring Routing Options for MPLS VPNs (CLI Procedure)" on page 3795.
5. For each PE router in the VPN configuration, configure a routing instance for each VPN. The routing instance should have the same name on each PE router. Each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP distinguish between potentially identical network layer reachable information [NLRI] messages received from different VPNs.) See "Configuring a Routing Instance for MPLS VPNs (CLI Procedure)" on page 3796.
6. For CE routers, configure a routing policy. In addition, if you are not using a route target, configure a VPN routing policy for each PE router in the VPN configuration. Within the policy, describe which packets are sent and received across the VPN and specify how routes are imported into and exported from the router's VRF table. Each advertisement must have an associated route target that uniquely identifies the VPN for which the advertisement is valid. See "Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure)" on page 3811.

Configuring a Routing Policy for MPLS Layer 3 VPNs (CLI Procedure)

To configure a Layer 3 VPN routing policy on a CE router:

1. Configure the routing policy for the loopback interface.

   ```
   [edit]
   user@host# edit policy-options policy-statement policy-name
   ```

2. Define the term for accepting packets.

   ```
   [edit policy-options policy-statement policy-name]
   user@host# set term term-name-accept from protocol direct route-filter
     local-loopback-address/netmask exact
   user@host# set termterm-name-accept then accept
   ```

3. Define the term for rejecting packets.

   ```
   [edit policy-options policy-statement policy-name]
   user@host# set termterm-name-reject then reject
   ```

4. Commit the configuration if you are finished configuring the device.

   ```
   [edit]
   user@host# commit
   ```

CHAPTER 163

Introduction to CLNS

- CLNS Overview on page 3815
- CLNS Configuration Overview on page 3815

CLNS Overview

Connectionless Network Service (CLNS) is a Layer 3 protocol similar to IP version 4 (IPv4) for linking hosts (end systems) with routers (intermediate systems) in an Open Systems Interconnection (OSI) network. CLNS and its related OSI protocols, Intermediate System-to-Intermediate System (IS-IS) and End System-to-Intermediate System (ES-IS), are International Organization for Standardization (ISO) standards.

You can configure devices running Junos OS as provider edge (PE) routers within a CLNS network. CLNS networks can be connected over an IP MPLS network core using Border Gateway Protocol (BGP) and MPLS Layer 3 virtual private networks (VPNs). See RFC 2547, *BGP/MPLS VPNs*.

CLNS uses network service access points (NSAPs), similar to IP addresses found in IPv4, to identify end systems (hosts) and intermediate systems (routers). ES-IS enables the hosts and routers to discover each other. IS-IS is the interior gateway protocol (IGP) that carries ISO CLNS routes through a network.

For more information about CLNS, see the ISO 8473 standards.

- Understanding IS-IS for CLNS on page 3823
- Understanding Static Routes for CLNS on page 3827
- Understanding BGP for CLNS VPNs on page 3831

CLNS Configuration Overview

To configure CLNS:

1. Configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.
2. If applicable, configure BGP and VPNs. See:

Copyright © 2016, Juniper Networks, Inc.

- Example: Configuring BGP for CLNS VPNs on page 3832
- MPLS Layer 2 VPN Configuration Overview on page 3799
- MPLS Layer 3 VPN Configuration Overview on page 3810

3. Configure a VPN routing instance. You typically configure ES-IS, IS-IS, and CLNS static routes using a VPN routing instance. See "Example: Configuring a VPN Routing Instance for CLNS" on page 3834.
4. Configure one or more of the following protocols for CLNS (depending on your network).

   - ES-IS—If a device is a PE router within a CLNS island that contains any end systems, you must configure ES-IS on the device. If a CLNS island does not contain any end systems, you do not need to configure ES-IS on a device. See "Example: Configuring ES-IS for CLNS" on page 3820.

     NOTE: ES-IS is enabled only if either ES-IS or IS-IS is configured on the router. ES-IS must not be disabled. If ES-IS is not explicitly configured, the interface sends and receives only intermediate system hello (ISH) messages. If ES-IS is explicitly configured and disabled, the interface does not send or receive ES-IS packets. If ES-IS is explicitly configured and not disabled, the interface sends and receives ISH messages as well as ES-IS packets.

     One of the interfaces that is configured for ES-IS must be configured with an ISO address for hello messages. The ISO address family must be configured on an interface to support ES-IS on that interface.

   - IS-IS—You can configure IS-IS to exchange CLNS routes within a CLNS island. See "Example: Configuring IS-IS for CLNS" on page 3823.

     NOTE: If you have a pure CLNS island—an island that does not contain any IP devices—you must disable IPv4 and IPv6 routing. Also, to export BGP routes into IS-IS, you must configure and apply an export policy.

   - Static routes—If some devices in your network do not support IS-IS, you must configure CLNS static routes. You can use static routing with or without IS-IS. You might also consider using static routes if your network is simple. See "Example: Configuring Static Routes for CLNS" on page 3827.
   - BGP—See "Example: Configuring BGP for CLNS VPNs" on page 3832.

NOTE: Many of the configuration statements used to configure CLNS and routing protocols can be included at different hierarchy levels in the configuration.

CHAPTER 164

Configuring ES-IS for CLNS

- Understanding ES-IS for CLNS on page 3819
- Example: Configuring ES-IS for CLNS on page 3820

Understanding ES-IS for CLNS

End System-to-Intermediate System (ES-IS) is a protocol that resolves Layer 3 ISO network service access points (NSAP) to Layer 2 addresses. ES-IS has an equivalent role as Address Resolution Protocol (ARP) in IP version 4 (IPv4).

ES-IS provides the basic interaction between Connectionless Network Service (CLNS) hosts (end systems) and routers (intermediate systems). ES-IS allows hosts to advertise NSAP addresses to other routers and hosts attached to the network. Those routers can then advertise the address to the rest of the network by using Intermediate System-to-Intermediate System (IS-IS). Routers use ES-IS to advertise their network entity title (NET) to hosts and routers that are attached to that network.

ES-IS routes are exported to Layer 1 IS-IS by default. You can also export ES-IS routes into Layer 2 IS-IS by configuring a routing policy. ES-IS generates and receives end system hello (ESH) hello messages when the protocol is configured on an interface. ES-IS is a resolution protocol that allows a network to be fully ISO integrated at both the network layer and the data layer.

The resolution of Layer 3 ISO NSAPs to Layer 2 subnetwork point of attachments (SNPAs) by ES-IS is equivalent to ARP within an IPv4 network. If a device is a provider edge (PE) router within a CLNS island that contains any end systems, you must configure ES-IS on the device.

For more information about ES-IS, see the ISO 9542 standard.

Related Documentation

Example: Configuring ES-IS for CLNS

This example shows how to create a routing instance and enable ES-IS for CLNS on all interfaces.

- Requirements on page 3820
- Overview on page 3820
- Configuration on page 3820
- Verification on page 3821

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

The configuration instructions in this topic describe how to create a routing-instance called aaaa, set the end system configuration timer for the interfaces to 180, and set a preference value to 30 for ES-IS.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa protocols esis interface all end-system-configuration-timer
  180
set routing-instances aaaa protocols esis preference 30
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure ES-IS for CLNS:

1. Configure the routing instance.

   ```
   [edit]
   user@host# edit routing-instances aaaa
   ```

2. Enable ES-IS on all interfaces.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols esis interface all
   ```

3. Configure the end system configuration timer.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols esis interface all end-system-configuration-timer 180
   ```

4. Configure the preference value.

Copyright © 2016, Juniper Networks, Inc.

```
[edit routing-instances aaaa]
user@host# set protocols esis preference 30
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances
aaaa {
  protocols {
    esis {
      preference 30;
      interface all {
        end-system-configuration-timer 180;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Routing-Instance for CLNS on page 3821
- Verifying ES-IS for CLNS on page 3821

Verifying Routing-Instance for CLNS

Purpose Verify that the policy options are enabled for the routing instance.

Action From operational mode, enter the **show routing-instances** command.

Verifying ES-IS for CLNS

Purpose Verify that ES-IS is enabled.

Action From operational mode, enter the **show protocols** command.

Example: Configuring IS-IS for CLNS

This example shows how to create a routing instance and enable IS-IS protocol on all interfaces.

- Requirements on page 3823
- Overview on page 3823
- Configuration on page 3824
- Verification on page 3825

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

The configuration instructions in this topic describe how to create a routing-instance called aaaa, enable IS-IS on all interfaces, and define BGP export policy name (dist-bgp), family (ISO), and protocol (BP), and apply the export policy to IS-IS.

Copyright © 2016, Juniper Networks, Inc.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa protocols isis clns-routing
set routing-instances aaaa protocols isis interface all
set routing-instances aaaa protocols isis no-ipv4-routing no-ipv6-routing
set policy-options policy-statement dist-bgp from family iso protocol bgp
set policy-options policy-statement dist-bgp then accept
set routing-instances aaaa protocols isis export dist-bgp
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure IS-IS for CLNS:

1. Configure the routing instance.

   ```
   [edit]
   user@host# edit routing-instances aaaa
   ```

2. Enable CLNS routing.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis clns-routing
   ```

3. Enable IS-IS on all interfaces.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis interface all
   ```

4. (Optional) Disable IPv4 and IPv6 routing to configure a pure CLNS network .

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis no-ipv4-routing no-ipv6-routing
   ```

5. Define the BGP export policy name, family, and protocol.

   ```
   [edit policy-options]
   user@host# set policy-statement dist-bgp from family iso protocol bgp
   ```

6. Define the action for the export policy.

   ```
   [edit policy-options]
   user@host# set policy-statement dist-bgp then accept
   ```

7. Apply the export policy to IS-IS.

   ```
   [edit routing-instances aaaa]
   user@host# set protocols isis export dist-bgp
   ```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Copyright © 2016, Juniper Networks, Inc.

```
[edit]
user@host# show routing-instances
aaaa {
  protocols {
    isis {
      export dist-bgp;
      no-ipv4-routing;
      no-ipv6-routing;
      clns-routing;
      interface all;
    }
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Routing-Instance for CLNS on page 3825
- Verifying IS-IS for CLNS on page 3825

Verifying Routing-Instance for CLNS

Purpose Verify that the policy options are enabled for the routing instance.

Action From operational mode, enter the **show routing-instances** command.

Verifying IS-IS for CLNS

Purpose Verify that IS-IS is enabled.

Action From operational mode, enter the **show protocols** command.

CHAPTER 166

Configuring Static Routes for CLNS

- Understanding Static Routes for CLNS on page 3827
- Example: Configuring Static Routes for CLNS on page 3827

Understanding Static Routes for CLNS

The Connectionless Network Service (CLNS) is an ISO Layer 3 protocol that uses network service access point (NSAP) reachability information instead of IPv4 or IPv6 prefixes.

You can configure static routes to exchange CLNS routes within a CLNS island. A CLNS island is typically an IS-IS level 1 area that is part of a single IGP routing domain. An island can contain more than one area. CLNS islands can be connected by VPNs.

Related Documentation

- Example: Configuring Static Routes for CLNS on page 3827

Example: Configuring Static Routes for CLNS

This example shows how to configure static routes for CLNS.

- Requirements on page 3827
- Overview on page 3827
- Configuration on page 3828
- Verification on page 3829

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

In this example, you configure static routes for CLNS. In the absence of an interior gateway protocol (IGP) on a certain link, a routing device might need to be configured with static routes for CLNS prefixes to be reachable by way of that link. This might be useful, for example, at an autonomous system (AS) boundary.

Copyright © 2016, Juniper Networks, Inc.

When you configure static routes for CLNS, consider the following tasks:

- Specify the **iso.0** routing table option to configure a primary instance CLNS static route.
- Specify the **instance-name.iso.0** routing table option to configure a CLNS static route for a particular routing instance.
- Specify the **route** ***nsap-prefix*** statement to configure the destination for the CLNS static route.
- Specify the **next-hop (*interface-name* | *iso-net*)** statement to configure the next hop, specified as an ISO network entity title (NET) or interface name.
- Include the **qualified-next-hop (*interface-name* | *iso-net*)** statement to configure a secondary backup next hop, specified as an ISO network entity title or interface name.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
set routing-options rib iso.0 static iso-route
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.eee0/152
  qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference
  20
set routing-options rib iso.0 static iso-route 47.0005.80ff.f800.0000.eee0/152
  qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

Step-by-Step Procedure

To configure static routes for CLNS:

1. Configure the routes.

```
[edit routing-options rib iso.0 static]
user@host# set iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4212
user@host# set iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152
  next-hop t1-0/2/2.0
user@host# set iso-route 47.0005.80ff.f800.0000.eee0/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 preference 20
user@host# set iso-route 47.0005.80ff.f800.0000.eee0/152 qualified-next-hop
  47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 metric 10
```

2. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Results

Confirm your configuration by issuing the **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Copyright © 2016, Juniper Networks, Inc.

```
user@host# show routing-options
rib iso.0 {
  static {
    iso-route 47.0005.80ff.f800.0000.ffff.ffff/152 next-hop
      47.0005.80ff.f800.0000.0108.0001.1921.6800.4212;
    iso-route 47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152 next-hop t1-0/2/2.0;
    iso-route 47.0005.80ff.f800.0000.eee0/152 {
      qualified-next-hop 47.0005.80ff.f800.0000.0108.0001.1921.6800.4002 {
        preference 20;
        metric 10;
      }
    }
  }
}
```

Verification

Checking the Routing Table

Purpose Make sure that the expected routes appear in the routing table.

Action

```
user@host> show route table iso.0

iso.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

47.0005.80ff.f800.0000.0108.0001.1921.6800.4212/152
                   *[Static/5] 00:00:25
                    > via t1-0/2/2.0
47.0005.80ff.f800.0000.eee0/84
                   *[Static/20] 00:04:01, metric 10, metric2 10
                    > to #75 0.12.0.34.0.56 via fe-0/0/1.0
47.0005.80ff.f800.0000.ffff.ffff/104
                   *[Static/5] 00:04:01, metric2 0
                    > via t1-0/2/2.0
```

Meaning The static routes appear in the routing table.

Understanding BGP for CLNS VPNs

BGP extensions allow BGP to carry Connectionless Network Service (CLNS) virtual private network (VPN) network layer reachability information (NLRI) between provider edge (PE) routers. Each CLNS route is encapsulated into a CLNS VPN NLRI and propagated between remote sites in a VPN.

CLNS is a Layer 3 protocol similar to IP version 4 (IPv4). CLNS uses network service access points (NSAPs) to address end systems. This allows for a seamless autonomous system (AS) based on International Organization for Standardization (ISO) NSAPs.

A single routing domain consisting of ISO NSAP devices are considered to be CLNS islands. CLNS islands are connected together by VPNs.

You can configure BGP to exchange ISO CLNS routes between PE routers connecting various CLNS islands in a VPN using multiprotocol BGP extensions. These extensions are the ISO VPN NLRIs.

Each CLNS network island is treated as a separate VPN routing and forwarding instance (VRF) instance on the PE router.

You can configure CLNS on the global level, group level, and neighbor level.

Example: Configuring BGP for CLNS VPNs

This example shows how to create a BGP group for CLNS VPNs, define the BGP peer neighbor address for the group, and define the family.

- Requirements on page 3832
- Overview on page 3832
- Configuration on page 3832
- Verification on page 3833

Requirements

Before you begin, configure the network interfaces. See the *Interfaces Feature Guide for Security Devices*.

Overview

In this example, you create the BGP group called pedge-pedge, define the BGP peer neighbor address for the group as 10.255.245.215, and define the BGP family.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols bgp group pedge-pedge neighbor 10.255.245.213
set protocols bgp family iso-vpn unicast
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure BGP for CLNS VPNs:

1. Configure the BGP group and define the BGP peer neighbor address.

   ```
   [edit protocols bgp]
   user@host# set group pedge-pedge neighbor 10.255.245.213
   ```

2. Define the family.

   ```
   [edit protocols bgp]
   user@host# set family iso-vpn unicast
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Copyright © 2016, Juniper Networks, Inc.

Verification

Verifying the Neighbor Status

Purpose Display information about the BGP peer.

Action From operational mode, run the **show bgp neighbor 10.255.245.213** command. Look for **iso-vpn-unicast** in the output.

```
user@host> show bgp neighbor 10.255.245.213

Example: Configuring a VPN Routing Instance for CLNS

This example shows how to create a CLNS routing instance and set the instance type for Layer 3 VPNs.

- Requirements on page 3834
- Overview on page 3834
- Configuration on page 3834
- Verification on page 3835

Requirements

Before you begin, configure the network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

The following example shows how to create a CLNS routing instance called aaaa and set the instance type to VRF for Layer 3 VPNs. Within the example, you specify that the lo0.1 interface, e1–2/0/0.0 interface, and t1–3/0/0.0 interface all belong to the routing instance. The route distinguisher is set as 10.255.245.1:1 and the policy for the Layer 3 VRF table is set as target:11111:1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances aaaa instance-type vrf
set routing-instances aaaa interface lo0.1
set routing-instances aaaa interface ge-0/0/3
set routing-instances aaaa interface ge-0/0/2
set routing-instances aaaa route-distinguisher 10.255.245.1:1
set routing-instances aaaa vrf-target target:11111:1
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPN routing instance:

1. Create the routing instance.

   ```
   [edit]
   user@host# edit routing-instances aaaa
   ```

2. Specify the routing instance type.

   ```
   [edit routing-instances aaaa]
   user@host# set instance-type vrf
   ```

Copyright © 2016, Juniper Networks, Inc.

3. Specify the interfaces that belong to the routing instance.

```
[edit routing-instances aaaa]
user@host# set interface lo0.1
user@host# set interface ge-0/0/3
user@host# set interface ge-0/0/2
```

4. Specify the route distinguisher.

```
[edit routing-instances aaaa]
user@host# set route-distinguisher 10.255.245.1:1
```

5. Specify the policy for the Layer 3 VRF table.

```
[edit routing-instances aaaa]
user@host# set vrf-target target:11111:1
```

6. Enable family ISO on the interfaces edit interfaces interface-name unit-id.

```
[edit routing-instances aaaa]
user@host# set family ISO
```

Results From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit ]
user@host# show routing-instances
instance-type vrf;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
interface lo0.1;
route-distinguisher 10.255.245.1:1;
vrf-target target:11111:1;
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying the Configured CLNS Routing Instance

Purpose Confirm that the configuration is working properly.

Verify that the CLNS routing instance is configured.

Action From operational mode, enter the **show routing-instances** command.

CHAPTER 168

Introduction to VPLS

- VPLS Overview on page 3841
- VPLS Configuration Overview on page 3846

VPLS Overview

Virtual private LAN service (VPLS) is an Ethernet-based point-to-multipoint Layer 2 VPN. It allows you to connect geographically dispersed Ethernet LAN sites to each other across an MPLS backbone. For customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

VPLS, in its implementation and configuration, has much in common with an MPLS Layer 2 VPN. In a VPLS topology, a packet originating within a customer's network is sent first to a customer edge (CE) device (for example, a router or Ethernet switch). It is then sent to a provider edge (PE) router within the service provider's network. The packet traverses the service provider's network over an MPLS label-switched path (LSP). It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

The difference is that for VPLS, packets can traverse the service provider's network in point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to all the PE routers participating in a VPLS routing instance. In contrast, a Layer 2 VPN forwards packets in point-to-point fashion only. The paths carrying VPLS traffic between each PE router participating in a routing instance are signaled using BGP.

NOTE: **The RSVP automatic mesh feature with multiple RSVP neighbors on a single LAN is not supported on branch SRX Series devices because RSVP runs on WAN links in a service provider network. Most of these WAN interfaces are point-to-point and are rarely seen in LAN networks.**

This topic contains the following sections:

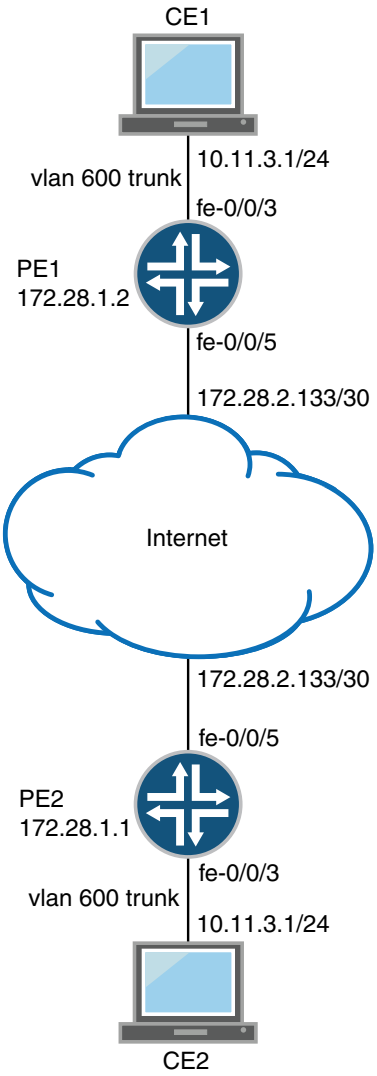
- Sample VPLS Topology on page 3842
- VPLS on PE Routers on page 3843
- Using an Ethernet Switch as the VPLS CE Device on page 3845
- VPLS Exceptions on SRX Series Devices on page 3845

Copyright © 2016, Juniper Networks, Inc.

Sample VPLS Topology

Figure 145 shows a basic VPLS topology.

Figure 145: Basic VPLS Topology



In this sample, the PE routers use the same autonomous system (AS). Within the AS, routing information is communicated through an interior gateway protocol (IGP). Outside the AS, routing information is shared with other ASs through BGP. The PE routers must use the same signaling protocols to communicate.

Copyright © 2016, Juniper Networks, Inc.

VPLS on PE Routers

Within a VPLS configuration, a device running Junos OS can act as a PE router. Junos OS passes the VPLS traffic through the following ports and PIMs on the Juniper Networks device to CE routers in the VPLS network:

- Built-in Ethernet ports on front panel
- Gigabit Ethernet uPIMs
- Gigabit Ethernet ePIMs
- Fast Ethernet PIMs
- Fast Ethernet ePIMs

NOTE: **Ports on uPIMs and ePIMs must be in routing mode before you can configure the corresponding interfaces for VPLS.**

Because a VPLS carries Ethernet traffic across a service provider network, it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

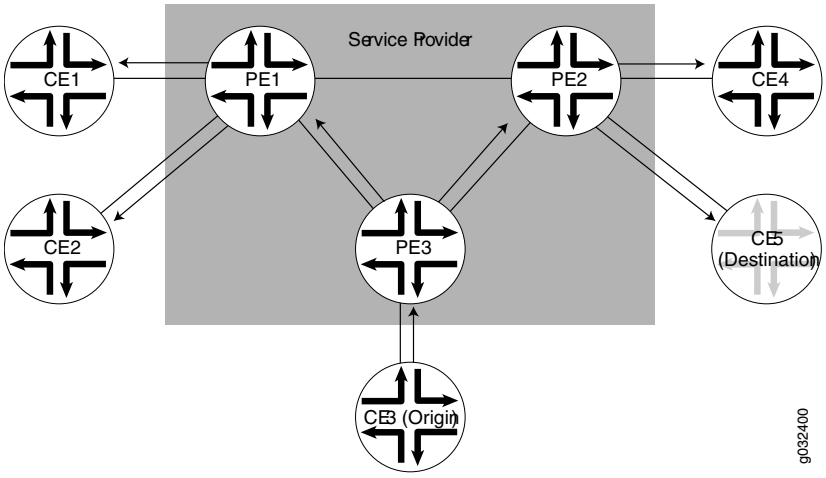
When a PE router receives a packet from another PE router, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, the PE router either forwards the packet or drops it depending on whether the destination is a local or remote CE device:

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), the PE router discards the packet.

If the PE router cannot determine the destination of the VPLS packet, it floods the packet to all attached CE devices. Figure 146 illustrates this process.

Copyright © 2016, Juniper Networks, Inc.

Figure 146: Flooding a Packet with an Unknown Destination



A VPLS interface can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch, for example, MAC addresses and interface ports, is included in the VPLS routing instance table.

An MPLS label-switched interface (LSI) label is used as the inner label for VPLS. This label maps to a VPLS routing instance on the ingress PE router. On the egress PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. However, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops.

NOTE: Under certain circumstances, VPLS PE routers might duplicate an Internet Control Message Protocol (ICMP) reply from a CE device when a PE router has to flood an ICMP request because the destination MAC address has not yet been learned. The duplicate ICMP reply can be triggered when a CE device with promiscuous mode enabled is connected to a PE router. The PE router automatically floods the promiscuous mode enabled CE device, which then returns the ICMP request to the VPLS PE routers. The VPLS PE routers consider the ICMP request to be new and flood the request again, creating a duplicate ping reply.

Copyright © 2016, Juniper Networks, Inc.

Using an Ethernet Switch as the VPLS CE Device

For VPLS configurations, the CE device does not necessarily need to be a router. You can link the PE routers directly to Ethernet switches. However, be aware of the following configuration issues:

- When you configure VPLS routing instances and establish two or more connections between a CE Ethernet switch and a PE router, you must enable the Spanning Tree Protocol (STP) on the switch to prevent loops.
- Junos OS allows standard bridge protocol data unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

VPLS Exceptions on SRX Series Devices

The VPLS implementation on SRX Series device is similar to VPLS implementations on M Series, T Series, and MX Series routers, with the following exceptions:

- SRX Series devices do not support aggregated Ethernet interfaces. Therefore, aggregated Ethernet interfaces between CE devices and PE routers are not supported for VPLS routing instances on SRX Series devices.
- SRX Series devices do not support aggregated Ethernet interfaces. Therefore, aggregated Ethernet interfaces between PE devices and PE routers are not supported for VPLS routing instances on SRX Series devices.
- VPLS multihoming, which allows connecting a CE device to multiple PE routers to provide redundant connectivity, is not supported on SRX Series devices.
- SRX Series devices do not support BGP mesh groups.
- SRX Series devices support only the following encapsulation types on VPLS interfaces that face CE devices: extended VLAN VPLS, Ethernet VPLS, and VLAN VPLS. Ethernet VPLS over ATM LLC encapsulation is not supported.
- Virtual ports are generated dynamically on a Tunnel Services PIC on some Juniper Networks routing platforms. SRX Series devices do not support Tunnel Services modules or virtual ports.
- The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

VPLS Configuration Overview

To configure VPLS functionality, you must enable VPLS support on the provider edge (PE) routers. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the customer edge (CE) devices, as explained in the steps that follow.

NOTE: **Many configuration procedures for VPLS are identical to the procedures for Layer 2 and Layer 3 VPNs.**

To configure VPLS:

1. Determine which uPIM and ePIM ports correspond to the interfaces that will carry the VPLS traffic and enable routing mode on those ports.
2. Configure the interfaces that will carry the VPLS traffic between the PE router and CE devices. On the PE router interfaces that are facing the CE devices, specify a VPLS encapsulation type. The type of encapsulation depends on the interface type. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
3. Create a VPLS routing instance on each PE router that is participating in the VPLS. For each VPLS routing instance, specify which interfaces will carry the VPLS traffic between the PE and CE devices. On the CE device interface that faces the PE router, you must specify inet (for IPv4), and include the IP address. Additionally, each routing instance must have a unique route distinguisher associated with it. (VPN routing instances need a route distinguisher to help BGP identify overlapping network layer reachability information (NLRI) messages from different VPNs.) See "Example: Configuring the VPLS Routing Instance" on page 3862.
4. Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 3903.
5. Configure MPLS LSPs between the PE routers. See "Example: Configuring MPLS on the VPLS PE Router" on page 3869.
6. Configure RSVP on the PE routers. Enable RSVP for all connections that participate in the MPLS LSP. See "Example: Configuring RSVP on the VPLS PE Router" on page 3868.
7. Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 3902.

Copyright © 2016, Juniper Networks, Inc.

8. Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.
9. Configure VLAN encapsulation. See "Example: Configuring VPLS VLAN Encapsulation on Gigabit Ethernet Interfaces" on page 3909,"Example: Configuring VPLS VLAN Encapsulation" on page 3906, and "Example: Configuring Extended VLAN VPLS Encapsulation" on page 3910.

CHAPTER 169

Configuring Interfaces

- Understanding VPLS Interfaces on page 3849
- Example: Configuring Routing Interfaces on the VPLS PE Router on page 3851
- Example: Configuring the Interface to the VPLS CE Device on page 3852
- VPLS Filters and Policers Overview on page 3853
- Example: Configuring VPLS Filters on page 3853
- Example: Configuring VPLS Policers on page 3855

Understanding VPLS Interfaces

For each VPLS routing instance on a PE router, you specify which interfaces are to be used to carry VPLS traffic between the PE and CE devices.

This topic contains the following sections:

- Interface Name on page 3849
- Encapsulation Type on page 3849
- Flexible VLAN Tagging on page 3850
- VLAN Rewrite on page 3850

Interface Name

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in ge-1/2/1.2, ge-1/0/1 is the physical portion of the interface name and 2 is the logical portion. If you do not specify the logical portion of the interface name, 0 is set by default. A logical interface can be associated with only one routing instance.

Encapsulation Type

The physical link-layer encapsulation type for a VPLS interface can be one of the following:

Copyright © 2016, Juniper Networks, Inc.

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol Identifier (TPID) values.
- **extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. All VLAN IDs from 1 through 1023 are valid for VPLS VLANs on Fast Ethernet interfaces, and all VLAN IDs from 1 through 4094 are valid for VPLS VLANs on Gigabit Ethernet interfaces.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. You must configure this encapsulation type on both the physical interface and the logical interface. VLAN IDs 1 through 511 are reserved for normal Ethernet VLANs, IDs 512 through 1023 are reserved for VPLS VLANs on Fast Ethernet interfaces, and IDs 512 through 4094 are reserved for VPLS VLANs on Gigabit Ethernet interfaces.
- **flexible-ethernet-services**—Use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. This encapsulation type allows you to configure any combination of route, TCC, CCC, and VPLS encapsulations on a single physical port. Aggregated Ethernet bundles cannot use this encapsulation type.

  For flexible Ethernet services encapsulation, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

Flexible VLAN Tagging

For untagged packets to be accepted on an 802.1Q VLAN-tagged port, specify the native VLAN ID with the flexible VLAN tagging option. (No other flexible VLAN tagging features are supported.)

VLAN Rewrite

You can rewrite VLAN tags on VPLS interfaces. Rewriting VLAN tags allows you to use an additional (outer) VLAN tag to differentiate between CE devices that share a VLAN ID.

You can configure rewrite operations to stack (push), remove (pop), or rewrite (swap) tags on single-tagged frames. If a port is not configured for VLAN tagging, rewrite operations are not supported on any logical interface on that port.

You can configure the following VLAN rewrite operations:

- pop—Remove a VLAN tag from the top of the VLAN tag stack. The outer VLAN tag of the frame is removed.
- push—Add a new VLAN tag to the top of the VLAN stack. An outer VLAN tag is pushed in front of the existing VLAN tag.
- swap—Replace the VLAN tag at the top of the VLAN tag stack with a user-specified VLAN tag value.

Copyright © 2016, Juniper Networks, Inc.

You perform VLAN rewrite operations by applying input and output VLAN maps at the ingress and egress, respectively, of the interface. For incoming frames, use the input-vlan-map; for outgoing frames, use the output-vlan-map.

The VPLS implementation on SRX Series devices does not support dual-tagged frames. Therefore, VLAN rewrite operations are not supported on dual-tagged frames. VLAN rewrite operations such as pop-pop, pop-swap, push-push, swap-push, and swap-swap, which are supported on M Series and T Series routing platforms, are not supported on SRX Series devices.

Example: Configuring Routing Interfaces on the VPLS PE Router

This example shows how to configure routing interfaces on the VPLS PE router.

- Requirements on page 3851
- Overview on page 3851
- Configuration on page 3851
- Verification on page 3852

Requirements

Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.

Overview

In this example, you configure the PE1 router loopback interface and the interface to the PE2 router ge-2/0/1.

Configuration

Step-by-Step Procedure

To configure the routing interface on the VPLS PE router:

1. Configure the loopback interface.

   ```
   [edit]
   user@host# set interfaces lo0 unit 0 family inet address 10.255.7.168/32 primary
   ```

2. Configure the IP address on the MPLS core interface.

   ```
   [edit]
   user@host# set interfaces ge-3/0/2 unit 0 family inet address 100.1.1.1/30
   ```

3. Configure the MPLS family.

Copyright © 2016, Juniper Networks, Inc.

```
[edit]
user@host# set interfaces ge-3/0/2 unit 0 family mpls
```

4. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

Requirements

Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.

Overview

In this example, you configure the router interface ge-1/2/1 that is connected to the CE device to include VPLS encapsulation.

Configuration

Step-by-Step Procedure

To configure the interface to the VPLS CE device:

1. Configure VPLS encapsulation for the interface facing the CE router.

```
[edit]
user@host# set interfaces ge-1/2/1 encapsulation ethernet-vpls
```

2. Configure the interface for the VPLS family group.

```
[edit]
user@host# set interfaces ge-1/2/1 unit 0 family vpls
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

VPLS Filters and Policers Overview

This feature permits users to configure both firewall filters and policers for virtual private LAN service (VPLS). Firewall filters enable you to filter packets based on their components and perform an action on packets that match the filter. Policers enable you to limit the amount of traffic that passes into or out of an interface.

This feature can be enabled by configuring VPLS filters, policers, and accounting through various CLI commands. VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but that does not include the cyclical redundancy check (CRC) field.

NOTE: **You can apply VPLS filters and policers on the PE routers only to customer-facing (PE-CE) interfaces.**

Related Documentation

Example: Configuring VPLS Filters

This example shows how to configure VPLS filters.

- Requirements on page 3853
- Overview on page 3854
- Configuration on page 3854
- Verification on page 3855

Requirements

Before you begin:

- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.

Copyright © 2016, Juniper Networks, Inc.

- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.
- Configure RSVP-TE on the PE routers. See "Example: Configuring RSVP on the VPLS PE Router" on page 3868.

Overview

This example describes how to configure filtering and accounting for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS filters, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall family vpls filter blue term term1 from interface ge-3/0/0.512
set firewall family vpls filter blue term term1 from interface fe-5/0/0.512
set firewall family vpls filter blue term term1 then count count1
set firewall family vpls filter blue accounting-profile fw_profile
set accounting-options file fw_acc size 500k
set accounting-options file fw_acc transfer-interval 5
set accounting-options filter-profile fw_profile file fw_acc
set accounting-options filter-profile fw_profile interval 1
set accounting-options filter-profile fw_profile counters count1
set interfaces ge-0/0/1 unit 512 family vpls filter input blue
```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure a filter with a GE interface as the match condition and count as the action.

   ```
   [edit ]
   user@host# set firewall family vpls filter blue term term1 from interface ge-3/0/0.512
   ```

2. Configure a filter with an FE interface as the match condition and count as the action.

   ```
   [edit ]
   user@host# set firewall family vpls filter blue term term1 from interface fe-5/0/0.512
   ```

3. Configure the count.

   ```
   [edit ]
   user@host# set firewall family vpls filter blue term term1 then count count1
   ```

4. Configure the accounting profile to refer it to the counter.

Copyright © 2016, Juniper Networks, Inc.

```
[edit ]
user@host# set firewall family vpls filter blue accounting-profile fw_profile
```

5. Configure the account file size.

```
[edit ]
user@host# set accounting-options file fw_acc size 500k
```

6. Configure the account transfer interval.

```
[edit ]
user@host# set accounting-options file fw_acc transfer-interval 5
```

7. Configure the filter for the accounting profile.

```
[edit ]
user@host# set accounting-options filter-profile fw_profile file fw_acc
```

8. Configure the filter for the interval.

```
[edit ]
user@host# set accounting-options filter-profile fw_profile interval 1
```

9. Configure the counter.

```
[edit ]
user@host# set accounting-options filter-profile fw_profile counters count1
```

10. Apply the filter to the interface.

```
[edit ]
user@host# set interfaces ge-0/0/1 unit 512 family vpls filter input blue
```

11. If you are done configuring the device, commit the configuration.

```
[edit ]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show firewall** and **show accounting records** commands.

- Configure RSVP-TE on the PE routers. See "Example: Configuring RSVP on the VPLS PE Router" on page 3868.

Overview

This example describes how to configure policing and apply it on the interface for VPLS.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your device to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the device performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the device.

Configuration

CLI Quick Configuration

To quickly configure VPLS policers, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall policer police2 if-exceeding bandwidth-percent 10
set firewall policer police2 if-exceeding burst-size-limit 1500
set firewall policer police2 then discard
set interfaces ge-0/0/1 unit 512 family vpls policer input police2
```

Step-by-Step Procedure

To configure filters for VPLS:

1. Configure bandwidth percentage.

   ```
   [edit ]
   user@host# set firewall policer police2 if-exceeding bandwidth-percent 10
   ```

2. Configure the burst size limit.

   ```
   [edit ]
   user@host# set firewall policer police2 if-exceeding burst-size-limit 1500
   ```

3. Configure the terminal action on the packet.

Copyright © 2016, Juniper Networks, Inc.

```
[edit ]
user@host# set firewall policer police2 then discard
```

4. Apply the policer to the interface.

```
[edit ]
user@host# set interfaces ge-0/0/1 unit 512 family vpls policer input police2
```

5. If you are done configuring the device, commit the configuration.

```
[edit ]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show firewall** command.

CHAPTER 170

Configuring Routing Instances

- Understanding VPLS Routing Instances on page 3859
- Example: Configuring the VPLS Routing Instance on page 3862
- Example: Configuring Automatic Site Identifiers for VPLS on page 3864

Understanding VPLS Routing Instances

To configure VPLS functionality, you must enable VPLS support on the PE router. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the CE devices.

You create a VPLS routing instance on each PE router that is participating in the VPLS. The routing instance has the same name on each PE router. To configure the VPLS routing instance, you specify the following:

- Route distinguisher—Helps BGP distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPLS instances. Each routing instance that you configure on a PE router must have a unique route distinguisher.
- Route target—Defines which route is part of a VPLS. A unique route target helps distinguish between different VPLS services on the same router.
- Site name—Provides unique name for the VPLS site.
- Site identifier—Provides unique numerical identifier for the VPLS site.
- Site range—Specifies total number of sites in the VPLS. The site range must be greater than the site identifier.
- Interface to the CE router—Specifies the physical interface to the CE router that carries VPLS traffic. The interface must be configured for a VPLS encapsulation type.

NOTE: In addition to the VPLS routing instance, you must configure MPLS label-switched paths (LSPs) between the PE routers, internal BGP (IBGP) sessions between the PE routers, and an interior gateway protocol (IGP) on the PE routers.

Copyright © 2016, Juniper Networks, Inc.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your router to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the router performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the router.

This topic contains the following sections:

- BGP Signaling on page 3860
- VPLS Routing Table on page 3860
- Trace Options on page 3861

BGP Signaling

BGP is used to signal the paths between each of the PE routers participating in the VPLS routing instance. These paths carry VPLS traffic across the service provider's network between the VPLS sites.

NOTE: LDP signaling is not supported for the VPLS routing instance.

To configure BGP signaling, you specify the following:

- VPLS site name and site identifier—When you configure BGP signaling for the VPLS routing instance, you must specify each VPLS site that has a connection to the router. For each VPLS site, you must configure a site name and site identifier (a numerical identifier between 1 to 65,534 that uniquely identifies the VPLS site).
- Site range—When you enable BGP signaling for the VPLS routing instance, you need to configure a site range. The site range specifies the total number of sites in the VPLS.

  NOTE: The site range value must be greater than the largest site identifier.

- Site preference—You can specify the preference value advertised for a particular VPLS site. The site preference value is encoded in the BGP local preference attribute. When a PE router receives multiple advertisements with the same VPLS edge (VE) device identifier, the advertisement with the highest local preference value is preferred.

VPLS Routing Table

The VPLS routing table contains MAC addresses and interface information for both physical and virtual ports. You can configure the following characteristics for the table:

- Table size—You can modify the size of the VPLS MAC address table. The default table size is 512 MAC addresses; the minimum is 16 addresses, and the maximum is 65,536 addresses.

Copyright © 2016, Juniper Networks, Inc.

If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

The interfaces affected include all of the interfaces within the VPLS routing instance, including the local interfaces and the LSI interfaces.

- Timeout interval—You can modify the timeout interval for the VPLS table. The default timeout interval is 300 seconds; the minimum is 10 seconds, and the maximum is 1,000,000 seconds. We recommend you configure longer values for small, stable VPLS networks and shorter values for large, dynamic VPLS networks. If the VPLS table does not receive any updates during the timeout interval, the router waits one additional interval before automatically clearing the MAC address entries from the VPLS table.
- Number of addresses learned from an interface—You can configure a limit on the number of MAC addresses learned by a VPLS routing instance by setting the MAC table size. The default is 512 addresses; the minimum is 16, and the maximum is 65,536 addresses. If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

  Because this limit applies to each VPLS routing instance, the MAC addresses of a single interface can consume all the available space in the table, preventing the routing instance from acquiring addresses from other interfaces. You can limit the number of MAC addresses learned from all interfaces configured for a VPLS routing instance, as well as limit the number of MAC addresses learned from a specific interface.

  The MAC limit configured for an individual interface overrides the limit configured for all interfaces for the VPLS routing instance. Also, the table limit can override the limits configured for the interfaces.

  The MAC address limit applies only to interfaces to CE devices.

Trace Options

The following trace flags display operations associated with VPLS:

- **all**—All VPLS tracing options
- **connections**—VPLS connections (events and state changes)
- **error**—Error conditions
- **nlri**—VPLS advertisements received or sent using BGP
- **route**—Trace-routing information
- **topology**—VPLS topology changes caused by reconsideration or advertisements received from other PE routers using BGP

Example: Configuring the VPLS Routing Instance

This example shows how to create a VPLS routing instance on each PE router that is participating in the VPLS.

- Requirements on page 3862
- Overview on page 3862
- Configuration on page 3862
- Verification on page 3864

Requirements

Before you begin:

- Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.

Overview

This example describes how to create a VPLS routing instance; configure VPLS site identifier, site range, no tunnel services option, route distinguisher, and route target for the VPLS routing instance; and specify the VPLS interface to the CE router.

NOTE: You must specify no tunnel services in the VPLS routing instance configuration, because SRX Series devices do not support tunnel serial PICs.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instances green instance-type vpls
set routing-instances green protocols vpls site-range 10 site R3 site-identifier 2
set routing-instances green protocols vpls no-tunnel-services
set routing-instances green route-distinguisher 10.255.7.1:1
set routing-instances green vrf-target target:11111:1
set routing-instances green instance-type vpls interface ge-1/2/1.0
```

Copyright © 2016, Juniper Networks, Inc.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a VPLS routing instance:

1. Configure the routing instance of type VPLS.

   ```
   [edit]
   user@host# edit routing-instances green
   ```

2. Enable the VPLS instance type.

   ```
   [edit routing-instances green]
   user@host# set instance-type vpls
   ```

3. Configure the VPLS site identifier and range for the VPLS routing instance.

   ```
   [edit routing-instances green protocols vpls]
   user@host# set site-range 10 site R3 site-identifier 2
   ```

4. Configure the no-tunnel-services option for the VPLS routing instance.

   ```
   [edit routing-instances green protocols vpls]
   user@host# set no-tunnel-services
   ```

5. Configure the route distinguisher.

   ```
   [edit routing-instances green]
   user@host# set route-distinguisher 10.255.7.1:1
   ```

6. Configure the route target.

   ```
   [edit routing-instances green]
   user@host# set vrf-target target:11111:1
   ```

7. Specify the VPLS interface to the CE router.

   ```
   [edit routing-instances green]
   user@host# set instance-type vpls interface ge-1/2/1.0
   ```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances green** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show routing-instances green
instance-type vpls;
interface ge-1/2/1.0;
route-distinguisher 10.255.7.1:1;
vrf-target target:11111:1;
protocols {
  vpls {
    site-range 10;
    no-tunnel-services;
    site R3 {
      site-identifier 2;
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying VPLS Routing Instance Is Configured on page 3864
- Verifying VPLS Routing Attributes Are Configured on page 3864

Verifying VPLS Routing Instance Is Configured

Purpose Verify that the VPLS routing instance is configured.

Action From operational mode, enter the **show routing-instances** command.

Verifying VPLS Routing Attributes Are Configured

Purpose Verify that attributes such as VPLS site identifier, site range, no tunnel services option, route distinguisher, and route target for the VPLS routing instance are configured.

Action From operational mode, enter the **show routing-instances green protocols vpls** command.

Example: Configuring Automatic Site Identifiers for VPLS

This example shows how to configure automatic site identifiers for VPLS sites.

Requirements

Before you begin, see information on selective stateless packet-based services in *Interfaces Feature Guide for Security Devices*.

Overview

When you enable automatic site identifiers, the Junos OS automatically assigns site identifiers to VPLS sites. In this example, you configure a routing instance called vpls instance and enable automatic site identifiers for VPLS.

NOTE: **Site identifiers for VPLS sites can be different for different routing instances.**

Copyright © 2016, Juniper Networks, Inc.

Configuration

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure automatic site identifiers:

1. Configure the routing instance of type VPLS.

   ```
   [edit]
   user@host#set routing-instances vpls-instance
   ```

2. Enable automatic site identifiers.

   ```
   [edit routing-instances vpls-instance]
   user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
     collision-detect-time 10
   user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
     new-site-wait-time 20
   user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
     reclaim-wait-time minimum 5 maximum 20
   user@host#set protocols vpls no-tunnel-services site site10 automatic-site-id
     startup-wait-time 5
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show vpls connections** command.

Example: Configuring OSPF on the VPLS PE Router

This example shows how to configure OSPF on the VPLS PE router.

- Requirements on page 3867
- Overview on page 3868
- Configuration on page 3868
- Verification on page 3868

Requirements

Before you begin:

- Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.

Copyright © 2016, Juniper Networks, Inc.

Overview

The PE routers exchange routing information using an IGP such as OSPF. In this example, you configure OSPF area 0.0.0.0 on the VPLS PE router and traffic engineering for OSPF.

Configuration

Step-by-Step Procedure

To configure OSPF on the VPLS PE router:

1. Configure the OSPF area on the VPLS PE router.

   ```
   [edit]
   user@host# set protocols ospf area 0.0.0.0 interface t1-1/0/1.0
   user@host# set protocols ospf area 0.0.0.0 interface lo0.0
   ```

2. Configure traffic engineering for OSPF.

   ```
   [edit]
   user@host# set protocols ospf traffic-engineering
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.

Overview

This example describes how to enable RSVP for all connections that participate in the LSP on the PE1 router.

Configuration

Step-by-Step Procedure

To configure RSVP on the VPLS PE router:

1. Configure the interface to the PE2 router for RSVP.

   ```
   [edit ]
   user@host# set protocols rsvp interface t1-1/0/1.0
   ```

2. Configure the loopback interface for RSVP.

   ```
   [edit ]
   user@host# set protocols rsvp interface lo0.0
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Requirements

Before you begin:

- Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.
- Configure RSVP-TE on the PE routers. See "Example: Configuring RSVP on the VPLS PE Router" on page 3868.

Overview

This example shows you how to configure MPLS on the PE1 router to advertise the Layer 2 VPN interface that communicates with the PE2 router.

CAUTION: MPLS is disabled by default on SRX Series devices. You must explicitly configure your router to allow MPLS traffic. However, when MPLS is enabled, all flow-based security features are deactivated and the router performs packet-based processing. Flow-based services such as security policies, zones, NAT, ALGs, chassis clustering, screens, firewall authentication, and IPsec VPNs are unavailable on the router.

Configuration

Step-by-Step Procedure

To configure MPLS on the VPLS PE router:

1. Configure the interface to the PE2 router for MPLS.

   ```
   [edit ]
   user@host# set protocols mpls interface t1-1/0/1.0
   ```

2. Configure the loopback for MPLS.

   ```
   [edit ]
   user@host# set protocols mpls interface lo0.0
   ```

3. Configure the path to destination 10.255.7.164.

   ```
   [edit ]
   user@host# set protocols mpls label-switched-path chelsea-sagar to 10.255.7.164
   ```

4. If you are done configuring the device, commit the configuration.

   ```
   [edit ]
   user@host# commit
   ```

Example: Configuring VPLS over GRE with IPsec VPNs

This example demonstrates a network scenario consisting of a central office and one branch office that will use VPLS, MPLS, GRE, and IPsec to create secure Ethernet connectivity over a Layer 3 network. This configuration can be expanded to add many other branch sites.

- Requirements on page 3872
- Overview on page 3872
- Configuration on page 3877
- Verification on page 3888

Requirements

Before you begin:

- Ensure that a layer 3 network is in place for all branch offices and that there is an ingress (head-end) device at the central office configured to terminate the VPNs from each branch office.
- Obtain IDP licenses for each SRX Series device. IDP is used to reassemble GRE packets that might become fragmented.

Overview

Junos OS can selectively choose whether traffic is processed by the flow engine or packet engine using the selective stateless packet-based feature. This feature allows you to combine flow and packet-based services in a single device. In this example, we describe a deployment scenario that uses this feature to deploy large-scale VPLS over GRE. This enables branch devices to securely transport Ethernet traffic over Layer 3 networks when used in conjunction with IPsec.

In this scenario you configure a central office ingress (head-end) using an SRX650 device and one branch office using an SRX240 device. This setup is accomplished by carrying MPLS pseudowires over GRE, which in turn, is encapsulated in IPsec in order to guarantee data integrity and confidentiality. By default, SRX Series devices use secure flow forwarding. Because VPLS services are provided in packet-mode only, the configuration requires the GRE tunnel to be terminated in a packet-mode routing instance (the default routing instance).

Copyright © 2016, Juniper Networks, Inc.

NOTE: You can also use an MX Series device as the ingress (head-end) device, which is mentioned later in this topic.

To better understand this configuration, we will discuss two scenarios. The first scenario uses pseudowires to allow the creation of point-to-point circuits between two endpoints carried over the MPLS network. If we leave the signaling protocols aside (that is, there are a few ways to provision the pseudowires), these connections are just point-to-point connections. Using this approach provides an end-to-end wire between sites. This is beneficial from a traffic processing point of view because the gateways do not need to do MAC address learning, they simply forward anything they receive to the pseudowire. Because of this, it may be difficult to deploy this setup when trying to provide connectivity to multiple branch offices.

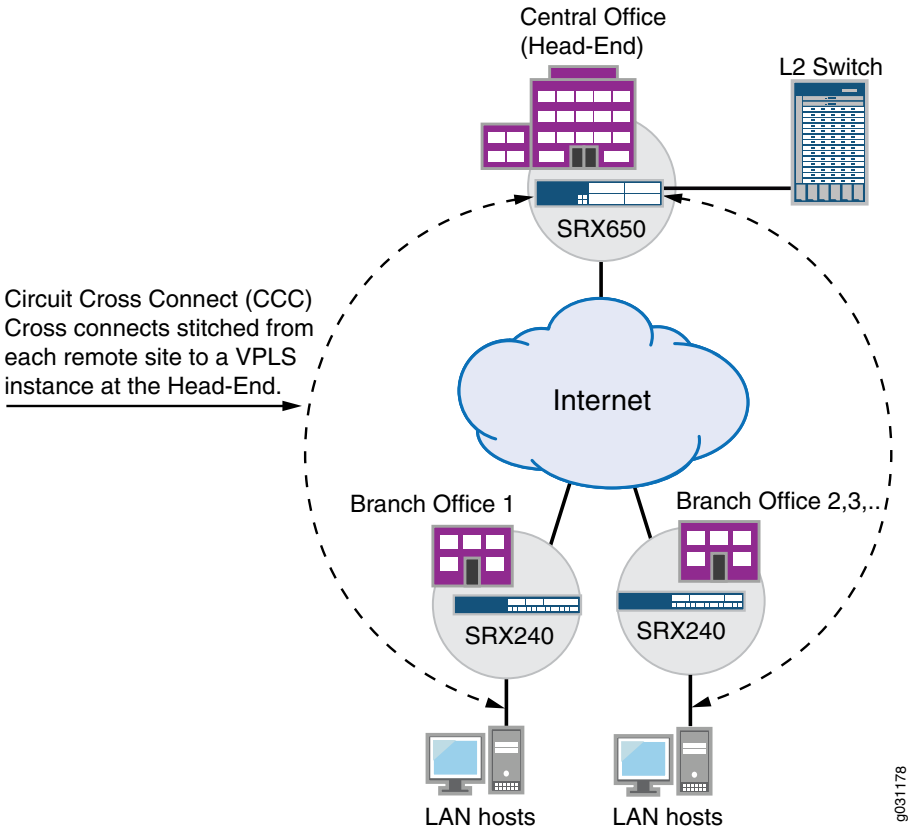
The second scenario could use VPLS to provide a Layer 2 network abstraction. With VPLS, endpoints are expected to negotiate LSPs and pseudowires with every other endpoint (that is, they are fully meshed). When a node receives an Ethernet frame from one of its LAN interfaces the source MAC address is learned, if it's not already known, and flooded using every pseudowire connecting to all other branch nodes. However, if the destination has been previously learned, then the frame is sent to the appropriate destination. When an Ethernet frame is received through one of the pseudowires (that is, from the MPLS network), source MAC address learning is performed. The next time a frame is sent to that MAC it does not need to be flooded and the frame is flooded to every single LAN interface in the node, but not over the pseudowires. In other words, the network acts as a distributed Layer 2 switch providing any-to-any Ethernet connectivity between the devices connected to the different nodes in the network.

While the advantages of this second scenario is evident (any-to-any connectivity, automated provisioning, and simple abstraction), it comes at the cost of complexity. Every PE node has to perform Layer 2 learning and flooding of traffic, which can cause problems when either multiple broadcast/multicast or frames to unknown MAC addresses are used. As an example, if you had a topology with a thousand branch offices, each office that receives a broadcast packet must replicate it 999 times, encapsulate each copy in GRE and IPsec and forward the resulting traffic. Additionally, because each node performs Layer 2 learning, there are limitations in the maximum number of MAC addresses that each node can learn, limiting the total number of nodes in the domain.

In this example, we use a hybrid approach to these two scenarios. We use a circuit cross connect (CCC) at each branch office stitched to a VPLS instance at central office (ingress). This solution makes sense if most of the traffic flows from the branch offices to central office, and the branch-to-branch office traffic is always forwarded through the hub. The use of CCCs at branch offices combined with VPLS stitching at the central office provides a scalable way to deploy large hub-and-spoke topologies where Ethernet must be transported over an IP network (with or without encryption). At the expense of configuration complexity, it is possible to use branch SRX Series devices to terminate such connections, providing a scalable and cost-effective way to deploy small-to-large networks where Ethernet traffic is carried transparently using lower cost IP connections. Figure 147 shows this topology.

Copyright © 2016, Juniper Networks, Inc.

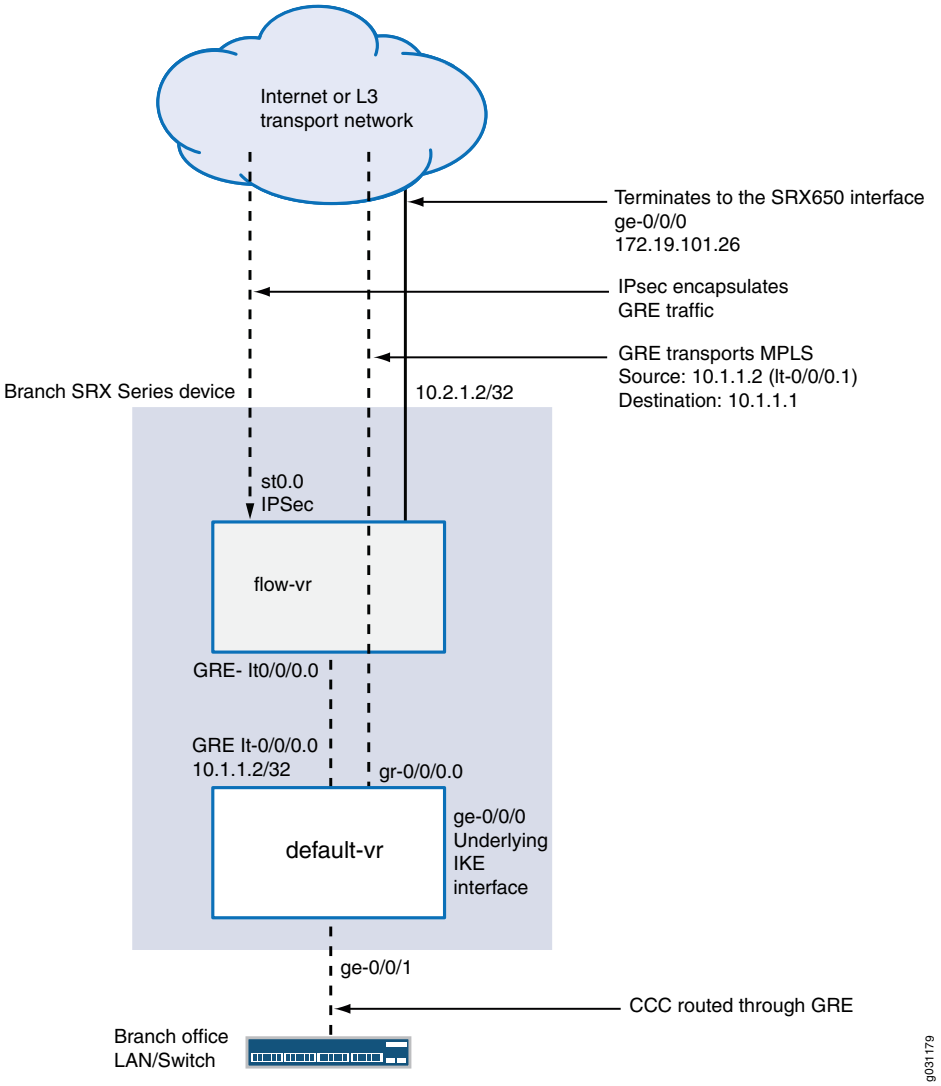
Figure 147: VPLS Deployment Scenario



In this deployment, VPLS services are provided only in packet mode and must be configured in the default routing instance. Unfortunately, IPsec is only provided in flow mode. Hence, a flow-mode routing-instance is used that provides both GRE reassembly and IPsec termination. While the GRE termination is done in the default routing instance, a flow-mode routing instance is connected between the default routing instance and the Internet (or whatever Layer 3 network is used as a transport), and it terminates the IPsec tunnel towards the ingress device. Because it is likely that a single public IP address is available, the Internet-facing Interface is connected to the default routing instance and is used to terminate IKE; however, the tunnel interface (st0) is bound to the flow-mode routing instance. See Figure 148.

Copyright © 2016, Juniper Networks, Inc.

Figure 148: Branch Office Circuit Cross Connect Termination

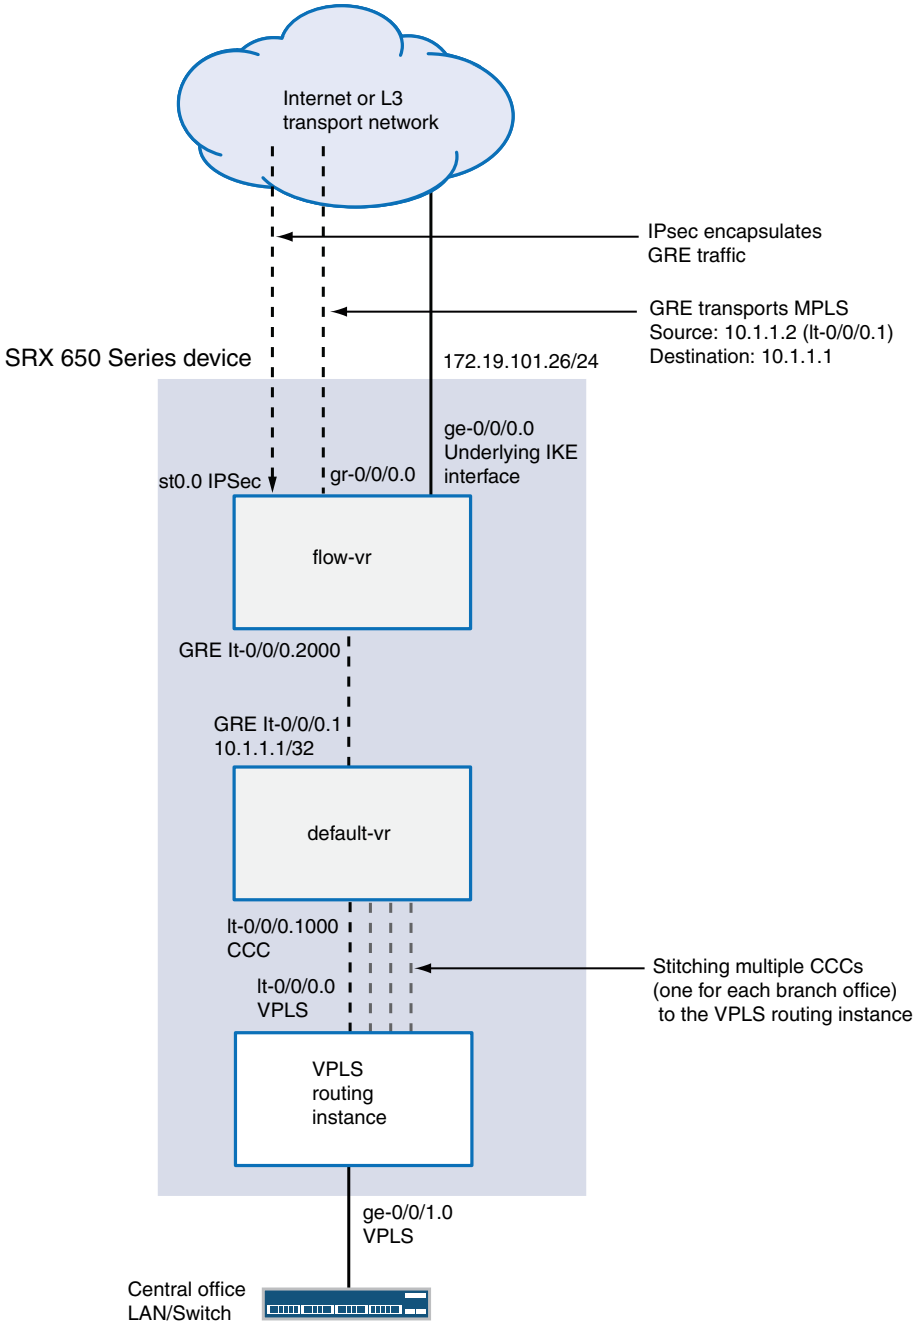


When configuring the central office SRX650, the first thing you do is terminate the IPsec tunnels, GRE, and CCC connections. Because a branch SRX Series device is used as the ingress (head-end), the configuration to terminate the CCC circuits is identical to the one used at each branch office, with the exception that instead of one tunnel, multiple tunnels (and pseudowires) are terminated.

The pseudowires are stitched to a VPLS routing instance using logical tunnel (lt) interfaces. It is possible to use an lt interface unit to terminate a CCC connection and connect this unit to a different unit that is part of a VPLS routing instance. The overall result is as if the pseudowires were terminated directly in the VPLS routing instance. Figure 149 illustrates this configuration.

Copyright © 2016, Juniper Networks, Inc.

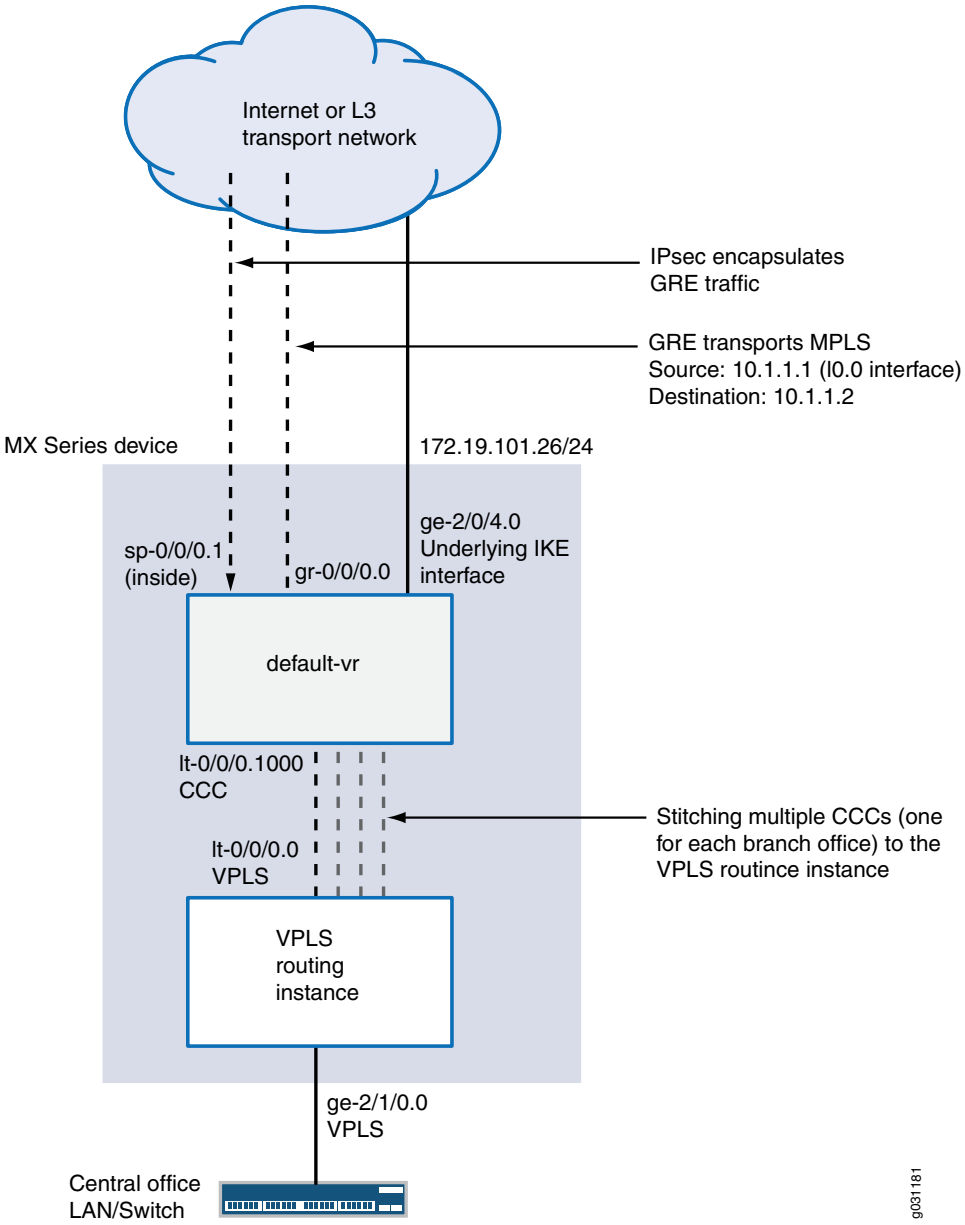
Figure 149: Central Office Ingress (Head-End) Configuration with an SRX Series Device



You can also use an MX Series device as the central office ingress (head-end) to terminate all branch office connections. The differences in the configuration are due to the way IPsec is configured and the fact that on MX Series devices IDP is not required to reassemble the GRE packets; MX Series devices natively support GRE reassembly. With this configuration, you still use lt interfaces to stitch the CCCs between the remote branch offices and the VPLS routing instance as shown in Figure 150.

Copyright © 2016, Juniper Networks, Inc.

Figure 150: Central Office Ingress (Head-End) Configuration with an MX Series Device



Configuration

In this example, we use SRX Series devices and the branch and ingress (head-end) sites will typically be connected to the Internet by Frame-Relay/T1-E1/xDSL/T3/E3 or even Ethernet. A provider MPLS network is not required.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the SRX240 at the branch office:

1. Configure a GRE tunnel to the central office.

```
[edit interfaces]
user@host# set gr-0/0/0 description "GRE tunnel to SRX650"
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 2000
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls mtu 1900
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode
```

Copyright © 2016, Juniper Networks, Inc.

2. Create a logical interface that connects to the default routing instance.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 0 encapsulation frame-relay
user@host# set lt-0/0/0 unit 0 dlci 16
user@host# set lt-0/0/0 unit 0 peer-unit 1
user@host# set lt-0/0/0 unit 0 family inet
user@host# set lt-0/0/0 unit 0 description "Flow-vr Instance"
```

3. Connect the logical tunnel interface to the flow mode virtual router.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 1 encapsulation frame-relay
user@host# set lt-0/0/0 unit 1 dlci 16
user@host# set lt-0/0/0 unit 1 peer-unit 0
user@host# set lt-0/0/0 unit 1 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 1 family inet address 10.1.1.2/32
```

4. Connect the CCC interface to the branch LAN.

```
[edit interfaces]
user@host# set ge-0/0/1 encapsulation ethernet-ccc
user@host# set ge-0/0/1 unit 0 description "CCC Interface to customer LAN"
user@host# set ge-0/0/1 unit 0 family ccc filter input ccc-packet-mode
```

5. Configure the interface bound to the default virtual router.

```
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.45/24
```

6. Set the loopback interface to terminate the CCC connection.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.2.1.2/32
```

7. Bind the IPsec tunnel interface to the flow-mode virtual router.

```
[edit interfaces]
user@host# set st0 unit 0 family inet
```

8. Set a static route address, which will be the default gateway to the Internet.

```
[edit routing-options]
user@host# set static route 0.0.0.0/0 next-hop 172.19.101.1
```

9. Set a static route for the remote GRE tunnel endpoint.

```
[edit routing-options]
user@host# set static route 10.1.1.1/32 next-hop lt-0/0/0.1
```

10. Set a static route for the loopback interface of the SRX650 ingress (head-end) device.

```
[edit routing-options]
user@host# set static route 10.2.1.1/32 next-hop gr-0/0/0.0
```

11. Configure MPLS and the CCC using LDP as the label protocol.

```
[edit]
user@host# set routing-options router-id 10.2.1.2
user@host# set protocols mpls interface gr-0/0/0.0
user@host# set protocols ldp interface gr-0/0/0.0
user@host# set protocols ldp interface lo0.0
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set protocols l2circuit neighbor 10.2.1.1 interface ge-0/0/1.0
  virtual-circuit-id 1
```

12. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX650 mode main
user@host# set ike policy SRX650 proposal-set standard
user@host# set ike policy SRX650 pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX650 ike-policy SRX650
user@host# set ike gateway SRX650 address 172.19.101.26
user@host# set ike gateway SRX650 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX650 proposal-set standard
user@host# set ipsec vpn SRX650 bind-interface st0.0
user@host# set ipsec vpn SRX650 ike gateway SRX650
user@host# set ipsec vpn SRX650 ike ipsec-policy SRX650
user@host# set ipsec vpn SRX650 establish-tunnels immediately
```

13. Configure security zones.

NOTE: In a production environment, host-inbound traffic should be restricted to only allow the necessary protocols and services.

```
[edit security]
user@host# set zones security-zone untrust host-inbound-traffic system-services
  all
user@host# set zones security-zone untrust host-inbound-traffic protocols all
user@host# set zones security-zone untrust interfaces gr-0/0/0.0
user@host# set zones security-zone untrust interfaces lo0.0
user@host# set zones security-zone untrust interfaces lt-0/0/0.1
user@host# set zones security-zone untrust interfaces ge-0/0/0.0

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the ingress (head-end) SRX650 device at the central office:

1. Configure the interface bound to the default virtual router.

   ```
   [edit interfaces]
   user@host# set ge-0/0/0 unit 0 family inet address 172.19.101.26/24
   ```

2. Create the GRE tunnel from the SRX650 to the SRX240 device.

Copyright © 2016, Juniper Networks, Inc.

NOTE: As the network expands to include multiple branch offices, you will need to add a similar GRE tunnel configuration on the SRX650 device (head-end) along with a corresponding IPsec configuration to connect to each additional branch device (SRX240).

```
[edit interfaces]
user@host# set gr-0/0/0 unit 0 clear-dont-fragment-bit
user@host# set gr-0/0/0 unit 0 tunnel source 10.1.1.1
user@host# set gr-0/0/0 unit 0 tunnel destination 10.1.1.2
user@host# set gr-0/0/0 unit 0 tunnel allow-fragmentation
user@host# set gr-0/0/0 unit 0 family inet mtu 1500
user@host# set gr-0/0/0 unit 0 family inet filter input inet-packet-mode
user@host# set gr-0/0/0 unit 0 family mpls filter input mpls-packet-mode
```

3. Configure a logical tunnel interface to stitch the CCC connection to the VPLS instance.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 0 description "VPLS hub port - Interconnect for CCC
   to SRX240"
user@host# set lt-0/0/0 unit 0 encapsulation ethernet-vpls
user@host# set lt-0/0/0 unit 0 peer-unit 1000
```

4. Set unit 1000 to terminate the CCC connection.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 1000 description "Stitch to VPLS for CCC to SRX240"
user@host# set lt-0/0/0 unit 1000 encapsulation ethernet-ccc
user@host# set lt-0/0/0 unit 1000 peer-unit 0
user@host# set lt-0/0/0 unit 1000 family ccc filter input ccc-packet-mode
```

5. Configure the logical tunnel interface.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 2000 encapsulation frame-relay
user@host# set lt-0/0/0 unit 2000 dlci 1
user@host# set lt-0/0/0 unit 2000 peer-unit 2001
user@host# set lt-0/0/0 unit 2000 family inet
```

6. Bind the logical tunnel interface to the default virtual router.

```
[edit interfaces]
user@host# set lt-0/0/0 unit 2001 encapsulation frame-relay
user@host# set lt-0/0/0 unit 2001 dlci 1
user@host# set lt-0/0/0 unit 2001 peer-unit 2000
user@host# set lt-0/0/0 unit 2001 family inet filter input inet-packet-mode
user@host# set lt-0/0/0 unit 2001 family inet address 10.1.1.1/32
```

7. Set the interface to the central office LAN network.

```
[edit interfaces]
user@host# set ge-0/0/1 unit 0
user@host# set ge-0/0/1 encapsulation ethernet-vpls
```

8. Set the loopback interface to terminate the CCC connections to each branch device.

```
[edit interfaces]
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set lo0 unit 0 family inet address 10.2.1.1/32
```

9. Bind the IPsec interface to the flow-mode virtual router.

```
[edit interfaces]
user@host# set st0 unit 0 family inet
```

10. Set a static route for the remote GRE tunnel endpoint.

```
[edit routing-options]
user@host# set static route 10.1.1.2/32 next-hop lt-0/0/0.2001
```

11. Set a static route for the loopback interface of the branch device.

```
[edit]
user@host# set routing-options static route 10.2.1.2/32 next-hop gr-0/0/0.0
```

12. Configure MPLS and CCC using LDP as the label protocol.

```
[edit protocols]
user@host# set mpls interface gr-0/0/0.0
user@host# set ldp interface gr-0/0/0.0
user@host# set ldp interface lo0.0
user@host# set l2circuit neighbor 10.2.1.2 interface lt-0/0/0.1000 virtual-circuit-id
  1
```

13. Configure the IPsec tunnel.

NOTE: The underlying IKE interface is not in the same routing instance as the tunnel interface.

```
[edit security]
user@host# set ike policy SRX mode main
user@host# set ike policy SRX proposal-set standard
user@host# set ike policy SRX pre-shared-key ascii-text "$ABC123"
user@host# set ike gateway SRX240-1 ike-policy SRX
user@host# set ike gateway SRX240-1 address 172.19.101.45
user@host# set ike gateway SRX240-1 external-interface ge-0/0/0.0
user@host# set ipsec policy SRX proposal-set standard
user@host# set ipsec vpn SRX240-1 bind-interface st0.0
user@host# set ipsec vpn SRX240-1 ike gateway SRX240-1
user@host# set ipsec vpn SRX240-1 ike ipsec-policy SRX
user@host# set ipsec vpn SRX240-1 establish-tunnels immediately
```

14. Configure security zones.

NOTE: In a production environment, restrict host-inbound traffic to only the necessary protocols and services.

```
[edit security]
user@host# set zones security-zone untrust host-inbound-traffic system-services
  all
user@host# set zones security-zone untrust host-inbound-traffic protocols all
user@host# set zones security-zone untrust interfaces lo0.0
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set zones security-zone untrust interfaces lt-0/0/0.2001
user@host# set zones security-zone untrust interfaces gr-0/0/0.0
user@host# set zones security-zone untrust interfaces ge-0/0/0.0
user@host# set zones security-zone vpn host-inbound-traffic system-services all
user@host# set zones security-zone vpn host-inbound-traffic protocols all
user@host# set zones security-zone vpn interfaces st0.0
user@host# set zones security-zone trust-flow host-inbound-traffic system-services
  all
user@host# set zones security-zone trust-flow host-inbound-traffic protocols all
user@host# set zones security-zone trust-flow interfaces lt-0/0/0.2000
```

15. Configure IDP.

```
[edit security]
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match
  source-address any
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match
  destination-address any
user@host# set policies from-zone trust-flow to-zone vpn policy GRE match
  application junos-gre
user@host# set policies from-zone trust-flow to-zone vpn policy GRE then permit
  application-services idp
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match
  source-address any
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match
  destination-address any
user@host# set policies from-zone vpn to-zone trust-flow policy GRE match
  application junos-gre
user@host# set policies from-zone vpn to-zone trust-flow policy GRE then permit
  application-services idp
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre match
  application junos-gre
user@host# set idp idp-policy gre-reassembly rulebase-ips rule match-gre then
  action ignore-connection
user@host# set idp active-policy gre-reassembly
```

16. Configure packet-mode filters.

```
[edit firewall]
user@host# set family inet filter inet-packet-mode term control-traffic from protocol
  tcp
user@host# set family inet filter inet-packet-mode term control-traffic from port
  22
user@host# set family inet filter inet-packet-mode term control-traffic from port
  80
user@host# set family inet filter inet-packet-mode term control-traffic from port
  8080
user@host# set family inet filter inet-packet-mode term control-traffic then accept
user@host# set family inet filter inet-packet-mode term packet-mode then
  packet-mode
user@host# set family inet filter inet-packet-mode term packet-mode then accept
user@host# set family mpls filter mpls-packet-mode term packet-mode then
  packet-mode
user@host# set family mpls filter mpls-packet-mode term packet-mode then accept
user@host# set family ccc filter ccc-packet-mode term all then packet-mode
user@host#set family ccc filter ccc-packet-mode term all then accept
```

Copyright © 2016, Juniper Networks, Inc.

17. Configure the flow-mode virtual router.

```
[edit routing-instances]
user@host# set flow-vr instance-type virtual-router
user@host# set flow-vr interface lt-0/0/0.2000
user@host# set flow-vr interface st0.0
user@host# set flow-vr routing-options static route 10.1.1.1/32 next-hop
  lt-0/0/0.2000
user@host# set flow-vr routing-options static route 10.1.1.2/32 next-hop st0.0
```

18. Configure the VPLS instance.

```
[edit routing-instances]
user@host# set vpls-hub instance-type vpls
user@host# set vpls-hub interface lt-0/0/0.0
user@host# set vpls-hub interface ge-0/0/1.0
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Interfaces on page 3888
- Verifying an IPsec tunnel on page 3888
- Verifying GRE on page 3888
- Verifying the CCC/L2 circuit. on page 3889
- Verifying that LDP sessions are working. on page 3889

Verifying Interfaces

Purpose Verify that the interfaces are configured properly on each device in the VPLS network.

Action From configuration mode, enter **show interfaces** and verify that the IP addressing is correct for each interface, including logical tunnel (lt), loopback (lo), GRE (gr), IPsec tunnel st0, and GE interfaces.

Verifying an IPsec tunnel

Purpose Verify that an IPsec tunnel is working.

Action From operational mode, enter the **show security ipsec security associations** and the **show security ipsec statistics** command.

Verifying GRE

Purpose Verify that GRE is working.

Copyright © 2016, Juniper Networks, Inc.

Action From operational mode, enter the **show security flow session protocol gre** command. You can also do a ping between loopback addresses.

Verifying the CCC/L2 circuit.

Purpose Verify that the CCC/L2 circuit is working.

Action From operational mode, enter the **show connections** command.

Verifying that LDP sessions are working.

Purpose Verify that LDP sessions are being created between devices.

Action From operational mode, enter the **show interfaces gr-0/0/0 detail** command.

Example: Configuring VPLS with BGP Signaling

This example shows how to configure VPLS with BGP signaling between two devices.

- Requirements on page 3889
- Overview on page 3889
- Configuration on page 3890
- Verification on page 3900

Requirements

Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.

Overview

This example shows a minimum configuration for PE devices and CE devices to create a VPLS network with BGP signaling. The topology consists of two PE devices and two CE devices. In this example, you configure a VPLS routing instance vpls-instance between two PE devices, PE1 and PE2. You also configure the CE1 and CE2 devices that use Ethernet-based interfaces to connect VLAN 600 to their local PE devices. On the CE1 device, configure the Fast Ethernet interface that connects to the PE1 device. The VLAN identifier and IP address must match those of the CE2 device.

Figure 151 shows the topology used in this example.

Copyright © 2016, Juniper Networks, Inc.

Configuration

- Configuring the CE1 Device on page 3890
- Configuring the PE1 Device on page 3891
- Configuring the PE2 Device on page 3895
- Configuring the CE2 Device on page 3899

Configuring the CE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces fe-0/0/3 vlan-tagging
```

Copyright © 2016, Juniper Networks, Inc.

```
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family inet address 10.11.3.1/24
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

   ```
   [edit interfaces fe-0/0/3]
   user@host# set vlan-tagging
   ```

2. Configure the VLAN ID on the logical interface.

   ```
   [edit interfaces fe-0/0/3 unit 0]
   user@host# set vlan-id 600
   ```

3. Configure the VPLS family on the logical interface.

   ```
   [edit interfaces fe-0/0/3 unit 0]
   user@host# set family inet address 10.11.3.1/24
   ```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {
    vlan-tagging;
    unit 0 {
        vlan-id 600;
        family inet {
            address 10.11.3.1/24;
        }
    }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE1 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system host-name PE1
set interfaces fe-0/0/3 description "CE1 on PE1"
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 encapsulation vlan-vpls

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE1:

1. Configure the hostname for the PE1 device.

```
[edit ]
user@host# set system host-name PE1
```

2. Configure VPLS VLAN encapsulation on the VPLS PE1 device.

```
[edit interfaces]
user@host# set fe-0/0/3 description "CE1 on PE1"
user@host# set fe-0/0/3 vlan-tagging
user@host# set fe-0/0/3 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
user@host# set fe-0/0/3 unit 0 vlan-id 600
user@host# set fe-0/0/3 unit 0 family vpls
```

3. Configure the routing interface on the VPLS PE1 device.

```
[edit interfaces]
user@host# set fe-0/0/5 vlan-tagging
user@host# set fe-0/0/5 unit 37 vlan-id 37
user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
user@host# set fe-0/0/5 unit 37 family mpls
user@host# set lo0 unit 0 family inet address 172.28.1.2/32
```

NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

Copyright © 2016, Juniper Networks, Inc.

4. Configure the routing options on the VPLS PE1 device.

```
[edit routing-options]
user@host# set router-id 172.28.1.2
user@host# set autonomous-system 65512
```

5. Configure RSVP on the VPLS PE1 device.

```
[edit protocols]
user@host# set rsvp interface fe-0/0/5.37
```

6. Configure MPLS on the VPLS PE1 device.

```
[edit protocols]
user@host# set mpls label-switched-path pe1-to-pe2 to 172.28.1.1
user@host# set mpls interface fe-0/0/5.37
user@host# set mpls interface lo0.0
```

7. Configure BGP on the VPLS PE1 device.

```
[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.2
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.1
```

8. (Optional) Configure OSPF on the VPLS PE1 device.

NOTE: For this example, it is optional to configure OFPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance from VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.2:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site10 automatic-site-id
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the PE2 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system host-name PE2
set interfaces fe-0/0/3 description "CE2 on PE2"
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 encapsulation vlan-vpls
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family vpls
set interfaces fe-0/0/5 vlan-tagging
set interfaces fe-0/0/5 unit 37 vlan-id 37
set interfaces fe-0/0/5 unit 37 family inet address 172.28.2.133/30
set interfaces fe-0/0/5 unit 37 family mpls
set interfaces lo0 unit 0 family inet address 172.28.1.1/32
set routing-options router-id 172.28.1.1
set routing-options autonomous-system 65512
set protocols rsvp interface fe-0/0/5.37
set protocols mpls label-switched-path pe2-to-pe1 to 172.28.1.2
```

Copyright © 2016, Juniper Networks, Inc.

```
set protocols mpls interface fe-0/0/5.37
set protocols mpls interface lo0.0
set protocols bgp group vpls-peering type internal
set protocols bgp group vpls-peering local-address 172.28.1.1
set protocols bgp group vpls-peering family l2vpn signaling
set protocols bgp group vpls-peering neighbor 172.28.1.2
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface fe-0/0/5.37
set routing-instances vpls-instance description "Routing instance for VPLS routing"
set routing-instances vpls-instance instance-type vpls
set routing-instances vpls-instance interface fe-0/0/3.0
set routing-instances vpls-instance route-distinguisher 172.28.1.1:1
set routing-instances vpls-instance vrf-target target:65512:1
set routing-instances vpls-instance protocols vpls site-range 10
set routing-instances vpls-instance protocols vpls no-tunnel-services site site11
  automatic-site-id
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure PE2:

1. Configure the hostname for the device.

   ```
   [edit ]
   user@host# set system host-name PE2
   ```

2. Configure VPLS VLAN encapsulation on the VPLS PE2 device.

   ```
   [edit interfaces]
   user@host# set fe-0/0/3 description "CE2 on PE2"
   user@host# set fe-0/0/3 vlan-tagging
   user@host# set fe-0/0/3 encapsulation vlan-vpls
   user@host# set fe-0/0/3 unit 0 encapsulation vlan-vpls
   user@host# set fe-0/0/3 unit 0 vlan-id 600
   user@host# set fe-0/0/3 unit 0 family vpls
   ```

3. Configure the routing interface on the VPLS PE2 device.

   ```
   [edit interfaces]
   user@host# set fe-0/0/5 vlan-tagging
   user@host# set fe-0/0/5 unit 37 vlan-id 37
   user@host# set fe-0/0/5 unit 37 family inet address 172.28.2.133/30
   user@host# set fe-0/0/5 unit 37 family mpls
   user@host# set lo0 unit 0 family inet address 172.28.1.1/32
   ```

   NOTE: For this example, it is optional to configure VLAN tagging. Remove the VLAN tagging configuration on the physical interfaces if you do not plan to configure VLAN tagging.

4. Configure the routing options on the VPLS PE2 device.

   ```
   [edit routing-options]
   user@host# set router-id 172.28.1.1
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set autonomous-system 65512
```

5. Configure RSVP on the VPLS PE2 device.

```
[edit protocols]
user@host# set rsvp interface fe-0/0/5.37
```

6. Configure MPLS on the VPLS PE2 device.

```
[edit protocols]
user@host# set mpls label-switched-path pe2-to-pe1 to 172.28.1.2
user@host# set mpls interface fe-0/0/5.37
user@host# set mpls interface lo0.0
```

7. Configure BGP on the VPLS PE2 device.

```
[edit protocols]
user@host# set bgp group vpls-peering type internal
user@host# set bgp group vpls-peering local-address 172.28.1.1
user@host# set bgp group vpls-peering family l2vpn signaling
user@host# set bgp group vpls-peering neighbor 172.28.1.2
```

8. (Optional) Configure OSPF on the VPLS PE2 device.

NOTE: For this example, it is optional to configure OFPF. You must configure OSPF only in cases where two PE devices are not connected directly.

```
[edit protocols]
user@host# set ospf area 0.0.0.0 interface lo0.0 passive
user@host# set ospf area 0.0.0.0 interface fe-0/0/5.37
```

9. Create a VPLS routing instance.

```
[edit ]
user@host# set routing-instances vpls-instance
```

10. Configure a VPLS routing instance.

```
[edit routing-instances vpls-instance]
user@host# set description "Routing instance for VPLS routing"
user@host# set instance-type vpls
user@host# set interface fe-0/0/3.0
user@host# set route-distinguisher 172.28.1.1:1
user@host# set vrf-target target:65512:1
user@host# set protocols vpls site-range 10
user@host# set protocols vpls no-tunnel-services site site11 automatic-site-id
```

Results From configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

        automatic-site-id;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Configuring the CE2 Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces fe-0/0/3 vlan-tagging
set interfaces fe-0/0/3 unit 0 vlan-id 600
set interfaces fe-0/0/3 unit 0 family inet address 10.11.3.2/24
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

1. Enable VLAN tagging on the VPLS interface.

   ```
   [edit interfaces fe-0/0/3]
   user@host# set vlan-tagging
   ```

2. Configure the VLAN ID on the logical interface.

   ```
   [edit interfaces fe-0/0/3 unit 0]
   user@host# set vlan-id 600
   ```

3. Configure the VPLS family on the logical interface.

   ```
   [edit interfaces fe-0/0/3 unit 0]
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set family inet address 10.11.3.2/24
```

Results From configuration mode, confirm your configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
fe-0/0/3 {
  vlan-tagging;
  unit 0 {
    vlan-id 600;
    family inet {
      address 10.11.3.2/24;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: If VLAN trunking is not needed between the CE devices, remove the configuration on VLAN tagging on the interfaces connecting the CE and PE devices. Also, use ethernet-VPLS-encapsulation instead of vlan-vpls on the CE facing interfaces of the PE devices.

Verification

Confirm that the configuration is working properly.

- Verifying Interfaces on page 3900
- Verifying Routing Information on page 3900
- Verifying VPLS Information on page 3901
- Verifying Automatic Site Identifier Generation on page 3901

Verifying Interfaces

Purpose Verify that the interfaces are configured correctly.

Action From operational mode, enter the **show interfaces terse** command.

Verifying Routing Information

Purpose Verify that the routing information is configured correctly.

Action From operational mode, enter the following commands:

- **show route forwarding-table family mpls**
- **show route forwarding-table family vpls (destination | extensive | matching | table)**
- **show route instance (detail)**

Copyright © 2016, Juniper Networks, Inc.

Verifying VPLS Information

Purpose Verify that the VPLS is configured correctly.

Action From operational mode, enter the following commands:

- **show system statistics vpls**
- **show vpls connections**
- **show vpls statistics**

Verifying Automatic Site Identifier Generation

Purpose Verify that the automatic site identifier has been generated.

Action From operational mode, enter the **show vpls connections** command.

```
[edit]
user@host# show vpls connections

Example: Configuring BGP on the VPLS PE Router

This example shows how to configure BGP on the VPLS PE router.

- Requirements on page 3902
- Overview on page 3902
- Configuration on page 3903
- Verification on page 3903

Requirements

Before you begin:

- See "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.
- Configure RSVP-TE. See "Example: Configuring RSVP on the VPLS PE Router" on page 3868. Then configure MPLS LSPs on the PE routers. See "Example: Configuring MPLS on the VPLS PE Router" on page 3869. Alternatively, configure LDP on the PE routers. See "Example: Configuring LDP on the VPLS PE Router" on page 3871.
- Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 3903.

Overview

In this example, you configure an internal BGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. The PE routers use this information to determine which labels to use for traffic destined for remote sites.

Copyright © 2016, Juniper Networks, Inc.

NOTE: On all high-end SRX Series devices, BGP-based virtual private LAN service (VPLS) works on child ports and physical interfaces, but not over aggregated Ethernet (ae) interfaces.

Configuration

Step-by-Step Procedure

To configure BGP on the VPLS PE router:

1. Configure the BGP internal group on the VPLS PE router.

   ```
   [edit ]
   user@host# set protocols bgp group ibgp type internal local-address 10.255.7.168
     neighbor 10.255.7.164
   ```

2. Configure the BGP family L2vpn and specify NLRI signaling.

   ```
   [edit ]
   user@host# set protocols bgp family L2 VPN signaling
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show protocols** command.

Related Documentation

- VPLS Configuration Overview on page 3846

Example: Configuring Routing Options on the VPLS PE Router

This example shows how to configure the routing options on the VPLS PE router.

- Requirements on page 3903
- Overview on page 3904
- Configuration on page 3904
- Verification on page 3904

Requirements

Before you begin:

- Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See"Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.

Copyright © 2016, Juniper Networks, Inc.

- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867
- Configure RSVP-TE, see "Example: Configuring RSVP on the VPLS PE Router" on page 3868 and then MPLS LSPs on the PE routers, see "Example: Configuring MPLS on the VPLS PE Router" on page 3869. Alternatively configure LDP on the PE routers, see "Example: Configuring LDP on the VPLS PE Router" on page 3871.

Overview

This example describes how to specify the router ID and the AS number for each router involved in the VPLS . In this example, the routers PE1 and PE2 use the same AS number (100).

Configuration

Step-by-Step Procedure

To configure the routing options on the VPLS PE router:

1. Configure the router ID on the VPLS PE router.

   ```
   [edit]
   user@host# set routing-options router-id 10.255.7.168
   ```

2. Configure the AS number on the VPLS PE router.

   ```
   [edit]
   user@host# set routing-options autonomous-system 100
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show routing-options** command.

Understanding VPLS VLAN Encapsulation

Gigabit Ethernet IQ, Gigabit Ethernet PIMs with small form-factor pluggable optics (SFPs), SRX Series devices with Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with VLAN tagging enabled can use flexible Ethernet services, VLAN virtual private LAN service (VPLS) encapsulation.

NOTE: **VLAN encapsulation is not supported on SRX100 devices because there is no Gigabit Ethernet port.**

Aggregated Ethernet interfaces configured for VPLS can use Ethernet VPLS or VLAN VPLS.

To configure the encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface, include the **encapsulation** statement at the **[edit interfaces interface-name]** hierarchy level, specifying **vlan-ccc** or **vlan-vpls**:

[edit interfaces *interface-name*] encapsulation (vlan-ccc | vlan-vpls);

To configure the encapsulation on an aggregated Ethernet interface, include the encapsulation statement at the **[edit interfaces *interface-name*]** hierarchy level, specifying **ethernet-vpls** or **vlan-vpls**:

[edit interfaces interface-name] encapsulation (ethernet-vpls | vlan-vpls);

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In CCC and VPLS modes, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512

Copyright © 2016, Juniper Networks, Inc.

through 4094 are reserved for CCC or VPLS VLANs. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for CCC or VPLS VLANs.

Understanding VPLS VLAN Encapsulation on a Logical Interface

You cannot configure a logical interface with VLAN VLAN VPLS encapsulation unless you also configure the physical device with the same encapsulation or with flexible Ethernet services encapsulation. In general, the logical interface must have a VLAN ID of 512 or higher; if the VLAN ID is 511 or lower, it will be subject to the normal destination filter lookups in addition to source address filtering. However if you configure flexible Ethernet services encapsulation, this VLAN ID restriction is removed.

Ethernet interfaces in VLAN mode can have multiple logical interfaces. In VPLS mode, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for VPLS VLAN. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for VPLS VLAN.

For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.

Requirements

Before you begin:

- Before you begin, see "Understanding Selective Stateless Packet-Based Services" on page 1804.
- Configure the interfaces that will carry the VPLS traffic between the PE router and the CE devices. See "Example: Configuring Routing Interfaces on the VPLS PE Router" on page 3851 and "Example: Configuring the Interface to the VPLS CE Device" on page 3852.
- Create a VPLS routing instance on each PE router that is participating in the VPLS. See "Example: Configuring the VPLS Routing Instance" on page 3862.
- Configure an IGP on the PE routers to exchange routing information. See "Example: Configuring OSPF on the VPLS PE Router" on page 3867.
- Configure RSVP-TE, see "Example: Configuring RSVP on the VPLS PE Router" on page 3868 and then MPLS LSPs on the PE routers, see "Example: Configuring MPLS on the VPLS PE Router" on page 3869. Alternatively configure LDP on the PE routers, see "Example: Configuring LDP on the VPLS PE Router" on page 3871.
- Configure routing options on the PE router. See "Example: Configuring Routing Options on the VPLS PE Router" on page 3903.
- Configure an IBGP session between PE routers so that the routers can exchange information about routes originating and terminating in the VPLS. See "Example: Configuring BGP on the VPLS PE Router" on page 3902.

Overview

This example describes how to enable VLAN tagging on VPLS interface ge-3/0/6, configure the encapsulation type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: Perform the following CLI quick configuration and procedures on all of the PE interfaces (CE facing).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 encapsulation vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 512
set interfaces ge-3/0/6 unit 0 family vpls
```

Copyright © 2016, Juniper Networks, Inc.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set vlan-tagging
   ```

2. Configure the encapsulation type on the physical interface.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
   ```

3. Configure the encapsulation type on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set encapsulation vlan-vpls
   ```

4. Configure the VLAN ID on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set vlan-id 512
   ```

5. Configure the family VPLS on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set family vpls
   ```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces ge-3/0/6
vlan-tagging;
encapsulation vlan-vpls;
unit 0 {
   encapsulation vlan-vpls;
   vlan-id 512;
   family vpls;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying VPLS VLAN Encapsulation on page 3908

Overview

This example describes how to configure Ethernet VPLS encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface and enable the VPLS family on the interface.

Configuration

Step-by-Step Procedure

To configure VPLS VLAN encapsulation on a Gigabit Ethernet IQ or Gigabit Ethernet physical interface:

1. Configure the ethernet-vpls encapsulation on the interface.

   ```
   [edit ]
   user@host# set interfaces ge-3/0/6 encapsulation ethernet-vpls
   ```

2. Enable the VPLS family on the interface.

   ```
   [edit ]
   user@host# set interfaces ge-3/0/6 unit 0 family vpls
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, enter the **show interfaces** command.

Overview

This example describes how to enable VLAN tagging on the VPLS interface ge-3/0/6, configure the extended-vlan-vpls type on the physical and logical interfaces, and configure the VPLS family on the logical interface.

NOTE: Perform the following CLI quick configurations and procedures on all PE interfaces (CE facing).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-3/0/6 vlan-tagging
set interfaces ge-3/0/6 encapsulation extended-vlan-vpls
set interfaces ge-3/0/6 unit 0 vlan-id 100
set interfaces ge-3/0/6 unit 0 family vpls
```

Copyright © 2016, Juniper Networks, Inc.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure extended VPLS VLAN encapsulation:

1. Enable VLAN tagging on the VPLS interface as it will receive tagged packets from CE.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set vlan-tagging
   ```

2. Configure the encapsulation type on the physical interface.

   ```
   [edit interfaces ge-3/0/6]
   user@host# set interfaces ge-3/0/6 encapsulation vlan-vpls
   ```

3. Configure the VLAN ID on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set encapsulation vlan-vpls vlan-id 100
   ```

4. Configure the VPLS family on the logical interface.

   ```
   [edit interfaces ge-3/0/6 unit 0]
   user@host# set family vpls
   ```

Results

From configuration mode, confirm your configuration by entering the **show interfaces ge-3/0/6** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces ge-3/0/6
vlan-tagging;
encapsulation extended-vlan-vpls;
unit 0 {
   encapsulation vlan-vpls;
   vlan-id 100;
   family vpls;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying Extended VLAN VPLS Encapsulation on page 3912

Forwarding-Options Configuration Statement Hierarchy

Use the statements in the **forwarding-options** configuration hierarchy to configure forwarding options including protocol family, flow monitoring, accounting properties, load-balancing, port mirroring, traffic sampling, and packet capture.

```
forwarding-options {
  accounting group-name {
    output {
      aggregate-export-interval seconds;
      cflowd hostname {
        aggregation {
          autonomous-system;
          destination-prefix;
          protocol-port;
          source-destination-prefix {
            caida-compliant;
          }
          source-prefix;
        }
        autonomous-system-type (origin | peer);
        port port-number;
        version (5 | 8);
      }
```

```
      flow-active-timeout seconds;
      flow-inactive-timeout seconds;
      interface interface-name {
        engine-id number;
        engine-type number;
        source-address ip-address;
      }
    }
  }

Interfaces Configuration Statement Hierarchy

Use the statements in the **interfaces** configuration hierarchy to configure interfaces on the device.

Copyright © 2016, Juniper Networks, Inc.

NOTE: For a gigabit ethernet interface, the **gigether-options** and **ether-options** are identical, but only the **gigether-options** are documented.

```
interfaces {
  interface-name {
    accounting-profile name;
    clocking (external | internal);

Policy-Options Configuration Statement Hierarchy

Use the statements in the **policy-options** configuration hierarchy to configure routing policies that control information from routing protocols that the device imports into its routing table and exports to its neighbors.

```
policy-options {
  application-maps application-map-name{
    application application-name;
      code-points [value ];
    }
  }
  as-path aspath-name {
    as-path-regular-expression;
    dynamic-db ;
  }
  as-path-group group-name {
    as-path as-path-name {
      as-path-regular-expression;;
    }
    dynamic-db;
  }
  community community-name {
    dynamic-db;
    invert-match;
    members [value];
  }
  condition condition-name {
    dynamic-db;
    if-route-exists {
      address;
      table table-name;
    }
    route-active-on (node0 | node1);
  }
  damping name {
    disable;
    half-life minutes;
    max-supress minutes;
    reuse number;
    suppress number;
  }
```

condition (Policy Options)

Syntax

```
condition condition-name {
  dynamic-db;
  if-route-exists {
    address;
    table table-name;
  }
  route-active-on (node0 | node1);
}
```

Hierarchy Level [edit policy-options]

Release Information Statement introduced in Junos OS Release 9.0.

Description For chassis cluster configurations, specify the match condition for use in routing to a redundant Ethernet (**reth**) interface.

Options ***condition-name*** —Name of the routing policy match condition.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

family (Security Forwarding Options)

Syntax

```
family {
  inet6 {
    mode (drop | flow-based | packet-based);
  }
  iso {
    mode packet-based;
  }
  mpls {
    mode packet-based;
  }
}
```

Hierarchy Level [edit security forwarding-options]

Release Information Statement introduced in Junos OS Release 8.5 .

Description Determine the protocol family to be used for packet forwarding.

NOTE: Packet-based processing is not supported on the following SRX Series devices: SRX5400, SRX5600, and SRX5800.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level
security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation

flow-server (Forwarding Options)

Syntax

```
flow-server ip-address-or-host-name {
  aggregation {
    autonomous-system;
    destination-prefix;
    protocol-port;
    source-destination-prefix {
      caida-compliant;
    }
    source-prefix;
  }
  autonomous-system-type (origin | peer);
  (local-dump | no-local-dump);
  port port-number;
  source-address ip-address;
  version (5 | 500 |8);
  version9 {
    template template-name;
  }
}
```

Hierarchy Level

[edit forwarding-options sampling family inet output]
[edit forwarding-options sampling family inet6 output]

Release Information

Statement introduced in Junos OS Release 10.4. Support for family inet6 added in Junos OS Release 12.1X45-D10.

Description

Configure sending traffic aggregates in cflowd format.

Options

- **aggregation (version 8 only**—Aggregations to perform for exported flows.
- **autonomous-system-type**—Type of autonomous system number to export.
- **local-dump**—Dump cflowd records to log file before exporting.
- **no-local-dump**—Do not dump cflowd records to log file before exporting.
- **port**—UDP port number on host collecting cflowd packets.
- **source-address**—Source IPv4/IPv6 address for cflowd packets.

NOTE: The flow server may be IPv4 or IPv6 when you configure the collector IP address using the **set forwarding-options sampling family inet flow server** command, but only IPv4 sampling is achieved.

The flow server may be IPv4 or IPv6 when you configure the collector IP address using the **set forwarding-options sampling family inet6 flow server** command, but only IPv6 sampling is achieved.

- **version**—Format of exported cflowd aggregates.

Copyright © 2016, Juniper Networks, Inc.

- **version9**—Exported data in version 9 format.

Required Privilege Level

security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

forwarding-options (Security)

Syntax

```
forwarding-options {
  family {
    inet6 {
      mode (drop | flow-based | packet-based);
    }
    iso {
      mode packet-based;
    }
    mpls {
      mode packet-based;
    }
  }
}
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5 .

Description Determine how the **inet6, iso**, and **mpls** protocol families manage security forwarding options.

NOTE:

- Packet-based processing is not supported on the following SRX Series devices: SRX5400, SRX5600, and SRX5800.
- On SRX Series devices, the default mode for processing traffic is flow mode. To configure an SRX Series device as a border router, you must change the mode from flow-based processing to packet-based processing. Use the **set security forwarding-options family mpls mode packet-based** statement to configure the SRX device to packet mode. You must reboot the device for the configuration to take effect.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

hash-key (Forwarding Options)

Syntax

```
hash-key {
  family inet {
    layer-3;
    layer-4;
    session-id;
  }
  family mpls {
    label-1;
    label 2;
    label-3;
    no-labels;
    payload {
      ip {
        layer-3-only;
        port-data {
          destination-lsb;
          destination-msb;
          source-lsb;
          source-msb;
        }
      }
    }
  }
  family multiservice {
    destination-mac;
    source-mac;
  }
}
```

Hierarchy Level [edit forwarding-options]

Release Information Statement modified in Junos OS Release 10.2.

Description Select which packet header data to use for per-flow load balancing.

Options

- **inet**—IPv4 protocol family.
- **mpls**—MPLS protocol family.
- **layer-3**—Incorporate Layer 3 data into the hash key.
- **layer-4**—Incorporate Layer 4 data into the hash key.
- **session-id**—Incorporate session ID data into the hash key (SRX3000 and SRX5000 lines only). The session ID data has higher precedence than the Layer 3 or 4 information.
- **label-1**—Incorporate the first MPLS label into the hash key.
- **label-2**—Incorporate the second MPLS label into the hash key.
- **label-3**—Incorporate the third MPLS label into the hash key.
- **no-labels**—Include no MPLS labels into the hash key.

Copyright © 2016, Juniper Networks, Inc.

- **payload**—Incorporate payload data into the hash key.
- **ip**—Include the IP address of the IPv4 or IPv6 payload into the hash key.
- **layer-3–only**—Include only Layer 3 IP information.
- **port-data**—Include the source and destination port field information.
- **source-msb**—Include the most significant byte of the source port.
- **source-lsb**—Include the least significant byte of the source port.
- **destination-msb**—Include the most significant byte of the destination port.
- **destinatione-lsb**—Include the least significant byte of the destination port.
- **source-mac**—Include source MAC address in hash key.
- **destinatione-mac**—Include destination MAC address in hash key.

Required Privilege Level
system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

iso (Security Forwarding Options)

Syntax

```
iso {
  mode packet-based;
}
```

Hierarchy Level
[edit security forwarding-options family]

Release Information
Statement introduced in Junos OS Release 8.5.

Description
Enable the forwarding of IS-IS traffic. By default, the device drops IS-IS traffic.

NOTE: Junos OS security processing is not applied to IS-IS packets forwarded by the device.

NOTE: Packet-based processing is not supported on the following SRX Series devices: SRX1500, SRX5600, and SRX5800.

Required Privilege Level
security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation
- [edit security forwarding-options] Hierarchy Level on page 3006

Copyright © 2016, Juniper Networks, Inc.

mpls (Security Forwarding Options)

Syntax

```
mpls {
  mode packet-based;
}
```

Hierarchy Level [edit security forwarding-options family]

Release Information Statement introduced in Junos OS Release 9.0.

Description Enable the forwarding of MPLS traffic. By default, the device drops MPLS traffic.

CAUTION: Because MPLS operates in packet mode, security services are not available.

NOTE: Packet-based processing is not supported on the following SRX Series devices: SRX1500, SRX5600, and SRX5800.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

Related Documentation

- MPLS Overview on page 3743

multicast-scope

Syntax multicast-scope (*scope-value* | global | link-local | node-local | organization-local | orhigher | orlower | site-local);

Hierarchy Level [edit policy-options policy-statement *policy-name* from]

Release Information Statement introduced in Junos OS Release 9.5.

Description Configure multicast scoping to match the routing policy.

Options

- ***scope-value* <orhigher | orlower>**—The multicast-scope value is a number from 0 through 15.
- **global <orhigher | orlower>**—Global multicast scope
- **link-local <orhigher | orlower>**—Link-local scope
- **node-local <orhigher | orlower>**—Node-local scope
- **organization-local <orhigher | orlower>**—Organizational-local scope
- **orhigher**—Match on numerically higher scopes
- **orlower**—Match on numerically lower scopes
- **site-local <orhigher | orlower>**—Site-local values

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

policer (Firewall)

Syntax

```
policer policer-name {
  filter-specific;
  if-exceeding {
    (bandwidth-limit bps | bandwidth-percent percentage);
    burst-size-limit bytes;
  }
  logical-interface-policer;
  then {
    discard;
    forwarding-class forwarding-class-name;
    loss-priority (high | low |medium-high |medium-low);
    out-of-profile;
  }
}
```

Hierarchy Level [edit firewall]

Release Information Command introduced in Junos OS Release 9.5.

Description Configure policer rate limits and actions. To activate a policer, you must include the policer action modifier in the **then** statement in a firewall filter term or on an interface.

Options

- ***policer-name***—Name of the policer to evaluate when packets are received on the interface
- **bandwidth-limit *bps***—Specify the bandwidth limit as a number of bits per second
- **bandwidth-percent *percentage***—Specify the bandwidth limit in percentage value
- **burst-size-limit *bytes***—Specify the burst size limit as a number of bytes
- **filter-specific**— Specify that policer is filter-specific
- **logical-interface-policer**— Specify that policer is logical interface policer
- **discard**—Always discard non conforming red packets.
- **forwarding-class *classname***—Specify the particular forwarding class
- **loss-priority**—Set the loss priority to high or low
- **out-of-profile**— Discard packets only if both congested and over threshold

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Firewall Configuration Statement Hierarchy on page 3919

simple-filter (Firewall)

Syntax

```
simple-filter filter-name {
  term term-name {
    from {
      match-conditions;
    }
    then {
      (accept | discard);
      forwarding-class class-name;
      policer policer-name;
      three-color-policer policer-name {
        (single-rate single-rate-policer-name | two-rate two-rate-policer-name);
      }
    }
  }
}
```

Hierarchy Level [edit firewall family *family-name*]

Release Information Statement introduced in Junos OS Release 9.5.

Description Define a simple filter. Simple filters are recommended for metropolitan Ethernet applications.

Options

- **from**—Match packet fields to values. If the **from** option is not included, all packets are considered to match and the actions and action modifiers in the **then** statement are taken.
- **match-conditions**—One or more conditions to use to make a match.
- ***term-name***—Name that identifies the term. The name can contain letters, numbers, and hyphens (-), and can be up to 255 characters long. To include space in the name, enclose it in quotation marks (“ ”).
- **then**—Actions to take on matching packets. If the then option is not included and a packet matches all the conditions in the from statement, the packet is accepted.

NOTE: On SRX1400, SRX3400, and SRX3600 devices, the Forwarding class as match condition feature is not supported by a simple filter.

NOTE: SRX3400 and SRX3600 devices have the following limitations of a simple filter:

- The forwarding class is the match condition.
- In the packet processor on an IOC, up to 400 logical interfaces can be applied with simple filters.

Copyright © 2016, Juniper Networks, Inc.

- In the packet processor on an IOC, the maximum number of terms of all simple filters is 2000.
- In the packet processor on an IOC, the maximum number of policers is 2000
- In the packet processor on an IOC, the maximum number of three-color-policers is 2000
- The maximum burst size of a policer or three-color-policer is 16 MB.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

template (Flow Monitoring)

Syntax

```
template template-name {
  flow-active-timeout seconds;
  flow-inactive-timeout seconds;
  ipv4-template;
  ipv6-template;
  option-refresh-rate {
    packets packets;
    seconds seconds;
  }
  template-refresh-rate {
    packets packets;
    seconds seconds;
  }
}
```

Hierarchy Level [edit services flow-monitoring version9]

Release Information Statement introduced in Junos OS Release 10.4. Support for family inet6 added in Junos OS Release 12.1X45-D10.

Description Specify one or more version 9 templates.

Options

- **flow-active-timeout**—Interval after which active flow is exported. The range is from 10 through 600. The default value is 60.
- **flow-inactive-timeout**—Period of inactivity that marks a flow inactive. The range is from 10 through 600. The default value is 60.
- **ipv4-template**—IPv4 template configuration.
- **ipv6-template**—IPv6 template configuration.
- **option-refresh-rate**—Rate at which the device sends options. The range is from 1 through 480,000. The default value is 4800.
  - **packets**—Specify the number of packets. The range is from 1 through 480,000.
  - **seconds**—Specify the number of seconds. The range is from 10 through 600.
- **template-refresh-rate**—Rate at which the device sends template definitions. The range is from 1 through 480,000. The default value is 4800.
  - **packets**—Specify the number of packets. The range is from 1 through 480,000.
  - **seconds**—Specify the number of seconds. The range is from 10 through 600.

Required Privilege Level services—To view this statement in the configuration.
services-control—To add this statement to the configuration.

traceoptions (Security Flow)

Syntax

```
traceoptions {
  file {
    filename;
    files number;
    match regular-expression;
    size maximum-file-size;
    (world-readable | no-world-readable);
  }
  flag flag;
  no-remote-trace;
  packet-filter filter-name {
    destination-port port-identifier;
    destination-prefix address;
    interface interface-name;
    protocol protocol-identifier;
    source-port port-identifier;
    source-prefix address;
  }
  rate-limit messages-per-second;
  trace-level (brief | detail | error);
}
```

Hierarchy Level [edit security flow]

Release Information Statement introduced in Junos OS Release 8.5. Statement updated in Junos OS Release 12.1X46-D10 with the **trace-level** option and additional flags.

Description Configure flow tracing options.

Options **file**—Configure the trace file options.

filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. By default, the name of the file is the name of the process being traced.

files *number*—Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed to ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option and a filename.

Range: 2 through 1000 files

Default: 10 files

match *regular-expression*—Refine the output to include lines that contain the regular expression.

size *maximum-file-size*—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the **trace-file** again reaches its maximum size,

Copyright © 2016, Juniper Networks, Inc.

trace-file*.0** is renamed ***trace-file*.1** and ***trace-file is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.

Syntax: ***x* K** to specify KB, ***x* m** to specify MB, or ***x* g** to specify GB

Range: 0 KB through 1 GB

Default: 128 KB

Copyright © 2016, Juniper Networks, Inc.

world-readable | no-world-readable—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

flag—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.

all—Trace with all flags enabled

basic-datapath—Trace basic packet flow activity

fragmentation—Trace IP fragmentation and reassembly events

high-availability—Trace flow high-availability information

host-traffic—Trace flow host traffic information

multicast—Trace multicast flow information

route—Trace route lookup information

session—Trace session creation and deletion events

session-scan—Trace session scan information

tcp-basic—Trace TCP packet flow information

tunnel—Trace tunnel information

no-remote-trace—Set remote tracing as disabled.

packet-filter ***filter-name***—Packet filter to enable during the tracing operation. Configure the filtering options.

destination-port ***port-identifier***—Match TCP/UDP destination port

destination-prefix ***address***—Destination IP address prefix

interface ***interface-name***—Logical interface

protocol ***protocol-identifier***—Match IP protocol type

source-port ***port-identifier***—Match TCP/UDP source port

source-prefix ***address***—Source IP address prefix

rate-limit ***messages-per-second***—Limit the incoming rate of trace messages.

Copyright © 2016, Juniper Networks, Inc.

trace-level—Set the level for trace logging. This option is available only when the flag is set.

brief—Trace key flow information, such as message types sent between SPU and central point, policy match, and packet drop reasons.

detail—Trace extensive flow information, such as detailed information about sessions and fragments. Detail is the default level.

error—Trace error information, such as system failure, unknown message type, and packet drop.

Required Privilege Level
trace—To view this statement in the configuration.
trace-control—To add this statement to the configuration.

version9 (Flow Server)

Syntax

```
version9 {
  template template-name;
}
```

Hierarchy Level
[edit forwarding-options sampling family inet output flow-server *ip-address*]
[edit forwarding-options sampling family inet6 output flow-server *ip-address*]

Release Information
Statement introduced in Junos OS Release 10.4. Support for family inet6 added in Junos OS Release 12.1X45-D10.

Description
Export data in version 9 format.

Options
- **apply-groups**—Groups from which to inherit configuration data.
- **apply-groups-except**—Do not inherit configuration data from these groups.
- **template**—Template configuration.

Required Privilege Level
security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

show bgp neighbor (View)

Syntax **show bgp neighbor**
< *neighbor-address*>
<**instance** *instance* >

Release Information Command modified in Junos OS Release 8.5.

Description Display the state of the specified Border Gateway Protocol (BGP) neighbor. If a peer is forced to Idle state because of license check failure, the output displays the state and the reason—**LicenseCheckFailed**.

Options
- **instance** ***instance***—(Optional) Display peer information for a particular routing instance.
- ***neighbor-address***—(Optional) Display information for only the BGP peer at the specified IP address.

Required Privilege Level view

Related Documentation
- MPLS Overview on page 3743

List of Sample Output
show bgp neighbor 5.5.5.2 on page 3988
show bgp neighbor instance master on page 3989

Output Fields Table 374 lists the output fields for the **show bgp neighbor** command. Output fields are listed in the approximate order in which they appear.

Table 374: show bgp neighbor Output Fields

Field Name	Field Description
Peer	Address of the BGP neighbor. The address is followed by the neighbor's port number.
AS	AS number of the peer.
Local	Address of the local device. The address is followed by the peer's port number.
Type	Type of peer: Internal or External.
State	Current state of the BGP session: • **Active**—BGP is initiating a transport protocol connection in an attempt to connect to a peer. If the connection is successful, BGP sends an open message. • **Connect**—BGP is waiting for the transport protocol connection to complete. • **Established**—The BGP session has been established, and the peers are exchanging update messages. • **Idle**—Either the BGP license check failed, or this is the first stage of a connection and BGP is waiting for a Start event. • **OpenConfirm**—BGP has acknowledged receipt of an open message from the peer and is waiting to receive a keepalive or notification message. • **OpenSent**—BGP has sent an open message and is waiting to receive an open message from the peer.

Copyright © 2016, Juniper Networks, Inc.

Table 374: show bgp neighbor Output Fields *(continued)*

Field Name	Field Description
Flags	Internal BGP flags: • **Aggregate Label**—BGP has aggregated a set of incoming labels (labels received from the peer) into a single forwarding label. • **CleanUp**—The peer session is being shut down. • **Delete**—This peer has been deleted. • **Idled**—This peer has been permanently idled. • **Initializing**—The peer session is initializing. • **SendRtn**—Messages are being sent to the peer. • **Sync**—This peer is synchronized with the rest of the peer group. • **TryConnect**—Another attempt is being made to connect to the peer. • **Unconfigured**—This peer is not configured. • **WriteFailed**—An attempt to write to this peer failed. • **Last State**—Previous state of the BGP session.
Last State	Previous state of the BGP session.
Last Event	Last activity that occurred in the BGP session: • **Closed**—The BGP session closed. • **ConnectRetry**—The transport protocol connection failed, and BGP is trying again to connect. • **HoldTime**—The session ended because the hold timer expired. • **KeepAlive**—The local device sent a BGP keepalive message to the peer. • **Open**—The local device sent a BGP open message to the peer. • **OpenFail**—The local device did not receive an acknowledgment of a BGP open message from the peer. • **RecvKeepAlive**—The local device received a BGP keepalive message from the peer. • **RecvNotify**—The local device received a BGP notification message from the peer. • **RecvOpen**—The local device received a BGP open message from the peer. • **RecvUpdate**—The local device received a BGP update message from the peer. • **Start**—The peering session started. • **Stop**—The peering session stopped. • **TransportError**—A TCP error occurred.
Last Error	Last error that occurred in the BGP session: • **Cease**—An error occurred, such as a version mismatch, that caused the session to close. • **Finite State Machine Error**—In setting up the session, BGP received a message that it did not understand. • **Hold Time Expired**—The session's hold time expired. • **Message Header Error**—The header of a BGP message was malformed. • **Open Message Error**—A BGP open message contained an error. • **None**—No errors occurred in the BGP session. • **Update Message Error**—A BGP update message contained an error.
Export	Name of the export policy that is configured on the peer.
Import	Name of the import policy that is configured on the peer.

Copyright © 2016, Juniper Networks, Inc.

Table 374: show bgp neighbor Output Fields *(continued)*

Field Name	Field Description
Options	Configured BGP options: • **AddressFamily**—Configured address family: inet or inet-vpn. • **GracefulRestart**—Graceful restart is configured. • **HoldTime**—Hold time configured with the **hold-time** statement. The hold time is three times the interval at which keepalive messages are sent. • **Local Address**—Address configured with the **local-address** statement. • **NLRI**—Configured multicast BGP state for the BGP group: multicast, unicast, or both if you have configured **nlri any**. • **Peer AS**—Configured peer autonomous system (AS). • **Preference**—Preference value configured with the **preference** statement. • **Refresh**—Configured to refresh automatically when the policy changes. • **Rib-group**—Configured routing table group.
Address families configured	Names of configured address families for the VPN.
Local Address	Address of the local device.
Holdtime	Hold time configured with the **hold-time** statement. The hold time is three times the interval at which keepalive messages are sent.
Preference	Preference value configured with the **preference** statement.
Number of flaps	Number of times the BGP session has gone down and then come back up.
Trace file	Name of the file to receive the output of the tracing operation.

show interfaces flow-statistics

Syntax **show interfaces flow-statistics** *<interface-name>*

Release Information Command introduced in Junos OS Release 9.2.

Description Display interfaces flow statistics.

Options *Interface-name*—(Optional) Display flow statistics about the specified interface. Following is a list of typical interface names. Replace *pim* with the PIM slot and *port* with the port number. For a complete list, see the "Interface Naming Conventions" on page 2446.

- **at-*pim*/0/*port***—ATM-over-ADSL or ATM-over-SHDSL interface.
- **br-*pim*/0/*port***—Basic Rate Interface for establishing ISDN connections.
- **ce1-*pim*/0/*port***—Channelized E1 interface.
- **ct1-*pim*/0/*port***—Channelized T1 interface.
- **dl0**—Dialer Interface for initiating ISDN and USB modem connections.
- **e1-*pim*/0/*port***—E1 interface.
- **e3-*pim*/0/*port***—E3 interface.
- **fe-*pim*/0/ *port***—Fast Ethernet interface.
- **ge-*pim*/0/*port***—Gigabit Ethernet interface.
- **se-*pim*/0/*port***—Serial interface.
- **t1-*pim*/0/*port***—T1 (also called DS1) interface.
- **t3-*pim*/0/ *port***—T3 (also called DS3) interface.
- **wx-*slot*/0/0**—WAN acceleration interface, for the WXC Integrated Services Module (ISM 200).

List of Sample Output **show interfaces flow-statistics (Gigabit Ethernet) on page 3993**

Output Fields Table 196 lists the output fields for the **show interfaces flow-statistics** command. Output fields are listed in the approximate order in which they appear.

Table 375: show interfaces flow-statistics Output Fields

Field Name	Field Description
Traffic statistics	Number of packets and bytes transmitted and received on the physical interface.

Copyright © 2016, Juniper Networks, Inc.

Table 375: show interfaces flow-statistics Output Fields *(continued)*

Field Name	Field Description
Local statistics	Number of packets and bytes transmitted and received on the physical interface.
Transit statistics	Number of packets and bytes transiting the physical interface.
Flow input statistics	Statistics on packets received by flow module.
Flow output statistics	Statistics on packets sent by flow module.
Flow error statistics	Packet drop statistics for the flow module. For further details, see Table 197.

Table 376: Flow Error Statistics (Packet Drop Statistics for the Flow Module)

Error	Error Description
Screen:	
Address spoofing	The packet was dropped when the screen module detected address spoofing.
Syn-attack protection	The packet was dropped because of SYN attack protection or SYN cookie protection.
VPN:	
Authentication failed	The packet was dropped because the IPsec Encapsulating Security Payload (ESP) or Authentication Header (AH) authentication failed.
No SA for incoming SPI	The packet was dropped because the incoming IPsec packet's security parameter index (SPI) does not match any known SPI.
Security association not active	The packet was dropped because an IPsec packet was received for an inactive SA.
NAT:	
Incoming NAT errors	The source NAT rule search failed, an invalid source NAT binding was found, or the NAT allocation failed.
Multiple incoming NAT	Sometimes packets are looped through the system more than once; if source NAT is specified more than once, the packet will be dropped.
Auth:	
Multiple user authentications	Sometimes packets are looped through the system more than once. Each time a packet passes through the system, that packet must be permitted by a policy. If the packet matches more than one policy that specifies user authentication, then it will be dropped.
User authentication errors	Packet was dropped because policy requires authentication; however: • Only Telnet, FTP, and HTTP traffic can be authenticated. • The corresponding authentication entry could not be found, if web-auth is specified. • The maximum number of authenticated sessions per user was exceeded.

Copyright © 2016, Juniper Networks, Inc.

Table 376: Flow Error Statistics (Packet Drop Statistics for the Flow Module) *(continued)*

Flow:	
No one interested in self packets	This counter is incremented for one of the following reasons: • The outbound interface is a self interface, but the packet is not marked as a to-self packet and the destination address is in a source NAT pool. • No service is interested in the to-self packet • When a zone has ident-reset service enabled, the TCP RST to IDENT request for port 113 is sent back and this counter is incremented.
No minor session	The packet was dropped because no minor sessions are available and a minor session was requested. Minor sessions are allocated for storing additional TCP state information.
No more sessions	The packet was dropped because there were no more free sessions available.
No route present	The packet was dropped because a valid route was not available to forward the packet. For new sessions, the counter is incremented for one of the following reasons: • No valid route was found to forward the packet. • A discard or reject route was found. • The route could not be added due to lack of memory. • The reverse path forwarding check failed for an incoming multicast packet. For existing sessions, the prior route was changed or deleted, or a more specific route was added. The session is rerouted, and this reroute could fail because: • A new route could not be found; either the previous route was removed, or the route was changed to discard or reject. • Multiple packets may concurrently force rerouting to occur, and only one packet can successfully complete the rerouting process. Other packets will be dropped. • The route table was locked for updates by the Routing Engine. Packets that match a new session are retried, whereas packets that match an existing session are not.
No tunnel found	The packet was dropped because a valid tunnel could not be found
No session for a gate	This counter is incremented when a packet is destined for an ALG, and the ALG decides to drop this packet.
No zone or NULL zone binding	The packet was dropped because its incoming interface was not bound to any zone.
Policy denied	The error counter is incremented for one of the following reasons: • Source and/or destination NAT has occurred and policy says to drop the packet. • Policy specifies user authentication, which failed. • Policy was configured to deny this packet.
TCP sequence number out of window	A TCP packet with a sequence number failed the TCP sequence number check that was received.
Counters Not Currently in Use	
No parent for a gate	-

show security flow status

Syntax **show security flow status**

Release Information Command introduced in Junos OS Release 10.2; session distribution mode option added in Junos OS Release 12.1X44-D10; enhanced route scaling mode option added in Junos OS Release 12.1X45-D10. GTP-U distribution option added in Junos OS Release 15.1X49-D40.
Starting with Junos OS Release 15.1X49-D10, SRX5K-MPC3-100G10G (IOC3) and SRX5K-MPC3-40G10G (IOC3) are introduced for SRX5400, SRX5600, and SRX5800 devices that perform hash-based data path packet forwarding to interconnect with all existing IOC and SPC cards using the XL chip (packet-processing chip).
The IOC3 XL chip uses a hash-based method to distribute ingress traffic to a pool of SPUs by default. Selection of hash keys depends on application protocols.

Description Display the flow processing modes and logging status.

show security ipsec security-associations

Syntax

show security ipsec security-associations
brief | detail
family (inet | inet6)
fpc *slot-number*
index *SA-index-number*
kmd-instance (all | *kmd-instance-name*)
pic *slot-number>*
sa-type shortcut
vpn-name *vpn-name* <traffic-selector *traffic-selector-name*>

Release Information

Command introduced in Junos OS Release 8.5. Support for the **fpc**, **pic**, and **kmd-instance** options added in Junos OS Release 9.3. Support for the **family** option added in Junos OS Release 11.1. Support for the **vpn-name** option added in Junos OS Release 11.4R3. Support for the **traffic-selector** option and traffic selector field added in Junos OS Release 12.1X46-D10. Support for Auto Discovery VPN (ADVPN) added in Junos OS Release 12.3X48-D10.

Description

Display information about the IPsec security associations (SAs).

Options

- none—Display information about all SAs.
- **brief** | **detail**—(Optional) Display the specified level of output.
- **family**—(Optional) Display SAs by family. This option is used to filter the output.
  - **inet**—IPv4 address family.
  - **inet6**—IPv6 address family.
- **fpc** ***slot-number***—(Optional) Display information about existing IPsec SAs in this Flexible PIC Concentrator (FPC) slot. This option is used to filter the output.
- **index** ***SA-index-number***—(Optional) Display detailed information about the specified SA identified by this index number. To obtain a list of all SAs that includes their index numbers, use the command with no options.
- **kmd-instance**—(Optional) Display information about existing IPsec SAs in the key management process (in this case, it is KMD) identified by the FPC *slot-number* and PIC *slot-number*. This option is used to filter the output.
  - **all**—All KMD instances running on the Services Processing Unit (SPU).
  - ***kmd-instance-name***—Name of the KMD instance running on the SPU.
- **pic** ***slot-number***—(Optional) Display information about existing IPsec SAs in this PIC slot. This option is used to filter the output.
- **sa-type**—(Optional for ADVPN) Type of SA. **shortcut** is the only option for this release.
- **vpn-name** ***vpn-name***—Name of the VPN. If configured, **traffic-selector** ***traffic-selector-name*** can optionally be specified.

Output Fields Table 363 lists the output fields for the **show security ipsec security-associations** command. Output fields are listed in the approximate order in which they appear.

Table 378: show security ipsec security-associations

Field Name	Field Description
Total active tunnels	Total number of active IPsec tunnels.
ID	Index number of the SA. You can use this number to get additional information about the SA.
VPN name	IPsec name for VPN.
Gateway	IP address of the remote gateway.
Port	If Network Address Translation (NAT) is used, this value is 4500. Otherwise, it is the standard IKE port, 500.
Algorithm	Cryptography used to secure exchanges between peers during the IKE Phase 2 negotiations includes: • An authentication algorithm used to authenticate exchanges between the peers. Options are **hmac-md5-95**, **hmac-sha1-96,** or **ESP**. • An encryption algorithm used to encrypt data traffic. Options are **3des-cbc, aes-128-cbc, aes-192-cbc**, **aes-256-cbc**, or **des-cbc.**

Copyright © 2016, Juniper Networks, Inc.

Table 378: show security ipsec security-associations *(continued)*

Field Name	Field Description
SPI	Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase 1 and Phase 2.
Life: sec/kb	The lifetime of the SA, after which it expires, expressed either in seconds or kilobytes.
Sta	State has two options, **Installed** and **Not Installed**. • **Installed**—The SA is installed in the SA database. • **Not Installed**—The SA is not installed in the SA database. For transport mode, the value of State is always **Installed**.
Mon	The Mon field refers to VPN monitoring status. If VPN monitoring is enabled, then this field displays **U** (up) or **D** (down). A hyphen (-) means VPN monitoring is not enabled for this SA.
vsys or Virtual-system	The root system.
Tunnel index	Numeric identifier of the specific IPsec tunnel for the SA.
Local gateway	Gateway address of the local system.
Remote gateway	Gateway address of the remote system.
Traffic selector	Name of the traffic selector.
Local identity	Identity of the local peer so that its partner destination gateway can communicate with it. The value is specified as an IP address, fully qualified domain name, e-mail address, or distinguished name (DN).
Remote identity	IP address of the destination peer gateway.
DF-bit	State of the don't fragment bit: **set** or **cleared**.
Policy-name	Name of the applicable policy.
Location	**FPC**—Flexible PIC Concentrator (FPC) slot number. **PIC**—PIC slot number. **KMD-Instance**—The name of the KMD instance running on the SPU, identified by FPC *slot-number* and PIC *slot-number*. Currently, 4 KMD instances running on each SPU, and any particular IPsec negotiation is carried out by a single KMD instance.
Tunnel events	Tunnel event and the number of times the event has occurred. See "Tunnel Events" on page 6797 for descriptions of tunnel events and the action you can take.
Direction	Direction of the SA; it can be inbound or outbound.

Copyright © 2016, Juniper Networks, Inc.

Table 378: show security ipsec security-associations *(continued)*

Field Name	Field Description
AUX-SPI	Value of the auxiliary security parameter index(SPI). • When the value is **AH** or **ESP**, **AUX-SPI** is always 0. • When the value is **AH+ESP**, **AUX-SPI** is always a positive integer.
Mode	Mode of the SA: • **transport**—Protects host-to-host connections. • **tunnel—**Protects connections between security gateways.
Type	Type of the SA: • **manual**—Security parameters require no negotiation. They are static and are configured by the user. • **dynamic**—Security parameters are negotiated by the IKE protocol. Dynamic SAs are not supported in transport mode.
State	State of the SA: • **Installed**—The SA is installed in the SA database. • **Not Installed**—The SA is not installed in the SA database. For transport mode, the value of State is always **Installed**.

Protocol	Protocol supported.
	• Transport mode supports Encapsulation Security Protocol (ESP) and Authentication Header (AH).
	• Tunnel mode supports ESP and AH.
	  ◦ **Authentication**—Type of authentication used.
	  ◦ **Encryption**—Type of encryption used.

Soft lifetime	The soft lifetime informs the IPsec key management system that the SA is about to expire. Each lifetime of an SA has two display options, hard and soft, one of which must be present for a dynamic SA. This allows the key management system to negotiate a new SA before the hard lifetime expires. • **Expires in seconds**—Number of seconds left until the SA expires.
Hard lifetime	The hard lifetime specifies the lifetime of the SA. • **Expires in seconds**—Number of seconds left until the SA expires.
Lifesize Remaining	The lifesize remaining specifies the usage limits in kilobytes. If there is no lifesize specified, it shows unlimited. • **Expires in kilobytes**—Number of kilobytes left until the SA expires.
Anti-replay service	State of the service that prevents packets from being replayed. It can be **Enabled** or **Disabled**.

Table 378: show security ipsec security-associations *(continued)*

Field Name	Field Description
Replay window size	Configured size of the antireplay service window. It can be 32 or 64 packets. If the replay window size is 0, the antireplay service is disabled. The antireplay window size protects the receiver against replay attacks by rejecting old or duplicate packets.
Bind-interface	The tunnel interface to which the route-based VPN is bound.
Copy-Outer-DSCP	Indicates if copying outer IP header DSCP and ECN to inner IP header is enabled or disabled.

Sample Output

show security ipsec security-associations (IPv4)

show security ipsec statistics

Syntax

show security ipsec statistics
<**fpc** *slot-number* >
<**index** *SA-index-number* >
<**kmd-instance** *kmd-instance-name* >
pic *slot-number*

Release Information

Command introduced in Junos OS Release 8.5. **fpc** and **pic** options added in Junos OS Release 9.3. **kmd-instance** option added in Junos OS Release 10.4.

Description

Display standard IPsec statistics.

Options

- none—Display statistics about all IPsec security associations (SAs).
- **fpc** ***slot-number*** —Specific to SRX Series devices. Display statistics about existing IPsec SAs in this Flexible PIC Concentrator (FPC) slot. This option is used to filter the output.
- **index** ***SA-index-number*** —(Optional) Display statistics for the SA with this index number.
- **kmd-instance** ***kmd-instance-name*** —Specific to SRX Series devices. Display information about existing IKE SAs in the key management process (the daemon, which in this case is KMD) identified by FPC *slot-number* and PIC *slot-number*. This option is used to filter the output.
  - **all**—All KMD instances running on the Services Processing Unit (SPU).
  - ***kmd-instance-name***—Name of the KMD instance running on the SPU.
- **pic** ***slot-number*** —Specific to SRX Series devices. Display statistics about existing IPsec SAs in this PIC slot. This option is used to filter the output.

Output Fields

Table 379 lists the output fields for the **show security ipsec statistics** command. Output fields are listed in the approximate order in which they appear.

Table 379: show security ipsec statistics Output Fields

Field Name	Field Description
Virtual-system	The root system.

Table 379: show security ipsec statistics Output Fields *(continued)*

Field Name	Field Description
ESP Statistics	• **Encrypted bytes**—Total number of bytes encrypted by the local system across the IPsec tunnel. • **Decrypted bytes**—Total number of bytes decrypted by the local system across the IPsec tunnel. • **Encrypted packets**—Total number of packets encrypted by the local system across the IPsec tunnel. • **Decrypted packets**—Total number of packets decrypted by the local system across the IPsec tunnel.
AH Statistics	• **Input bytes**—Total number of bytes received by the local system across the IPsec tunnel. • **Output bytes**—Total number of bytes transmitted by the local system across the IPsec tunnel. • **Input packets**—Total number of packets received by the local system across the IPsec tunnel. • **Output packets**—Total number of packets transmitted by the local system across the IPsec tunnel.
Errors	• **AH authentication failures**—Total number of authentication header (AH) failures. An AH failure occurs when there is a mismatch of the authentication header in a packet transmitted across an IPsec tunnel. • **Replay errors**—Total number of replay errors. A replay error is generated when a duplicate packet is received within the replay window. • **ESP authentication failures**—Total number of Encapsulation Security Payload (ESP) failures. An ESP failure occurs when there is an authentication mismatch in ESP packets. • **ESP decryption failures**—total number of ESP decryption errors. • **Bad headers**—Total number of invalid headers detected. • **Bad trailers**—Total number of invalid trailers detected.

Sample Output

show security ipsec statistics

```
user@host> show security ipsec statistics
Virtual-system: Root
ESP Statistics:
  Encrypted bytes:                0
  Decrypted bytes:                0
  Encrypted packets:              0
  Decrypted packets:              0
AH Statistics:
  Input bytes:                    0
  Output bytes:                   0
  Input packets:                  0
  Output packets:                 0
Errors:
  AH authentication failures: 0, Replay errors: 0
  ESP authentication failures: 0, ESP decryption failures: 0
  Bad headers: 0, Bad trailers: 0
```

Multicast Overview

IP has three fundamental types of addresses: unicast, broadcast, and multicast. A *unicast address* is used to send a packet to a single destination. A *broadcast address* is used to send a datagram to an entire subnetwork. A *multicast address* is used to send a datagram to a set of hosts that can be on different subnetworks and that are configured as members of a multicast group.

A multicast datagram is delivered to destination group members with the same best-effort reliability as a standard unicast IP datagram. This means that multicast datagrams are not guaranteed to reach all members of a group or to arrive in the same order in which they were transmitted. The only difference between a multicast IP packet and a unicast IP packet is the presence of a group address in the IP header destination address field. Multicast addresses use the Class D address format.

NOTE: On all SRX Series devices, reordering is not supported for multicast fragments. Reordering of unicast fragments is supported.

Individual hosts can join or leave a multicast group at any time. There are no restrictions on the physical location or the number of members in a multicast group. A host can be a member of more than one multicast group at any time. A host does not have to belong to a group to send packets to members of a group.

Routers use a group membership protocol to learn about the presence of group members on directly attached subnetworks. When a host joins a multicast group, it transmits a group membership protocol message for the group or groups that it wants to receive and sets its IP process and network interface card to receive frames addressed to the multicast group.

Comparing Multicast to Unicast

The Junos® operating system (Junos OS) routing protocol process supports a wide variety of routing protocols. These routing protocols carry network information among routing devices not only for *unicast* traffic streams sent between one pair of clients and servers, but also for *multicast* traffic streams containing video, audio, or both, between a single server source and many client receivers. The routing protocols used for multicast differ in many key ways from unicast routing protocols.

Information is delivered over a network by three basic methods: unicast, broadcast, and multicast.

The differences among unicast, broadcast, and multicast can be summarized as follows:

- Unicast: One-to-one, from one source to one destination.
- Broadcast: One-to-all, from one source to all possible destinations.
- Multicast: One-to-many, from one source to multiple destinations expressing an interest in receiving the traffic.

NOTE: This list does not include a special category for many-to-many applications, such as online gaming or videoconferencing, where there are many sources for the same receiver and where receivers often double as sources. Many-to-many is a service model that repeatedly employs one-to-many multicast and therefore requires no unique protocol. The original multicast specification, RFC 1112, supports both the any-source multicast (ASM) many-to-many model and the source-specific multicast (SSM) one-to-many model.

With unicast traffic, many streams of IP packets that travel across networks flow from a single source, such as a website server, to a single destination such as a client PC. Unicast traffic is still the most common form of information transfer on networks.

Broadcast traffic flows from a single source to all possible destinations reachable on the network, which is usually a LAN. Broadcasting is the easiest way to make sure traffic reaches its destinations.

Television networks use broadcasting to distribute video and audio. Even if the television network is a cable television (CATV) system, the source signal reaches all possible destinations, which is the main reason that some channels' content is scrambled. Broadcasting is not feasible on the Internet because of the enormous amount of unnecessary information that would constantly arrive at each end user's device, the complexities and impact of scrambling, and related privacy issues.

Multicast traffic lies between the extremes of unicast (one source, one destination) and broadcast (one source, all destinations). Multicast is a "one source, many destinations" method of traffic distribution, meaning only the destinations that explicitly indicate their need to receive the information from a particular source receive the traffic stream.

Copyright © 2016, Juniper Networks, Inc.

On an IP network, because destinations (clients) do not often communicate directly with sources (servers), the routing devices between source and destination must be able to determine the topology of the network from the unicast or multicast perspective to avoid routing traffic haphazardly. Multicast routing devices replicate packets received on one input interface and send the copies out on multiple output interfaces.

In IP multicast, the source and destination are almost always hosts and not routing devices. Multicast routing devices distribute the multicast traffic across the network from source to destinations. The multicast routing device must find multicast sources on the network, send out copies of packets on several interfaces, prevent routing loops, connect interested destinations with the proper source, and keep the flow of unwanted packets to a minimum. Standard multicast routing protocols provide most of these capabilities, but some router architectures cannot send multiple copies of packets and so do not support multicasting directly.

IP Multicast Uses

Multicast allows an IP network to support more than just the unicast model of data delivery that prevailed in the early stages of the Internet. Multicast, originally defined as a host extension in RFC 1112 in 1989, provides an efficient method for delivering traffic flows that can be characterized as one-to-many or many-to-many.

Unicast traffic is not strictly limited to data applications. Telephone conversations, wireless or not, contain digital audio samples and might contain digital photographs or even video and still flow from a single source to a single destination. In the same way, multicast traffic is not strictly limited to multimedia applications. In some data applications, the flow of traffic is from a single source to many destinations that require the packets, as in a news or stock ticker service delivered to many PCs. For this reason, the term *receiver* is preferred to *listener* for multicast destinations, although both terms are common.

Network applications that can function with unicast but are better suited for multicast include collaborative groupware, teleconferencing, periodic or “push” data delivery (stock quotes, sports scores, magazines, newspapers, and advertisements), server or website replication, and distributed interactive simulation (DIS) such as war simulations or virtual reality. Any IP network concerned with reducing network resource overhead for one-to-many or many-to-many data or multimedia applications with multiple receivers benefits from multicast.

If unicast were employed by radio or news ticker services, each radio or PC would have to have a separate traffic session for each listener or viewer at a PC (this is actually the method for some Web-based services). The processing load and bandwidth consumed by the server would increase linearly as more people “tune in” to the server. This is extremely inefficient when dealing with the global scale of the Internet. Unicast places the burden of packet duplication on the server and consumes more and more backbone bandwidth as the number of users grows.

If broadcast were employed instead, the source could generate a single IP packet stream using a broadcast destination address. Although broadcast eliminates the server packet duplication issue, this is not a good solution for IP because IP broadcasts can be sent only to a single subnetwork, and IP routing devices normally isolate IP subnetworks on

Copyright © 2016, Juniper Networks, Inc.

separate interfaces. Even if an IP packet stream could be addressed to literally go everywhere, and there were no need to “tune” to any source at all, broadcast would be extremely inefficient because of the bandwidth strain and need for uninterested hosts to discard large numbers of packets. Broadcast places the burden of packet rejection on each host and consumes the maximum amount of backbone bandwidth.

For radio station or news ticker traffic, multicast provides the most efficient and effective outcome, with none of the drawbacks and all of the advantages of the other methods. A single source of multicast packets finds its way to every *interested* receiver. As with broadcast, the transmitting host generates only a single stream of IP packets, so the load remains constant whether there is one receiver or one million. The network routing devices replicate the packets and deliver the packets to the proper receivers, but only the replication role is a new one for routing devices. The links leading to subnets consisting of entirely uninterested receivers carry no multicast traffic. Multicast minimizes the burden placed on sender, network, and receiver.

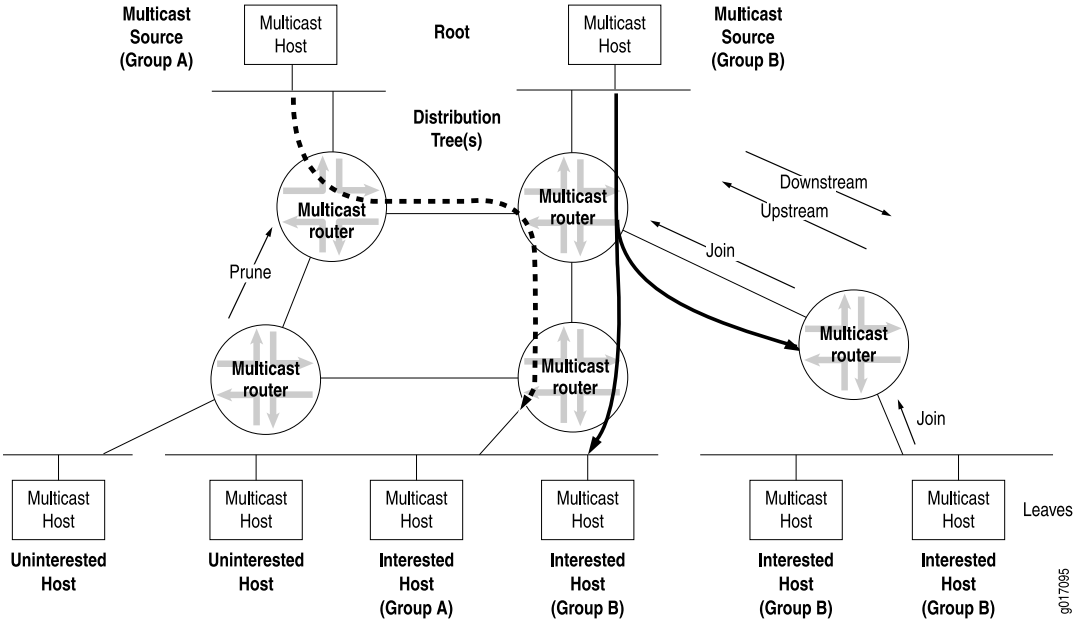
IP Multicast Terminology

Multicast has its own particular set of terms and acronyms that apply to IP multicast routing devices and networks. Figure 152 depicts some of the terms commonly used in an IP multicast network.

In a multicast network, the key component is the *routing device*, which is able to replicate packets and is therefore multicast-capable. The routing devices in the IP multicast network, which has exactly the same topology as the unicast network it is based on, use a *multicast routing protocol* to build a *distribution tree* that connects receivers (preferred to the multimedia implications of listeners, but listeners is also used) to *sources*. In multicast terminology, the distribution tree is *rooted at the source* (the root of the distribution tree is the source). The interface on the routing device leading toward the source is the *upstream* interface, although the less precise terms *incoming* or *inbound* interface are used as well. To keep bandwidth use to a minimum, it is best for only one upstream interface on the routing device to receive multicast packets. The interface on the routing device leading toward the receivers is the *downstream* interface, although the less precise terms *outgoing* or *outbound* interface are used as well. There can be 0 to *N*–1 downstream interfaces on a routing device, where *N* is the number of logical interfaces on the routing device. To prevent looping, the upstream interface must never receive copies of downstream multicast packets.

Copyright © 2016, Juniper Networks, Inc.

Figure 152: Multicast Terminology in an IP Network



Routing loops are disastrous in multicast networks because of the risk of repeatedly replicated packets. One of the complexities of modern multicast routing protocols is the need to avoid routing loops, packet by packet, much more rigorously than in unicast routing protocols.

Reverse-Path Forwarding for Loop Prevention

The routing device's multicast forwarding state runs more logically based on the reverse path, from the receiver back to the root of the distribution tree. In RPF, every multicast packet received must pass an RPF check before it can be replicated or forwarded on any interface. When it receives a multicast packet on an interface, the routing device verifies that the *source* address in the multicast IP packet is the *destination* address for a unicast IP packet back to the source.

If the outgoing interface found in the unicast routing table is the same interface that the multicast packet was received on, the packet passes the RPF check. Multicast packets that fail the RPF check are dropped, because the incoming interface is not on the shortest path back to the source. routing devices can build and maintain separate tables for RPF purposes.

Shortest-Path Tree for Loop Prevention

The distribution tree used for multicast is rooted at the source and is the shortest-path tree (SPT), but this path can be long if the source is at the periphery of the network. Providing a *shared tree* on the backbone as the distribution tree locates the multicast source more centrally in the network. Shared distribution trees with roots in the core network are created and maintained by a multicast routing device operating as a rendezvous point (RP), a feature of sparse mode multicast protocols.

Copyright © 2016, Juniper Networks, Inc.

Administrative Scoping for Loop Prevention

Scoping limits the routing devices and interfaces that can forward a multicast packet. Multicast scoping is *administrative* in the sense that a range of multicast addresses is reserved for scoping purposes, as described in RFC 2365, *Administratively Scoped IP Multicast*. routing devices at the boundary must filter multicast packets and ensure that packets do not stray beyond the established limit.

Multicast Leaf and Branch Terminology

Each subnetwork with hosts on the routing device that has at least one interested receiver is a *leaf* on the distribution tree. routing devices can have multiple leaves on different interfaces and must send a copy of the IP multicast packet out on each interface with a leaf. When a new leaf subnetwork is added to the tree (that is, the interface to the host subnetwork previously received no copies of the multicast packets), a new *branch* is built, the leaf is joined to the tree, and replicated packets are sent out on the interface. The number of leaves on a particular interface does not affect the routing device. The action is the same for one leaf or a hundred.

NOTE: On Juniper Networks security devices, if the maximum number of leaves on a multicast distribution tree is exceeded, multicast sessions are created up to the maximum number of leaves, and any multicast sessions that exceed the maximum number of leaves are ignored. The maximum number of leaves on a multicast distribution tree is device specific.

When a branch contains no leaves because there are no interested hosts on the routing device interface leading to that IP subnetwork, the branch is *pruned* from the distribution tree, and no multicast packets are sent out that interface. Packets are replicated and sent out multiple interfaces only where the distribution tree branches at a routing device, and no link ever carries a duplicate flow of packets.

Collections of hosts all receiving the same stream of IP packets, usually from the same multicast source, are called *groups*. In IP multicast networks, traffic is delivered to multicast groups based on an IP multicast address, or *group address*. The groups determine the location of the leaves, and the leaves determine the branches on the multicast network.

IP Multicast Addressing

Multicast uses the Class D IP address range (224.0.0.0 through 239.255.255.255). Class D addresses are commonly referred to as *multicast addresses* because the entire classful address concept is obsolete. Multicast addresses can never appear as the source address in an IP packet and can only be the destination of a packet.

Multicast addresses usually have a prefix length of /32, although other prefix lengths are allowed. Multicast addresses represent logical groupings of receivers and not physical collections of devices. Blocks of multicast addresses can still be described in terms of prefix length in traditional notation, but only for convenience. For example, the multicast

Copyright © 2016, Juniper Networks, Inc.

address range from 232.0.0.0 through 232.255.255.255 can be written as 232.0.0.0/8 or 232/8.

Internet service providers (ISPs) do not typically allocate multicast addresses to their customers because multicast addresses relate to content, not to physical devices. Receivers are not assigned their own multicast addresses, but need to know the multicast address of the content. Sources need to be assigned multicast addresses only to produce the content, not to identify their place in the network. Every source and receiver still needs an ordinary, unicast IP address.

Multicast addressing most often references the receivers, and the source of multicast content is usually not even a member of the multicast group for which it produces content. If the source needs to monitor the packets it produces, monitoring can be done locally, and there is no need to make the packets traverse the network.

Many applications have been assigned a range of multicast addresses for their own use. These applications assign multicast addresses to sessions created by that application. You do not usually need to statically assign a multicast address, but you can do so.

Multicast Addresses

Multicast host group addresses are defined to be the IP addresses whose high-order four bits are 1110, giving an address range from 224.0.0.0 through 239.255.255.255, or simply 224.0.0.0/4. (These addresses also are referred to as Class D addresses.)

The Internet Assigned Numbers Authority (IANA) maintains a list of registered IP multicast groups. The base address 224.0.0.0 is reserved and cannot be assigned to any group. The block of multicast addresses from 224.0.0.1 through 224.0.0.255 is reserved for local wire use. Groups in this range are assigned for various uses, including routing protocols and local discovery mechanisms.

The range from 239.0.0.0 through 239.255.255.255 is reserved for administratively scoped addresses. Because packets addressed to administratively scoped multicast addresses do not cross configured administrative boundaries, and because administratively scoped multicast addresses are locally assigned, these addresses do not need to be unique across administrative boundaries.

Layer 2 Frames and IPv4 Multicast Addresses

Multicasting on a LAN is a good place to start an investigation of multicasting at Layer 2. At Layer 2, multicast deals with media access control (MAC) frames and addresses instead of IPv4 or IPv6 packets and addresses. Consider a single LAN, without routing devices, with a multicast source sending to a certain group. The rest of the hosts are receivers interested in the multicast group's content. So the multicast source host generates packets with its unicast IP address as the source, and the multicast group address as the destination.

Which MAC addresses are used on the frame containing this packet? The packet source address—the unicast IP address of the host originating the multicast content—translates easily and directly to the MAC address of the source. But what about the packet's destination address? This is the IP multicast group address. Which destination MAC address for the frame corresponds to the packet's multicast group address?

Copyright © 2016, Juniper Networks, Inc.

One option is for LANs simply to use the LAN broadcast MAC address, which guarantees that the frame is processed by every station on the LAN. However, this procedure defeats the whole purpose of multicast, which is to limit the circulation of packets and frames to interested hosts. Also, hosts might have access to many multicast groups, which multiplies the amount of traffic to noninterested destinations. Broadcasting frames at the LAN level to support multicast groups makes no sense.

However, there is an easy way to effectively use Layer 2 frames for multicast purposes. The MAC address has a bit that is set to 0 for unicast (the LAN term is *individual address*) and set to 1 to indicate that this is a multicast address. Some of these addresses are reserved for multicast groups of specific vendors or MAC-level protocols. Internet multicast applications use the range 0x01-00-5E-00-00-00 to 0x01-00-5E-FF-FF-FF. Multicast receivers (hosts running TCP/IP) listen for frames with one of these addresses when the application joins a multicast group. The host stops listening when the application terminates or the host leaves the group at the packet layer (Layer 3).

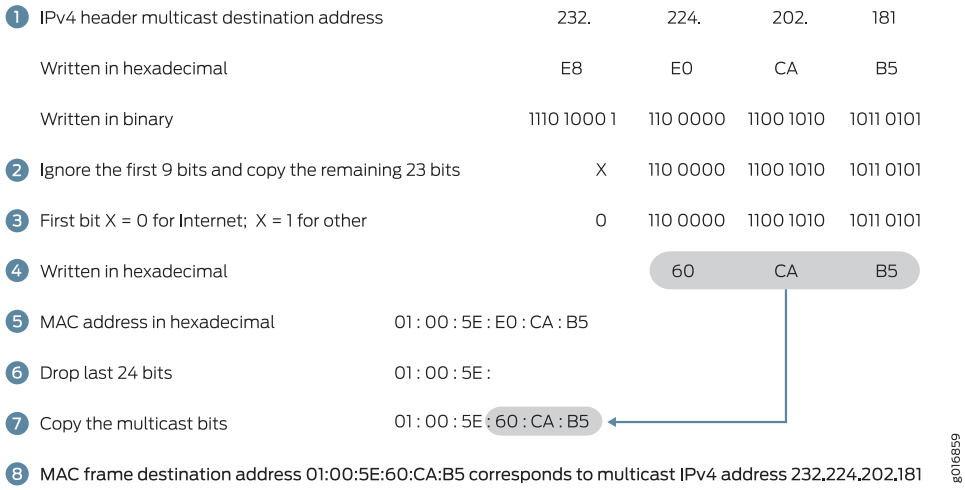
This means that 3 bytes, or 24 bits, are available to map IPv4 multicast addresses at Layer 3 to MAC multicast addresses at Layer 2. However, all IPv4 addresses, including multicast addresses, are 32 bits long, leaving 8 IP address bits left over. Which method of mapping IPv4 multicast addresses to MAC multicast addresses minimizes the chance of “collisions” (that is, two different IP multicast groups at the packet layer mapping to the same MAC multicast address at the frame layer)?

First, it is important to realize that all IPv4 multicast addresses begin with the same 4 bits (**1110**), so there are really only 4 bits of concern, not 8. A LAN must not drop the last bits of the IPv4 address because these are almost guaranteed to be host bits, depending on the subnet mask. But the high-order bits, the leftmost address bits, are almost always network bits, and there is only one LAN (for now).

One other bit of the remaining 24 MAC address bits is reserved (an initial **0** indicates an Internet multicast address), so the 5 bits following the initial 1110 in the IPv4 address are dropped. The 23 remaining bits are mapped, one for one, into the last 23 bits of the MAC address. An example of this process is shown in Figure 153.

Copyright © 2016, Juniper Networks, Inc.

Figure 153: Converting MAC Addresses to Multicast Addresses



Note that this process means that there are 32 (2^5) IPv4 multicast addresses that could map to the same MAC multicast addresses. For example, multicast IPv4 addresses 224.8.7.6 and 229.136.7.6 translate to the same MAC address (0x01-00-5E-08-07-06). This is a real concern, and because the host could be interested in frames sent to both of the those multicast groups, the IP software must reject one or the other.

NOTE: This “collision” problem does not exist in IPv6 because of the way IPv6 handles multicast groups, but it is always a concern in IPv4. The procedure for placing IPv6 multicast packets inside multicast frames is nearly identical to that for IPv4, except for the MAC destination address 0x3333 prefix (and the lack of “collisions”).

Once the MAC address for the multicast group is determined, the host's operating system essentially orders the LAN interface card to join or leave the multicast group. Once joined to a multicast group, the host accepts frames sent to the multicast address as well as the host’s unicast address and ignores other multicast group’s frames. It is possible for a host to join and receive multicast content from more than one group at the same time, of course.

Multicast Interface Lists

To avoid multicast routing loops, every multicast routing device must always be aware of the interface that leads to the source of that multicast group content by the shortest path. This is the upstream (incoming) interface, and packets are never to be forwarded back toward a multicast source. All other interfaces are potential downstream (outgoing) interfaces, depending on the number of branches on the distribution tree.

routing devices closely monitor the status of the incoming and outgoing interfaces, a process that determines the *multicast forwarding state*. A routing device with a multicast forwarding state for a particular multicast group is essentially “turned on” for that group's

Copyright © 2016, Juniper Networks, Inc.

content. Interfaces on the routing device's outgoing interface list send copies of the group's packets received on the incoming interface list for that group. The incoming and outgoing interface lists might be different for different multicast groups.

The multicast forwarding state in a routing device is usually written in either (S,G) or (*,G) notation. These are pronounced “ess comma gee” and “star comma gee,” respectively. In (S,G), the S refers to the unicast IP address of the source for the multicast traffic, and the G refers to the particular multicast group IP address for which S is the source. All multicast packets sent from this source have S as the source address and G as the destination address.

The asterisk (*) in the (*,G) notation is a wildcard indicating that the state applies to any multicast application source sending to group G. So, if two sources are originating exactly the same content for multicast group 224.1.1.2, a routing device could use (*,224.1.1.2) to represent the state of a routing device forwarding traffic from both sources to the group.

Multicast Routing Protocols

Multicast routing protocols enable a collection of multicast routing devices to build (join) distribution trees when a host on a directly attached subnet, typically a LAN, wants to receive traffic from a certain multicast group, prune branches, locate sources and groups, and prevent routing loops.

There are several multicast routing protocols:

- Distance Vector Multicast Routing Protocol (DVMRP)—The first of the multicast routing protocols and hampered by a number of limitations that make this method unattractive for large-scale Internet use. DVMRP is a dense-mode-only protocol, and uses the flood-and-prune or implicit join method to deliver traffic everywhere and then determine where the uninterested receivers are. DVMRP uses source-based distribution trees in the form (S,G), and builds its own multicast routing tables for RPF checks.
- Multicast OSPF (MOSPF)—Extends OSPF for multicast use, but only for dense mode. However, MOSPF has an explicit join message, so routing devices do not have to flood their entire domain with multicast traffic from every source. MOSPF uses source-based distribution trees in the form (S,G).
- *Bidirectional PIM mode*—A variation of PIM. Bidirectional PIM builds bidirectional shared trees that are rooted at a rendezvous point (RP) address. Bidirectional traffic does not switch to shortest path trees as in PIM-SM and is therefore optimized for routing state size instead of path length. This means that the end-to-end latency might be longer compared to PIM sparse mode. Bidirectional PIM routes are always wildcard-source (*,G) routes. The protocol eliminates the need for (S,G) routes and data-triggered events. The bidirectional (*,G) group trees carry traffic both upstream from senders toward the RP, and downstream from the RP to receivers. As a consequence, the strict reverse path forwarding (RPF)-based rules found in other PIM modes do not apply to bidirectional PIM. Instead, bidirectional PIM (*,G) routes forward traffic from all sources and the RP. Bidirectional PIM routing devices must have the ability to accept traffic on many potential incoming interfaces. Bidirectional PIM scales well because it needs no source-specific (S,G) state. Bidirectional PIM is recommended in deployments with many dispersed sources and many dispersed receivers.

Copyright © 2016, Juniper Networks, Inc.

- PIM *dense mode*—In this mode of PIM, the assumption is that almost all possible subnets have at least one receiver wanting to receive the multicast traffic from a source, so the network is *flooded* with traffic on all possible branches, then pruned back when branches do not express an interest in receiving the packets, explicitly (by message) or implicitly (time-out silence). This is the *dense mode* of multicast operation. LANs are appropriate networks for dense-mode operation. Some multicast routing protocols, especially older ones, support only dense-mode operation, which makes them inappropriate for use on the Internet. In contrast to DVMRP and MOSPF, PIM dense mode allows a routing device to use any unicast routing protocol and performs RPF checks using the unicast routing table. PIM dense mode has an implicit join message, so routing devices use the flood-and-prune method to deliver traffic everywhere and then determine where the uninterested receivers are. PIM dense mode uses source-based distribution trees in the form (S,G), as do all dense-mode protocols. PIM also supports sparse-dense mode, with mixed sparse and dense groups, but there is no special notation for that operational mode. If *sparse-dense mode* is supported, the multicast routing protocol allows some multicast groups to be sparse and other groups to be dense.
- PIM *sparse mode*—In this mode of PIM, the assumption is that very few of the possible receivers want packets from each source, so the network establishes and sends packets only on branches that have at least one leaf indicating (by message) an interest in the traffic. This multicast protocol allows a routing device to use any unicast routing protocol and performs reverse-path forwarding (RPF) checks using the unicast routing table. PIM sparse mode has an *explicit* join message, so routing devices determine where the interested receivers are and send join messages upstream to their neighbors, building trees from receivers to the rendezvous point (RP). PIM sparse mode uses an RP routing device as the initial source of multicast group traffic and therefore builds distribution trees in the form (*,G), as do all sparse-mode protocols. PIM sparse mode migrates to an (S,G) source-based tree if that path is shorter than through the RP for a particular multicast group's traffic. WANs are appropriate networks for sparse-mode operation, and indeed a common multicast guideline is not to run dense mode on a WAN under any circumstances.
- Core Based Trees (CBT)—Shares all of the characteristics of PIM sparse mode (sparse mode, explicit join, and shared (*,G) trees), but is said to be more efficient at finding sources than PIM sparse mode. CBT is rarely encountered outside academic discussions. There are no large-scale deployments of CBT, commercial or otherwise.
- PIM source-specific multicast (SSM)—Enhancement to PIM sparse mode that allows a client to receive multicast traffic directly from the source, without the help of an RP. Used with IGMPv3 to create a shortest-path tree between receiver and source.
- IGMPv1—The original protocol defined in RFC 1112, *Host Extensions for IP Multicasting*. IGMPv1 sends an explicit join message to the routing device, but uses a timeout to determine when hosts leave a group. Three versions of the Internet Group Management Protocol (IGMP) run between receiver hosts and routing devices.
- IGMPv2—Defined in RFC 2236, *Internet Group Management Protocol, Version 2*. Among other features, IGMPv2 adds an explicit leave message to the join message.
- IGMPv3—Defined in RFC 3376, *Internet Group Management Protocol, Version 3.* Among other features, IGMPv3 optimizes support for a single source of content for a multicast

Copyright © 2016, Juniper Networks, Inc.

group, or source-specific multicast (SSM). Used with PIM SSM to create a shortest-path tree between receiver and source.

- Bootstrap Router (BSR) and Auto-Rendezvous Point (RP)—Allow sparse-mode routing protocols to find RPs within the routing domain (autonomous system, or AS). RP addresses can also be statically configured.
- Multicast Source Discovery Protocol (MSDP)—Allows groups located in one multicast routing domain to find RPs in other routing domains. MSDP is not used on an RP if all receivers and sources are located in the same routing domain. Typically runs on the same routing device as PIM sparse mode RP. Not appropriate if all receivers and sources are located in the same routing domain.
- Session Announcement Protocol (SAP) and Session Description Protocol (SDP)—Display multicast session names and correlate the names with multicast traffic. SDP is a session directory protocol that advertises multimedia conference sessions and communicates setup information to participants who want to join the session. A client commonly uses SDP to announce a conference session by periodically multicasting an announcement packet to a well-known multicast address and port using SAP.
- Pragmatic General Multicast (PGM)—Special protocol layer for multicast traffic that can be used between the IP layer and the multicast application to add reliability to multicast traffic. PGM allows a receiver to detect missing information in all cases and request replacement information if the receiver application requires it.

The differences among the multicast routing protocols are summarized in Table 380.

Table 380: Multicast Routing Protocols Compared

Multicast Routing Protocol	Dense Mode	Sparse Mode	Implicit Join	Explicit Join	(S,G) SBT	(*,G) Shared Tree
DVMRP	Yes	No	Yes	No	Yes	No
MOSPF	Yes	No	No	Yes	Yes	No
PIM dense mode	Yes	No	Yes	No	Yes	No
PIM sparse mode	No	Yes	No	Yes	Yes, maybe	Yes, initially
Bidirectional PIM	No	No	No	Yes	No	Yes
CBT	No	Yes	No	Yes	No	Yes
SSM	No	Yes	No	Yes	Yes, maybe	Yes, initially
IGMPv1	No	Yes	No	Yes	Yes, maybe	Yes, initially
IGMPv2	No	Yes	No	Yes	Yes, maybe	Yes, initially
IGMPv3	No	Yes	No	Yes	Yes, maybe	Yes, initially

Table 380: Multicast Routing Protocols Compared *(continued)*

Multicast Routing Protocol	Dense Mode	Sparse Mode	Implicit Join	Explicit Join	(S,G) SBT	(*,G) Shared Tree
BSR and Auto-RP	No	Yes	No	Yes	Yes, maybe	Yes, initially
MSDP	No	Yes	No	Yes	Yes, maybe	Yes, initially

It is important to realize that retransmissions due to a high bit-error rate on a link or overloaded routing device can make multicast as inefficient as repeated unicast. Therefore, there is a trade-off in many multicast applications regarding the session support provided by the Transmission Control Protocol (TCP) (but TCP always resends missing segments), or the simple drop-and-continue strategy of the User Datagram Protocol (UDP) datagram service (but reordering can become an issue). Modern multicast uses UDP almost exclusively.

T Series Router Multicast Performance

The Juniper Networks T Series Core Routers handle extreme multicast packet replication requirements with a minimum of router load. Each memory component replicates a multicast packet twice at most. Even in the worst-case scenario involving maximum fan-out, when 1 input port and 63 output ports need a copy of the packet, the T Series routing platform copies a multicast packet only six times. Most multicast distribution trees are much sparser, so in many cases only two or three replications are necessary. In no case does the T Series architecture have an impact on multicast performance, even with the largest multicast fan-out requirements.

Understanding Layer 3 Multicast Functionality on the SRX5K-MPC

Multicast is a “one source, many destinations” method of traffic distribution, meaning that only the destinations that explicitly indicate their need to receive the information from a particular source receive the traffic stream.

In the data plane of the SRX Series chassis, the SRX5000 line Module Port Concentrator (SRX5K-MPC) forwards Layer 3 IP multicast data packets, which include multicast protocol packets (for example, MLD, IGMP and PIM packets), and the data packets.

In incoming direction, the MPC receives multicast packets from an interface and forwards them to the central point or to a Services Processing Unit (SPU). The SPU performs multicast route lookup, flow-based security check, and packet replication.

In outgoing direction, the MPC receives copies of a multicast packet or Layer 3 multicast control protocol packets from SPU, and transmits them to either multicast capable routers or to hosts in a multicast group.

In the SRX Series chassis, the SPU perform multicast route lookup, if available, to forward an incoming multicast packet and replicates it for each multicast outgoing interface. After receiving replicated multicast packets and their corresponding outgoing interface information from the SPU, the MPC transmits these packets to next hops.

Copyright © 2016, Juniper Networks, Inc.

NOTE: On all high-end SRX Series devices, during RG1 failover with multicast traffic and high number of multicast sessions, the failover delay is from 90 through 120 seconds for traffic to resume on the secondary node. The delay of 90 through 120 seconds is only for the first failover. For subsequent failovers, the traffic resumes within 8 through 18 seconds.

Understanding Group Membership Protocols

There is a big difference between the multicast protocols used between host and routing device and between the multicast routing devices themselves. Hosts on a given subnetwork need to inform their routing device only whether or not they are interested in receiving packets from a certain multicast group. The source host needs to inform its routing devices only that it is the source of traffic for a particular multicast group. In other words, no detailed knowledge of the distribution tree is needed by any hosts; only a group membership protocol is needed to inform routing devices of their participation in a multicast group. Between adjacent routing devices, on the other hand, the multicast routing protocols must avoid loops as they build a detailed sense of the network topology

Copyright © 2016, Juniper Networks, Inc.

and distribution tree from source to leaf. So, different multicast protocols are used for the host-router portion and the router-router portion of the multicast network.

Multicast group membership protocols enable a routing device to detect when a host on a directly attached subnet, typically a LAN, wants to receive traffic from a certain multicast group. Even if more than one host on the LAN wants to receive traffic for that multicast group, the routing device sends only one copy of each packet for that multicast group out on that interface, because of the inherent broadcast nature of LANs. When the multicast group membership protocol informs the routing device that there are no interested hosts on the subnet, the packets are withheld and that leaf is pruned from the distribution tree.

The Internet Group Management Protocol (IGMP) and the Multicast Listener Discovery (MLD) Protocol are the standard IP multicast group membership protocols: IGMP and MLD have several versions that are supported by hosts and routing devices:

- IGMPv1—The original protocol defined in RFC 1112. An explicit join message is sent to the routing device, but a timeout is used to determine when hosts leave a group. This process wastes processing cycles on the routing device, especially on older or smaller routing devices.
- IGMPv2—Defined in RFC 2236. Among other features, IGMPv2 adds an explicit leave message to the join message so that routing devices can more easily determine when a group has no interested listeners on a LAN.
- IGMPv3—Defined in RFC 3376. Among other features, IGMPv3 optimizes support for a single source of content for a multicast group, or *source-specific multicast* (*SSM*).
- MLDv1—Defined in RFC 2710. MLDv1 is similar to IGMPv2.
- MLDv2—Defined in RFC 3810. MLDv2 similar to IGMPv3.

The various versions of IGMP and MLD are backward compatible. It is common for a routing device to run multiple versions of IGMP and MLD on LAN interfaces. Backward compatibility is achieved by dropping back to the most basic of all versions run on a LAN. For example, if one host is running IGMPv1, any routing device attached to the LAN running IGMPv2 can drop back to IGMPv1 operation, effectively eliminating the IGMPv2 advantages. Running multiple IGMP versions ensures that both IGMPv1 and IGMPv2 hosts find peers for their versions on the routing device.

Related Documentation

- Examples: Configuring MLD on page 4063

Understanding IGMP

The Internet Group Management Protocol (IGMP) manages the membership of hosts and routing devices in multicast groups. IP hosts use IGMP to report their multicast group memberships to any immediately neighboring multicast routing devices. Multicast routing devices use IGMP to learn, for each of their attached physical networks, which groups have members.

Copyright © 2016, Juniper Networks, Inc.

IGMP is also used as the transport for several related multicast protocols (for example, Distance Vector Multicast Routing Protocol [DVMRP] and Protocol Independent Multicast version 1 [PIMv1]).

A routing device receives explicit join and prune messages from those neighboring routing devices that have downstream group members. When PIM is the multicast protocol in use, IGMP begins the process as follows:

1. To join a multicast group, G, a host conveys its membership information through IGMP.
2. The routing device then forwards data packets addressed to a multicast group G to only those interfaces on which explicit join messages have been received.
3. A designated router (DR) sends periodic join and prune messages toward a group-specific rendezvous point (RP) for each group for which it has active members. One or more routing devices are automatically or statically designated as the RP, and all routing devices must explicitly join through the RP.
4. Each routing device along the path toward the RP builds a wildcard (any-source) state for the group and sends join and prune messages toward the RP.

   The term *route entry* is used to refer to the state maintained in a routing device to represent the distribution tree.

   A route entry can include such fields as:

   - source address
   - group address
   - incoming interface from which packets are accepted
   - list of outgoing interfaces to which packets are sent
   - timers
   - flag bits

   The wildcard route entry's incoming interface points toward the RP.

   The outgoing interfaces point to the neighboring downstream routing devices that have sent join and prune messages toward the RP as well as the directly connected hosts that have requested membership to group G.
5. This state creates a shared, RP-centered, distribution tree that reaches all group members.

IGMP is an integral part of IP and must be enabled on all routing devices and hosts that need to receive IP multicast traffic.

For each attached network, a multicast routing device can be either a querier or a nonquerier. The querier routing device periodically sends general query messages to solicit group membership information. Hosts on the network that are members of a multicast group send report messages. When a host leaves a group, it sends a leave group message.

Copyright © 2016, Juniper Networks, Inc.

IGMP version 3 (IGMPv3) supports inclusion and exclusion lists. Inclusion lists enable you to specify which sources can send to a multicast group. This type of multicast group is called a source-specific multicast (SSM) group, and its multicast address is 232/8.

IGMPv3 provides support for source filtering. For example, a routing device can specify particular routing devices from which it accepts or rejects traffic. With IGMPv3, a multicast routing device can learn which sources are of interest to neighboring routing devices.

Exclusion mode works the opposite of an inclusion list. It allows any source but the ones listed to send to the SSM group.

IGMPv3 interoperates with versions 1 and 2 of the protocol. However, to remain compatible with older IGMP hosts and routing devices, IGMPv3 routing devices must also implement versions 1 and 2 of the protocol. IGMPv3 supports the following membership-report record types: mode is allowed, allow new sources, and block old sources.

Related Documentation

- Supported IP Multicast Protocol Standards on page 4032
- Configuring IGMP on page 4037

Configuring IGMP

Before you begin:

1. Determine whether the routing device is directly attached to any multicast sources. Receivers must be able to locate these sources.
2. Determine whether the routing device is directly attached to any multicast group receivers. If receivers are present, IGMP is needed.
3. Determine whether to configure multicast to use sparse, dense, or sparse-dense mode. Each mode has different configuration considerations.
4. Determine the address of the RP if sparse or sparse-dense mode is used.
5. Determine whether to locate the RP with the static configuration, BSR, or auto-RP method.
6. Determine whether to configure multicast to use its own RPF routing table when configuring PIM in sparse, dense, or sparse-dense mode.
7. Configure the SAP and SDP protocols to listen for multicast session announcements. See *Configuring the Session Announcement Protocol*.

To configure the Internet Group Management Protocol (IGMP), include the **igmp** statement:

```
igmp {
    accounting;
    interface interface-name {
        disable;
        (accounting | no-accounting);
        group-policy [ policy-names ];
        immediate-leave;
        oif-map map-name;
```

Copyright © 2016, Juniper Networks, Inc.

```
        promiscuous-mode;
        ssm-map ssm-map-name;
        static {
          group multicast-group-address {
            exclude;
            group-count number;
            group-increment increment;
            source ip-address {
              source-count number;
              source-increment increment;
            }
          }
        }
        version version;
      }
      query-interval seconds;
      query-last-member-interval seconds;
      query-response-interval seconds;
      robust-count number;
      traceoptions {
        file filename <files number> <size size> <world-readable | no-world-readable>;
        flag flag <flag-modifier> <disable>;
      }
    }
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

By default, IGMP is enabled on all interfaces on which you configure Protocol Independent Multicast (PIM), and on all broadcast interfaces on which you configure the Distance Vector Multicast Routing Protocol (DVMRP).

NOTE: You can configure IGMP on an interface without configuring PIM. PIM is generally not needed on IGMP downstream interfaces. Therefore, only one "pseudo PIM interface" is created to represent all IGMP downstream (IGMP-only) interfaces on the router. This reduces the amount of router resources, such as memory, that are consumed. You must configure PIM on upstream IGMP interfaces to enable multicast routing, perform reverse-path forwarding for multicast data packets, populate the multicast forwarding table for upstream interfaces, and in the case of bidirectional PIM and PIM sparse mode, to distribute IGMP group memberships into the multicast routing domain.

Enabling IGMP

The Internet Group Management Protocol (IGMP) manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use IGMP to learn which groups have members on each of their attached physical

Copyright © 2016, Juniper Networks, Inc.

networks. IGMP must be enabled for the router to receive IPv4 multicast packets. IGMP is only needed for IPv4 networks, because multicast is handled differently in IPv6 networks. IGMP is automatically enabled on all IPv4 interfaces on which you configure PIM and on all IPv4 broadcast interfaces when you configure DVMRP.

If IGMP is not running on an interface—either because PIM and DVMRP are not configured on the interface or because IGMP is explicitly disabled on the interface—you can explicitly enable IGMP.

To explicitly enable IGMP:

1. If PIM and DVMRP are not running on the interface, explicitly enable IGMP by including the interface name.

   ```
   [edit protocols igmp]
   user@host# set interface fe-0/0/0.0
   ```

2. See if IGMP is disabled on any interfaces. In the following example, IGMP is disabled on a Gigabit Ethernet interface.

   ```
   [edit protocols igmp]
   user@host# show
   interface fe-0/0/0.0;
   interface ge-1/0/0.0 {
     disable;
   }
   ```

3. Enable IGMP on the interface by deleting the **disable** statement.

   ```
   [edit protocols igmp]
   delete interface ge-1/0/0.0 disable
   ```

4. Verify the configuration.

   ```
   [edit protocols igmp]
   user@host# show
   interface fe-0/0/0.0;
   interface ge-1/0/0.0;
   ```

5. Verify the operation of IGMP on the interfaces by checking the output of the **show igmp interface** command.

Modifying the IGMP Host-Query Message Interval

The objective of IGMP is to keep routers up to date with group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The IGMP querier router periodically sends general host-query messages on each attached network to solicit membership information. The messages are sent to the all-systems multicast group address, 224.0.0.1.

Copyright © 2016, Juniper Networks, Inc.

The query interval, the response interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the group membership timeout has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of IGMP messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

   ```
   [edit protocols igmp]
   user@host# set query-interval 200
   ```

   The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the IGMP Query Interval field in the output of the **show igmp interface** command.

3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

Related Documentation

- **show igmp statistics on page 4692**

Modifying the IGMP Query Response Interval

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. Configuring this interval allows you to adjust the burst peaks of IGMP messages on the subnet. Set a larger interval to make the traffic less bursty. Bursty traffic refers to an uneven pattern of data transmission: sometimes a very high data transmission rate, whereas at other times a very low data transmission rate.

The query response interval, the host-query interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the

Copyright © 2016, Juniper Networks, Inc.

group membership timeout has expired, the routing device stops forwarding remotely originated multicast packets for that group onto the attached network.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.

   ```
   [edit protocols igmp]
   user@host# set query-response-interval 0.4
   ```

2. Verify the configuration by checking the IGMP Query Response Interval field in the output of the **show igmp interface** command.
3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

Specifying Immediate-Leave Host Removal for IGMP

The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.

Copyright © 2016, Juniper Networks, Inc.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave on an interface:

1. Configure immediate leave on the IGMP interface.

   ```
   [edit protocols IGMP]
   user@host# set interface ge-0/0/0.1 immediate-leave
   ```

2. Verify the configuration by checking the Immediate Leave field in the output of the **show igmp interface** command.

Filtering Unwanted IGMP Reports at the IGMP Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted IGMP reports at the interface level. When this statement is enabled on a routing device running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), after the routing device receives an IGMP report, the routing device compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only IGMP group addresses (for IGMPv2) by using the policy's **route-filter** statement to match the group address. You define the policy to match IGMP (source, group) addresses (for IGMPv3) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

To filter unwanted IGMP reports:

1. Configure an IGMPv2 policy.

   ```
   [edit policy-statement reject_policy_v2]
   user@host# set from route-filter 224.1.1.1/32 exact
   user@host# set from route-filter 239.0.0.0/8 orlonger
   user@host# set then reject
   ```

2. Configure an IGMPv3 policy.

Copyright © 2016, Juniper Networks, Inc.

```
[edit policy-statement reject_policy_v3]
user@host# set from route-filter 224.1.1.1/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set from source-address-filter 10.0.0.0/8 orlonger
user@host# set from source-address-filter 127.0.0.0/8 orlonger
user@host# set then reject
```

3. Apply the policies to the IGMP interfaces on which you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running IGMPv2, and **ge-0/1/1.0** is running IGMPv3.

```
[edit protocols igmp]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v2
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v3
```

4. Verify the operation of the filter by checking the Rejected Report field in the output of the **show igmp statistics** command.

Accepting IGMP Messages from Remote Subnetworks

By default, IGMP interfaces accept IGMP messages only from the same subnet. Including the **promiscuous-mode** statement enables the routing device to accept IGMP messages from indirectly connected subnets.

NOTE: When you enable IGMP on an unnumbered Ethernet interface that uses a /32 loopback address as a donor address, you must configure IGMP promiscuous mode to accept the IGMP packets received on this interface.

NOTE: When enabling promiscuous-mode, all routing devices on the ethernet segment must be configured with the promiscuous mode statement. Otherwise, only the interface configured with lowest IPv4 address acts as the querier for IGMP for this Ethernet segment.

To enable IGMP promiscuous mode on an interface:

1. Configure the IGMP interface.

```
[edit protocols igmp]
user@host# set interface ge-0/1/1.0 promiscuous-mode
```

2. Verify the configuration by checking the Promiscuous Mode field in the output of the **show igmp interface** command.
3. Verify the operation of the filter by checking the Rx non-local field in the output of the **show igmp statistics** command.

Modifying the IGMP Last-Member Query Interval

The last-member query interval is the maximum amount of time between group-specific query messages, including those sent in response to leave-group messages. You can configure this interval to change the amount of time it takes a routing device to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group message from a host, the routing device sends multiple group-specific queries to the group being left. The querier sends a specific number of these queries at a specific interval. The number of queries sent is called the last-member query count. The interval at which the queries are sent is called the last-member query interval. Because both settings are configurable, you can adjust the leave latency. The IGMP leave latency is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-member query count x (times) the last-member query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-member query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

   ```
   [edit protocols igmp]
   user@host# set query-last-member-interval 0.1
   ```

2. Verify the configuration by checking the **IGMP Last Member Query Interval** field in the output of the **show igmp interfaces** command.

NOTE: You can configure the last-member query count by configuring the robustness variable. The two are always equal.

Related Documentation
- Modifying the IGMP Robustness Variable on page 4047

Modifying the IGMP Robustness Variable

Fine-tune the IGMP robustness variable to allow for expected packet loss on a subnet. The robust count automatically changes certain IGMP message intervals for IGMPv2 and

Copyright © 2016, Juniper Networks, Inc.

IGMPv3. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

When the query router receives an IGMP leave message on a shared network running IGMPv2, the query router must send an IGMP group query message a specified number of times. The number of IGMP group query messages sent is determined by the robust count.

The value of the robustness variable is also used in calculating the following IGMP message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is calculated as follows: (robustness variable x query-interval) + (1 x query-response-interval).
- Other querier present interval—The robust count is used to calculate the amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows: (robustness variable x query-interval) + (0.5 x query-response-interval).
- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The number of queries is equal to the value of the robustness variable.

In IGMPv3, a change of interface state causes the system to immediately transmit a state-change report from that interface. In case the state-change report is missed by one or more multicast routers, it is retransmitted. The number of times it is retransmitted is the robust count minus one. In IGMPv3, the robust count is also a factor in determining the group membership interval, the older version querier interval, and the other querier present interval.

By default, the robustness variable is set to 2. You might want to increase this value if you expect a subnet to lose packets.

The number can be from 2 through 10.

To change the value of the robustness variable:

1. Configure the robust count.

   When you set the robust count, you are in effect configuring the number of times the querier retries queries on the connected subnets.

   ```
   [edit protocols igmp]
   user@host# set robust-count 5
   ```

2. Verify the configuration by checking the IGMP Robustness Count field in the output of the **show igmp interfaces** command.

Limiting the Maximum IGMP Message Rate

This section describes how to change the limit for the maximum number of IGMP packets transmitted in 1 second by the routing device.

Increasing the maximum number of IGMP packets transmitted per second might be useful on a routing device with a large number of interfaces participating in IGMP.

To change the limit for the maximum number of IGMP packets the routing device can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

Related Documentation

- maximum-transmit-rate (Protocols IGMP) on page 4501

Changing the IGMP Version

By default, the routing device runs IGMPv2. Routing devices running different versions of IGMP determine the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version.

To enable source-specific multicast (SSM) functionality, you must configure version 3 on the host and the host's directly connected routing device. If a source address is specified in a multicast group that is statically configured, the version must be set to IGMPv3.

If a static multicast group is configured with the source address defined, and the IGMP version is configured to be version 2, the source is ignored and only the group is added. In this case, the join is treated as an IGMPv2 group join.

If you configure the IGMP version setting at the individual interface hierarchy level, it overrides the **interface all** statement.

If you have already configured the routing device to use IGMP version 1 (IGMPv1) and then configure it to use IGMPv2, the routing device continues to use IGMPv1 for up to 6 minutes and then uses IGMPv2.

To change to IGMPv3 for SSM functionality:

1. Configure the IGMP interface.

   ```
   [edit protocols igmp]
   user@host# set interface ge-0/0/0 version 3
   ```

2. Verify the configuration by checking the version field in the output of the **show igmp interfaces** command. The **show igmp statistics** command has version-specific output fields, such as V1 Membership Report, V2 Membership Report, and V3 Membership Report.

Enabling IGMP Static Group Membership

You can create IGMP static group membership to test multicast forwarding without a receiver host. When you enable IGMP static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts. The router on which you enable static IGMP group membership must be the designated router (DR) for the subnet. Otherwise, traffic does not flow downstream.

When enabling IGMP static group membership, you cannot configure multiple groups using the **group-count**, **group-increment**, **source-count**, and **source-increment** statements if the **all** option is specified as the IGMP interface.

Class-of-service (CoS) adjustment is not supported with IGMP static group membership.

In this example, you create static group 225.1.1.1.

1. On the DR, configure the static groups to be created by including the **static** statement and **group** statement and specifying which IP multicast address of the group to be created. When creating groups individually, you must specify a unique address for each group.

   ```
   [edit protocols igmp]
   user@host# set interface fe-0/1/2 static group 225.1.1.1
   ```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

   ```
   user@host> show configuration protocol igmp

   interface fe-0/1/2.0 {
     static {
       group 225.1.1.1 ;
     }
   }
   ```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created.

   ```
   user@host> show igmp group
   Interface: fe-0/1/2
        Group: 225.1.1.1
            Source: 10.0.0.2
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

NOTE: When you configure static IGMP group entries on point-to-point links that connect routing devices to a rendezvous point (RP), the static IGMP group entries do not generate join messages toward the RP.

Copyright © 2016, Juniper Networks, Inc.

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. On the DR, configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

   ```
   [edit protocols igmp]
   user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3
   ```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

   ```
   user@host> show configuration protocol igmp
   ```

   ```
   interface fe-0/1/2.0 {
     static {
       group 225.1.1.1 {
         group-count 3;
       }
     }
   }
   ```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.2, and 225.1.1.3 have been created.

   ```
   user@host> show igmp group
   Interface: fe-0/1/2
        Group: 225.1.1.1
            Source: 10.0.0.2
            Last reported by: Local
            Timeout: 0 Type: Static
        Group: 225.1.1.2
            Source: 10.0.0.2
            Last reported by: Local
            Timeout: 0 Type: Static
        Group: 225.1.1.3
            Source: 10.0.0.2
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can also configure the group address to be automatically incremented for each group created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and when you do not want the group addresses to be sequential.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. On the DR, configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented

Copyright © 2016, Juniper Networks, Inc.

for each group. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3 group-increment
  0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      group-increment 0.0.0.2;
      group-count 3;
    }
  }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.3, and 225.1.1.5 have been created.

```
user@host> show igmp group
Interface: fe-0/1/2
     Group: 225.1.1.1
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.3
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.5
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, and your network is operating in source-specific multicast (SSM) mode, you can also specify that the multicast source address be accepted. This is useful when you want to test forwarding to multicast receivers from a specific multicast source.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you create group 225.1.1.1 and accept IP address 10.0.0.2 as the only source.

1. On the DR, configure the source address by including the **source** statement and specifying the IPv4 address of the source host.

 Copyright © 2016, Juniper Networks, Inc.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      source 10.0.0.2;
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that source 10.0.0.2 has been accepted.

```
user@host> show igmp group
Interface: fe-0/1/2
     Group: 225.1.1.1
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of multicast sources be automatically accepted. This is useful when you want to test forwarding to multicast receivers from more than one specified multicast source.

In this example, you create group 255.1.1.1 and accept addresses 10.0.0.2, 10.0.0.3, and 10.0.0.4 as the sources.

1. On the DR, configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count
  3
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      source 10.0.0.2 {
        source-count 3;
      }
    }
  }
```

Copyright © 2016, Juniper Networks, Inc.

```
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.3, and 10.0.0.4 have been accepted.

```
user@host> show igmp group
Interface: fe-0/1/2
     Group: 225.1.1.1
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.1
         Source: 10.0.0.3
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.1
         Source: 10.0.0.4
         Last reported by: Local
         Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic, and specify that a number of multicast sources be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and you do not want the source addresses to be sequential.

In this example, you create group 225.1.1.1 and accept addresses 10.0.0.2, 10.0.0.4, and 10.0.0.6 as the sources.

1. Configure the multicast source address increment by including the **source-increment** statement and specifying the number by which the address should be incremented for each source. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count
  3 source-increment 0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      source 10.0.0.2 {
        source-count 3;
        source-increment 0.0.0.2;
      }
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.4, and 10.0.0.6 have been accepted.

```
user@host> show igmp group
Interface: fe-0/1/2
     Group: 225.1.1.1
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.1
         Source: 10.0.0.4
         Last reported by: Local
         Timeout: 0 Type: Static
     Group: 225.1.1.1
         Source: 10.0.0.6
         Last reported by: Local
         Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the source address configured. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the source address configured.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you exclude address 10.0.0.2 as a source for group 225.1.1.1.

1. On the DR, configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv4 source address to exclude.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 exclude source 10.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
  version 3;
  static {
    group 225.1.1.1 {
      exclude;
      source 10.0.0.2;
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group detail** command to verify that static group 225.1.1.1 has been created and that the static group is operating in exclude mode.

```
user@host> show igmp group detail
Interface: fe-0/1/2
     Group: 225.1.1.1
         Group mode: Exclude
         Source: 10.0.0.2
         Last reported by: Local
         Timeout: 0 Type: Static
```

Recording IGMP Join and Leave Events

To determine whether IGMP tuning is needed in a network, you can configure the routing device to record IGMP join and leave events. You can record events globally for the routing device or for individual interfaces.

Table 381 describes the recordable IGMP events.

Table 381: IGMP Event Messages

ERRMSG Tag	Definition
RPD_IGMP_JOIN	Records IGMP join events.
RPD_IGMP_LEAVE	Records IGMP leave events.
RPD_IGMP_ACCOUNTING_ON	Records when IGMP accounting is enabled on an IGMP interface.
RPD_IGMP_ACCOUNTING_OFF	Records when IGMP accounting is disabled on an IGMP interface.
RPD_IGMP_MEMBERSHIP_TIMEOUT	Records IGMP membership timeout events.

To enable IGMP accounting:

1. Enable accounting globally or on an IGMP interface. This example shows both options.

```
[edit protocols igmp]
user@host# set accounting
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set interface fe-0/1/0.2 accounting
```

2. Configure the events to be recorded and filter the events to a system log file with a descriptive filename, such as **igmp-events**.

```
[edit system syslog file igmp-events]
user@host# set any info
user@host# set match ".*RPD_IGMP_JOIN.* | .*RPD_IGMP_LEAVE.* |
  .*RPD_IGMP_ACCOUNTING.* | .*RPD_IGMP_MEMBERSHIP_TIMEOUT.*"
```

3. Periodically archive the log file.

   This example rotates the file size when it reaches 100 KB and keeps three files.

```
[edit system syslog file igmp-events]
user@host# set archive size 100000
user@host# set archive files 3
user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
  "anonymous"
user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
user@host# set archive transfer-interval 24
user@host# set archive start-time 2011-01-07:12:30
```

4. You can monitor the system log file as entries are added to the file by running the ***monitor start*** and ***monitor stop*** commands.

```
user@host> monitor start igmp-events
```

```
*** igmp-events ***
Apr 16 13:08:23  host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command
'run monitor start igmp-events '
monitor
```

Limiting the Number of IGMP Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of IGMP multicast group joins for logical interfaces. When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for IGMP multicast groups, keep the following in mind:

- Each any-source group (*,G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in IGMPv3 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.
- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (*, G1) and (S, G1) would count as two groups toward the configured limit.

Copyright © 2016, Juniper Networks, Inc.

- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The groups must then request to rejoin the network (up to the newly configured group limit).
- You can dynamically limit multicast groups on IGMP logical interfaces using dynamic profiles.

Beginning with Junos OS 12.2, you can optionally configure a system log warning threshold for IGMP multicast group joins received on the logical interface. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of IGMP multicast group joins have been received on the interface. These log messages convey when the configured group limit has been exceeded, when the configured threshold has been exceeded, and when the number of groups drop below the configured threshold.

The **group-threshold** statement enables you to configure the threshold at which a warning message is logged. The range is 1 through 100 percent. The warning threshold is a percentage of the group limit, so you must configure the **group-limit** statement to configure a warning threshold. For instance, when the number of groups exceed the configured warning threshold, but remain below the configured group limit, multicast groups continue to be accepted, and the device logs the warning message. In addition, the device logs a warning message after the number of groups drop below the configured warning threshold. You can further specify the amount of time (in seconds) between the log messages by configuring the **log-interval** statement. The range is 6 through 32,767 seconds.

You might consider throttling log messages because every entry added after the configured threshold and every entry rejected after the configured limit causes a warning message to be logged. By configuring a log interval, you can throttle the amount of system log warning messages generated for IGMP multicast group joins.

To limit multicast group joins on an IGMP logical interface:

1. Access the logical interface at the IGMP protocol hierarchy level.

   [edit]
   user@host# **edit protocols igmp interface** ***interface-name***

2. Specify the group limit for the interface.

   [edit protocols igmp interface *interface-name*]
   user@host# **set group-limit** ***limit***

3. (Optional) Configure the amount of time between log messages.

   [edit protocols igmp interface *interface-name*]
   user@host# **set log-interval** ***seconds***

To confirm your configuration, use the **show protocols igmp** command. To verify the operation of IGMP on the interface, including the configured group limit and the optional warning threshold and interval between log messages, use the **show igmp interface** command.

Tracing IGMP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
all	Trace all operations.
client-notification	Trace notifications.
general	Trace general flow.
group	Trace group operations.
host-notification	Trace host notifications.
leave	Trace leave group messages (IGMPv2 only).
mtrace	Trace mtrace packets. Use the **mtrace** command to troubleshoot the software.
normal	Trace normal events.
packets	Trace all IGMP packets.
policy	Trace policy processing.
query	Trace IGMP membership query messages, including general and group-specific queries.
report	Trace membership report messages.
route	Trace routing information.
state	Trace state transitions.
task	Trace task processing.
timer	Trace timer processing.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on IGMP packets of a particular type. To configure tracing operations for IGMP:

1. (Optional) Configure tracing at the routing options level to trace all protocol packets.

   [edit routing-options traceoptions]

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the IGMP trace file.

```
[edit protocols igmp traceoptions]
user@host# set file igmp-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols igmp traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols igmp traceoptions]
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols igmp traceoptions]
user@host# set file world-readable
```

6. Configure tracing flags. Suppose you are troubleshooting issues with a particular multicast group. The following example shows how to flag all events for packets associated with the group IP address.

```
[edit protocols igmp traceoptions]
user@host# set flag group | match 232.1.1.2
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/igmp-trace
```

Disabling IGMP

To disable IGMP on an interface, include the **disable** statement:

```
disable;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols igmp interface *interface-name*]**
- **[edit logical-systems *logical-system-name* protocols igmp interface *interface-name*]**

IGMP and Nonstop Active Routing

Nonstop active routing (NSR) configurations include two Routing Engines that share information so that routing is not interrupted during Routing Engine failover. These NSR configurations include passive support with IGMP in connection with PIM. The master

Copyright © 2016, Juniper Networks, Inc.

Routing Engine uses IGMP to determine its PIM multicast state, and this IGMP-derived information is replicated on the backup Routing Engine. IGMP on the new master Routing Engine (after failover) relearns the state information quickly through IGMP operation. In the interim, the new master Routing Engine retains the IGMP-derived PIM state as received by the replication process from the old master Routing Engine. This state information times out unless refreshed by IGMP on the new master Routing Engine. No additional IGMP configuration is required.

Understanding MLD

The Multicast Listener Discovery (MLD) Protocol manages the membership of hosts and routers in multicast groups. IP version 6 (IPv6) multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. Each router maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the router does not need to know the address of each listener—just the address of each host. The router provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol.

MLD is an integral part of IPv6 and must be enabled on all IPv6 routers and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

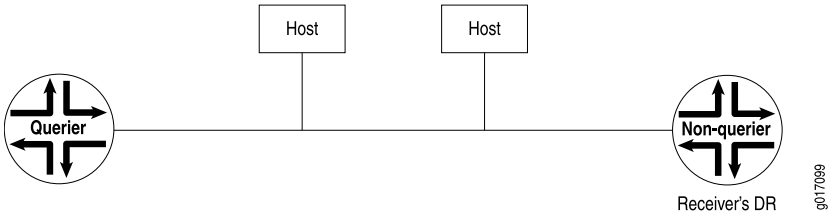
Copyright © 2016, Juniper Networks, Inc.

In include mode, the receiver specifies the source or sources it is interested in receiving the multicast group traffic from. Exclude mode works the opposite of include mode. It allows the receiver to specify the source or sources it is not interested in receiving the multicast group traffic from.

For each attached network, a multicast router can be either a querier or a nonquerier. A querier router, usually one per subnet, solicits group membership information by transmitting MLD queries. When a host reports to the querier router that it has interested listeners, the querier router forwards the membership information to the rendezvous point (RP) router by means of the receiver's (host's) designated router (DR). This builds the rendezvous-point tree (RPT) connecting the host with interested listeners to the RP router. The RPT is the initial path used by the sender to transmit information to the interested listeners. Nonquerier routers do not transmit MLD queries on a subnet but can do so if the querier router fails.

All MLD-configured routers start as querier routers on each attached subnet (see Figure 154). The querier router on the right is the receiver's DR.

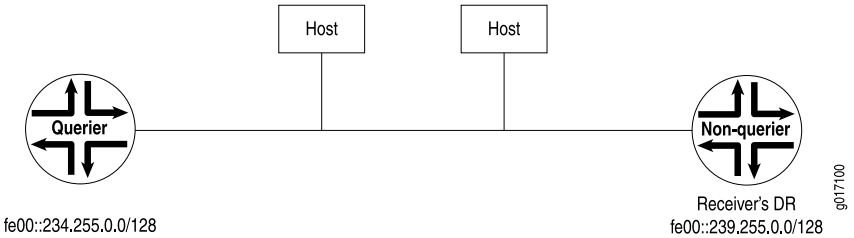
Figure 154: Routers Start Up on a Subnet



To elect the querier router, the routers exchange query messages containing their IPv6 source addresses. If a router hears a query message whose IPv6 source address is numerically lower than its own selected address, it becomes a nonquerier. In Figure 155, the router on the left has a source address numerically lower than the one on the right and therefore becomes the querier router.

NOTE: In the practical application of MLD, several routers on a subnet are nonqueriers. If the elected querier router fails, query messages are exchanged among the remaining routers. The router with the lowest IPv6 source address becomes the new querier router. The IPv6 Neighbor Discovery Protocol (NDP) implementation drops incoming Neighbor Announcement (NA) messages that have a broadcast or multicast address in the target link-layer address option. This behavior is recommended by RFC 2461.

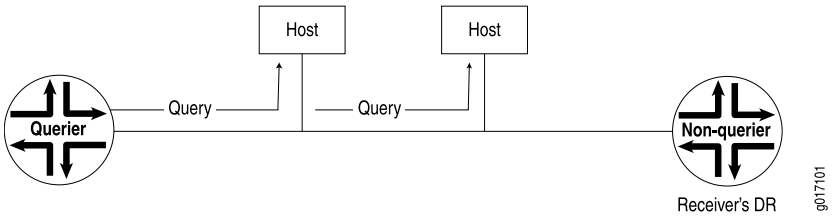
Figure 155: Querier Router Is Determined



Copyright © 2016, Juniper Networks, Inc.

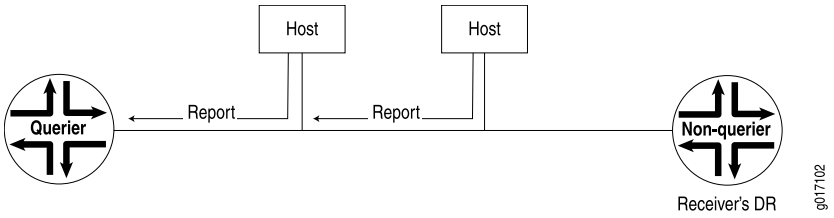
The querier router sends general MLD queries on the **link-scope all-nodes** multicast address FF02::1 at short intervals to all attached subnets to solicit group membership information (see Figure 156). Within the query message is the *maximum response delay* value, specifying the maximum allowed delay for the host to respond with a report message.

Figure 156: General Query Message Is Issued



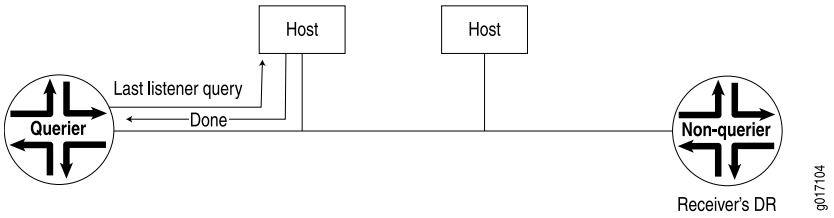
If interested listeners are attached to the host receiving the query, the host sends a report containing the host's IPv6 address to the router (see Figure 157). If the reported address is not yet in the router's list of multicast addresses with interested listeners, the address is added to the list and a timer is set for the address. If the address is already on the list, the timer is reset. The host's address is transmitted to the RP in the PIM domain.

Figure 157: Reports Are Received by the Querier Router



If the host has no interested multicast listeners, it sends a done message to the querier router. On receipt, the querier router issues a multicast address-specific query containing the last **listener query interval** value to the multicast address of the host. If the router does not receive a report from the multicast address, it removes the multicast address from the list and notifies the RP in the PIM domain of its removal (see Figure 158).

Figure 158: Host Has No Interested Receivers and Sends a Done Message to Router



If a done message is not received by the querier router, the querier router continues to send multicast address-specific queries. If the timer set for the address on receipt of the last report expires, the querier router assumes there are no longer interested listeners on that subnet, removes the multicast address from the list, and notifies the RP in the PIM domain of its removal (see Figure 159).

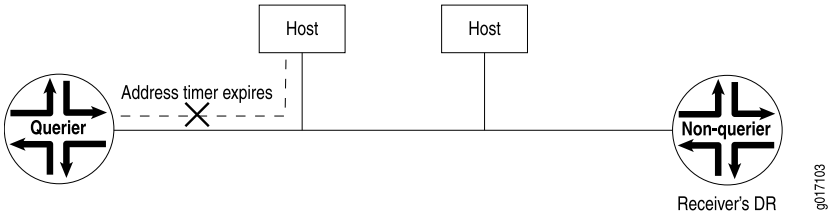
Figure 159: Host Address Timer Expires and Address Is Removed from Multicast Address List



Configuring MLD

To configure the Multicast Listener Discovery (MLD) Protocol, include the **mld** statement:

```
mld {
  accounting;
  interface interface-name {
    disable;
    (accounting | no-accounting);
    group-policy [ policy-names ];
    immediate-leave;
    oif-map [ map-names ];
    passive;
    ssm-map ssm-map-name;
    static {
      group multicast-group-address {
        exclude;
        group-count number;
        group-increment increment;
        source ip-address {
          source-count number;
          source-increment increment;
        }
      }
    }
    version version;
  }
  maximum-transmit-rate packets-per-second;
  query-interval seconds;
  query-last-member-interval seconds;
  query-response-interval seconds;
  robust-count number;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

Copyright © 2016, Juniper Networks, Inc.

By default, MLD is enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or the Distance Vector Multicast Routing Protocol (DVMRP).

Enabling MLD

The Multicast Listener Discovery (MLD) Protocol manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use MLD to learn which groups have members on each of their attached physical networks. MLD must be enabled for the router to receive IPv6 multicast packets. MLD is only needed for IPv6 networks, because multicast is handled differently in IPv4 networks. MLD is enabled on all IPv6 interfaces on which you configure PIM and on all IPv6 broadcast interfaces when you configure DVMRP.

MLD specifies different behaviors for multicast listeners and for routers. When a router is also a listener, the router responds to its own messages. If a router has more than one interface to the same link, it needs to perform the router behavior over only one of those interfaces. Listeners, on the other hand, must perform the listener behavior on all interfaces connected to potential receivers of multicast traffic.

If MLD is not running on an interface—either because PIM and DVMRP are not configured on the interface or because MLD is explicitly disabled on the interface—you can explicitly enable MLD.

To explicitly enable MLD:

1. If PIM and DVMRP are not running on the interface, explicitly enable MLD by including the interface name.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/0/0.0
   ```

2. Check to see if MLD is disabled on any interfaces. In the following example, MLD is disabled on a Gigabit Ethernet interface.

   ```
   [edit protocols mld]
   user@host# show
   ```

   ```
   interface fe-0/0/0.0;
   interface ge-0/0/0.0 {
       disable;
   }
   ```

3. Enable MLD on the interface by deleting the **disable** statement.

   ```
   [edit protocols mld]
   delete interface ge-0/0/0.0 disable
   ```

4. Verify the configuration.

   ```
   [edit protocols mld]
   user@host# show
   ```

   ```
   interface fe-0/0/0.0;
   interface ge-0/0/0.0;
   ```

5. Verify the operation of MLD by checking the output of the **show mld interface** command.

Copyright © 2016, Juniper Networks, Inc.

Related Documentation

- Disabling MLD on page 4085
- **show mld interface on page 4699** in the CLI Explorer

Modifying the MLD Version

By default, the router supports MLD version 1 (MLDv1). To enable the router to use MLD version 2 (MLDv2) for source-specific multicast (SSM) only, include the **version 2** statement.

If you configure the MLD version setting at the individual interface hierarchy level, it overrides configuring the IGMP version using the **interface all** statement.

If a source address is specified in a multicast group that is statically configured, the version must be set to MLDv2.

To change an MLD interface to version 2:

1. Configure the MLD interface.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/0/0.0 version 2
   ```

2. Verify the configuration by checking the **version** field in the output of the **show mld interface** command. The **show mld statistics** command has version-specific output fields, such as the counters in the **MLD Message type** field.

Modifying the MLD Host-Query Message Interval

The objective of MLD is to keep routers up to date with IPv6 group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The MLD querier router periodically sends general host-query messages on each attached network to solicit membership information. These messages solicit group membership information and are sent to the **link-scope all-nodes** address **FF02::1**. A general host-query message has a maximum response time that you can set by configuring the query response interval.

Copyright © 2016, Juniper Networks, Inc.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of MLD messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

   ```
   [edit protocols mld]
   user@host# set query-interval 200
   ```

   The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the **MLD Query Interval** field in the output of the **show mld interface** command.

3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

Related Documentation

- **show mld statistics on page 4702** in the CLI Explorer

Modifying the MLD Query Response Interval

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. You can change this interval to adjust the burst peaks of MLD messages on the subnet. Set a larger interval to make the traffic less bursty.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

Copyright © 2016, Juniper Networks, Inc.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.

   ```
   [edit protocols mld]
   user@host# set query-response-interval 0.5
   ```

2. Verify the configuration by checking the **MLD Query Response Interval** field in the output of the **show mld interface** command.
3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

Related Documentation

- Example: Modifying the MLD Robustness Variable on page 4073
- **show mld interface on page 4699** in the CLI Explorer
- **show mld statistics on page 4702** in the CLI Explorer

Modifying the MLD Last-Member Query Interval

The last-member query interval (also called the last-listener query interval) is the maximum amount of time between group-specific query messages, including those sent in response to done messages sent on the **link-scope-all-routers** address FF02::2. You can lower this interval to reduce the amount of time it takes a router to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group (done) message from a host, the routing device sends multiple group-specific queries to the group. The querier sends a specific number of these queries, and it sends them at a specific interval. The number of queries sent is called the last-listener query count. The interval at which the queries are sent is called the last-listener query interval. Both settings are configurable, thus allowing you to adjust the leave latency. The IGMP leave latency is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-listener query count x (times) the last-listener query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-listener query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

Copyright © 2016, Juniper Networks, Inc.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

   ```
   [edit protocols mld]
   user@host# set query-last-member-interval 0.1
   ```

2. Verify the configuration by checking the **MLD Last Member Query Interval** field in the output of the **show igmp interfaces** command.

NOTE: You can configure the last-member query count by configuring the robustness variable. The two are always equal.

Specifying Immediate-Leave Host Removal for MLD

The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.

Copyright © 2016, Juniper Networks, Inc.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave:

1. Configure immediate leave on the MLD interface.

   ```
   [edit protocols mld]
   user@host# set interface ge-0/0/0.1 immediate-leave
   ```

2. Verify the configuration by checking the **Immediate Leave** field in the output of the **show mld interface** command.

Related Documentation

- show mld interface on page 4699 in the CLI Explorer

Filtering Unwanted MLD Reports at the MLD Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted MLD reports at the interface level.

When the **group-policy** statement is enabled on a router, after the router receives an MLD report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only MLD group addresses (for MLDv1) by using the policy's **route-filter** statement to match the group address. You define the policy to match MLD (source, group) addresses (for MLDv2) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

To filter unwanted MLD reports:

1. Configure an MLDv1 policy.

   ```
   [edit policy-statement reject_policy_v1]
   user@host# set from route-filter fec0:1:1:4::/64 exact
   user@host# set then reject
   ```

2. Configure an MLDv2 policy.

   ```
   [edit policy-statement reject_policy_v2]
   user@host# set from route-filter fec0:1:1:4::/64 exact
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set from source-address-filter fe80::2e0:81ff:fe05:1a8d/32 orlonger
user@host# set then reject
```

3. Apply the policies to the MLD interfaces where you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running MLDv1 and **ge-0/1/1.0** is running MLDv2.

```
[edit protocols mld]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v1
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v2
```

4. Verify the operation of the filter by checking the **Rejected Report** field in the output of the **show mld statistics** command.

Example: Modifying the MLD Robustness Variable

This example shows how to configure and verify the MLD robustness variable in a multicast domain.

- Requirements on page 4073
- Overview on page 4073
- Configuration on page 4074
- Verification on page 4074

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable PIM. See "PIM Overview" on page 4089.

Overview

The MLD robustness variable can be fine-tuned to allow for expected packet loss on a subnet. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

The value of the robustness variable is used in calculating the following MLD message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is

Copyright © 2016, Juniper Networks, Inc.

calculated as follows: (robustness variable x query-interval) + (1 x query-response-interval).

- Other querier present interval—Amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows: (robustness variable x query-interval) + (0.5 x query-response-interval).
- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The default number is the value of the robustness variable.

By default, the robustness variable is set to 2. The number can be from 2 through 10. You might want to increase this value if you expect a subnet to lose packets.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols mld robust-count 5
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To change the value of the robustness variable:

1. Configure the robust count.

   ```
   [edit protocols mld]
   user@host# set robust-count 5
   ```

2. If you are done configuring the device, commit the configuration.

   ```
   [edit protocols mld]
   user@host# commit
   ```

Verification

To verify the configuration is working properly, check the **MLD Robustness Count** field in the output of the **show mld interfaces** command.

Limiting the Maximum MLD Message Rate

You can change the limit for the maximum number of MLD packets transmitted in 1 second by the router.

Increasing the maximum number of MLD packets transmitted per second might be useful on a router with a large number of interfaces participating in MLD.

To change the limit for the maximum number of MLD packets the router can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

Enabling MLD Static Group Membership

You can create MLD static group membership to test multicast forwarding without a receiver host. When you enable MLD static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts.

Class-of-service (CoS) adjustment is not supported with MLD static group membership.

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify the number of static groups to be automatically created.

In this example, you create static group ff02::1:ff05:1a8d.

1. Configure the static groups to be created by including the **static** statement and **group** statement and specifying which IPv6 multicast address of the group to be created.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d
   ```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

   ```
   user@host> show configuration protocol mld

   interface fe-0/1/2.0 {
     static {
       group ff02::1:ff05:1a8d;
     }
   }
   ```

3. After you have committed the configuration and after the source is sending traffic, use the **show mld group** command to verify that static group ff02::1:ff05:1a8d has been created.

   ```
   user@host> show mld group
   Interface: fe-0/1/2
   Group: ff02::1:ff05:1a8d
   Group mode: Include
   Source: fe80::2e0:81ff:fe05:1a8d
   Last reported by: Local
   Timeout: 0 Type: Static
   ```

Copyright © 2016, Juniper Networks, Inc.

NOTE: You must specify a unique address for each group.

Automatically create static groups

When you create MLD static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. Configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d group-count 3
   ```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

   ```
   user@host> show configuration protocol mld

   interface fe-0/1/2.0 {
     static {
       group ff02::1:ff05:1a8d {
         group-count 3;
       }
     }
   }
   ```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff02::1:ff05:1a8d, ff02::1:ff05:1a8e, and ff02::1:ff05:1a8f have been created.

   ```
   user@host> show mld group

   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8d
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8e
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8f
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

Automatically increment group addresses

Copyright © 2016, Juniper Networks, Inc.

When you configure static groups on an interface on which you want to receive multicast traffic and you specify the number of static groups to be automatically created, you can also configure the group address to be automatically incremented by some number of addresses.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. Configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented for each group. The increment is specified in a format similar to an IPv6 address.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d group-count 3
     group-increment ::2
   ```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

   ```
   user@host> show configuration protocol mld

   interface fe-0/1/2.0 {
     static {
       group ff02::1:ff05:1a8d {
         group-increment ::2;
         group-count 3;
       }
     }
   }
   ```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff02::1:ff05:1a8d, ff02::1:ff05:1a8f, and ff02::1:ff05:1a91 have been created.

   ```
   user@host> show mld group

   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8d
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8f
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a91
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

Specify multicast source address (in SSM mode)

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify the multicast source address to be accepted.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you create group ff02::1:ff05:1a8d and accept IPv6 address fe80::2e0:81ff:fe05:1a8d as the only source.

1. Configure the source address by including the **source** statement and specifying the IPv6 address of the source host.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d source
     fe80::2e0:81ff:fe05:1a8d
   ```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

   ```
   user@host> show configuration protocol mld

   interface fe-0/1/2.0 {
     static {
       group ff02::1:ff05:1a8d {
         source fe80::2e0:81ff:fe05:1a8d;
       }
     }
   }
   ```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff02::1:ff05:1a8d has been created and that source fe80::2e0:81ff:fe05:1a8d has been accepted.

   ```
   user@host> show mld group

   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8d
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

Automatically specify multicast sources

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify a number of multicast sources to be automatically accepted.

In this example, you create static group ff02::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f as the source addresses.

1. Configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

   ```
   [edit protocols mld]
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d source
  fe80::2e0:81ff:fe05:1a8d source-count 3
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
  static {
    group ff02::1:ff05:1a8d {
      source fe80::2e0:81ff:fe05:1a8d {
        source-count 3;
      }
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff02::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f have been accepted.

```
user@host> show mld group

Interface: fe-0/1/2
     Group: ff02::1:ff05:1a8d
         Source: fe80::2e0:81ff:fe05:1a8d
         Last reported by: Local
         Timeout: 0 Type: Static
Interface: fe-0/1/2
     Group: ff02::1:ff05:1a8d
         Source: fe80::2e0:81ff:fe05:1a8e
         Last reported by: Local
         Timeout: 0 Type: Static
Interface: fe-0/1/2
     Group: ff02::1:ff05:1a8d
         Source: fe80::2e0:81ff:fe05:1a8f
         Last reported by: Local
         Timeout: 0 Type: Static
```

Automatically increment source addresses

When you configure static groups on an interface on which you want to receive multicast traffic, and specify a number of multicast sources to be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted.

In this example, you create static group ff02::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 as the sources.

1. Configure the number of multicast source addresses to be accepted by including the **source-increment** statement and specifying the number of sources to be accepted.

```
[edit protocols mld]
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d source
  fe80::2e0:81ff:fe05:1a8d source-count 3 source-increment ::2
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
  static {
    group ff02::1:ff05:1a8d {
      source fe80::2e0:81ff:fe05:1a8d {
        source-count 3;
        source-increment ::2;
      }
    }
  }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff02::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 have been accepted.

```
user@host> show mld group

Interface: fe-0/1/2
     Group: ff02::1:ff05:1a8d
         Source: fe80::2e0:81ff:fe05:1a8d
         Last reported by: Local
         Timeout: 0 Type: Static
Interface: fe-0/1/2

Exclude multicast source addresses (in SSM mode)

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the configured source address. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the configured source address.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you exclude address fe80::2e0:81ff:fe05:1a8d as a source for group ff02::1:ff05:1a8d.

1. Configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv6 source address to be excluded.

   ```
   [edit protocols mld]
   user@host# set interface fe-0/1/2 static group ff02::1:ff05:1a8d exclude source
     fe80::2e0:81ff:fe05:1a8d
   ```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

   ```
   user@host> show configuration protocol mld

   interface fe-0/1/2.0 {
     static {
       group ff02::1:ff05:1a8d {
         exclude;
         source fe80::2e0:81ff:fe05:1a8d;
       }
     }
   }
   ```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group detail** command to verify that static group ff02::1:ff05:1a8d has been created and that the static group is operating in exclude mode.

   ```
   user@host> show mld group detail
   Interface: fe-0/1/2
        Group: ff02::1:ff05:1a8d
            Group mode: Exclude
            Source: fe80::2e0:81ff:fe05:1a8d
            Last reported by: Local
            Timeout: 0 Type: Static
   ```

Similar configuration is available for IPv4 multicast traffic using the IGMP protocol.

Related Documentation

- Enabling IGMP Static Group Membership on page 4050

Example: Recording MLD Join and Leave Events

This example shows how to determine whether MLD tuning is needed in a network by configuring the routing device to record MLD join and leave events.

- Requirements on page 4082
- Overview on page 4082
- Configuration on page 4082
- Verification on page 4084

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable PIM. See "PIM Overview" on page 4089.

Overview

Table 382 describes the recordable MLD join and leave events.

Table 382: MLD Event Messages

ERRMSG Tag	Definition
RPD_MLD_JOIN	Records MLD join events.
RPD_MLD_LEAVE	Records MLD leave events.
RPD_MLD_ACCOUNTING_ON	Records when MLD accounting is enabled on an MLD interface.
RPD_MLD_ACCOUNTING_OFF	Records when MLD accounting is disabled on an MLD interface.
RPD_MLD_MEMBERSHIP_TIMEOUT	Records MLD membership timeout events.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Copyright © 2016, Juniper Networks, Inc.

```
set protocols mld interface fe-0/1/0.2 accounting
set system syslog file mld-events any info
set system syslog file mld-events match ".*RPD_MLD_JOIN.* | .*RPD_MLD_LEAVE.* |
  .*RPD_MLD_ACCOUNTING.* | .*RPD_MLD_MEMBERSHIP_TIMEOUT.*"
set system syslog file mld-events archive size 100000
set system syslog file mld-events archive files 3
set system syslog file mld-events archive transfer-interval 1440
set system syslog file mld-events archive archive-sites "ftp://user@host1//var/tmp"
  password "anonymous"
set system syslog file mld-events archive archive-sites "ftp://user@host2//var/tmp"
  password "test"
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure recording of MLD join and leave events:

1. Enable accounting globally or on an MLD interface. This example shows the interface configuration.

   ```
   [edit protocols mld]
   user@host# set interface fe–0/1/0.2 accounting
   ```

2. Configure the events to be recorded, and filter the events to a system log file with a descriptive filename, such as **mld-events**.

   ```
   [edit system syslog file mld-events]
   user@host# set any info
   [edit system syslog file mld-events]
   user@host# set match ".*RPD_MLD_JOIN.* | .*RPD_MLD_LEAVE.* |
     .*RPD_MLD_ACCOUNTING.* | .*RPD_MLD_MEMBERSHIP_TIMEOUT.*"
   ```

3. Periodically archive the log file.

   This example rotates the file every 24 hours (1440 minutes) when it reaches 100 KB and keeps three files.

   ```
   [edit system syslog file mld-events]
   user@host# set archive size 100000
   [edit system syslog file mld-events]
   user@host# set archive files 3
   [edit system syslog file mld-events]
   user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
     "anonymous"
   [edit system syslog file mld-events]
   user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
   [edit system syslog file mld-events]
   user@host# set archive transfer-interval 1440
   [edit system syslog file mld-events]
   user@host# set archive start-time 2011–01–07:12:30
   ```

4. If you are done configuring the device, commit the configuration.

   ```
   [edit system syslog file mld-events]]
   user@host# commit
   ```

Copyright © 2016, Juniper Networks, Inc.

Verification

You can view the system log file by running the **file show** command.

```
user@host> file show mld-events
```

You can monitor the system log file as entries are added to the file by running the ***monitor start*** and ***monitor stop*** commands.

```
user@host> monitor start mld-events
```

```
*** mld-events ***
Apr 16 13:08:23  host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command 'run
 monitor start mld-events '
monitor
```

Configuring the Number of MLD Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of MLD multicast group joins for logical interfaces. When this statement is enabled on a router running MLD version 2, the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for MLD multicast groups, keep the following in mind:

- Each any-source group (*,G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in MLDv2 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.
- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (*, G1) and (S, G1) would count as two groups toward the configured limit.
- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The groups must then request to rejoin the network (up to the newly configured group limit).
- You can dynamically limit multicast groups on MLD logical interfaces by using dynamic profiles.

To limit multicast group joins on an MLD logical interface:

1. Access the logical interface at the MLD protocol hierarchy level.

   ```
   [edit]
   user@host# edit protocols mld interface interface-name
   ```

Copyright © 2016, Juniper Networks, Inc.

2. Specify the group limit for the interface.

```
[edit protocols mld interface interface-name]
user@host# set group-limit limit
```

Related Documentation

- Enabling MLD Static Group Membership on page 4075

Disabling MLD

To disable MLD on an interface, include the **disable** statement:

```
interface interface-name {
  disable;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols** mld**]**
- **[edit logical-systems** *logical-system-name* **protocols** mld**]**

CHAPTER 178

Understanding PIM

- PIM Overview on page 4089

PIM Overview

The predominant multicast routing protocol in use on the Internet today is Protocol Independent Multicast, or PIM. The type of PIM used on the Internet is PIM sparse mode. PIM sparse mode is so accepted that when the simple term “PIM” is used in an Internet context, some form of sparse mode operation is assumed.

PIM emerged as an algorithm to overcome the limitations of dense-mode protocols such as the Distance Vector Multicast Routing Protocol (DVMRP), which was efficient for dense clusters of multicast receivers, but did not scale well for the larger, sparser, groups encountered on the Internet. The Core Based Trees (CBT) Protocol was intended to support sparse mode as well, but CBT, with its all-powerful core approach, made placement of the core critical, and large conference-type applications (many-to-many) resulted in bottlenecks in the core. PIM was designed to avoid the dense-mode scaling issues of DVMRP and the potential performance issues of CBT at the same time.

PIM is one of the most rapidly evolving specifications on the Internet today. Since its introduction in 1995, PIM has already seen two major revisions to its packet structure (PIM version 1 [PIMv1] and PIM version 2 [PIMv2]), two major RFCs (RFC 2362 obsoleted RFC 2117), and numerous drafts describing major components of PIM, such as many-to-many trees and source-specific multicast (SSM). Long-lasting RFCs are not a feature of PIM, and virtually all of PIM must be researched, understood, and implemented directly from Internet drafts. In fact, no current RFC describes PIMv1 at all. The drafts have all expired, and PIMv1 was never issued as an official RFC.

PIM itself is not nonstandard or unstable, however. PIM has been a promising multicast routing protocol since its inception, especially PIM sparse mode, the first real sparse-mode multicast routing protocol. Work continues on PIM in a number of areas, from bidirectional trees to network management, and the rapid pace of development makes drafts essential for PIM.

PIMv1 and PIMv2 can coexist on the same router and even on the same interface. The main difference between PIMv1 and PIMv2 is the packet format. PIMv1 messages use Internet Group Management Protocol (IGMP) packets, whereas PIMv2 has its own IP protocol number (103) and packet structure. All routers connecting to an IP subnet such as a LAN must use the same PIM version. Some PIM implementations can recognize

Copyright © 2016, Juniper Networks, Inc.

PIMv1 packets and automatically switch the router interface to PIMv1. Because the difference between PIMv1 and PIMv2 involves the message format, but not the meaning of the message or how the router processes the PIM message, a router can easily mix PIMv1 and PIMv2 interfaces.

PIM is used for efficient routing to multicast groups that might span wide-area and interdomain internetworks. It is called "protocol independent" because it does not depend on a particular unicast routing protocol. Junos OS supports bidirectional mode, sparse mode, dense mode, and sparse-dense mode.

PIM operates in several modes: bidirectional mode, sparse mode, dense mode, and sparse-dense mode. In sparse-dense mode, some multicast groups are configured as dense mode (flood-and-prune, [S,G] state) and others are configured as sparse mode (explicit join to rendezvous point [RP], [*,G] state).

PIM drafts also establish a mode known as PIM source-specific mode, or PIM SSM. In PIM SSM there is only one specific source for the content of a multicast group within a given domain.

Because the PIM mode you choose determines the PIM configuration properties, you first must decide whether PIM operates in bidirectional, sparse, dense, or sparse-dense mode in your network. Each mode has distinct operating advantages in different network environments.

- In sparse mode, routers must join and leave multicast groups explicitly. Upstream routers do not forward multicast traffic to a downstream router unless the downstream router has sent an explicit request (by means of a join message) to the rendezvous point (RP) router to receive this traffic. The RP serves as the root of the shared multicast delivery tree and is responsible for forwarding multicast data from different sources to the receivers.

  Sparse mode is well suited to the Internet, where frequent interdomain join messages and prune messages are common.

- Bidirectional PIM is similar to sparse mode, and is especially suited to applications that must scale to support a large number of dispersed sources and receivers. In bidirectional PIM, routers build shared bidirectional trees and do not switch to a source-based tree. Bidirectional PIM scales well because it needs no source-specific (S,G) state. Instead, it builds only group-specific (*,G) state.

- Unlike sparse mode and bidirectional mode, in which data is forwarded only to routers sending an explicit PIM join request, dense mode implements a *flood-and-prune* mechanism, similar to the Distance Vector Multicast Routing Protocol (DVMRP). In dense mode, a router receives the multicast data on the incoming interface, then forwards the traffic to the outgoing interface list. Flooding occurs periodically and is used to refresh state information, such as the source IP address and multicast group pair. If the router has no interested receivers for the data, and the outgoing interface list becomes empty, the router sends a PIM prune message upstream.

Copyright © 2016, Juniper Networks, Inc.

Dense mode works best in networks where few or no prunes occur. In such instances, dense mode is actually more efficient than sparse mode.

- Sparse-dense mode, as the name implies, allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as “dense” is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense mode rules. A group specified as “sparse” is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules. Sparse-dense mode is useful in networks implementing auto-RP for PIM sparse mode.

NOTE: On SRX Series devices, PIM does not support upstream and downstream interfaces across different virtual routers in flow mode.

Basic PIM Network Components

PIM dense mode requires only a multicast source and series of multicast-enabled routers running PIM dense mode to allow receivers to obtain multicast content. Dense mode makes sure that all multicast traffic gets everywhere by periodically flooding the network with multicast traffic, and relies on prune messages to make sure that subnets where all receivers are uninterested in that particular multicast group stop receiving packets.

PIM sparse mode is more complicated and requires the establishment of special routers called *rendezvous points* (*RPs*) in the network core. These routers are where upstream join messages from interested receivers meet downstream traffic from the source of the multicast group content. A network can have many RPs, but PIM sparse mode allows only one RP to be active for any multicast group.

If there is only one RP in a routing domain, the RP and adjacent links might become congested and form a single point of failure for all multicast traffic. Thus, multiple RPs are the rule, but the issue then becomes how other multicast routers find the RP that is the source of the multicast group the receiver is trying to join. This RP-to-group mapping is controlled by a special *bootstrap router* (*BSR*) running the PIM BSR mechanism. There can be more than one bootstrap router as well, also for single-point-of-failure reasons.

The bootstrap router does not have to be an RP itself, although this is a common implementation. The bootstrap router's main function is to manage the collection of RPs and allow interested receivers to find the source of their group's multicast traffic.

PIM SSM can be seen as a subset of a special case of PIM sparse mode and requires no specialized equipment other than that used for PIM sparse mode (and IGMP version 3).

Bidirectional PIM RPs, unlike RPs for PIM sparse mode, do not need to perform PIM Register tunneling or other specific protocol action. Bidirectional PIM RPs implement no specific functionality. RP addresses are simply a location in the network to rendezvous toward. In fact, for bidirectional PIM, RP addresses need not be loopback interface addresses or even be addresses configured on any router, as long as they are covered by a subnet that is connected to a bidirectional PIM-capable router and advertised to the network.

PIM Configuration Statements

To configure Protocol Independent Multicast (PIM), include the **pim** statement:

```
pim {
  disable;
  default-vpn-source {
    interface-name interface-name;
  }
  assert-timeout seconds;
  dense-groups {
    addresses;
  }
  dr-election-on-p2p;
  export;
  graceful-restart {
    disable;
    no-bidirectional-mode;
    restart-duration seconds;
  }
  idle-standby-path-switchover-delay seconds;
  import [ policy-names ];
  interface interface-name {
    bidirectional {
      df-election {
```

Copyright © 2016, Juniper Networks, Inc.

```
        backoff-period milliseconds;
        offer-period milliseconds;
        robustness-count number;
      }
    }
    import;
    hello-interval seconds;
    mode bidirectional-sparse | bidirectional-sparse-dense | (dense | sparse |
      sparse-dense);
    neighbor-policy [ policy-names ];
    override-interval milliseconds;
    priority number;
    propagation-delay milliseconds;
    reset-tracking-bit;
    version version;
  }
  join-load-balance {
    automatic;
  }
  join-prune-timeout;
  nonstop-routing {
    disable;
  }
  override-interval milliseconds;
  propagation-delay milliseconds;
  reset-tracking-bit;
  rib-group {
    inet group-name;
    inet6 group-name;
  }
  rp {
    auto-rp {
      (announce | discovery | mapping);
      (mapping-agent-election | no-mapping-agent-election);
    }
    bidirectional {
      address address {
        group-ranges {
          destination-ip-prefix</prefix-length>;
        }
        hold-time seconds;
        priority number;
        }
      }
    bootstrap {
      family (inet | inet6) {
        export [ policy-names ];
        import [ policy-names ];
        priority number;
      }
    }
    bootstrap-export [ policy-names ];
    bootstrap-import [ policy-names ];
    bootstrap-priority number;
    dr-register-policy [ policy-names ];
    embedded-rp {
```

Copyright © 2016, Juniper Networks, Inc.

```
        group-ranges {
          destination-ip-prefix</prefix-length>;
        }
        maximum-rps limit;
      }
      local {
        family (inet | inet6) {
          address address;
          anycast-pim {
            rp-set {
              address address <forward-msdp-sa>;
            }
            local-address address;
          }
          disable;
          group-ranges {
            destination-ip-prefix</prefix-length>;
          }
          hold-time seconds;
          override;
          priority number;
        }
      }
      rp-register-policy [ policy-names ];
      static {
        address address {
          override;
          version version;
          group-ranges {
            destination-ip-prefix</prefix-length>;
          }
          spt-threshold {
            infinity [ policy-names ];
          }
          traceoptions {
            file filename <files number> <size size> <world-readable | no-world-readable>;
            flag flag <flag-modifier> <disable>;
          }
        }
      }
    }
  }
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit routing-instances *routing-instance-name* protocols]**
- **[edit logical-systems *logical-system-name* protocols]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]**

By default, PIM is disabled.

Copyright © 2016, Juniper Networks, Inc.

NOTE: You cannot configure PIM within a nonforwarding instance. If you try to do so, the router displays a commit check error and does not complete the configuration commit process.

Changing the PIM Version

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default for rendezvous point (RP) mode (at the **[edit protocols pim rp static address *address*]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface *interface-name*]** hierarchy level). Explicitly configured versions override the defaults.

To configure the PIM version, include the **version** statement:

```
version (1 | 2);
```

Modifying the PIM Hello Interval

Routing devices send hello messages at a fixed interval on all PIM-enabled interfaces. By using hello messages, routing devices advertise their existence as PIM routing devices on the subnet. With all PIM-enabled routing devices advertised, a single designated router for the subnet is established.

When a routing device is configured for PIM, it sends a hello message at a 30-second default interval. The interval range is from 0 through 255. When the interval counts down to 0, the routing device sends another hello message, and the timer is reset. A routing device that receives no response from a neighbor in 3.5 times the interval value drops the neighbor. In the case of a 30-second interval, the amount of time a routing device waits for a response is 105 seconds.

If a PIM hello message contains the hold-time option, the neighbor timeout is set to the hold-time sent in the message. If a PIM hello message does not contain the hold-time option, the neighbor timeout is set to the default hello hold time.

To modify how often the routing device sends hello messages out of an interface:

1. This example shows the configuration for the routing instance. Configure the interface globally or in the routing instance.

   ```
   [edit routing-instances PIM.master protocols pim interface fe-3/0/2.0]
   user@host# set hello-interval 255
   ```

2. Verify the configuration by checking the **Hello Option Holdtime** field in the output of the **show pim neighbors detail** command.

   ```
   user@host> show pim neighbors detail
   Instance: PIM.master
   Interface: fe-3/0/2.0
   Address: 192.168.195.37, IPv4, PIM v2, Mode: Sparse
   Hello Option Holdtime: 255 seconds
   Hello Option DR Priority: 1
   ```

Copyright © 2016, Juniper Networks, Inc.

```
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
Rx Join: Group Source Timeout
225.1.1.1 192.168.195.78 0
225.1.1.1 0

Interface: lo0.0
Address: 10.255.245.91, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 255 seconds
Hello Option DR Priority: 1
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported

Interface: pd-6/0/0.32768
Address: 0.0.0.0, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 255 seconds
Hello Option DR Priority: 0
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
```

Preserving Multicast Performance by Disabling Response to the ping Utility

The ping utility uses ICMP Echo messages to verify connectivity to any device with an IP address. However, in the case of multicast applications, a single ping sent to a multicast address can degrade the performance of routers because the stream of packets is replicated multiple times.

You can disable the router's response to ping (ICMP Echo) packets sent to multicast addresses. The system responds normally to unicast ping packets.

To disable the router's response to ping packets sent to multicast addresses:

1. Include the **no-multicast-echo** statement:

   ```
   [edit system]
   user@host# set no-multicast-echo
   ```

2. Verify the configuration by checking the **echo drops with broadcast or multicast destination address** field in the output of the **show system statistics icmp** command.

   ```
   user@host> show system statistics icmp
   ```

   ```
   icmp:
   0 drops due to rate limit
   0 calls to icmp_error
   0 errors not generated because old message was icmp
   Output histogram:
   echo reply: 21
   0 messages with bad code fields
   0 messages less than the minimum length
   0 messages with bad checksum
   0 messages with bad source address
   0 messages with bad length
   100 echo drops with broadcast or multicast destination address
   0 timestamp drops with broadcast or multicast destination address
   Input histogram:
   echo: 21
   21 message responses generated
   ```

Copyright © 2016, Juniper Networks, Inc.

PIM on Aggregated Interfaces

You can configure several Protocol Independent Multicast (PIM) features on an interface regardless of its PIM mode (bidirectional, sparse, dense, or sparse-dense mode).

If you configure PIM on an aggregated (**ae-** or **as-**) interface, each of the interfaces in the aggregate is included in the multicast output interface list and carries the single stream of replicated packets in a load-sharing fashion. The multicast aggregate interface is "expanded" into its constituent interfaces in the next-hop database.

Configuring PIM Trace Options

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
all	Trace all operations.
assert	Trace assert messages, which are used to resolve which of the parallel routing devices connected to a multiaccess LAN is responsible for forwarding packets to the LAN.
autorp	Trace bootstrap, RP, and auto-RP messages.
bidirectional-df-election	Trace bidirectional PIM designated-forwarder (DF) election events.
bootstrap	Trace bootstrap messages, which are sent periodically by the PIM domain's bootstrap routing device and are forwarded, hop by hop, to all routing devices in that domain.
general	Trace general events.
graft	Trace graft and graft acknowledgment messages.
hello	Trace hello packets, which are sent so that neighboring routing devices can discover one another.
join	Trace join messages, which are sent to join a branch onto the multicast distribution tree.
mdt	Trace messages related to multicast data tunnels.
normal	Trace normal events.
nsr-synchronization	Trace nonstop routing synchronization events
packets	Trace all PIM packets.

Copyright © 2016, Juniper Networks, Inc.

Flag	Description
policy	Trace poison-route-reverse packets.
prune	Trace prune messages, which are sent to prune a branch off the multicast distribution tree.
register	Trace register and register-stop messages. Register messages are sent to the RP when a multicast source first starts sending to a group.
route	Trace routing information.
rp	Trace candidate RP advertisements.
state	Trace state transitions.
task	Trace task processing.
timer	Trace timer processing.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on PIM packets of a particular type.

To configure tracing operations for PIM:

1. (Optional) Configure tracing at the [**routing-options** hierarchy level to trace all protocol packets.

   ```
   [edit routing-options traceoptions]
   user@host# set file all-packets-trace
   user@host# set flag all
   ```

2. Configure the filename for the PIM trace file.

   ```
   [edit protocols pim traceoptions]
   user@host# set file pim-trace
   ```

3. (Optional) Configure the maximum number of trace files.

   ```
   [edit protocols pim traceoptions]
   user@host# set file files 5
   ```

4. (Optional) Configure the maximum size of each trace file.

   ```
   [edit protocols pim traceoptions]
   user@host# set file size 1m
   ```

5. (Optional) Enable unrestricted file access.

   ```
   [edit protocols pim traceoptions]
   user@host# set file world-readable
   ```

6. Configure tracing flags.

Copyright © 2016, Juniper Networks, Inc.

Suppose you are troubleshooting issues with PIM version 1 control packets that are received on an interface configured for PIM version 2. The following example shows how to trace messages associated with this problem.

```
[edit protocols pim traceoptions]
user@host# set flag packets | match “Rx V1 Require V2”
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/pim-trace
```

Disabling PIM

By default, when configured, the PIM protocol is enabled on all interfaces for all families. If desired, you can disable PIM at the protocol, interface, or family hierarchy levels.

The hierarchy in which you configure PIM is critical. In general, the most specific configuration takes precedence. However, if PIM is disabled at the protocol level, then any disable statements with respect to an interface or family are ignored.

For example, the order of precedence for disabling PIM on a particular interface family is:

1. If PIM is disabled at the **[edit protocols pim interface *interface-name* family]** hierarchy level, then PIM is disabled for that interface family.
2. If PIM is not configured at the **[edit protocols pim interface *interface-name* family]** hierarchy level, but is disabled at the **[edit protocols pim interface *interface-name*]** hierarchy level, then PIM is disabled for all families on the specified interface.
3. If PIM is not configured at either the **[edit protocols pim interface *interface-name* family]** hierarchy level or the **[edit protocols pim interface *interface-name*]** hierarchy level, but is disabled at the **[edit protocols pim]** hierarchy level, then the PIM protocol is disabled globally for all interfaces and all families.

The following sections describe how to disable PIM at the various hierarchy levels.

- Disabling the PIM Protocol on page 4101
- Disabling PIM on an Interface on page 4101
- Disabling PIM for a Family on page 4102
- Disabling PIM for a Rendezvous Point on page 4102

Copyright © 2016, Juniper Networks, Inc.

Disabling the PIM Protocol

You can explicitly disable the PIM protocol. Disabling the PIM protocol disables the protocol for all interfaces and all families. This is accomplished at the **[edit protocols pim]** hierarchy level:

```
[edit protocols]
pim {
    disable;
}
```

To disable the PIM protocol:

1. Include the **disable** statement.

   ```
   user@host# set protocols pim disable
   ```
2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

   ```
   user@host# run show protocols pim
   ```

Disabling PIM on an Interface

You can disable the PIM protocol on a per-interface basis. This is accomplished at the **[edit protocols pim interface *interface-name*]** hierarchy level:

```
[edit protocols]
pim {
    interface interface-name {
        disable;
    }
}
```

To disable PIM on an interface:

1. Include the **disable** statement.

   ```
   user@host# set protocols pim interface fe-0/1/0 disable
   ```
2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

   ```
   user@host# run show protocols pim
   ```

Copyright © 2016, Juniper Networks, Inc.

Disabling PIM for a Family

You can disable the PIM protocol on a per-family basis. This is accomplished at the **[edit protocols pim family]** hierarchy level:

```
[edit protocols]
pim {
   family inet {
      disable;
   }
   family inet6 {
      disable;
   }
}
```

To disable PIM for a family:

1. Include the **disable** statement.

   ```
   user@host# set protocols pim family inet disable
   user@host# set protocols pim family inet6 disable
   ```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

   ```
   user@host# run show protocols pim
   ```

Disabling PIM for a Rendezvous Point

You can disable the PIM protocol for a rendezvous point (RP) on a per-family basis. This is accomplished at the **[edit protocols pim rp local family]** hierarchy level:

```
[edit protocols]
pim {
   rp {
      local {
         family inet {
            disable;
         }
         family inet6 {
            disable;
         }
      }
   }
}
```

To disable PIM for an RP family:

1. Use the **disable** statement.

   ```
   user@host# set protocols pim rp local family inet disable
   user@host# set protocols pim rp local family inet6 disable
   ```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

   ```
   user@host# run show protocols pim
   ```

Configuring a Designated Router for PIM

- Configuring Interface Priority for PIM Designated Router Selection on page 4103
- Configuring PIM Designated Router Election on Point-to-Point Links on page 4104

Configuring Interface Priority for PIM Designated Router Selection

A designated router (DR) sends periodic join messages and prune messages toward a group-specific rendezvous point (RP) for each group for which it has active members. When a Protocol Independent Multicast (PIM) routing device learns about a source, it originates a Multicast Source Discovery Protocol (MSDP) source-address message if it is the DR on the upstream interface.

By default, every PIM interface has an equal probability (priority 1) of being selected as the DR. Configuring the interface DR priority helps ensure that changing an IP address does not alter your forwarding model.

To configure the interface designated router priority:

1. This example shows the configuration for the routing instance. Configure the interface globally or in the routing instance.

   ```
   [edit routing-instances PIM.master protocols pim interface ge-0/0/0.0 family inet]
   user@host# set priority 5
   ```

2. Verify the configuration by checking the **Hello Option DR Priority** field in the output of the **show pim neighbors detail** command.

   ```
   user@host> show pim neighbors detail
   ```

   ```
   Instance: PIM.master
   Interface: ge-0/0/0.0

Configuring PIM Designated Router Election on Point-to-Point Links

To comply with the latest PIM drafts, enable designated router (DR) election on all PIM interfaces, including point-to-point (P2P) interfaces. (DR election is enabled by default on all other interfaces.) One of the two routers might join a multicast group on its P2P link interface. The DR on that link is responsible for initiating the relevant join messages.

To enable DR election on point-to-point interfaces:

1. On both point-to-point link routers, configure the router globally or in the routing instance. This example shows the configuration for the routing instance.

   ```
   [edit routing-instances PIM.master protocols pim]
   user@host# set dr-election-on-p2p
   ```

2. Verify the configuration by checking the **State** field in the output of the **show pim interfaces** command. The possible values for the **State** field are DR, NotDR, and P2P. When a point-to-point link interface is elected to be the DR, the interface state becomes DR instead of P2P.

3. If the **show pim interfaces** command continues to report the P2P state, consider running the **restart routing** command on both routing devices on the point-to-point link. Then recheck the state.

   CAUTION: Do not restart a software process unless specifically asked to do so by your Juniper Networks customer support representative. Restarting a software process during normal operation of a routing platform could cause interruption of packet forwarding and loss of data.

   ```
   [edit]
   user@host# run restart routing
   ```

Routing Content to Densely Clustered Receivers with PIM Dense Mode

- Configuring PIM Dense Mode on page 4107
- Configuring PIM Sparse-Dense Mode on page 4110

Configuring PIM Dense Mode

- Understanding PIM Dense Mode on page 4107
- Configuring PIM Dense Mode Properties on page 4109

Understanding PIM Dense Mode

PIM dense mode is less sophisticated than PIM sparse mode. PIM dense mode is useful for multicast LAN applications, the main environment for all dense mode protocols.

PIM dense mode implements the same flood-and-prune mechanism that DVMRP and other dense mode routing protocols employ. The main difference between DVMRP and PIM dense mode is that PIM dense mode introduces the concept of protocol independence. PIM dense mode can use the routing table populated by any underlying unicast routing protocol to perform reverse-path-forwarding (RPF) checks.

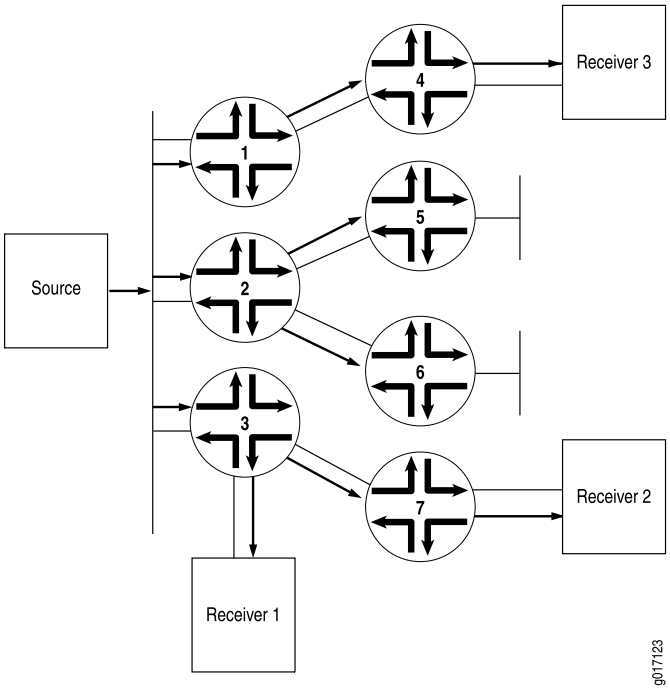
Internet service providers (ISPs) typically appreciate the ability to use any underlying unicast routing protocol with PIM dense mode because they do not need to introduce and manage a separate routing protocol just for RPF checks. While unicast routing protocols extended as multiprotocol BGP (MBGP) and Multitopology Routing in IS-IS (M-IS-IS) were later employed to build special tables to perform RPF checks, PIM dense mode does not require them.

PIM dense mode can use the unicast routing table populated by OSPF, IS-IS, BGP, and so on, or PIM dense mode can be configured to use a special multicast RPF table populated by MBGP or M-IS-IS when performing RPF checks.

Unlike sparse mode, in which data is forwarded only to routing devices sending an explicit request, dense mode implements a *flood-and-prune* mechanism, similar to DVMRP. In PIM dense mode, there is no RP. A routing device receives the multicast data on the interface closest to the source, then forwards the traffic to all other interfaces (see Figure 160).

Copyright © 2016, Juniper Networks, Inc.

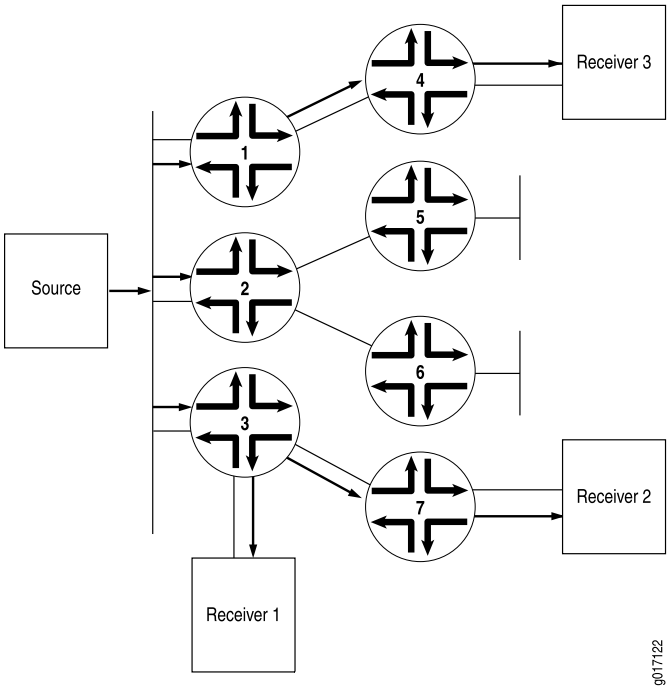
Figure 160: Multicast Traffic Flooded from the Source Using PIM Dense Mode



Flooding occurs periodically. It is used to refresh state information, such as the source IP address and multicast group pair. If the routing device has no interested receivers for the data, and the OIL becomes empty, the routing device sends a prune message upstream to stop delivery of multicast traffic (see Figure 161).

Copyright © 2016, Juniper Networks, Inc.

Figure 161: Prune Messages Sent Back to the Source to Stop Unwanted Multicast Traffic



Configuring PIM Dense Mode Properties

In PIM dense mode (PIM-DM), the assumption is that almost all possible subnets have at least one receiver wanting to receive the multicast traffic from a source, so the network is flooded with traffic on all possible branches, then pruned back when branches do not express an interest in receiving the packets, explicitly (by message) or implicitly (time-out silence). LANs are appropriate networks for dense-mode operation.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default.

You can configure PIM dense mode globally or for a routing instance. This example shows how to configure the routing instance and how to specify that PIM dense mode use **inet.2** as its RPF routing table instead of **inet.0**.

To configure the routing device properties for PIM dense mode:

1. (Optional) Create an IPv4 routing table group so that interface routes are installed into two routing tables, **inet.0** and **inet.2**.

   ```
   [edit routing-options rib-groups]
   user@host# set pim-rg export-rib inet.0
   user@host# set pim-rg import-rib [ inet.0 inet.2 ]
   ```

2. (Optional) Associate the routing table group with a PIM routing instance.

   ```
   [edit routing-instances PIM.dense protocols pim]
   user@host# set rib-group inet pim-rg
   ```

Copyright © 2016, Juniper Networks, Inc.

3. Configure the PIM interface. If you do not specify any interfaces, PIM is enabled on all routing device interfaces. Generally, you specify interface names only if you are disabling PIM on certain interfaces.

```
[edit routing-instances PIM.dense protocols pim]
user@host# set interface fe-0/0/1.0 mode dense
```

NOTE: You cannot configure both PIM and Distance Vector Multicast Routing Protocol (DVMRP) in forwarding mode on the same interface. You can configure PIM on the same interface only if you configured DVMRP in unicast-routing mode.

4. Monitor the operation of PIM dense mode by running the **show pim interfaces**, **show pim join**, **show pim neighbors**, and **show pim statistics** commands.

Understanding PIM Sparse-Dense Mode

Sparse-dense mode, as the name implies, allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as dense is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense-mode rules. A group specified as sparse is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules.

For information about PIM sparse-mode and PIM dense-mode rules, see "Understanding PIM Sparse Mode" on page 4113 and "Understanding PIM Dense Mode" on page 4107.

Mixing PIM Sparse and Dense Modes

It is possible to mix PIM dense mode, PIM sparse mode, and PIM source-specific multicast (SSM) on the same network, the same routing device, and even the same interface. This is because modes are effectively tied to multicast groups, an IP multicast group address must be unique for a particular group's traffic, and scoping limits enforce the division between potential or actual overlaps.

NOTE: PIM sparse mode was capable of forming shortest-path trees (SPTs) already. Changes to PIM sparse mode to support PIM SSM mainly involved defining behavior in the SSM address range, because shared-tree behavior is prohibited for groups in the SSM address range.

Copyright © 2016, Juniper Networks, Inc.

A multicast routing device employing sparse-dense mode is a good example of mixing PIM modes on the same network or routing device or interface. Dense modes are easy to support because of the flooding, but scaling issues make dense modes inappropriate for Internet use beyond very restricted uses.

Configuring PIM Sparse-Dense Mode Properties

Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as “dense” is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense mode rules. A group specified as “sparse” is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules. Sparse-dense mode is useful in networks implementing auto-RP for PIM sparse mode.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default.

You can configure PIM sparse-dense mode globally or for a routing instance. This example shows how to configure PIM sparse-dense mode globally on all interfaces, specifying that the groups 224.0.1.39 and 224.0.1.40 are using dense mode.

To configure the routing device properties for PIM sparse-dense mode:

1. Configure the dense-mode groups.

   ```
   [protocols pim]
   user@host# set dense-groups 224.0.1.39
   user@host# set dense-groups 224.0.1.40
   ```

2. Configure all interfaces on the routing device to use sparse-dense mode. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the disable statement for that interface.

   ```
   [edit protocols pim]
   user@host# set interface all mode sparse-dense
   user@host# set interface fxp0.0 disable
   ```

3. Monitor the operation of PIM sparse-dense mode by running the show pim interfaces, show pim join, show pim neighbors, and show pim statistics commands.

Understanding PIM Sparse Mode

A Protocol Independent Multicast (PIM) sparse-mode domain uses reverse-path forwarding (RPF) to create a path from a data source to the receiver requesting the data. When a receiver issues an explicit join request, an RPF check is triggered. A (*,G) PIM join message is sent toward the RP from the receiver's designated router (DR). (By definition, this message is actually called a join/prune message, but for clarity in this description, it is called either join or prune, depending on its context.) The join message is multicast hop by hop upstream to the ALL-PIM-ROUTERS group (224.0.0.13) by means of each

Copyright © 2016, Juniper Networks, Inc.

router's RPF interface until it reaches the RP. The RP router receives the (*,G) PIM join message and adds the interface on which it was received to the outgoing interface list (OIL) of the rendezvous-point tree (RPT) forwarding state entry. This builds the RPT connecting the receiver with the RP. The RPT remains in effect, even if no active sources generate traffic.

NOTE: State—the (*,G) or (S,G) entries—is the information used for forwarding unicast or multicast packets. S is the source IP address, G is the multicast group address, and * represents any source sending to group G. Routers keep track of the multicast forwarding state for the incoming and outgoing interfaces for each group.

When a source becomes active, the source DR encapsulates multicast data packets into a PIM register message and sends them by means of unicast to the RP router.

If the RP router has interested receivers in the PIM sparse-mode domain, it sends a PIM join message toward the source to build a shortest-path tree (SPT) back to the source. The source sends multicast packets out on the LAN, and the source DR encapsulates the packets in a PIM register message and forwards the message toward the RP router by means of unicast. The RP router receives PIM register messages back from the source, and thus adds a new source to the distribution tree, keeping track of sources in a PIM table. Once an RP router receives packets natively (with S,G), it sends a register stop message to stop receiving the register messages by means of unicast.

In actual application, many receivers with multiple SPTs are involved in a multicast traffic flow. To illustrate the process, we track the multicast traffic from the RP router to one receiver. In such a case, the RP router begins sending multicast packets down the RPT toward the receiver's DR for delivery to the interested receivers. When the receiver's DR receives the first packet from the RPT, the DR sends a PIM join message toward the source DR to start building an SPT back to the source. When the source DR receives the PIM join message from the receiver's DR, it starts sending traffic down all SPTs. When the first multicast packet is received by the receiver's DR, the receiver's DR sends a PIM prune message to the RP router to stop duplicate packets from being sent through the RPT. In turn, the RP router stops sending multicast packets to the receiver's DR, and sends a PIM prune message for this source over the RPT toward the source DR to halt multicast packet delivery to the RP router from that particular source.

If the RP router receives a PIM register message from an active source but has no interested receivers in the PIM sparse-mode domain, it still adds the active source into the PIM table. However, after adding the active source into the PIM table, the RP router sends a register stop message. The RP router discovers the active source's existence and no longer needs to receive advertisement of the source (which utilizes resources).

NOTE: If the number of PIM join messages exceeds the configured MTU, the messages are fragmented in IPv6 PIM sparse mode. To avoid the fragmentation of PIM join messages, the multicast traffic receives the interface MTU instead of the path MTU.

Copyright © 2016, Juniper Networks, Inc.

The major characteristics of PIM sparse mode are as follows:

- Routers with downstream receivers join a PIM sparse-mode tree through an explicit join message.
- PIM sparse-mode RPs are the routers where receivers meet sources.
- Senders announce their existence to one or more RPs, and receivers query RPs to find multicast sessions.
- Once receivers get content from sources through the RP, the last-hop router (the router closest to the receiver) can optionally remove the RP from the shared distribution tree (*,G) if the new source-based tree (S,G) is shorter. Receivers can then get content directly from the source.

  The transitional aspect of PIM sparse mode from shared to source-based tree is one of the major features of PIM, because it prevents overloading the RP or surrounding core links.

There are related issues regarding source, RPs, and receivers when sparse mode multicast is used:

- Sources must be able to send to all RPs.
- RPs must all know one another.
- Receivers must send explicit join messages to a known RP.
- Receivers initially need to know only one RP (they later learn about others).
- Receivers can explicitly prune themselves from a tree.
- Receivers that never transition to a source-based tree are effectively running Core Based Trees (CBT).

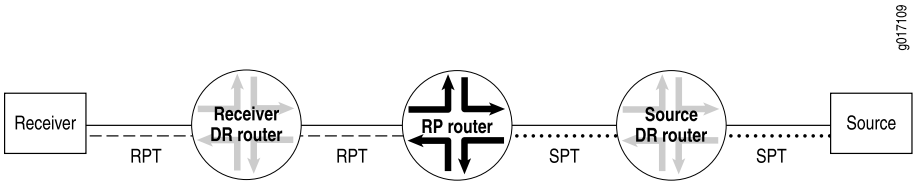
PIM sparse mode has standard features for all of these issues.

Rendezvous Point

The RP router serves as the information exchange point for the other routers. All routers in a PIM domain must provide mapping to an RP router. It is the only router that needs to know the active sources for a domain—the other routers just need to know how to reach the RP. In this way, the RP matches receivers with sources.

The RP router is downstream from the source and forms one end of the shortest-path tree. As shown in Figure 162, the RP router is upstream from the receiver and thus forms one end of the rendezvous-point tree.

Figure 162: Rendezvous Point As Part of the RPT and SPT



The benefit of using the RP as the information exchange point is that it reduces the amount of state in non-RP routers. No network flooding is required to provide non-RP routers information about active sources.

RP Mapping Options

RPs can be learned by one of the following mechanisms:

- Static configuration
- Anycast RP
- Auto-RP
- Bootstrap router

We recommend a static RP mapping with anycast RP and a bootstrap router (BSR) with auto-RP configuration, because static mapping provides all the benefits of a bootstrap router and auto-RP without the complexity of the full BSR and auto-RP mechanisms.

Designated Router

In a PIM sparse mode (PIM-SM) domain, there are two types of designated routers to consider:

- The receiver DR sends PIM join and PIM prune messages from the receiver network toward the RP.
- The source DR sends PIM register messages from the source network to the RP.

Neighboring PIM routers multicast periodic PIM hello messages to each other every 30 seconds (the default). The PIM hello message usually includes a holdtime value for the neighbor to use, but this is not a requirement. If the PIM hello message does not include a holdtime value, a default timeout value (in Junos OS, 105 seconds) is used. On receipt of a PIM hello message, a router stores the IP address and priority for that neighbor. If the DR priorities match, the router with the highest IP address is selected as the DR.

If a DR fails, a new one is selected using the same process of comparing IP addresses.

NOTE: In PIM dense mode (PIM-DM), a DR is elected by the same process that PIM-SM uses. However, the only time that a DR has any effect in PIM-DM is when IGMPv1 is used on the interface. (IGMPv2 is the default.) In this case, the DR also functions as the IGMP Query Router because IGMPv1 does not have a Query Router election mechanism.

Tunnel Services PICs and Multicast

On Juniper Networks routers, data packets are encapsulated and de-encapsulated into tunnels by means of hardware and not the software running on the router processor. The hardware used to create tunnel interfaces on M Series and T Series routers is a Tunnel Services PIC. If Juniper Networks M Series Multiservice Edge Routers and Juniper Networks T Series Core Routers are configured as rendezvous points or IP version 4 (IPv4) PIM

Copyright © 2016, Juniper Networks, Inc.

sparse-mode DRs connected to a source, a Tunnel Services PIC is required. Juniper Networks MX Series Ethernet Services Routers do not require Tunnel Services PICs. However, on MX Series routers, you must enable tunnel services with the **tunnel-services** statement on one or more online FPC and PIC combinations at the **[edit chassis fpc *number* pic *number*]** hierarchy level.

CAUTION: For redundancy, we strongly recommend that each routing device has multiple Tunnel Services PICs. In the case of MX Series routers, the recommendation is to configure multiple tunnel-services statements.

We also recommend that the Tunnel PICs be installed (or configured) on different FPCs. If you have only one Tunnel PIC or if you have multiple Tunnel PICs installed on a single FPC and then that FPC is removed, the multicast session will not come up. Having redundant Tunnel PICs on separate FPCs can help ensure that at least one Tunnel PIC is available and that multicast will continue working.

On MX Series routers, the redundant configuration looks like the following example:

```
[edit chassis]
user@mx-host# set fpc 1 pic 0 tunnel-services bandwidth 1g
user@mx-host# set fpc 2 pic 0 tunnel-services bandwidth 1g
```

In PIM sparse mode, the source DR takes the initial multicast packets and encapsulates them in PIM register messages. The source DR then unicasts the packets to the PIM sparse-mode RP router, where the PIM register message is de-encapsulated.

When a router is configured as a PIM sparse-mode RP router (by specifying an address using the **address** statement at the **[edit protocols pim rp local]** hierarchy level) and a Tunnel PIC is present on the router, a PIM register de-encapsulation interface, or **pd** interface, is automatically created. The **pd** interface receives PIM register messages and de-encapsulates them by means of the hardware.

If PIM sparse mode is enabled and a Tunnel Services PIC is present on the router, a PIM register encapsulation interface (**pe** interface) is automatically created for each RP address. The **pe** interface is used to encapsulate source data packets and send the packets to RP addresses on the PIM DR and the PIM RP. The **pe** interface receives PIM register messages and encapsulates the packets by means of the hardware.

Do not confuse the configurable **pe** and **pd** hardware interfaces with the nonconfigurable **pime** and **pimd** software interfaces. Both pairs encapsulate and de-encapsulate multicast packets, and are created automatically. However, the **pe** and **pd** interfaces appear only if a Tunnel Services PIC is present. The **pime** and **pimd** interfaces are not useful in situations requiring the **pe** and **pd** interfaces.

If the source DR is the RP, then there is no need for PIM register messages and consequently no need for a Tunnel Services PIC.

Copyright © 2016, Juniper Networks, Inc.

When PIM sparse mode is used with IP version 6 (IPv6), a Tunnel PIC is required on the RP, but not on the IPv6 PIM DR. The lack of a Tunnel PIC requirement on the IPv6 DR applies only to IPv6 PIM sparse mode and is not to be confused with IPv4 PIM sparse-mode requirements.

Table 383 shows the complete matrix of IPv4 and IPv6 PIM Tunnel PIC requirements.

Table 383: Tunnel PIC Requirements for IPv4 and IPv6 Multicast

IP Version	Tunnel PIC on RP	Tunnel PIC on DR
IPv4	Yes	Yes
IPv6	Yes	No

Enabling PIM Sparse Mode

In PIM sparse mode (PIM-SM), the assumption is that very few of the possible receivers want packets from a source, so the network establishes and sends packets only on branches that have at least one leaf indicating (by message) a desire for the traffic. WANs are appropriate networks for sparse-mode operation.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default. You do not need to configure Internet Group Management Protocol (IGMP) version 2 for a sparse mode configuration. After you enable PIM, by default, IGMP version 2 is also enabled.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default for rendezvous point (RP) mode (at the **[edit protocols pim rp static address *address*]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface *interface-name*]** hierarchy level). Explicitly configured versions override the defaults. The following example explicitly configures PIMv2 on the interfaces.

You can configure PIM sparse mode globally or for a routing instance. This example shows how to configure PIM sparse mode globally on all interfaces. It also shows how to configure a static RP router and how to configure the non-RP routers.

To configure the router properties for PIM sparse mode:

1. Configure the static RP router.

   ```
   [edit protocols pim]
   user@host# set rp local family inet address 192.168.3.253
   ```

2. Configure the RP router interfaces. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

   ```
   [edit protocols pim]
   user@host# set interface all mode sparse
   user@host# set interface all version 2
   user@host# set interface fxp0.0 disable
   ```

Copyright © 2016, Juniper Networks, Inc.

3. Configure the non-RP routers. Include the following configuration on all of the non-RP routers.

```
[edit protocols pim]
user@host# set rp static address 198.58.3.253 version 2
user@host# set interface all mode sparse
user@host# set interface all version 2
user@host# set interface fxp0.0 disable
```

4. Monitor the operation of PIM sparse mode.

   - show pim interfaces
   - show pim join
   - show pim neighbors
   - show pim rps

Configuring PIM Join Load Balancing

By default, PIM join messages are sent toward a source based on the RPF routing table check. If there is more than one equal-cost path toward the source, then one upstream interface is chosen to send the join message. This interface is also used for all downstream traffic, so even though there are alternative interfaces available, the multicast load is concentrated on one upstream interface and routing device.

For PIM sparse mode, you can configure PIM join load balancing to spread join messages and traffic across equal-cost upstream paths (interfaces and routing devices) provided by unicast routing toward a source. PIM join load balancing is only supported for PIM sparse mode configurations.

PIM join load balancing is supported on draft-rosen multicast VPNs (also referred to as dual PIM multicast VPNs). PIM join load balancing is not supported on multiprotocol BGP-based multicast VPNs (also referred to as next-generation Layer 3 VPN multicast). When PIM join load balancing is enabled in a draft-rosen Layer 3 VPN scenario, the load balancing is achieved based on the join counts for the far-end PE routing devices, not for any intermediate P routing devices.

If an internal BGP (IBGP) multipath forwarding VPN route is available, Junos OS uses the multipath forwarding VPN route to send join messages to the remote PE routers to achieve load balancing over the VPN.

By default, when multiple PIM joins are received for different groups, all joins are sent to the same upstream gateway chosen by the unicast routing protocol. Even if there are multiple equal-cost paths available, these alternative paths are not utilized to distribute multicast traffic from the source to the various groups.

When PIM join load balancing is configured, the PIM joins are distributed equally among all equal-cost upstream interfaces and neighbors. Every new join triggers the selection of the least-loaded upstream interface and neighbor. If there are multiple neighbors on the same interface (for example, on a LAN), join load balancing maintains a value for each of the neighbors and distributes multicast joins (and downstream traffic) among these as well.

Copyright © 2016, Juniper Networks, Inc.

Join counts for interfaces and neighbors are maintained globally, not on a per-source basis. Therefore, there is no guarantee that joins for a particular source are load-balanced. However, the joins for all sources and all groups known to the routing device are load-balanced. There is also no way to administratively give preference to one neighbor over another: all equal-cost paths are treated the same way.

You can configure message filtering globally or for a routing instance. This example shows the global configuration.

You configure PIM join load balancing on the non-RP routers in the PIM domain.

1. Determine if there are multiple paths available for a source (for example, an RP) with the output of the **show pim join extensive** or **show pim source** commands.

```
user@host> show pim join extensive
Instance: PIM.master Family: INET

Group: 224.1.1.1
    Source: *
    RP: 10.255.245.6
    Flags: sparse,rptree,wildcard
    Upstream interface: t1-0/2/3.0
    Upstream neighbor: 192.168.38.57
    Upstream state: Join to RP
    Downstream neighbors:
        Interface: t1-0/2/1.0
            192.168.38.16 State: JOIN Flags; SRW Timeout: 164
Group: 224.2.127.254
    Source: *
    RP: 10.255.245.6
    Flags: sparse,rptree,wildcard
    Upstream interface: so-0/3/0.0
    Upstream neighbor: 192.168.38.47
    Upstream state: Join to RP
    Downstream neighbors:
        Interface: t1-0/2/3.0
            192.168.38.16 State: JOIN Flags; SRW Timeout: 164
```

   Note that for this router, the RP at IP address 10.255.245.6 is the source for two multicast groups: 224.1.1.1 and 224.2.127.254. This router has two equal-cost paths through two different upstream interfaces (**t1-0/2/3.0** and **so-0/3/0.0**) with two different neighbors (192.168.38.57 and 192.168.38.47). This router is a good candidate for PIM join load balancing.

2. On the non-RP router, configure PIM join load balancing.

```
[edit protocols pim rp]
user@host# set static address 10.10.10.1
user@host# set interface all mode sparse version 2
user@host# set join-load-balance
```

   The static address is the address of the RP.

3. Monitor the operation.

   If load balancing is enabled for this router, the number of PIM joins sent on each interface is shown in the output for the **show pim interfaces** command.

```
user@host> show pim interfaces
```

Copyright © 2016, Juniper Networks, Inc.

```
Instance: PIM.master

Name             Stat Mode        IP V State NbrCnt JoinCnt   DR address
lo0.0            Up   Sparse       4 2 DR         0       0   10.255.168.58
pe-1/2/0.32769   Up   Sparse       4 2 P2P        0       0
so-0/3/0.0       Up   Sparse       4 2 P2P        1       1
t1-0/2/1.0       Up   Sparse       4 2 P2P        1       0
t1-0/2/3.0       Up   Sparse       4 2 P2P        1       1
lo0.0            Up   Sparse       6 2 DR         0       0   fe80::2a0:a5ff:4b7
```

Note that the two equal-cost paths shown by the **show pim interfaces** command now have nonzero join counts. If the counts differ by more than one and were zero (0) when load balancing commenced, an error occurs (joins before load balancing are not redistributed). The join count also appears in the **show pim neighbors detail** output:

```
user@host> show pim neighbors detail
Interface: so-0/3/0.0

    Address: 192.168.38.46, IPv4, PIM v2, Mode: Sparse, Join Count: 0
        Hello Option Holdtime: 65535 seconds

        Hello Option DR Priority: 1
        Hello Option Generation ID: 1854475503
        Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
```

Note that the join count is nonzero on the two load-balanced interfaces toward the upstream neighbors.

PIM join load balancing only takes effect when the feature is configured. Prior joins are not redistributed to achieve perfect load balancing. In addition, if an interface or neighbor fails, the new joins are redistributed among remaining active interfaces and neighbors. However, when the interface or neighbor is restored, prior joins are not redistributed. The **clear pim join-distribution** command redistributes the existing flows to new or restored upstream neighbors. Redistributing the existing flows causes traffic to be disrupted, so we recommend that you perform PIM join redistribution during a maintenance window.

Modifying the Join State Timeout

This section describes how to configure the join state timeout.

A downstream router periodically sends join messages to refresh the join state on the upstream router. If the join state is not refreshed before the timeout expires, the join state is removed.

By default, the join state timeout is 210 seconds. You can change this timeout to allow additional time to receive the join messages. Because the messages are called join-prune messages, the name used is the **join-prune-timeout** statement.

To modify the timeout, include the **join-prune-timeout** statement:

```
user@host# set protocols pim join-prune-timeout 230
```

The join timeout value can be from 210 through 240 seconds.

Example: Enabling Join Suppression

This example describes how to enable PIM join suppression.

- Requirements on page 4122
- Overview on page 4122
- Configuration on page 4125
- Verification on page 4126

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure PIM Sparse Mode on the interfaces. See "Enabling PIM Sparse Mode" on page 4118.

Overview

PIM join suppression enables a router on a multiaccess network to defer sending join messages to an upstream router when it sees identical join messages on the same network. Eventually, only one router sends these join messages, and the other routers suppress identical messages. Limiting the number of join messages improves scalability and efficiency by reducing the number of messages sent to the same router.

This example includes the following statements:

- **override-interval**—Sets the maximum time in milliseconds to delay sending override join messages. When a router sees a prune message for a join it is currently suppressing, it waits before it sends an override join message. Waiting helps avoid multiple

Copyright © 2016, Juniper Networks, Inc.

downstream routers sending override join messages at the same time. The override interval is a random timer with a value of 0 through the maximum override value.

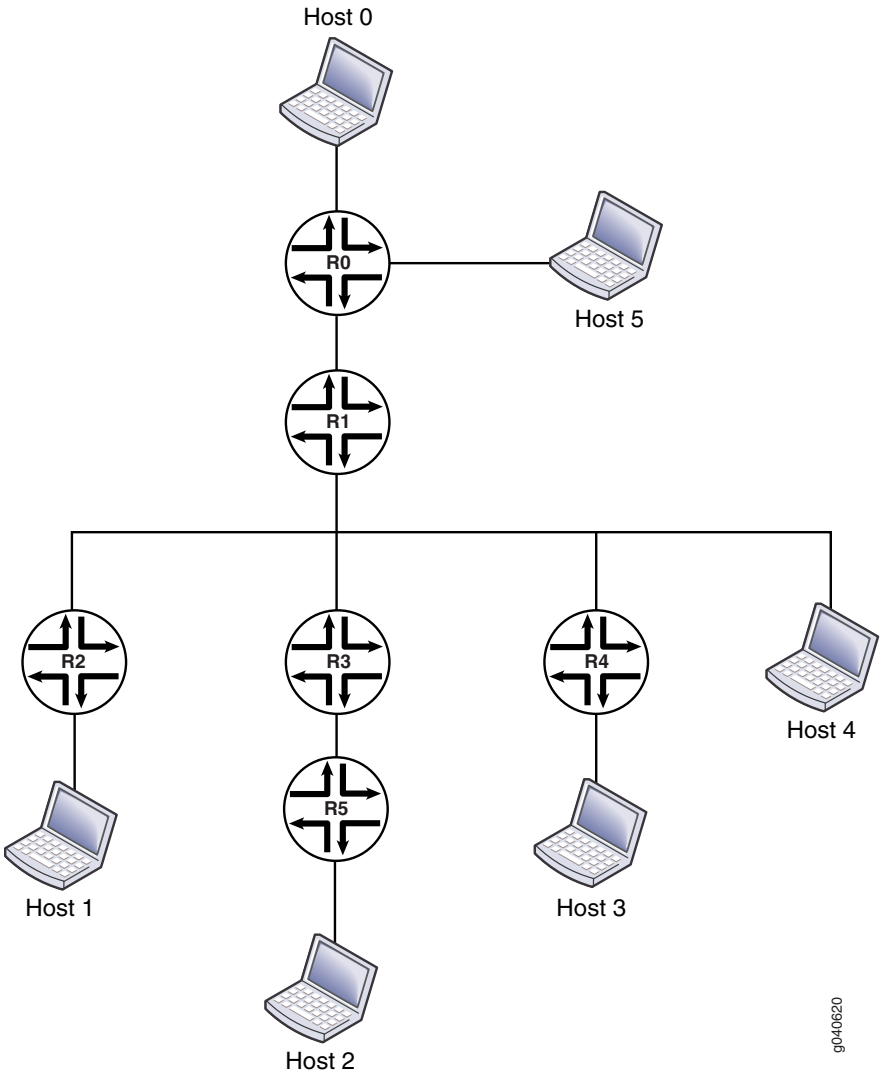
- **propagation-delay**—Sets a value in milliseconds for a prune pending timer, which specifies how long to wait before executing a prune on an upstream router. During this period, the router waits for any prune override join messages that might be currently suppressed. The period for the prune pending timer is the sum of the **override-interval** value and the value specified for **propagation-delay**.
- **reset-tracking-bit**—Enables PIM join suppression on each multiaccess downstream interface. This statement resets a tracking bit field (T-bit) on the LAN prune delay hello option from the default of 1 (join suppression disabled) to 0 (join suppression enabled).

  When multiple identical join messages are received, a random join suppression timer is activated, with a range of 66 through 84 milliseconds. The timer is reset each time join suppression is triggered.

Figure 163 shows the topology used in this example.

Copyright © 2016, Juniper Networks, Inc.

Figure 163: Join Suppression



The items in Figure 163 represent the following functions:

- Host 0 is the multicast source.
- Host 1, Host 2, Host 3, and Host 4 are receivers.
- Router R0 is the first-hop router and the RP.
- Router R1 is an upstream router.
- Routers R2, R3, R4, and R5 are downstream routers in the multicast LAN.

This example shows the configuration of the downstream devices: Routers R2, R3, R4, and R5.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set protocols pim traceoptions file pim.log
set protocols pim traceoptions file size 5m
set protocols pim traceoptions file world-readable
set protocols pim traceoptions flag join detail
set protocols pim traceoptions flag prune detail
set protocols pim traceoptions flag normal detail
set protocols pim traceoptions flag register detail
set protocols pim rp static address 10.255.112.160
set protocols pim interface all mode sparse
set protocols pim interface all version 2
set protocols pim interface fxp0.0 disable
set protocols pim reset-tracking-bit
set protocols pim propagation-delay 500
set protocols pim override-interval 4000
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PIM join suppression on a non-RP downstream router in the multicast LAN:

1. Configure PIM sparse mode on the interfaces.

```
[edit]
user@host# edit protocols pim
[edit protocols pim]
user@host# set rp static address 10.255.112.160
[edit protocols pim]
user@host# set interface all mode sparse version 2
[edit protocols pim]
user@host# set interface all version 2
[edit protocols pim]
user@host# set interface fxp0.0 disable
```

2. Enable the join suppression timer.

```
[edit protocols pim]
user@host# set reset-tracking-bit
```

3. Configure the prune override interval value.

```
[edit protocols pim]
user@host# set override-interval 4000
```

4. Configure the propagation delay of the link.

```
[edit protocols pim]
user@host# set propagation-delay 500
```

Copyright © 2016, Juniper Networks, Inc.

5. (Optional) Configure PIM tracing operations.

```
[edit protocols pim]
user@host# set traceoptions file pim.log size 5m world-readable
[edit protocols pim]
user@host# set traceoptions flag join detail
[edit protocols pim]
user@host# set traceoptions flag normal detail
[edit protocols pim]
user@host# set traceoptions flag register detail
```

6. If you are done configuring the device, commit the configuration.

```
[edit protocols pim]
user@host# commit
```

Results

From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show protocols
pim {
    traceoptions {
        file pim.log size 5m world-readable;
        flag join detail;
        flag prune detail;
        flag normal detail;
        flag register detail;
    }
    rp {
        static {
            address 10.255.112.160;
        }
    }
    interface all {
        mode sparse;
        version 2;
    }
    interface fxp0.0 {
        disable;
    }
    reset-tracking-bit;
    propagation-delay 500;
    override-interval 4000;
}
```

Verification

To verify the configuration, run the following commands on the upstream and downstream routers:

- show pim join **extensive**
- show multicast route **extensive**

Copyright © 2016, Juniper Networks, Inc.

Example: Configuring PIM Sparse Mode over an IPsec VPN

IPsec VPNs create secure point-to-point connections between sites over the Internet. The Junos OS implementation of IPsec VPNs supports multicast and unicast traffic. The following example shows how to configure PIM sparse mode for the multicast solution and how to configure IPsec to secure your traffic.

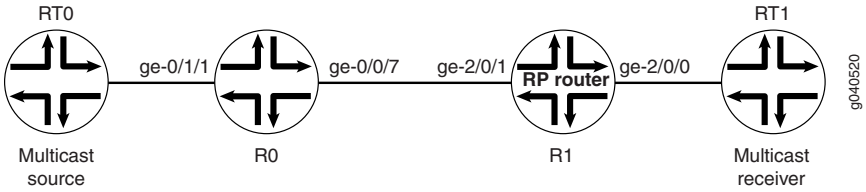
The configuration shown in this example works on the following platforms:

- M Series and T Series routers with one of the following PICs:
  - Adaptive Services (AS) PIC
  - Multiservices (MS) PIC
- JCS1200 platform with a Multiservices PIC (MS-500)

The tunnel endpoints do not need to be the same platform type. For example, the device on one end of the tunnel can be a JCS1200 router, while the device on the other end can be a standalone T Series router. The two routers that are the tunnel endpoints can be in the same autonomous system or in different autonomous systems.

In the configuration shown in this example, OSPF is configured between the tunnel endpoints. In Figure 164, the tunnel endpoints are R0 and R1. The network that contains the multicast source is connected to R0. The network that contains the multicast receivers is connected to R1. R1 serves as the statically configured rendezvous point (RP).

Figure 164: PIM Sparse Mode over an IPsec VPN



To configure PIM sparse mode with IPsec:

1. On R0, configure the incoming Gigabit Ethernet interface.

   ```
   [edit interfaces]
   user@host# set ge-0/1/1 description "incoming interface"
   user@host# set ge-0/1/1 unit 0 family inet address 10.20.0.1/30
   ```

2. On R0, configure the outgoing Gigabit Ethernet interface.

   ```
   [edit interfaces]
   user@host# set ge-0/0/7 description "outgoing interface"
   user@host# set ge-0/0/7 unit 0 family inet address 10.10.1.1/30
   ```

3. On R0, configure unit 0 on the **sp-** interface. The Junos OS uses unit 0 for service logging and other communication from the services PIC.

   ```
   [edit interfaces]
   user@host# set sp-0/2/0 unit 0 family inet
   ```

Copyright © 2016, Juniper Networks, Inc.

4. On R0, configure the logical interfaces that participate in the IPsec services. In this example, unit 1 is the inward-facing interface. Unit 1001 is the interface that faces the remote IPsec site.

   ```
   [edit interfaces]
   user@host# set sp-0/2/0 unit 1 family inet
   user@host# set sp-0/2/0 unit 1 service-domain inside
   user@host# set sp-0/2/0 unit 1001 family inet
   user@host# set sp-0/2/0 unit 1001 service-domain outside
   ```

5. On R0, direct OSPF traffic into the IPsec tunnel.

   ```
   [edit protocols ospf]
   user@host# set area 0.0.0.0 interface sp-0/2/0.1
   user@host# set parea 0.0.0.0 interface ge-0/1/1.0 passive
   user@host# set area 0.0.0.0 interface lo0.0
   ```

6. On R0, configure PIM sparse mode. This example uses static RP configuration. Because R0 is a non-RP router, configure the address of the RP router, which is the routable address assigned to the loopback interface on R1.

   ```
   [edit protocols pim]
   user@host# set rp static address 10.255.0.156
   user@host# set interfaces sp-0/2/0.1
   user@host# set interfaces ge-0/1/1.0
   user@host# set interfaces lo0.0
   ```

7. On R0, create a rule for a bidirectional dynamic IKE security association (SA) that references the IKE policy and the IPsec policy.

   ```
   [edit services ipsec-vpn rule ipsec_rule]
   user@host# set term ipsec_dynamic then remote-gateway 10.10.1.2
   user@host# set term ipsec_dynamic then dynamic ike-policy ike_policy
   user@host# set term ipsec_dynamic then dynamic ipsec-policy ipsec_policy
   user@host# set match-direction input
   ```

8. On R0, configure the IPsec proposal. This example uses the Authentication Header (AH) Protocol.

   ```
   [edit services ipsec-vpn ipsec proposal ipsec_prop]
   user@host# set protocol ah
   user@host# set authentication-algorithm hmac-md5-96
   ```

9. On R0, define the IPsec policy.

   ```
   [edit services ipsec-vpn ipsec policy ipsec_policy]
   user@host# set perfect-forward-secrecy keys group1
   user@host# set proposal ipsec_prop
   ```

10. On R0, configure IKE authentication and encryption details.

    ```
    [edit services ipsec-vpn ike proposal ike_prop]
    user@host# set authentication-method pre-shared-keys
    user@host# set dh-group group1
    user@host# set authentication-algorithm md5
    user@host# set authentication-algorithm 3des-cbc
    ```

11. On R0, define the IKE policy.

    ```
    [edit services ipsec-vpn ike policy ike_policy]
    user@host# set proposals ike_prop
    ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set pre-shared-key ascii-text "$ABC123"
```

12. On R0, create a service set that defines IPsec-specific information. The first command associates the IKE SA rule with IPsec. The second command defines the address of the local end of the IPsec security tunnel. The last two commands configure the logical interfaces that participate in the IPsec services. Unit 1 is for the IPsec inward-facing traffic. Unit 1001 is for the IPsec outward-facing traffic.

```
[edit services service-set ipsec_svc]
user@host# set ipsec-vpn-rules ipsec_rule
user@host# set ipsec-vpn-options local-gateway 10.10.1.1
user@host# set next-hop-service inside-service-interface sp-0/2/0.1
user@host# set next-hop-service outside-service-interface sp-0/2/0.1001
```

13. On R1, configure the incoming Gigabit Ethernet interface.

```
[edit interfaces]
user@host# set ge-2/0/1 description "incoming interface"
user@host# set ge-2/0/1 unit 0 family inet address 10.10.1.2/30
```

14. On R1, configure the outgoing Gigabit Ethernet interface.

```
[edit interfaces]
user@host# set ge-2/0/0 description "outgoing interface"
user@host# set ge-2/0/0 unit 0 family inet address 10.20.0.5/30
```

15. On R1, configure the loopback interface.

```
[edit interfaces]
user@host# set lo0.0 family inet address 10.255.0.156
```

16. On R1, configure unit 0 on the **sp-** interface. The Junos OS uses unit 0 for service logging and other communication from the services PIC.

```
[edit interfacesinterfaces]
user@host# set sp-2/1/0 unit 0 family inet
```

17. On R1, configure the logical interfaces that participate in the IPsec services. In this example, unit 1 is the inward-facing interface. Unit 1001 is the interface that faces the remote IPsec site.

```
[edit interfaces]
user@host# set sp-2/1/0 unit 1 family inet
user@host# set sp-2/1/0 unit 1 service-domain inside
user@host# set sp-2/1/0 unit 1001 family inet
user@host# set sp-2/1/0 unit 1001 service-domain outside
```

18. On R1, direct OSPF traffic into the IPsec tunnel.

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface sp-2/1/0.1
user@host# set area 0.0.0.0 interface ge-2/0/0.0 passive
user@host# set area 0.0.0.0 interface lo0.0
```

19. On R1, configure PIM sparse mode. R1 is an RP router. When you configure the local RP address, use the shared address, which is the address of R1's loopback interface.

```
[edit protocols pim]
user@host# set rp local address 10.255.0.156
user@host# set interface sp-2/1/0.1
user@host# set interface ge-2/0/0.0
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set interface lo0.0 family inet
```

20. On R1, create a rule for a bidirectional dynamic Internet Key Exchange (IKE) security association (SA) that references the IKE policy and the IPsec policy.

```
[edit services ipsec-vpn rule ipsec_rule]
user@host# set term ipsec_dynamic from source-address 192.168.195.34/32
user@host# set term ipsec_dynamic then remote-gateway 10.10.1.1
user@host# set term ipsec_dynamic then dynamic ike-policy ike_policy
user@host# set term ipsec_dynamic then dynamic ipsec-policy ipsec_policy
user@host# set match-direction input
```

21. On R1, define the IPsec proposal for the dynamic SA.

```
[edit services ipsec-vpn ipsec proposal ipsec_prop]
user@host# set protocol ah
user@host# set authentication-algorithm hmac-md5-96
```

22. On R1, define the IPsec policy.

```
[edit services ipsec-vpn ipsec policy ipsec_policy]
user@host# set perfect-forward-secrecy keys group1
user@host# set proposal ipsec_prop
```

23. On R1, configure IKE authentication and encryption details.

```
[edit services ipsec-vpn ike proposal ike_prop]
user@host# set authentication-method pre-shared-keys
user@host# set dh-group group1
user@host# set authentication-algorithm md5
user@host# set authentication-algorithm 3des-cbc
```

24. On R0, define the IKE policy.

```
[edit services ipsec-vpn ike policy ike_policy]
user@host# set proposal ike_prop
user@host# set pre-shared-key ascii-text "$ABC123"
```

25. On R1, create a service set that defines IPsec-specific information. The first command associates the IKE SA rule with IPsec. The second command defines the address of the local end of the IPsec security tunnel. The last two commands configure the logical interfaces that participate in the IPsec services. Unit 1 is for the IPsec inward-facing traffic. Unit 1001 is for the IPsec outward-facing traffic.

```
[edit services service-set ipsec_svc]
user@host# set ipsec-vpn-rules ipsec_rule
user@host# set ipsec-vpn-options local-gateway 10.10.1.2
user@host# set next-hop-service inside-service-interface sp-2/1/0.1
user@host# set next-hop-service outside-service-interface sp-2/1/0.1001
```

To verify the configuration, run the following commands:

Check which RPs the various routers have learned about.

```
user@host> show pim rps extensive inet
```

Check that the IPsec SA negotiation is successful.

```
user@host> show services ipsec-vpn ipsec security-associations
```

Check that the IKE SA negotiation is successful.

Copyright © 2016, Juniper Networks, Inc.

```
user@host> show services ipsec-vpn ike security-associations
```

Check that traffic is traveling over the IPsec tunnel.

```
user@host> show services ipsec-vpn ipsec statistics
```

Example: Configuring Multicast for Virtual Routers with IPv6 Interfaces

A virtual router is a type of simplified routing instance that has a single routing table. This example shows how to configure PIM in a virtual router.

- Requirements on page 4131
- Overview on page 4131
- Configuration on page 4132
- Verification on page 4134

Requirements

Before you begin, configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.

Overview

You can configure PIM for the **virtual-router** instance type as well as for the **vrf** instance type. The **virtual-router** instance type is similar to the **vrf** instance type used with Layer 3 VPNs, except that it is used for non-VPN-related applications.

The **virtual-router** instance type has no VPN routing and forwarding (VRF) import, VRF export, VRF target, or route distinguisher requirements. The **virtual-router** instance type is used for non-Layer 3 VPN situations.

When PIM is configured under the **virtual-router** instance type, the VPN configuration is not based on RFC 2547, *BGP/MPLS VPNs*, so PIM operation does not comply with the Internet draft draft-rosen-vpn-mcast-07.txt, *Multicast in MPLS/BGP VPNs*. In the **virtual-router** instance type, PIM operates in a routing instance by itself, forming adjacencies with PIM neighbors over the routing instance interfaces as the other routing protocols do with neighbors in the routing instance.

This example includes the following general steps:

1. On R1, configure a virtual router instance with three interfaces (**ge-0/0/0.0**, **ge-0/1/0.0**, and **ge-0/1/1.0**).
2. Configure PIM and the RP.
3. Configure an MLD static group containing interfaces **ge-0/1/0.0** and **ge-0/1/1.0**.

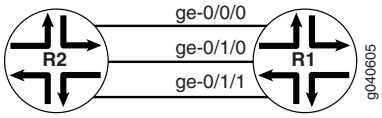
After you configure this example, you should be able to send multicast traffic from R2 through **ge-0/0/0** on R1 to the static group and verify that the traffic egresses from **ge-0/1/0.0** and **ge-0/1/1.0**.

Copyright © 2016, Juniper Networks, Inc.

NOTE: Do not include the **group-address** statement for the **virtual-router** instance type.

Figure 165 shows the topology for this example.

Figure 165: Virtual Router Instance with Three Interfaces



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set interfaces ge-0/0/0 unit 0 family inet6 address 2001:4:4:4::1/64
set interfaces ge-0/1/0 unit 0 family inet6 address 2001:24:24:24::1/64
set interfaces ge-0/1/1 unit 0 family inet6 address 2001:7:7:7::1/64
set protocols mld interface ge-0/1/0.0 static group ff0e::10
set protocols mld interface ge-0/1/1.0 static group ff0e::10
set routing-instances mvrf1 instance-type virtual-router
set routing-instances mvrf1 interface ge-0/0/0.0
set routing-instances mvrf1 interface ge-0/1/0.0
set routing-instances mvrf1 interface ge-0/1/1.0
set routing-instances mvrf1 protocols pim rp local family inet6 address 2001:1:1:1::1
set routing-instances mvrf1 protocols pim interface ge-0/0/0.0
set routing-instances mvrf1 protocols pim interface ge-0/1/0.0
set routing-instances mvrf1 protocols pim interface ge-0/1/1.0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure multicast for virtual routers:

1. Configure the interfaces.

```
[edit]
user@host# edit interfaces
[edit interfaces]
user@host# set ge-0/0/0 unit 0 family inet6 address 2001:4:4:4::1/64
[edit interfaces]
user@host# set ge-0/1/0 unit 0 family inet6 address 2001:24:24:24::1/64
[edit interfaces]
user@host# set ge-0/1/1 unit 0 family inet6 address 2001:7:7:7::1/64
[edit interfaces]
user@host# exit
```

Copyright © 2016, Juniper Networks, Inc.

2. Configure the routing instance type.

```
[edit]
user@host# edit routing-instances
[edit routing-instances]
user@host# set mvrf1 instance-type virtual-router
```

3. Configure the interfaces in the routing instance.

```
[edit routing-instances]
user@host# set mvrf1 interface ge-0/0/0
[edit routing-instances]
user@host# set mvrf1 interface ge-0/1/0
[edit routing-instances]
user@host# set mvrf1 interface ge-0/1/1
```

4. Configure PIM and the RP in the routing instance.

```
[edit routing-instances]
user@host# set mvrf1 protocols pim rp local family inet6 address 2001:1:1:1::1
```

5. Configure PIM on the interfaces.

```
[edit routing-instances]
user@host# set mvrf1 protocols pim interface ge-0/0/0
[edit routing-instances]
user@host# set mvrf1 protocols pim interface ge-0/1/0
[edit routing-instances]
user@host# set mvrf1 protocols pim interface ge-0/1/1
[edit routing-instances]
user@host# exit
```

6. Configure the MLD group.

```
[edit]
user@host# edit protocols mld
[edit protocols mld]
user@host# set interface ge-0/1/0.0 static group ff0e::10
[edit protocols mld]
user@host# set interface ge-0/1/1.0 static group ff0e::10
```

7. If you are done configuring the device, commit the configuration.

```
[edit routing-instances]
user@host# commit
```

Results

Confirm your configuration by entering the **show interfaces**, **show routing-instances**, and **show protocols** commands.

```
user@host# show interfaces
ge-0/0/0 {
    unit 0 {
        family inet6 {
            address 2001:4:4:4::1/64;
        }
    }
```

Copyright © 2016, Juniper Networks, Inc.

```
}
  ge-0/1/0 {
    unit 0 {
      family inet6 {
        address 2001:24:24:24::1/64;
      }
    }
  }
  ge-0/1/1 {
    unit 0 {
      family inet6 {
        address 2001:7:7:7::1/64;
      }
    }
  }
```

```
user@host# show routing-instances
mvrf1 {
  instance-type virtual-router;
  interface ge-0/0/0.0;
  interface ge-0/1/0.0;
  interface ge-0/1/1.0;
  protocols {
    pim {
      rp {
        local {
          family inet6 {
            address 2001:1:1:1::1;
          }
        }
      }
      interface ge-0/0/0.0;
      interface ge-0/1/0.0;
      interface ge-0/1/1.0;
    }
  }
}
```

```
user@host# show protocols
mld {
  interface ge-0/1/0.0 {
    static {
      group ff0e::10;
    }
  }
  interface ge-0/1/1.0 {
    static {
      group ff0e::10;
    }
  }
}
```

Verification

To verify the configuration, run the following commands:

Copyright © 2016, Juniper Networks, Inc.

- show mld group
- show mld interface
- show mld statistics
- show multicast interface
- show multicast route
- show multicast rpf
- show pim interfaces
- show pim join
- show pim neighbors
- *show route forwarding-table*
- *show route instance*
- show route table

Configuring Static RP

- Understanding Static RP on page 4135
- Configuring Local PIM RPs on page 4136
- Configuring the Static PIM RP Address on the Non-RP Routing Device on page 4137

Understanding Static RP

You can configure a static rendezvous point (RP) configuration that is similar to static routes. A static configuration has the benefit of operating in PIM version 1 or version 2. When you configure the static RP, the RP address that you select for a particular group must be consistent across all routers in a multicast domain.

A static configuration is simple and convenient. However, if the statically defined RP router becomes unreachable, there is no automatic failover to another RP router. To remedy this problem, you can use anycast RP.

Copyright © 2016, Juniper Networks, Inc.

Configuring Local PIM RPs

Local RP configuration makes the routing device a statically defined RP. Consider statically defining an RP if the network does not have many different RPs defined or if the RP assignment does not change very often. The Junos IPv6 PIM implementation supports only static RP configuration. Automatic RP announcement and bootstrap routers are not available with IPv6.

You can configure a local RP globally or for a routing instance. This example shows how to configure a local RP in a routing instance for IPv4 or IPv6.

To configure the routing device's RP properties:

1. Configure the routing instance as the local RP.

   ```
   [routing-instances VPN-A protocols pim]
   user@host# set rp local
   ```

2. Configure the IP protocol family and IP address.

   IPv6 PIM hello messages are sent to every interface on which you configure **family inet6**, whether at the PIM level of the hierarchy or not. As a result, if you configure an interface with both **family inet** at the **[edit interface *interface-name*]** hierarchy level and **family inet6** at the **[edit protocols pim interface *interface-name*]** hierarchy level, PIM sends both IPv4 and IPv6 hellos to that interface.

   By default, PIM operates in sparse mode on an interface. If you explicitly configure sparse mode, PIM uses this setting for all IPv6 multicast groups. However, if you configure sparse-dense mode, PIM does not accept IPv6 multicast groups as dense groups and operates in sparse mode over them.

   ```
   [edit routing-instances VPN-A protocols pim rp local]
   user@host# set family inet6 address 2001:db8:85a3::8a2e:370:7334
   user@host# set family inet address 10.1.2.254
   ```

3. (IPv4 only) Configure the routing device's RP priority.

   NOTE: The priority statement is not supported for IPv6, but is included here for informational purposes. The routing device's priority value for becoming the RP is included in the bootstrap messages that the routing device sends. Use a smaller number to increase the likelihood that the routing device becomes the RP for local multicast groups. Each PIM routing device uses the priority value and other factors to determine the candidate RPs for a particular group range. After the set of candidate RPs is distributed, each routing device determines algorithmically the RP from the candidate RP set using a hash function. By default, the priority value is set to 1. If this value is set to 0, the bootstrap router can override the group range being advertised by the candidate RP.

   ```
   [edit routing-instances VPN-A protocols pim rp local]
   user@host# set priority 5
   ```

4. Configure the groups for which the routing device is the RP.

Copyright © 2016, Juniper Networks, Inc.

By default, a routing device running PIM is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12). The following example limits the groups for which this routing device can be the RP.

```
[edit routing-instances VPN-A protocols pim rp local]
user@host# set group-ranges fec0::/10
user@host# set group-ranges 10.1.2.0/24
```

5. (IPv4 only) Modify the local RP hold time.

   If the local routing device is configured as an RP, it is considered a candidate RP for its local multicast groups. For candidate RPs, the hold time is used by the bootstrap router to time out RPs, and applies to the bootstrap RP-set mechanism. The RP hold time is part of the candidate RP advertisement message sent by the local routing device to the bootstrap router. If the bootstrap router does not receive a candidate RP advertisement from an RP within the hold time, it removes that routing device from its list of candidate RPs. The default hold time is 150 seconds.

   ```
   [edit routing-instances VPN-A protocols pim rp local]
   user@host# set hold-time 200
   ```

6. (Optional) Override dynamic RP for the specified group address range.

   If you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for the given static RP group range, and allow dynamic RP mapping for all other groups.

   If you exclude this statement from the configuration and you use both static and dynamic RP mechanisms for different group ranges within the same routing instance, the dynamic RP mapping takes precedence over the static RP mapping, even if static RP is defined for a specific group range.

   ```
   [edit routing-instances VPN-A protocols pim rp local]
   user@host# set override
   ```

7. Monitor the operation of PIM by running the **show pim** commands. Run **show pim ?** to display the supported commands.

Configuring the Static PIM RP Address on the Non-RP Routing Device

Consider statically defining an RP if the network does not have many different RPs defined or if the RP assignment does not change very often. The Junos IPv6 PIM implementation supports only static RP configuration. Automatic RP announcement and bootstrap routers are not available with IPv6.

You configure a static RP address on the non-RP routing device. This enables the non-RP routing device to recognize the local statically defined RP. For example, if R0 is a non-RP router and R1 is the local RP router, you configure R0 with the static RP address of R1. The static IP address is the routable address assigned to the loopback interface on R1. In the following example, the loopback address of the RP is 2001:db8:85a3::8a2e:370:7334.

Copyright © 2016, Juniper Networks, Inc.

You can configure a static RP address globally or for a routing instance. This example shows how to configure a static RP address in a routing instance for IPv6.

To configure the static RP address:

1. On a non-RP routing device, configure the routing instance to point to the routable address assigned to the loopback interface of the RP.

   ```
   [routing-instances VPN-A protocols pim rp]
   user@host# set static address 2001:db8:85a3::8a2e:370:7334
   ```

   NOTE: Logical systems are also supported. You can configure a static RP address in a logical system only if the logical system is not directly connected to a source.

2. (Optional) Set the PIM sparse mode version.

   For each static RP address, you can optionally specify the PIM version. The default PIM version is version 1.

   ```
   [edit routing-instances VPN-A protocols pim rp]
   user@host# set static address 2001:db8:85a3::8a2e:370:7334 version 2
   ```

   NOTE: The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIM version 1 is the default for RP mode (**[edit pim rp static address *address*]**). PIM version 2 is the default for interface mode (**[edit pim interface *interface-name*]**). Explicitly configured versions override the defaults.

3. (Optional) Set the group address range.

   By default, a routing device running PIM is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12). The following example limits the groups for which the 2001:db8:85a3::8a2e:370:7334 address can be the RP.

   ```
   [edit routing-instances VPN-A protocols pim rp]
   user@host# set static address 2001:db8:85a3::8a2e:370:7334 group-ranges fec0::/10
   ```

   The RP that you select for a particular group must be consistent across all routers in a multicast domain.

4. (Optional) Override dynamic RP for the specified group address range.

   If you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for the given static RP group range, and allow dynamic RP mapping for all other groups.

   If you exclude this statement from the configuration and you use both static and dynamic RP mechanisms for different group ranges within the same routing instance, the dynamic RP mapping takes precedence over the static RP mapping, even if static RP is defined for a specific group range.

Copyright © 2016, Juniper Networks, Inc.

```
[edit routing-instances VPN-A protocols pim rp static address
  2001:db8:85a3::8a2e:370:7334]
user@host# set override
```

5. Monitor the operation of PIM by running the **show pim** commands. Run **show pim ?** to display the supported commands.

Understanding RP Mapping with Anycast RP

Having a single active rendezvous point (RP) per multicast group is much the same as having a single server providing any service. All traffic converges on this single point, although other servers are sitting idle, and convergence is slow when the resource fails. In multicast specifically, there might be closer RPs on the shared tree, so the use of a single RP is suboptimal.

For the purposes of load balancing and redundancy, you can configure anycast RP. You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP fails, sources and receivers are taken to a new RP by means of unicast routing. When you configure anycast RP, you bypass the restriction of having one active RP per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

Anycast means that multiple RP routers share the same unicast IP address. Anycast addresses are advertised by the routing protocols. Packets sent to the anycast address are sent to the nearest RP with this address. Anycast addressing is a generic concept and is used in PIM sparse mode to add load balancing and service reliability to RPs.

Anycast RP is defined in Internet draft draft-ietf-mboned-anycast-rp-08.txt, *Anycast RP Mechanism Using PIM and MSDP*. To access Internet RFCs and drafts, go to the IETF website at http://www.ietf.org .

Copyright © 2016, Juniper Networks, Inc.

Example: Configuring Multiple RPs in a Domain with Anycast RP

This example shows how to configure anycast RP on each RP router in the PIM-SM domain. With this configuration you can deploy more than one RP for a single group range. This enables load balancing and redundancy.

- Requirements on page 4140
- Overview on page 4140
- Configuration on page 4140
- Verification on page 4142

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure PIM Sparse Mode on the interfaces. See "Enabling PIM Sparse Mode" on page 4118.

Overview

When you configure anycast RP, the RP routers in the PIM-SM domain use a shared address. In this example, the shared address is 10.1.1.2/32. Anycast RP uses Multicast Source Discovery Protocol (MSDP) to discover and maintain a consistent view of the active sources. Anycast RP also requires an RP selection method, such as static, auto-RP, or bootstrap RP. This example uses static RP and shows only one RP router configuration.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

RP Routers

```
set interfaces lo0 unit 0 family inet address 192.168.132.1/32 primary
set interfaces lo0 unit 0 family inet address 10.1.1.2/32
set protocols msdp local-address 192.168.132.1
set protocols msdp peer 192.168.12.1
set protocols pim rp local address 10.1.1.2
set routing-options router-id 192.168.132.1
```

Non-RP Routers

```
set protocols pim rp static address 10.1.1.2
```

Copyright © 2016, Juniper Networks, Inc.

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure anycast RP:

1. On each RP router in the domain, configure the shared anycast address on the router's loopback address.

   ```
   [edit interfaces]
   user@host# set lo0 unit 0 family inet address 10.1.1.2/32
   ```

2. On each RP router in the domain, make sure that the router's regular loopback address is the primary address for the interface, and set the router ID.

   ```
   [edit interfaces]
   user@host# set lo0 unit 0 family inet address 192.168.132.1/32 primary

   [edit routing-options]
   user@host# set router-id 192.168.132.1
   ```

3. On each RP router in the domain, configure the local RP address, using the shared address.

   ```
   [edit protocols pim]
   user@host# set rp local address 10.1.1.2
   ```

4. On each RP router in the domain, create MSDP sessions to the other RPs in the domain.

   ```
   [edit protocols msdp]
   user@host# set local-address 192.168.132.1
   user@host# set peer 192.168.12.1
   ```

5. On each non-RP router in the domain, configure a static RP address using the shared address.

   ```
   [edit protocols pim]
   user@host# set rp static address 10.1.1.2
   ```

6. If you are done configuring the devices, commit the configuration.

   ```
   user@host# commit
   ```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces
lo0 {
   unit 0 {
      family inet {
         address 192.168.132.1/32 {
            primary;
         }
         address 10.1.1.2/32;
```

Copyright © 2016, Juniper Networks, Inc.

```
        }
    }
}
```

On the RP routers:

```
user@host# show protocols
msdp {
    local-address 192.168.132.1;
    peer 192.168.12.1;
}
pim {
    rp {
        local {
            address 10.1.1.2;
        }
    }
}
```

On the non-RP routers:

```
user@host# show protocols
pim {
    rp {
        static {
            address 10.1.1.2;
        }
    }
}

user@host# show routing-options
router-id 192.168.132.1;
```

Verification

To verify the configuration, run the show pim rps **extensive inet** command.

Example: Configuring PIM Anycast With or Without MSDP

When you configure anycast RP, you bypass the restriction of having one active rendezvous point (RP) per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP stops operating, sources and receivers are taken to a new RP by means of unicast routing.

You can configure anycast RP to use PIM and MSDP for IPv4, or PIM alone for both IPv4 and IPv6 scenarios. Both are discussed in this section.

We recommend a static RP mapping with anycast RP over a bootstrap router and auto-RP configuration because it provides all the benefits of a bootstrap router and auto-RP without the complexity of the BSR and auto-RP mechanisms.

Copyright © 2016, Juniper Networks, Inc.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default RP mode (at the **[edit protocols pim rp static address *address*]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface *interface-name*]** hierarchy level). Explicitly configured versions override the defaults. This example explicitly configures PIMv2 on the interfaces.

The following example shows an anycast RP configuration for the RP routers, first with MSDP and then using PIM alone, and for non-RP routers.

1. For a network using an RP with MSDP, configure the RP using the **lo0** loopback interface, which is always up. Include the **address** statement and specify the unique and routable router ID and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement for the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

   ```
   interfaces {
     lo0 {
       description "PIM RP";
       unit 0 {
         family inet {
           address 198.58.3.254/32;
           primary;
           address 198.58.3.253/32;
         }
       }
     }
   }
   ```

2. Specify the RP address. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level (the same address as the secondary **lo0** interface).

   For all interfaces, include the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

   ```
   protocols {
     pim {
       rp {
         local {
           family inet;
           address 198.58.3.253;
         }
         interface all {
           mode sparse;
           version 2;
         }
         interface fxp0.0 {
           disable;
         }
       }
   ```

Copyright © 2016, Juniper Networks, Inc.

```
    }
  }
```

3. Configure MSDP peering. Include the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, include the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
  msdp {
    peer 198.58.3.250 {
      local-address address 198.58.3.254;
    }
  }
}
```

NOTE: If you need to configure a PIM RP for both IPv4 and IPv6 scenarios, perform Step 4 and Step 5. Otherwise, go to Step 6.

4. Configure an RP using the **lo0** loopback interface, which is always up. Include the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement on the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32 {
          primary;
        }
        address 198.58.3.253/32;
      }
    }
  }
}
```

5. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

   For all interfaces, include the **mode** statement to set the mode to **sparse**, and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by Including the **disable** statement for that interface.

   Include the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP

Copyright © 2016, Juniper Networks, Inc.

address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

```
protocols {
  pim {
    rp {
      local {
        family inet {
          address 198.58.3.253;
          anycast-pim {
            rp-set {
              address 198.58.3.240;
              address 198.58.3.241 forward-msdp-sa;
            }
            local-address 198.58.3.254; #If not configured, use lo0 primary
          }
        }
      }
    }
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
```

6. Configure the non-RP routers. The anycast RP configuration for a non-RP router is the same whether MSDP is used or not. Specify a static RP by adding the address at the **[edit protocols pim rp static]** hierarchy level. Include the **version** statement at the **[edit protocols pim rp static address]** hierarchy level to specify PIM version 2.

```
protocols {
  pim {
    rp {
      static {
        address 198.58.3.253 {
          version 2;
        }
      }
    }
  }
}
```

7. Include the **mode** statement at the **[edit protocols pim interface all]** hierarchy level to specify sparse mode on all interfaces. Then include the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
  pim {
    interface all {
```

Copyright © 2016, Juniper Networks, Inc.

```
            mode sparse;
            version 2;
          }
          interface fxp0.0 {
            disable;
          }
        }
      }
```

Configuring a PIM Anycast RP Router Using Only PIM

In this example, configure an RP using the **lo0** loopback interface, which is always up. Use the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this case, the router ID is 198.58.3.254/32 and the shared RP address is 198.58.3.253/32. Add the flag statement **primary** to the first address. Using this flag selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
  lo0 {
    description "PIM RP";
    unit 0 {
      family inet {
        address 198.58.3.254/32 {
          primary;
        }
        address 198.58.3.253/32;
      }
    }
  }
}
```

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse**, and include the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

Use the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

```
protocols {
  pim {
    rp {
      local {
        family inet {
          address 198.58.3.253;
          anycast-pim {
            rp-set {

Understanding the PIM Bootstrap Router

To determine which routing device is the rendezvous point (RP), all routing devices within a PIM sparse-mode domain collect bootstrap messages. A PIM sparse-mode domain is a group of routing devices that all share the same RP router. The domain bootstrap routing device initiates bootstrap messages, which are sent hop by hop within the domain. The routing devices use bootstrap messages to distribute RP information dynamically and to elect a bootstrap routing device when necessary.

Configuring PIM Bootstrap Properties for IPv4

For correct operation, every multicast router within a PIM domain must be able to map a particular multicast group address to the same Rendezvous Point (RP). The bootstrap

Copyright © 2016, Juniper Networks, Inc.

router mechanism is one way that a multicast router can learn the set of group-to-RP mappings. Bootstrap routers are supported in IPv4 and IPv6.

NOTE: For legacy configuration purposes, there are two sections that describe the configuration of bootstrap routers: one section for both IPv4 and IPv6, and this section, which is for IPv4 only. The method described in "Configuring PIM Bootstrap Properties for IPv4 or IPv6" on page 4149 is recommended. A commit error occurs if the same IPv4 bootstrap statements are included in both the IPv4-only and the IPv4-and-IPv6 sections of the hierarchy. The error message is "duplicate IPv4 bootstrap configuration."

To determine which routing device is the RP, all routing devices within a PIM domain collect bootstrap messages. A PIM domain is a contiguous set of routing devices that implement PIM. All are configured to operate within a common boundary. The domain's bootstrap router initiates bootstrap messages, which are sent hop by hop within the domain. The routing devices use bootstrap messages to distribute RP information dynamically and to elect a bootstrap router when necessary.

You can configure bootstrap properties globally or for a routing instance. This example shows the global configuration.

To configure the bootstrap router properties:

1. Configure the bootstrap priority.

   By default, each routing device has a bootstrap priority of 0, which means the routing device can never be the bootstrap router. A priority of 0 disables the function for IPv4 and does not cause the routing device to send bootstrap router packets with a 0 in the priority field. The routing device with the highest priority value is elected to be the bootstrap router. In the case of a tie, the routing device with the highest IP address is elected to be the bootstrap router. A simple bootstrap configuration assigns a bootstrap priority value to a routing device.

   ```
   [edit protocols pim rp]
   user@host# set bootstrap-priority 3
   ```

2. (Optional) Create import and export policies to control the flow of IPv4 bootstrap messages to and from the RP, and apply the policies to PIM. Import and export policies are useful when some of the routing devices in your PIM domain have interfaces that connect to other PIM domains. Configuring a policy prevents bootstrap messages from crossing domain boundaries. The **bootstrap-import** statement prevents messages from being imported into the RP. The **bootstrap-export** statement prevents messages from being exported from the RP.

   ```
   [edit protocols pim rp]
   user@host# set bootstrap-import pim-bootstrap-import
   user@host# set bootstrap-export pim-bootstrap-export
   ```

3. Configure the policies.

   ```
   [edit policy-options policy-statement pim-bootstrap-import]
   user@host# set from interface se-0/0/0
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set then reject

[edit policy-options policy-statement pim-bootstrap-export]
user@host# set from interface se-0/0/0
user@host# set then reject
```

4. Monitor the operation of PIM bootstrap routing devices by running the **show pim bootstrap** command.

Configuring PIM Bootstrap Properties for IPv4 or IPv6

For correct operation, every multicast router within a PIM domain must be able to map a particular multicast group address to the same Rendezvous Point (RP). The bootstrap router mechanism is one way that a multicast router can learn the set of group-to-RP mappings. Bootstrap routers are supported in IPv4 and IPv6.

NOTE: For legacy configuration purposes, there are two sections that describe the configuration of bootstrap routers: one section for IPv4 only, and this section, which is for both IPv4 and IPv6. The method described in this section is recommended. A commit error occurs if the same IPv4 bootstrap statements are included in both the IPv4-only and the IPv4-and-IPv6 sections of the hierarchy. The error message is “duplicate IPv4 bootstrap configuration.”

To determine which routing device is the RP, all routing devices within a PIM domain collect bootstrap messages. A PIM domain is a contiguous set of routing devices that implement PIM. All devices are configured to operate within a common boundary. The domain's bootstrap router initiates bootstrap messages, which are sent hop by hop within the domain. The routing devices use bootstrap messages to distribute RP information dynamically and to elect a bootstrap router when necessary.

You can configure bootstrap properties globally or for a routing instance. This example shows the global configuration.

To configure the bootstrap router properties:

1. Configure the bootstrap priority.

   By default, each routing device has a bootstrap priority of 0, which means the routing device can never be the bootstrap router. The routing device with the highest priority value is elected to be the bootstrap router. In the case of a tie, the routing device with the highest IP address is elected to be the bootstrap router. A simple bootstrap configuration assigns a bootstrap priority value to a routing device.

Copyright © 2016, Juniper Networks, Inc.

NOTE: In the IPv4-only configuration, specifying a bootstrap priority of 0 disables the bootstrap function and does not cause the routing device to send BSR packets with a 0 in the priority field. In the configuration shown here, specifying a bootstrap priority of 0 does not disable the function, but causes the routing device to send BSR packets with a 0 in the priority field. To disable the bootstrap function in the IPv4 and IPv6 configuration, delete the **bootstrap** statement.

```
user@host# edit protocols pim rp
user@host# set bootstrap family inet priority 3
```

2. (Optional) Create import and export policies to control the flow of bootstrap messages to and from the RP, and apply the policies to PIM. Import and export policies are useful when some of the routing devices in your PIM domain have interfaces that connect to other PIM domains. Configuring a policy prevents bootstrap messages from crossing domain boundaries. The **import** statement prevents messages from being imported into the RP. The **export** statement prevents messages from being exported from the RP.

```
[edit protocols pim rp]
user@host# set bootstrap family inet import pim-bootstrap-import
user@host# set bootstrap family inet export pim-bootstrap-export
```

3. Configure the policies.

```
[edit policy-options policy-statement pim-bootstrap-import]
user@host# set from interface se-0/0/0
user@host# set then reject
user@host# exit
user@host# edit policy-options policy-statement pim-bootstrap-export
user@host# set from interface se-0/0/0
user@host# set then reject
```

4. Monitor the operation of PIM bootstrap routing devices by running the **show pim bootstrap** command.

Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain

In this example, the **from interface so-0-1/0 then reject** policy statement rejects bootstrap messages from the specified interface (the example is configured for both IPv4 and IPv6 operation):

```
protocols {
  pim {
    rp {
      bootstrap {
        family inet {
          priority 1;
          import pim-import;
          export pim-export;
        }
        family inet6 {
          priority 1;
```

Copyright © 2016, Juniper Networks, Inc.

```
            import pim-import;
            export pim-export;
          }
        }
      }
    }
  }
  policy-options {
    policy-statement pim-import {
      from interface so-0/1/0;
      then reject;
    }
    policy-statement pim-export {
      to interface so-0/1/0;
      then reject;
    }
  }
```

Example: Configuring PIM BSR Filters

Configure a filter to prevent BSR messages from entering or leaving your network. Add this configuration to all routers:

```
protocols {
  pim {
    rp {
      bootstrap-import no-bsr;
      bootstrap-export no-bsr;
    }
  }
}
policy-options {
  policy-statement no-bsr {
    then reject;
  }
}
```

Understanding PIM Auto-RP

You can configure a more dynamic way of assigning rendezvous points (RPs) in a multicast network by means of auto-RP. When you configure auto-RP for a router, the router learns

Copyright © 2016, Juniper Networks, Inc.

the address of the RP in the network automatically and has the added advantage of operating in PIM version 1 and version 2.

Although auto-RP is a nonstandard (non-RFC-based) function that typically uses dense mode PIM to advertise control traffic, it provides an important failover advantage that simple static RP assignment does not. You can configure multiple routers as RP candidates. If the elected RP fails, one of the other preconfigured routers takes over the RP functions. This capability is controlled by the auto-RP mapping agent.

Configuring PIM Auto-RP

For correct operation, every multicast within a PIM domain must be able to map a particular multicast group address to the same rendezvous point (RP). The auto-RP mechanism is one way that a multicast can learn the set of group-to-RP mappings. Auto-RP automatically distributes mapping information to routing devices. It simplifies use of multiple RPs for different multicast group ranges, thus allowing multiple RPs to act as backups for each other. Auto-RP relies on a to act as the RP mapping agent. Potential RPs announce themselves to the mapping agent, and the mapping agent resolves any conflicts.

The mapping agent sends the multicast group-RP mapping information to the other s using PIM dense mode. The specific groups used are 224.0.1.39 and .40. The first (.39) is used to advertise, the second (.40) is used for discovery. Because PIM dense mode is necessary to enable auto-RP to work, which in turns enables PIM sparse mode to work, you must configure PIM sparse-dense mode in the PIM domains that use auto-RP.

Although auto-RP is a nonstandard (non-RFC-based) function requiring dense mode PIM to advertise control traffic, it provides an important failover advantage that static RP assignment does not. That is, you can configure multiple routing devices as RP candidates. If the elected RP fails, one of the other preconfigured routing devices takes over the RP functions. This capability is controlled by the auto-RP mapping agent.

Auto-RP operates in PIM version 1 and version 2.

In most cases, how the routing device handles auto-RP discovery, announce, or mapping messages depends on whether the routing device is an RP (configured as local RP) or not. Table 384 shows how the routing device behaves depending on the local RP configuration.

Table 384: Local RP and Auto-RP Message Types

Auto-RP Message Type	Local RP?	Routing Device Behavior
discovery	No	Listen for auto-RP mapping messages.
discovery	Yes	Listen for auto-RP mapping messages.
announce	No	Listen for auto-RP mapping messages.
announce	Yes	Listen for auto-RP mapping messages. Send auto-RP announce messages.

Copyright © 2016, Juniper Networks, Inc.

Table 384: Local RP and Auto-RP Message Types *(continued)*

Auto-RP Message Type	Local RP?	Routing Device Behavior
mapping	No	Listen for auto-RP mapping messages. Listen for auto-RP announce messages. If elected mapping agent, send auto-RP mapping messages.
mapping	Yes	Listen for auto-RP mapping messages. Send auto-RP announce messages. Listen for auto-RP announce messages. If elected mapping agent, send auto-RP mapping messages.

NOTE: If the routing device receives auto-RP announcements split across multiple messages, the routing device loses the information in the previous part of the message as soon as the next part of the message is received.

You can configure auto-RP properties globally or for a routing instance. This example shows the global configuration.

To configure auto-RP properties:

1. Configure PIM in sparse-dense mode on all routing devices in the PIM domain.

   ```
   [edit protocols pim]
   user@host# edit
   user@host# set interface all mode sparse-dense
   ```

   This configuration allows the routing device to operate in sparse mode for most groups and dense mode for others. The default is to operate in sparse mode unless the routing device is specifically informed of a dense mode group.

2. Configure a routable loopback interface address on all routing devices in the PIM domain.

   The routing device joins the auto-RP groups on the configured interfaces and on the loopback interface **lo0.0**. For auto-RP to work correctly, configure a routable IP address on the loopback interface. The router ID is used as the address for auto-RP updates. You cannot use the loopback address 127.0.0.1. Also, you must enable PIM sparse-dense mode on the **lo0.0** interface if you do not specify **interface all**.

   ```
   [edit interfaces lo0.0 unit 0 family inet]
   user@host# set address 192.168.0.3 preferred
   ```

3. Configure the two multicast dense groups on all the routing devices.

   Auto-RP requires multicast flooding to announce potential RP candidates and to discover the elected RPs in the network. Multicast flooding occurs through a PIM dense mode model, where group 224.0.1.39 is used for **announce** messages and group 224.0.1.40 is used for **discovery** messages.

   ```
   [edit protocols pim]
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set dense-groups 224.0.1.39/32
user@host# set dense-groups 224.0.1.40/32
```

TIP: Step 3 is required. When auto-RP is enabled, the auto-RP announce group (224.0.1.39) and auto-RP-discovery group (224.0.1.40) must be configured explicitly as dense groups. When the auto-RP discovery group is not configured as a dense group, auto-RP is not enabled. When the auto-RP announce group is not configured as a dense group, auto-RP is enabled in the discovery mode only, and mapping and announce modes are disabled.

4. Configure the auto-RP **announce** option.

   At least one routing device in the PIM domain must announce auto-RP messages and at least one must map them, or you can configure a routing device to perform both functions.

   When a routing device sends announce messages in the network, it is advertising itself as a candidate RP. A routing device configured with this option must also be configured as an RP, or announce messages are not sent.

   ```
   [edit protocols pim rp]
   user@host# set local address 192.168.0.1
   user@host# set auto-rp announce
   ```

   NOTE: You cannot include the **auto-rp announce** option at the **[edit logical-systems** *logical-system-name* **routing-instances** *routing-instance-name* **protocols pim]** hierarchy level.

5. Configure the auto-RP mapping agent.

   The mapping agent sends discovery messages to the network, informing all routing devices in a multicast group of which RP to use. If the mapping agent is also an RP, the **mapping** option also allows the routing device to send auto-RP announcements (mapping on an RP allows the routing device to perform both the announcement and mapping functions).

   ```
   [edit protocols pim rp]
   user@host# set auto-rp mapping
   ```

   If the mapping agent is also an RP, configure the mapping agent as a local RP.

   ```
   [edit protocols pim rp]
   user@host# set local address 192.168.0.2
   ```

6. Configure mapping agent election.

   If you configure the **mapping** option on more than one routing device in the PIM domain, configure mapping agent election on each potential mapping agent.

   Auto-RP specifications state that mapping agents do not send mapping messages if they receive messages from a mapping agent with a higher IP address. However,

Copyright © 2016, Juniper Networks, Inc.

some vendors' mapping agents continue to announce mappings, even in the presence of higher-addressed mapping agents. In other words, some mapping agents will always send mapping messages.

The default auto-RP operation is to perform mapping agent election. To explicitly configure mapping agent election, you can include the **mapping-agent-election** statement. When this option is configured, the mapping agent will stop sending mapping messages if it receives messages from a mapping agent with a higher IP address.

```
[edit protocols pim rp]
user@host# set auto-rp mapping mapping-agent-election
```

Mapping message suppression is disabled with the **no-mapping-agent-election** statement. When this option is configured, the mapping agent will always send mapping messages even in the presence of higher-addressed mapping agents.

To disable mapping agent election for compatibility with other vendors' equipment, include the **no-mapping-agent-election** statement.

```
[edit protocols pim rp]
user@host# set auto-rp mapping no-mapping-agent-election
```

7. Configure the remaining routing devices in the PIM domain to discover the RP.

   Discovery enables the routing devices to receive and process discovery messages from the mapping agent. This is the most basic auto-RP option.

   ```
   [edit protocols pim rp]
   user@host# set auto-rp discovery
   ```

8. Monitor the operation of PIM auto-RP routers by running the following commands:

   - show pim interfaces
   - show pim rps

9. Issue the **show pim rps extensive** command to see information about how an RP is learned, what groups it handles, and the number of groups actively using the RP.

   ```
   user@host> show pim rps extensive
   RP: 192.168.5.1
   Learned from 192.168.5.1 via: auto-rp
   Time Active: 00:34:29
   Holdtime: 150 with 108 remaining
   Device Index: 6
   Subunit: 32769
   Interface: pd-0/0/0.32769
   Group Ranges:
           224.0.0.0/4
   Active groups using RP:
           224.2.2.100
           total 1 groups active
   Register State for RP:
   Group     Source FirstHop       RP Address      StateRP address Type Holdtime
    Timeout
   ```

   In the example, the RP at 192.168.5.1 was learned through auto-RP. The RP is able to support all groups in the 224.0.0.0/4 range (all possible groups). The local router has sent PIM control traffic for the 224.2.2.100 group to the RP.

Copyright © 2016, Juniper Networks, Inc.

Additionally, the presence of a Tunnel Physical Interface Card (PIC) in an RP router creates a de-encapsulation interface, which allows the RP to receive multicast traffic from the source. This interface is indicated by **pd-0/0/0.32769**.

Understanding Embedded RP for IPv6 Multicast

Global IPv6 multicast between routing domains has been possible only with source-specific multicast (SSM) because there is no way to convey information about IPv6 multicast RPs between PIM sparse mode RPs. In IPv4 multicast networks, this information is conveyed between PIM RPs using MSDP, but there is no IPv6 support in current MSDP standards. IPv6 uses the concept of an embedded RP to resolve this issue without requiring SSM. This feature embeds the RP address in an IPv6 multicast address.

All IPv6 multicast addresses begin with 8 1-bits (1111 1111) followed by a 4-bit flag field normally set to 0011. The flag field is set to 0111 when embedded RP is used. Then the low-order bits of the normally reserved field in the IPv6 multicast address carry the 4-bit RP interface identifier (RIID).

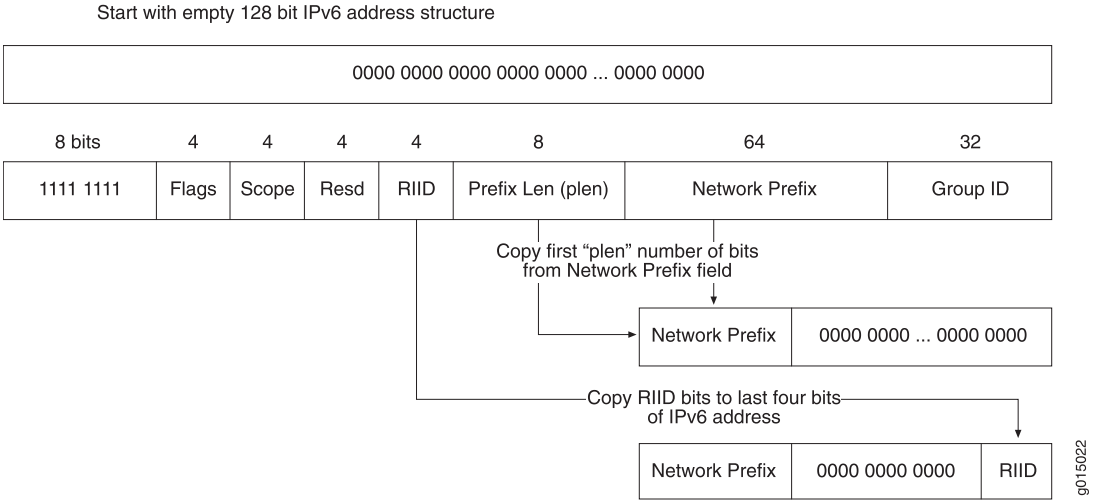
When the IPv6 address of the RP is embedded in a unicast-prefix-based any-source multicast (ASM) address, all of the following conditions must be true:

- The address must be an IPv6 multicast address and have 0111 in the flags field (that is, the address is part of the prefix FF70::/12).
- The 8-bit prefix length (plen) field must not be all 0. An all 0 plen field implies that SSM is in use.
- The 8-bit prefix length field value must not be greater than 64, which is the length of the network prefix field in unicast-prefix-based ASM addresses.

The routing platform derives the value of the interdomain RP by copying the prefix length field number of bits from the 64-bit network prefix field in the received IPv6 multicast address to an empty 128-bit IPv6 address structure and copying the last bits from the 4-bit RIID. For example, if the prefix length field bits have the value 32, then the routing platform copies the first 32 bits of the IPv6 multicast address network prefix field to an all-0 IPv6 address and appends the last four bits determined by the RIID. See Figure 166 for an illustration of this process.

Copyright © 2016, Juniper Networks, Inc.

Figure 166: Extracting the Embedded RP IPv6 Address



For example, the administrator of IPv6 network 2001:DB8::/32 sets up an RP for the 2001:DB8:BEEF:FEED::/96 subnet. In that case, the received embedded RP IPv6 ASM address has the form:

FF70:y40:2001:DB8:BEEF:FEED::/96

and the derived RP IPv6 address has the form:

2001:DB8:BEEF:FEED::y

where **y** is the RIID (**y** cannot be 0).

When configured, the routing platform checks for embedded RP information in every PIM join request received for IPv6. The use of embedded RP does not change the processing of IPv6 multicast and RPs in any way, except that the embedded RP address is used if available and selected for use. There is no need to specify the IPv6 address family for embedded RP configuration because the information can be used only if IPv6 multicast is properly configured on the routing platform.

The following receive events trigger extraction of an IPv6 embedded RP address on the routing platform:

- Multicast Listener Discovery (MLD) report for an embedded RP multicast group address
- PIM join message with an embedded RP multicast group address
- Static embedded RP multicast group address associated with an interface
- Packets sent to an embedded RP multicast group address received on the DR

The embedded RP node discovered through these events is added if it does not already exist on the routing platform. The routing platform chooses the embedded RP as the RP for a multicast group before choosing an RP learned through BSRs or a statically configured RP. The embedded RP is removed whenever all PIM join states using this RP are removed or the configuration changes to remove the embedded RP feature.

Copyright © 2016, Juniper Networks, Inc.

Configuring PIM Embedded RP for IPv6

You configure embedded RP to allow multidomain IPv6 multicast networks to find RPs in other routing domains. Embedded RP embeds an RP address inside PIM join messages and other types of messages sent between routing domains. Global IPv6 multicast between routing domains has been possible only with source-specific multicast (SSM) because there is no way to convey information about IPv6 multicast RPs between PIM sparse mode RPs. In IPv4 multicast networks, this information is conveyed between PIM RPs using MSDP, but there is no IPv6 support in current MSDP standards. IPv6 uses the concept of an embedded RP to resolve this issue without requiring SSM. Thus, embedded RP enables you can deploy IPv6 with any-source multicast (ASM).

Embedded RP is disabled by default.

When you configure embedded RP for IPv6, embedded RPs are preferred to RPs discovered by IPv6 any other way. You configure embedded RP independent of any other IPv6 multicast properties. This feature is applied only when IPv6 multicast is properly configured.

You can configure embedded RP globally or for a routing instance. This example shows the routing instance configuration.

To configure embedded RP for IPv6 PIM sparse mode:

1. Define which multicast addresses or prefixes can embed RP address information. If messages within a group range contain embedded RP information and the group range is not configured, the embedded RP in that group range is ignored. Any valid unicast-prefix-based ASM address can be used as a group range. The default group range is FF70::/12 to FFF0::/12. Messages with embedded RP information that do not match any configured group ranges are treated as normal multicast addresses.

   ```
   [edit routing-instances vpn-A protocols pim rp embedded-rp]
   user@host# set group-ranges fec0::/10
   ```

   If the derived RP address is not a valid IPv6 unicast address, it is treated as any other multicast group address and is not used for RP information. Verification fails if the extracted RP address is a local interface, unless the routing device is configured as an RP and the extracted RP address matches the configured RP address. Then the local RP determines whether it is configured to act as an RP for the embedded RP multicast address.

2. Limit the number of embedded RPs created in a specific routing instance. The range is from 1 through 500. The default is 100.

   ```
   [edit routing-instances vpn-A protocols pim rp]
   user@host# set maximum-rps 50
   ```

3. Monitor the operation by running the **show pim rps** and **show pim statistics** commands.

- Filtering Outgoing PIM Join Messages on page 4162
- Filtering Incoming PIM Join Messages on page 4163
- Configuring Register Message Filters on a PIM RP and DR on page 4164

Understanding Multicast Message Filters

Multicast sources and routers generate a considerable number of control messages, especially when using PIM sparse mode. These messages form distribution trees, locate rendezvous points (RPs) and designated routers (DRs), and transition from one type of tree to another. In most cases, this multicast messaging system operates transparently and efficiently. However, in some configurations, more control over the sending and receiving of multicast control messages is necessary.

You can configure multicast filtering to control the sending and receiving of multicast control messages.

To prevent unauthorized groups and sources from registering with an RP router, you can define a routing policy to reject PIM register messages from specific groups and sources and configure the policy on the designated router or the RP router.

- If you configure the reject policy on an RP router, it rejects incoming PIM register messages from the specified groups and sources. The RP router also sends a register stop message by means of unicast to the designated router. On receiving the register stop message, the designated router sends periodic null register messages for the specified groups and sources to the RP router.
- If you configure the reject policy on a designated router, it stops sending PIM register messages for the specified groups and sources to the RP router.

NOTE: If you have configured the reject policy on an RP router, we recommend that you configure the same policy on all the RP routers in your multicast network.

Copyright © 2016, Juniper Networks, Inc.

NOTE: If you delete a group and source address from the reject policy configured on an RP router and commit the configuration, the RP router will register the group and source only when the designated router sends a null register message.

Filtering MAC Addresses

When a router is exclusively configured with multicast protocols on an interface, multicast sets the interface media access control (MAC) filter to multicast promiscuous mode, and the number of multicast groups is unlimited. However, when the router is not exclusively used for multicasting and other protocols such as OSPF, Routing Information Protocol version 2 (RIPv2), or Network Time Protocol (NTP) are configured on an interface, each of these protocols individually requests that the interface program the MAC filter to pick up its respective multicast group only. In this case, without multicast configured on the interface, the maximum number of multicast MAC filters is limited to 20. For example, the maximum number of interface MAC filters for protocols such as OSPF (multicast group 224.0.0.5) is 20, unless a multicast protocol is also configured on the interface.

No configuration is necessary for MAC filters.

Filtering RP and DR Register Messages

You can filter Protocol Independent Multicast (PIM) register messages sent from the designated router (DR) or to the rendezvous point (RP). The PIM RP keeps track of all active sources in a single PIM sparse mode domain. In some cases, more control over which sources an RP discovers, or which sources a DR notifies other RPs about, is desired. A high degree of control over PIM register messages is provided by RP and DR register message filtering. Message filtering also prevents unauthorized groups and sources from registering with an RP router.

Register messages that are filtered at a DR are not sent to the RP, but the sources are available to local users. Register messages that are filtered at an RP arrive from source DRs, but are ignored by the router. Sources on multicast group traffic can be limited or directed by using RP or DR register message filtering alone or together.

If the action of the register filter policy is to discard the register message, the router needs to send a register-stop message to the DR. Register-stop messages are throttled to prevent malicious users from triggering them on purpose to disrupt the routing process.

Multicast group and source information is encapsulated inside unicast IP packets. This feature allows the router to inspect the multicast group and source information before sending or accepting the PIM register message.

Incoming register messages to an RP are passed through the configured register message filtering policy before any further processing. If the register message is rejected, the RP router sends a register-stop message to the DR. When the DR receives the register-stop message, the DR stops sending register messages for the filtered groups and sources to the RP. Two fields are used for register message filtering:

Copyright © 2016, Juniper Networks, Inc.

- Group multicast address
- Source address

The syntax of the existing policy statements is used to configure the filtering on these two fields. The **route-filter** statement is useful for multicast group address filtering, and the **source-address-filter** statement is useful for source address filtering. In most cases, the action is to **reject** the register messages, but more complex filtering policies are possible.

Filtering cannot be performed on other header fields, such as DR address, protocol, or port. In some configurations, an RP might not send register-stop messages when the policy action is to discard the register messages. This has no effect on the operation of the feature, but the router will continue to receive register messages.

When anycast RP is configured, register messages can be sent or received by the RP. All the RPs in the anycast RP set need to be configured with the same RP register message filtering policies. Otherwise, it might be possible to circumvent the filtering policy.

Filtering MSDP SA Messages

Along with applying MSDP source active (SA) filters on all external MSDP sessions (in and out) to prevent SAs for groups and sources from leaking in and out of the network, you need to apply bootstrap router (BSR) filters. Applying a BSR filter to the boundary of a network prevents foreign BSR messages (which announce RP addresses) from leaking into your network. Since the routers in a PIM sparse-mode domain need to know the address of only one RP router, having more than one in the network can create issues.

If you did not use multicast scoping to create boundary filters for all customer-facing interfaces, you might want to use PIM join filters. Multicast scopes prevent the actual multicast data packets from flowing in or out of an interface. PIM join filters prevent PIM sparse-mode state from being created in the first place. Since PIM join filters apply only to the PIM sparse-mode state, it might be more beneficial to use multicast scoping to filter the actual data.

NOTE: When you apply firewall filters, firewall action modifiers, such as log, sample, and count, work only when you apply the filter on an inbound interface. The modifiers do not work on an outbound interface.

Configuring Interface-Level PIM Neighbor Policies

You can configure a policy to filter unwanted PIM neighbors. In the following example, the PIM interface compares neighbor IP addresses with the IP address in the policy statement before any hello processing takes place. If any of the neighbor IP addresses (primary or secondary) match the IP address specified in the prefix list, PIM drops the hello packet and rejects the neighbor.

If you configure a PIM neighbor policy after PIM has already established a neighbor adjacency to an unwanted PIM neighbor, the adjacency remains intact until the neighbor

Copyright © 2016, Juniper Networks, Inc.

hold time expires. When the unwanted neighbor sends another hello message to update its adjacency, the router recognizes the unwanted address and rejects the neighbor.

To configure a policy to filter unwanted PIM neighbors:

1. Configure the policy. The neighbor policy must be a properly structured policy statement that uses a prefix list (or a route filter) containing the neighbor primary address (or any secondary IP addresses) in a prefix list, and the **reject** option to reject the unwanted address.

   ```
   [edit policy-options]
   user@host# set prefix-list nbrGroup 1 20.20.20.1/32
   user@host# set policy-statement nbr-policy from prefix-list nbrGroup1
   user@host# set policy-statement nbr-policy then reject
   ```

2. Configure the interface globally or in the routing instance. This example shows the configuration for the routing instance.

   ```
   [edit routing-instances PIM.master protocols pim]
   user@host# set neighbor-policy nbr-policy
   ```

3. Verify the configuration by checking the **Hello dropped on neighbor policy** field in the output of the **show pim statistics** command.

Filtering Outgoing PIM Join Messages

When the core of your network is using MPLS, PIM join and prune messages stop at the customer edge (CE) routers and are not forwarded toward the core, because these routers do not have PIM neighbors on the core-facing interfaces. When the core of your network is using IP, PIM join and prune messages are forwarded to the upstream PIM neighbors in the core of the network.

When the core of your network is using a mix of IP and MPLS, you might want to filter certain PIM join and prune messages at the upstream egress interface of the CE routers.

You can filter PIM sparse mode (PIM-SM) join and prune messages at the egress interfaces for IPv4 and IPv6 in the upstream direction. The messages can be filtered based on the group address, source address, outgoing interface, PIM neighbor, or a combination of these values. If the filter is removed, the join is sent after the PIM periodic join timer expires.

To filter PIM sparse mode join and prune messages at the egress interfaces, create a policy rejecting the group address, source address, outgoing interface, or PIM neighbor, and then apply the policy.

The following example filters PIM join and prune messages for group addresses 224.0.1.2 and 225.1.1.1.

1. In configuration mode, create the policy.

   ```
   user@host# set policy-options policy-statement block-groups term t1 from route-filter
     224.0.1.2/32 exact
   user@host# set policy-options policy-statement block-groups term t1 from route-filter
     225.1.1.1/32 exact
   user@host# set policy-options policy-statement block-groups term t1 then reject
   user@host# set policy-options policy-statement block-groups term last then accept
   ```

Copyright © 2016, Juniper Networks, Inc.

2. Verify the policy configuration by running the **show policy-options** command.

```
user@host# show policy-options
policy-statement block-groups {
  term t1 {
    from {
      route-filter 224.0.1.2/32 exact;
      route-filter 225.1.1.1/32 exact;
      then reject;
    }
    term last {
      then accept;
    }
  }
```

3. Apply the PIM join and prune message filter.

```
user@host> set protocols pim export block-groups
```

4. After the configuration is committed, use the **show pim statistics** command to verify that outgoing PIM join and prune messages are being filtered.

```
user@host>  show pim statistics | grep filtered
RP Filtered Source                  0

Rx Joins/Prunes filtered            0

Tx Joins/Prunes filtered            254
```

The egress filter count is shown on the **Tx Joins/Prunes filtered** line.

Filtering Incoming PIM Join Messages

Multicast scoping controls the propagation of multicast messages. Whereas multicast scoping prevents the actual multicast data packets from flowing in or out of an interface, PIM join filters prevent a state from being created in a router. A state—the (*,G) or (S,G) entries—is the information used for forwarding unicast or multicast packets. Using PIM join filters prevents the transport of multicast traffic across a network and the dropping of packets at a scope at the edge of the network. Also, PIM join filters reduce the potential for denial-of-service (DoS) attacks and PIM state explosion—large numbers of PIM join messages forwarded to each router on the rendezvous-point tree (RPT), resulting in memory consumption.

To use PIM join filters to efficiently restrict multicast traffic from certain source addresses, create and apply the routing policy across all routers in the network.

See Table 385 for a list of match conditions.

Table 385: PIM Join Filter Match Conditions

Match Condition	Matches On
interface	Router interface or interfaces specified by name or IP address
neighbor	Neighbor address (the source address in the IP header of the join and prune message)

Copyright © 2016, Juniper Networks, Inc.

Table 385: PIM Join Filter Match Conditions *(continued)*

Match Condition	Matches On
route-filter	Multicast group address embedded in the join and prune message
source-address-filter	Multicast source address embedded in the join and prune message

The following example shows how to create a PIM join filter. The filter is composed of a route filter and a source address filter—**bad-groups** and **bad-sources**, respectively. the **bad-groups** filter prevents (*,G) or (S,G) join messages from being received for all groups listed. The **bad-sources** filter prevents (S,G) join messages from being received for all sources listed. The **bad-groups** filter and **bad-sources** filter are in two different terms. If route filters and source address filters are in the same term, they are logically ANDed.

To filter incoming PIM join messages:

1. Configure the policy.

   ```
   [edit policy-statement pim-join-filter term bad-groups]
   user@host# set from route-filter 224.0.1.2/32 exact
   user@host# set from route-filter 239.0.0.0/8 orlonger
   user@host# set then reject

   [edit policy-statement pim-join-filter term bad-sources]
   user@host# set from source-address-filter 10.0.0.0/8 orlonger
   user@host# set from source-address-filter 127.0.0.0/8 orlonger
   user@host# set then reject

   [edit policy-statement pim-join-filter term last]
   user@host# set then accept
   ```

2. Apply one or more policies to routes being imported into the routing table from PIM.

   ```
   [edit protocols pim]
   user@host# set import pim-join-filter
   ```

3. Verify the configuration by checking the output of the **show pim join** and **show policy** commands.

Configuring Register Message Filters on a PIM RP and DR

PIM register messages are sent to the rendezvous point (RP) by a designated router (DR). When a source for a group starts transmitting, the DR sends unicast PIM register packets to the RP.

Register messages have the following purposes:

- Notify the RP that a source is sending to a group.
- Deliver the initial multicast packets sent by the source to the RP for delivery down the shortest-path tree (SPT).

The PIM RP keeps track of all active sources in a single PIM sparse mode domain. In some cases, you want more control over which sources an RP discovers, or which sources a DR notifies other RPs about. A high degree of control over PIM register messages is

Copyright © 2016, Juniper Networks, Inc.

provided by RP or DR register message filtering. Message filtering prevents unauthorized groups and sources from registering with an RP routing device.

You configure RP or DR register message filtering to control the number and location of multicast sources that an RP discovers. You can apply register message filters on a DR to control outgoing register messages, or apply them on an RP to control incoming register messages.

When anycast RP is configured, all RPs in the anycast RP set need to be configured with the same register message filtering policy.

You can configure message filtering globally or for a routing instance. These examples show the global configuration.

To configure an RP filter to drop the register packets for multicast group range 224.1.1.0/24 from source address 10.10.94.2:

1. On the RP, configure the policy.

```
[edit policy-options policy-statement incoming-policy-for-rp from]
user@host# set route-filter 224.1.1.0/24 orlonger
user@host# set source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the RP.

```
[edit protocols pim rp]
user@host# set rp-register-policy incoming-policy-for-rp
user@host# set local address 10.10.10.5
user@host# exit
```

To configure a DR filter to prevent sending register packets for group range 224.1.1.0/24 and source address 10.10.10.1/32:

1. On the DR, configure the policy.

```
[edit policy-options policy-statement outgoing-policy-for-rp]
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.10.1/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the DR.

   The static address is the address of the RP to which you do not want the DR to send the filtered register messages.

```
[edit protocols pim rp]
user@host# set dr-register-policy outgoing-policy-for-dr
user@host# set static 10.10.10.3
user@host# exit
```

To configure a policy expression to accept register messages for multicast group 224.1.1.5 but reject those for 224.1.1.1:

1. On the RP, configure the policies.

Copyright © 2016, Juniper Networks, Inc.

```
[edit policy-options policy-statement reject_224_1_1_1]
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit

[edit policy-options policy-statement accept_224_1_1_5]
user@host# set term one from route-filter 224.1.1.5/32 exact
user@host# set term one from source-address-filter 10.10.94.2/32 exact
user@host# set term one then accept
user@host# set term two then reject
user@host# exit
```

2. Apply the policies to the RP.

```
[edit protocols pim rp]
user@host# set rp-register-policy [ reject_224_1_1_1 | accept_224_1_1_5 ]
user@host# set local address 10.10.10.5
```

To monitor the operation of the filters, run the **show pim statistics** command. The command output contains the following fields related to filtering:

- **RP Filtered Source**
- **Rx Joins/Prunes filtered**
- **Tx Joins/Prunes filtered**
- **Rx Register msgs filtering drop**
- **Tx Register msgs filtering drop**

Understanding Multicast Rendezvous Points, Shared Trees, and Rendezvous-Point Trees

In a shared tree, the root of the distribution tree is a router, not a host, and is located somewhere in the core of the network. In the primary sparse mode multicast routing protocol, Protocol Independent Multicast sparse mode (PIM SM), the core router at the root of the shared tree is the rendezvous point (RP). Packets from the upstream source and join messages from the downstream routers “rendezvous” at this core router.

In the RP model, other routers do not need to know the addresses of the sources for every multicast group. All they need to know is the IP address of the RP router. The RP router discovers the sources for all multicast groups.

The RP model shifts the burden of finding sources of multicast content from each router (the (S,G) notation) to the network (the (*,G) notation knows only the RP). Exactly how the RP finds the unicast IP address of the source varies, but there must be some method to determine the proper source for multicast content for a particular group.

Consider a set of multicast routers without any active multicast traffic for a certain group. When a router learns that an interested receiver for that group is on one of its directly connected subnets, the router attempts to join the distribution tree for that group back to the RP, not to the actual source of the content.

To join the shared tree, or *rendezvous-point tree* (*RPT*) as it is called in PIM sparse mode, the router must do the following:

- Determine the IP address of the RP for that group. Determining the address can be as simple as static configuration in the router, or as complex as a set of nested protocols.
- Build the shared tree for that group. The router executes an RPF check on the RP address in its routing table, which produces the interface closest to the RP. The router now detects that multicast packets from this RP for this group need to flow into the router on this RPF interface.
- Send a join message out on this interface using the proper multicast protocol (probably PIM sparse mode) to inform the upstream router that it wants to join the shared tree for that group. This message is a (*,G) join message because S is not known. Only the RP is known, and the RP is not actually the source of the multicast packets. The router receiving the (*,G) join message adds the interface on which the message was received to its outgoing interface list (OIL) for the group and also performs an RPF check on the RP address. The upstream router then sends a (*,G) join message out from the RPF interface toward the source, informing the upstream router that it also wants to join the group.

Each upstream router repeats this process, propagating join messages from the RPF interface, building the shared tree as it goes. The process stops when the join message reaches one of the following:

- The RP for the group that is being joined

Copyright © 2016, Juniper Networks, Inc.

- A router along the RPT that already has a multicast forwarding state for the group that is being joined

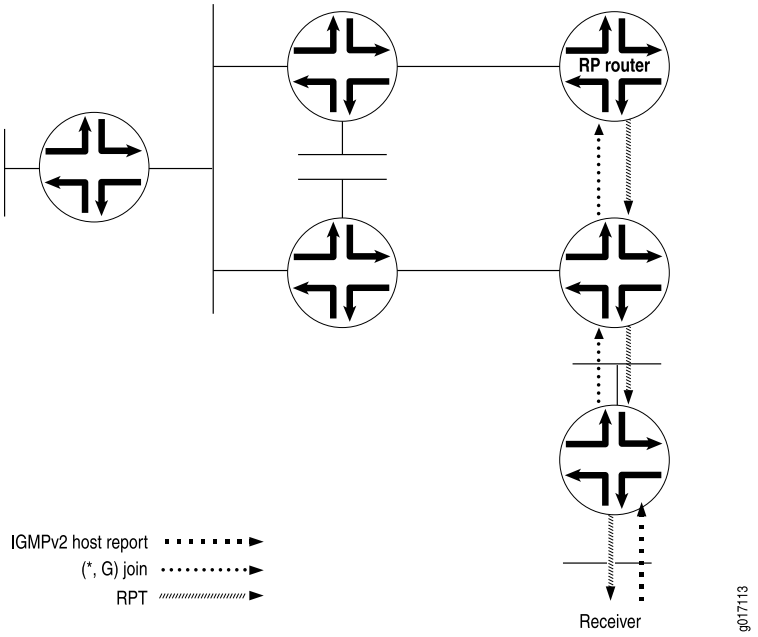
In either case, the branch is created, and packets can flow from the source to the RP and from the RP to the receiver. Note that there is no guarantee that the shared tree (RPT) is the shortest path tree to the source. Most likely it is not. However, there are ways to "migrate" a shared tree to an SPT once the flow of packets begins. In other words, the forwarding state can transition from (*,G) to (S,G). The formation of both types of tree depends heavily on the operation of the RPF check and the RPF table. For more information about the RPF table, see "Understanding Multicast Reverse Path Forwarding" on page 4315.

Building an RPT Between the RP and Receivers

The RPT is the path between the RP and receivers (hosts) in a multicast group (see Figure 167). The RPT is built by means of a PIM join message from a receiver's DR:

1. A receiver sends a request to join group (G) in an Internet Group Management Protocol (IGMP) host membership report. A PIM sparse-mode router, the receiver's DR, receives the report on a directly attached subnet and creates an RPT branch for the multicast group of interest.
2. The receiver's DR sends a PIM join message to its RPF neighbor, the next-hop address in the RPF table, or the unicast routing table.
3. The PIM join message travels up the tree and is multicast to the ALL-PIM-ROUTERS group (224.0.0.13). Each router in the tree finds its RPF neighbor by using either the RPF table or the unicast routing table. This is done until the message reaches the RP and forms the RPT. Routers along the path set up the multicast forwarding state to forward requested multicast traffic back down the RPT to the receiver.

Figure 167: Building an RPT Between the RP and the Receiver



Copyright © 2016, Juniper Networks, Inc.

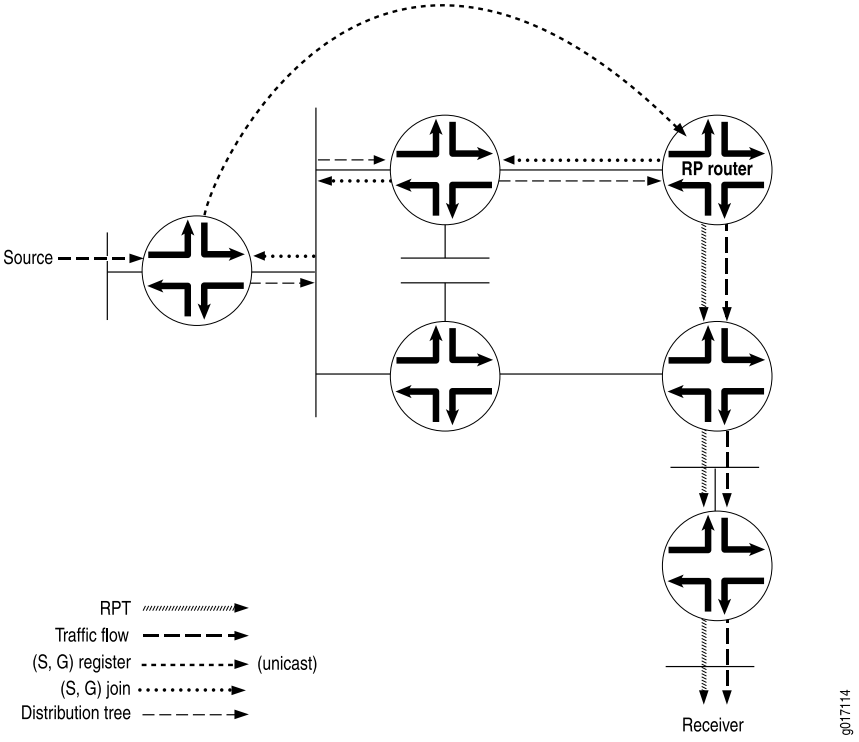
PIM Sparse Mode Source Registration

The RPT is a unidirectional tree, permitting traffic to flow down from the RP to the receiver in one direction. For multicast traffic to reach the receiver from the source, another branch of the distribution tree, called the shortest-path tree, needs to be built from the source's DR to the RP.

The shortest-path tree is created in the following way:

1. The source becomes active, sending out multicast packets on the LAN to which it is attached. The source's DR receives the packets and encapsulates them in a PIM register message, which it sends to the RP router (see Figure 168).
2. When the RP router receives the PIM register message from the source, it sends a PIM join message back to the source.

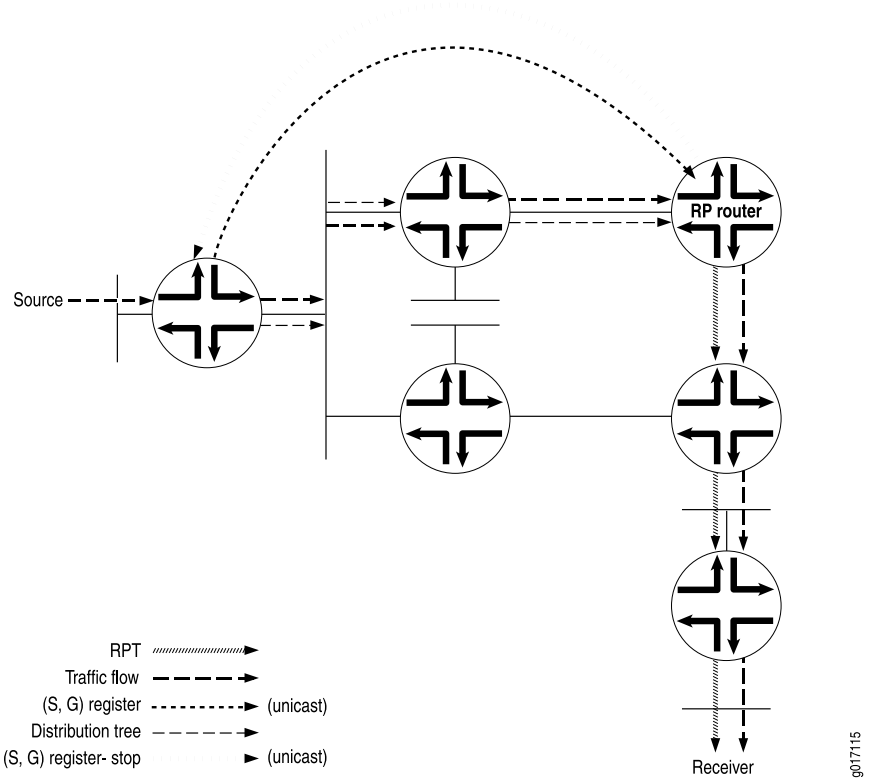
Figure 168: PIM Register Message and PIM Join Message Exchanged



3. The source's DR receives the PIM join message and begins sending traffic down the SPT toward the RP router (see Figure 169).
4. Once traffic is received by the RP router, it sends a register stop message to the source's DR to stop the register process.

Copyright © 2016, Juniper Networks, Inc.

Figure 169: Traffic Sent from the Source to the RP Router



5. The RP router sends the multicast traffic down the RPT toward the receiver (see Figure 170).

Figure 170: Traffic Sent from the RP Router Toward the Receiver

Multicast Shortest-Path Tree

The distribution tree used for multicast is rooted at the source and is the shortest-path tree (SPT) as well. Consider a set of multicast routers without any active multicast traffic for a certain group (that is, they have no multicast forwarding state for that group). When a router learns that an interested receiver for that group is on one of its directly connected subnets, the router attempts to join the tree for that group.

To join the distribution tree, the router determines the unicast IP address of the source for that group. This address can be a simple static configuration on the router, or as complex as a set of protocols.

To build the SPT for that group, the router executes an a reverse path forwarding (RPF) check on the source address in its routing table. The RPF check produces the interface closest to the source, which is where multicast packets from this source for this group need to flow into the router.

The router next sends a join message out on this interface using the proper multicast protocol to inform the upstream router that it wants to join the distribution tree for that group. This message is an (S,G) join message because both S and G are known. The router receiving the (S,G) join message adds the interface on which the message was received to its output interface list (OIL) for the group and also performs an RPF check on the source address. The upstream router then sends an (S,G) join message out on the RPF interface toward the source, informing the upstream router that it also wants to join the group.

Each upstream router repeats this process, propagating joins out on the RPF interface, building the SPT as it goes. The process stops when the join message does one of two things:

- Reaches the router directly connected to the host that is the source.
- Reaches a router that already has multicast forwarding state for this source-group pair.

In either case, the branch is created, each of the routers has multicast forwarding state for the source-group pair, and packets can flow down the distribution tree from source to receiver. The RPF check at each router makes sure that the tree is an SPT.

SPTs are always the shortest path, but they are not necessarily short. That is, sources and receivers tend to be on the periphery of a router network, not on the backbone, and multicast distribution trees have a tendency to sprawl across almost every router in the network. Because multicast traffic can overwhelm a slow interface, and one packet can easily become a hundred or a thousand on the opposite side of the backbone, it makes sense to provide a shared tree as a distribution tree so that the multicast source can be located more centrally in the network, on the backbone. This sharing of distribution trees with roots in the core network is accomplished by a multicast rendezvous point. For more information about RPs, see “Understanding Multicast Rendezvous Points, Shared Trees, and Rendezvous-Point Trees” on page 4167.

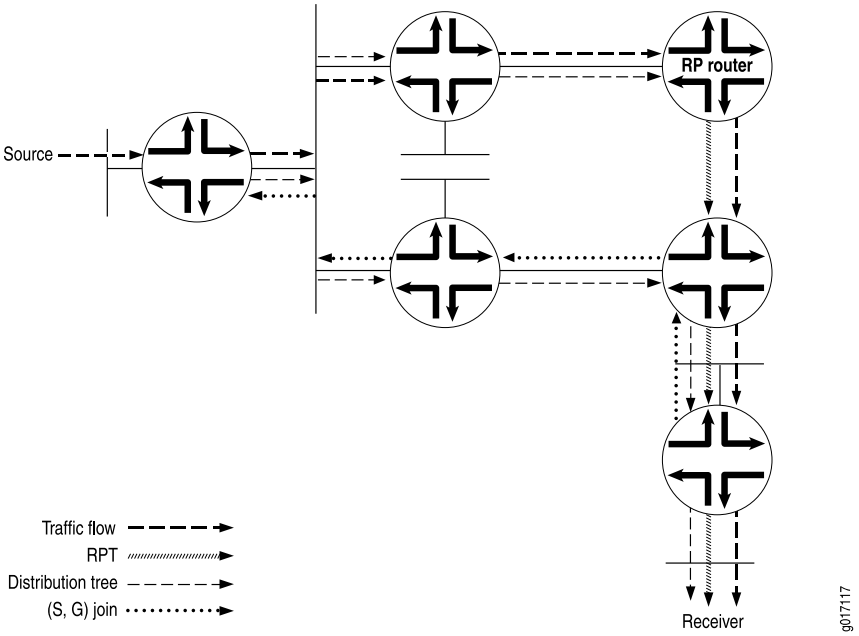
Copyright © 2016, Juniper Networks, Inc.

SPT Cutover

Instead of continuing to use the SPT to the RP and the RPT toward the receiver, a direct SPT is created between the source and the receiver in the following way:

1. Once the receiver's DR receives the first multicast packet from the source, the DR sends a PIM join message to its RPF neighbor (see Figure 171).
2. The source's DR receives the PIM join message, and an additional (S,G) state is created to form the SPT.
3. Multicast packets from that particular source begin coming from the source's DR and flowing down the new SPT to the receiver's DR. The receiver's DR is now receiving two copies of each multicast packet sent by the source—one from the RPT and one from the new SPT.

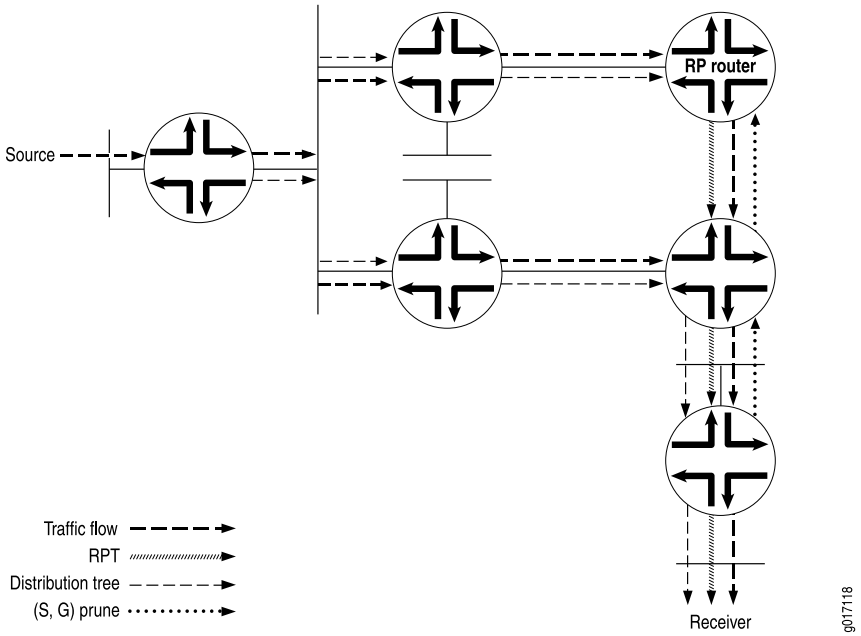
Figure 171: Receiver DR Sends a PIM Join Message to the Source



4. To stop duplicate multicast packets, the receiver's DR sends a PIM prune message toward the RP router, letting it know that the multicast packets from this particular source coming in from the RPT are no longer needed (see Figure 172).

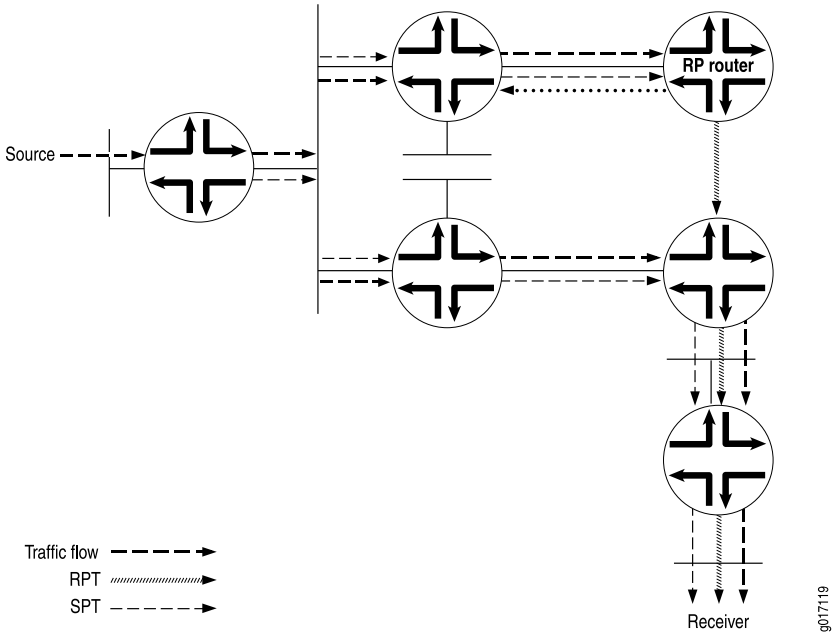
Copyright © 2016, Juniper Networks, Inc.

Figure 172: PIM Prune Message Is Sent from the Receiver's DR Toward the RP Router



5. The PIM prune message is received by the RP router, and it stops sending multicast packets down to the receiver's DR. The receiver's DR is getting multicast packets only for this particular source over the new SPT. However, multicast packets from the source are still arriving from the source's DR toward the RP router (see Figure 173).

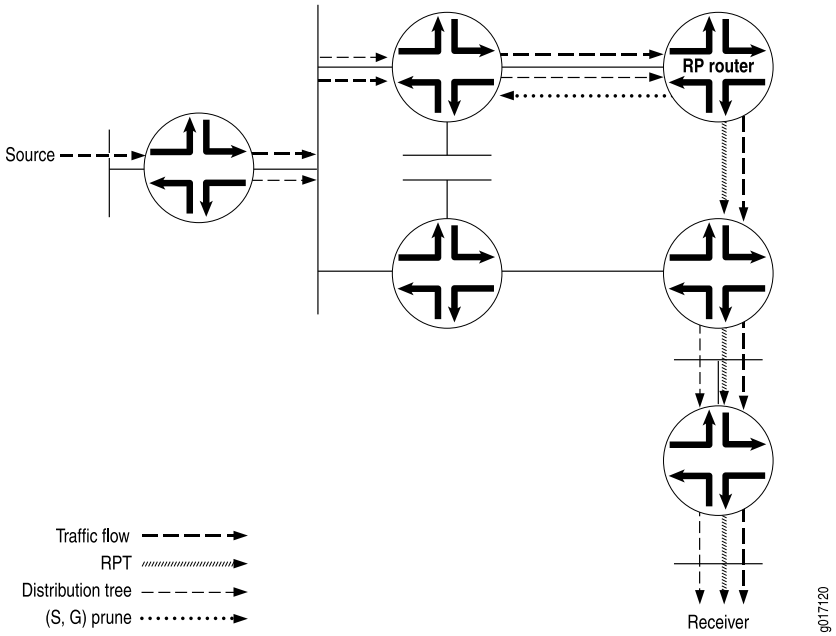
Figure 173: RP Router Receives PIM Prune Message



6. To stop the unneeded multicast packets from this particular source, the RP router sends a PIM prune message to the source's DR (see Figure 174).

Copyright © 2016, Juniper Networks, Inc.

Figure 174: RP Router Sends a PIM Prune Message to the Source DR



7. The receiver's DR now receives multicast packets only for the particular source from the SPT (see Figure 175).

Figure 175: Source's DR Stops Sending Duplicate Multicast Packets Toward the RP Router

SPT Cutover Control

In some cases, the last-hop router needs to stay on the shared tree to the RP and not transition to a direct SPT to the source. You might not want the last-hop router to transition when, for example, a low-bandwidth multicast stream is forwarded from the RP to a last-hop router. All routers between last hop and source must maintain and refresh the SPT state. This can become a resource-intensive activity that does not add much to the network efficiency for a particular pair of source and multicast group addresses.

In these cases, you configure an SPT threshold policy on the last-hop router to control the transition to a direct SPT. An SPT cutover threshold of infinity applied to a source-group address pair means the last-hop router will never transition to a direct SPT. For all other source-group address pairs, the last-hop router transitions immediately to a direct SPT rooted at the source DR.

Example: Configuring the PIM Assert Timeout

This example shows how to configure the timeout period for a PIM assert forwarder.

- Requirements on page 4175
- Overview on page 4175
- Configuration on page 4177

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure PIM Sparse Mode on the interfaces. See "Enabling PIM Sparse Mode" on page 4118.

Overview

The role of PIM assert messages is to determine the forwarder on a network with multiple routers. The forwarder is the router that forwards multicast packets to a network with multicast group members. The forwarder is generally the same as the PIM DR.

A router sends an assert message when it receives a multicast packet on an interface that is listed in the outgoing interface list of the matching routing entry. Receiving a message on an outgoing interface is an indication that more than one router forwards the same multicast packets to a network.

In Figure 176, both routing devices R1 and R2 forward multicast packets for the same (S,G) entry on a network. Both devices detect this situation and both devices send assert messages on the Ethernet network. An assert message contains, in addition to a source address and group address, a unicast cost metric for sending packets to the source, and a preference metric for the unicast cost. The preference metric expresses a preference

Copyright © 2016, Juniper Networks, Inc.

between unicast routing protocols. The routing device with the smallest preference metric becomes the forwarder (also called the assert winner). If the preference metrics are equal, the device that sent the lowest unicast cost metric becomes the forwarder. If the unicast metrics are also equal, the routing device with the highest IP address becomes the forwarder. After the transmission of assert messages, only the forwarder continues to forward messages on the network.

When an assert message is received and the RPF neighbor is changed to the assert winner, the assert timer is set to an assert timeout period. The assert timeout period is restarted every time a subsequent assert message for the route entry is received on the incoming interface. When the assert timer expires, the routing device resets its RPF neighbor according to its unicast routing table. Then, if multiple forwarders still exist, the forwarders reenter the assert message cycle. In effect, the assert timeout period determines how often multicast routing devices enter a PIM assert message cycle.

The range is from 5 through 210 seconds. The default is 180 seconds.

Assert messages are useful for LANs that connect multiple routing devices and no hosts.

Figure 176 shows the topology for this example.

Figure 176: PIM Assert Topology

Configuration

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an assert timeout:

1. Configure the timeout period, in seconds.

   ```
   [edit protocols pim]
   user@host# set assert-timeout 60
   ```

2. (Optional) Trace assert messages.

   ```
   [edit protocols pim]
   user@host# set traceoptions file PIM.log
   user@host# set traceoptions flag assert detail
   ```

3. If you are done configuring the device, commit the configuration.

   ```
   user@host# commit
   ```

4. To verify the configuration, run the following commands:

   - show pim join
   - show pim statistics

Example: Configuring the PIM SPT Threshold Policy

This example shows how to apply a policy that suppresses the transition from the rendezvous-point tree (RPT) rooted at the RP to the shortest-path tree (SPT) rooted at the source.

- Requirements on page 4177
- Overview on page 4178
- Configuration on page 4179
- Verification on page 4181

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure PIM Sparse Mode on the interfaces. See "Enabling PIM Sparse Mode" on page 4118.

Copyright © 2016, Juniper Networks, Inc.

Overview

Multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or through an SPT rooted at the source. In some cases, the last-hop routing device needs to stay on the shared RPT to the RP and not transition to a direct SPT to the source. Receiving the multicast data traffic on SPT is optimal but introduces more state in the network, which might not be desirable in some multicast deployments. Ideally, low-bandwidth multicast streams can be forwarded on the SPT, and high-bandwidth streams can use the SPT. This example shows how to configure such a policy.

This example includes the following settings:

- **spt-threshold**—Enables you to configure an SPT threshold policy on the last-hop routing device to control the transition to a direct SPT. When you include this statement in the main PIM instance, the PE router stays on the RPT for control traffic.
- **infinity**—Applies an SPT cutover threshold of infinity to a source-group address pair, so that the last-hop routing device never transitions to a direct SPT. For all other source-group address pairs, the last-hop routing device transitions immediately to a direct SPT rooted at the source DR. This statement must reference a properly configured policy to set the SPT cutover threshold for a particular source-group pair to infinity. The use of values other than infinity for the SPT threshold is not supported. You can configure more than one policy.
- **policy-statement**—Configures the policy. The simplest type of SPT threshold policy uses a route filter and source address filter to specify the multicast group and source addresses and to set the SPT threshold for that pair of addresses to infinity. The policy is applied to the main PIM instance.

  This example sets the SPT transition value for the source-group pair 10.10.10.1 and 224.1.1.1 to infinity. When the policy is applied to the last-hop router, multicast traffic from this source-group pair never transitions to a direct SPT to the source. Traffic will continue to arrive through the RP. However, traffic for any other source-group address combination at this router transitions to a direct SPT to the source.

Copyright © 2016, Juniper Networks, Inc.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.
- When the policy is configured for the first time, the routing device continues to transition to the direct SPT for the source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- If you do not clear the PIM-join state when you apply the infinity policy configuration for the first time, you must apply it before the PE router is brought up.
- When the policy is deleted for a source-group address pair for the first time, the routing device does not transition to the direct SPT for that source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- When the policy is changed for a source-group address pair for the first time, the routing device does not use the new policy until the PIM-join state is cleared with the **clear pim join** command.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set policy-options policy-statement spt-infinity-policy term one from route-filter
   224.1.1.1/32 exact
set policy-options policy-statement spt-infinity-policy term one from source-address-filter
   10.10.10.1/32 exact
set policy-options policy-statement spt-infinity-policy term one then accept
set policy-options policy-statement spt-infinity-policy term two then reject
set protocols pim spt-threshold infinity spt-infinity-policy
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure an SPT threshold policy:

1. Apply the policy.

```
[edit]
user@host# edit protocols pim
```

Copyright © 2016, Juniper Networks, Inc.

```
[edit protocols pim]
user@host# set spt-threshold infinity spt-infinity-policy
[edit protocols pim]
user@host# exit
```

2. Configure the policy.

```
[edit]
user@host# edit policy-options policy-statement spt-infinity-policy
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from route-filter 224.1.1.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from source-address-filter 10.10.10.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one then accept
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term two then reject
[edit policy-options policy-statement spt-infinity-policy]
user@host# exit
policy-statement {
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

4. Clear the PIM join cache to force the configuration to take effect.

```
[edit]
user@host# run clear pim join
```

Results

Confirm your configuration by entering the **show policy-options** command and the **show protocols** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
policy-statement spt-infinity-policy {
  term one {
    from {
      route-filter 224.1.1.1/32 exact;
      source-address-filter 10.10.10.1/32 exact;
    }
    then accept;
  }
  term two {
    then reject;
  }
}
```

```
user@host# show protocols
pim {
  spt-threshold {
    infinity spt-infinity-policy;
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

Verification

To verify the configuration, run the **show pim join** command.

Understanding PIM Source-Specific Mode

RFC 1112, the original multicast RFC, supported both many-to-many and one-to-many models. These came to be known collectively as any-source multicast (ASM) because ASM allowed one or many sources for a multicast group's traffic. However, an ASM network must be able to determine the locations of all sources for a particular multicast group whenever there are interested listeners, no matter where the sources might be located in the network. In ASM, the key function of *source discovery* is a required function of the network itself.

Multicast source discovery appears to be an easy process, but in sparse mode it is not. In dense mode, it is simple enough to flood traffic to every router in the whole network so that every router learns the source address of the content for that multicast group. However, the flooding presents scalability and network resource use issues and is not a viable option in sparse mode.

PIM sparse mode (like any sparse mode protocol) achieves the required source discovery functionality without flooding at the cost of a considerable amount of complexity. The RP routers must be added and must know all multicast sources, and complicated shared distribution trees must be built to the RPs.

Copyright © 2016, Juniper Networks, Inc.

In an environment where many sources come and go, such as for a videoconferencing service, ASM is appropriate. However, by ignoring the many-to-many model and focusing attention on the one-to-many source-specific multicast (SSM) model, several commercially promising multicast applications, such as television channel distribution over the Internet, might be brought to the Internet much more quickly and efficiently than if full ASM functionality were required of the network.

PIM SSM is simpler than PIM sparse mode because only the one-to-many model is supported. Initial commercial multicast Internet applications are likely to be available to *subscribers* (that is, receivers that issue join messages) from only a single source (a special case of SSM covers the need for a backup source). PIM SSM therefore forms a subset of PIM sparse mode. PIM SSM builds shortest-path trees (SPTs) rooted at the source immediately because in SSM, the router closest to the interested receiver host is informed of the unicast IP address of the source for the multicast traffic. That is, PIM SSM bypasses the RP connection stage through shared distribution trees, as in PIM sparse mode, and goes directly to the source-based distribution tree.

PIM SSM introduces new terms for many of the concepts in PIM sparse mode. PIM SSM can technically be used in the entire 224/4 multicast address range, although PIM SSM operation is guaranteed only in the 232/8 range (232.0.0/24 is reserved). The new SSM terms are appropriate for Internet video applications and are summarized in Table 386.

Table 386: ASM and SSM Terminology

Term	Any-Source Multicast	Source-Specific Multicast
Address identifier	G	S,G
Address designation	group	channel
Receiver operations	join, leave	subscribe, unsubscribe
Group address range	224/4 excluding 232/8	224/4 (guaranteed only for 232/8)

Although PIM SSM describes receiver operations as *subscribe* and *unsubscribe*, the same PIM sparse mode join and leave messages are used by both forms of the protocol. The terminology change distinguishes ASM from SSM even though the receiver messages are identical.

PIM SSM

PIM source-specific multicast (SSM) uses a subset of PIM sparse mode and IGMP version 3 (IGMPv3) to allow a client to receive multicast traffic directly from the source. PIM SSM uses the PIM sparse-mode functionality to create an SPT between the receiver and the source, but builds the SPT without the help of an RP.

By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the **ssm-groups** statement at the **[edit routing-options multicast]** hierarchy level. The default SSM address range from 232.0.0.0 through 232.255.255.255

Copyright © 2016, Juniper Networks, Inc.

cannot be used in the **ssm-groups** statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.

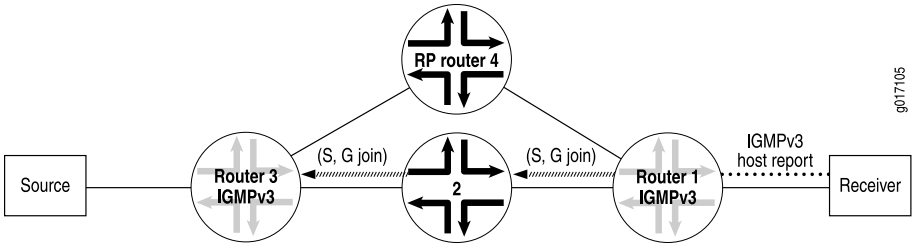
You can also configure Junos OS to accept any-source multicast (ASM) join messages (*,G) for group addresses that are within the default or configured range of source-specific multicast (SSM) groups. This allows you to support a mix of any-source and source-specific multicast groups simultaneously.

An SSM-configured network has distinct advantages over a traditionally configured PIM sparse-mode network. There is no need for shared trees or RP mapping (no RP is required), or for RP-to-RP source discovery through MSDP.

Deploying SSM is easy. You need to configure PIM sparse mode on all router interfaces and issue the necessary SSM commands, including specifying IGMPv3 on the receiver's LAN. If PIM sparse mode is not explicitly configured on both the source and group member interfaces, multicast packets are not forwarded. Source lists, supported in IGMPv3, are used in PIM SSM. As sources become active and start sending multicast packets, interested receivers in the SSM group receive the multicast packets.

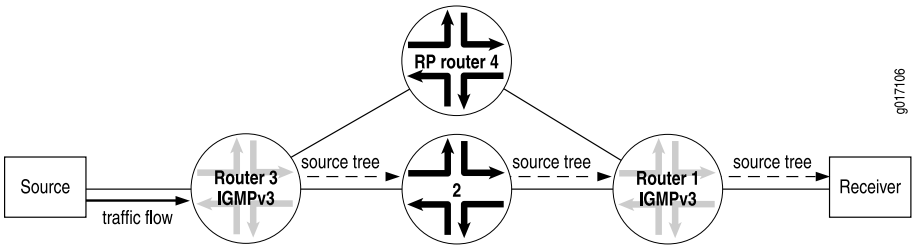
In a PIM SSM-configured network, a host subscribes to an SSM channel (by means of IGMPv3), announcing a desire to join group G and source S (see Figure 177). The directly connected PIM sparse-mode router, the receiver's DR, sends an (S,G) join message to its RPF neighbor for the source. Notice in Figure 177 that the RP is not contacted in this process by the receiver, as would be the case in normal PIM sparse-mode operations.

Figure 177: Receiver Announces Desire to Join Group G and Source S



The (S,G) join message initiates the source tree and then builds it out hop by hop until it reaches the source. In Figure 178, the source tree is built across the network to Router 3, the last-hop router connected to the source.

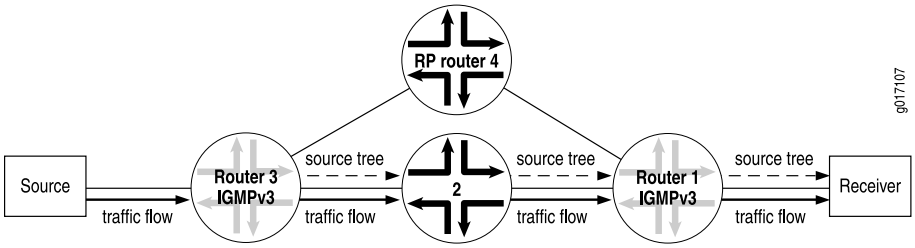
Figure 178: Router 3 (Last-Hop Router) Joins the Source Tree



Using the source tree, multicast traffic is delivered to the subscribing host (see Figure 179).

Copyright © 2016, Juniper Networks, Inc.

Figure 179: (S,G) State Is Built Between the Source and the Receiver



To configure additional SSM groups, include the **ssm-groups** statement at the **[edit routing-options multicast]** hierarchy level.

Source-Specific Multicast Groups Overview

Source-specific multicast (SSM) is a service model that identifies session traffic by both source and group address. SSM implemented in Junos OS has the efficient explicit join procedures of Protocol Independent Multicast (PIM) sparse mode but eliminates the immediate shared tree and rendezvous point (RP) procedures using (*,G) pairs. The (*) is a wildcard referring to any source sending to group G, and “G” refers to the IP multicast group. SSM builds shortest-path trees (SPTs) directly represented by (S,G) pairs. The “S” refers to the source's unicast IP address, and the “G” refers to the specific multicast group address. The SSM (S,G) pairs are called channels to differentiate them from any-source multicast (ASM) groups. Although ASM supports both one-to-many and many-to-many communications, ASM's complexity is in its method of source discovery. For example, if you click a link in a browser, the receiver is notified about the group information, but not the source information. With SSM, the client receives both source and group information.

SSM is ideal for one-to-many multicast services such as network entertainment channels. However, many-to-many multicast services might require ASM.

To deploy SSM successfully, you need an end-to-end multicast-enabled network and applications that use an Internet Group Management Protocol version 3 (IGMPv3) or Multicast Listener Discovery version 2 (MLDv2) stack, or you need to configure SSM mapping from IGMPv1 or IGMPv2 to IGMPv3. An IGMPv3 stack provides the capability of a host operating system to use the IGMPv3 protocol. IGMPv3 is available for Windows XP, Windows Vista, and most UNIX operating systems.

SSM mapping allows operators to support an SSM network without requiring all hosts to support IGMPv3. This support exists in static (S,G) configurations, but SSM mapping also supports dynamic per-source group state information, which changes as hosts join and leave the group using IGMP.

SSM is typically supported with a subset of IGMPv3 and PIM sparse mode known as *PIM SSM*. Using SSM, a client can receive multicast traffic directly from the source. PIM SSM uses the PIM sparse-mode functionality to create an SPT between the client and the source, but builds the SPT without the help of an RP.

An SSM-configured network has distinct advantages over a traditionally configured PIM sparse-mode network. There is no need for shared trees or RP mapping (no RP is required), or for RP-to-RP source discovery through the Multicast Source Discovery Protocol (MSDP).

Example: Configuring Source-Specific Multicast Groups with Any-Source Override

This example shows how to extend source-specific multicast (SSM) group operations beyond the default IP address range of 232.0.0.0 through 232.255.255.255. This example also shows how to accept any-source multicast (ASM) join messages (*,G) for group addresses that are within the default or configured range of SSM groups. This allows you to support a mix of any-source and source-specific multicast groups simultaneously.

- Requirements on page 4187
- Overview on page 4187
- Configuration on page 4188
- Verification on page 4190

Requirements

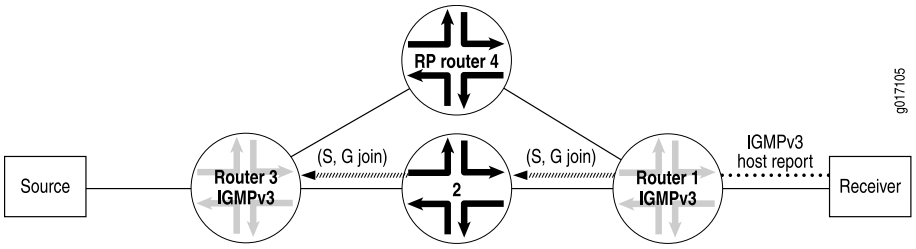
Before you begin, configure the router interfaces.

Overview

To deploy SSM, configure PIM sparse mode on all routing device interfaces and issue the necessary SSM commands, including specifying IGMPv3 or MLDv2 on the receiver's LAN. If PIM sparse mode is not explicitly configured on both the source and group members interfaces, multicast packets are not forwarded. Source lists, supported in IGMPv3 and MLDv2, are used in PIM SSM. Only sources that are specified send traffic to the SSM group.

In a PIM SSM-configured network, a host subscribes to an SSM channel (by means of IGMPv3 or MLDv2) to join group G and source S (see Figure 180). The directly connected PIM sparse-mode router, the receiver's designated router (DR), sends an (S,G) join message to its reverse-path forwarding (RPF) neighbor for the source. Notice in Figure 180 that the RP is not contacted in this process by the receiver, as would be the case in normal PIM sparse-mode operations.

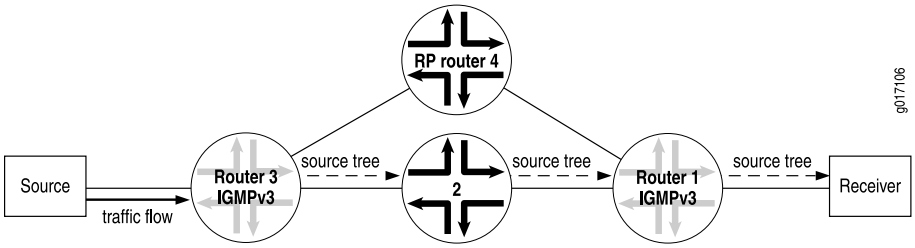
Figure 180: Receiver Sends Messages to Join Group G and Source S



The (S,G) join message initiates the source tree and then builds it out hop by hop until it reaches the source. In Figure 181, the source tree is built across the network to Router 3, the last-hop router connected to the source.

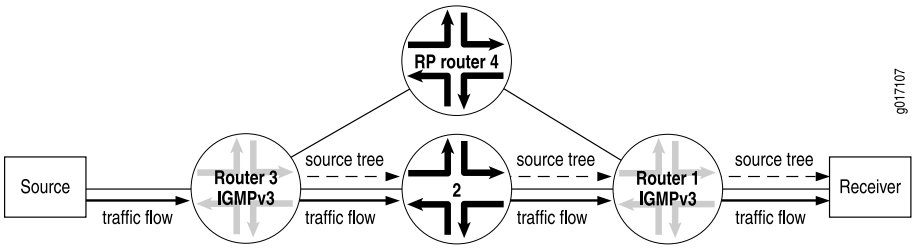
Copyright © 2016, Juniper Networks, Inc.

Figure 181: Router 3 (Last-Hop Router) Joins the Source Tree



Using the source tree, multicast traffic is delivered to the subscribing host (see Figure 182).

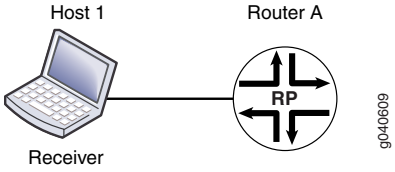
Figure 182: (S,G) State Is Built Between the Source and the Receiver



SSM can operate in include mode or in exclude mode. In exclude mode the receiver specifies a list of sources that it does not want to receive the multicast group traffic from. The routing device forwards traffic to the receiver from any source except the sources specified in the exclusion list. The receiver accepts traffic from any sources except the sources specified in the exclusion list.

This example works with the simple RPF topology shown in Figure 183.

Figure 183: Simple RPF Topology



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ospf area 0.0.0.0 interface all
set protocols pim rp local address 10.255.72.46
set protocols pim rp local group-ranges 239.0.0.0/24
set protocols pim interface fe-1/0/0.0 mode sparse
set protocols pim interface lo0.0 mode sparse
set routing-options multicast ssm-groups 232.0.0.0/8
set routing-options multicast ssm-groups 239.0.0.0/8
set routing-options multicast asm-override-ssm
```

Copyright © 2016, Juniper Networks, Inc.

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an RPF policy:

1. Configure OSPF.

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface fxp0.0 disable
user@host# set area 0.0.0.0 interface all
```

2. Configure PIM sparse mode.

```
[edit protocols pim]
user@host# set rp local address 10.255.72.46
user@host# set rp local group-ranges 239.0.0.0/24
user@host# set interface fe-1/0/0.0 mode sparse
user@host# set interface lo0.0 mode sparse
```

3. Configure additional SSM groups.

```
[edit routing-options]
user@host# set ssm-groups [ 232.0.0.0/8 239.0.0.0/8 ]
```

4. Configure the RP to accept ASM join messages for groups within the SSM address range.

```
[edit routing-options]
user@host# set multicast asm-override-ssm
```

5. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show protocols** and **show routing-options** commands.

```
user@host# show protocols
ospf {
    area 0.0.0.0 {
        interface fxp0.0 {
            disable;
        }
        interface all;
    }
}
pim {
    rp {
        local {
            address 10.255.72.46;
            group-ranges {
                239.0.0.0/24;
            }
        }
    }
```

Copyright © 2016, Juniper Networks, Inc.

```
    interface fe-1/0/0.0 {
      mode sparse;
    }
    interface lo0.0 {
      mode sparse;
    }
  }
```

```
user@host# show routing-options
multicast {
  ssm-groups [ 232.0.0.0/8 239.0.0.0/8 ];
  asm-override-ssm;
}
```

Verification

To verify the configuration, run the following commands:

- show igmp group
- show igmp statistics
- show pim join

Example: Configuring an SSM-Only Domain

Deploying an SSM-only domain is much simpler than deploying an ASM domain because it only requires a few configuration steps. Enable PIM sparse mode on all interfaces by adding the **mode** statement at the **[edit protocols pim interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface. Then configure IGMPv3 on all host-facing interfaces by adding the **version** statement at the **[edit protocols igmp interface *interface-name*]** hierarchy level.

In the following example, the host-facing interface is **fe-0/1/2**:

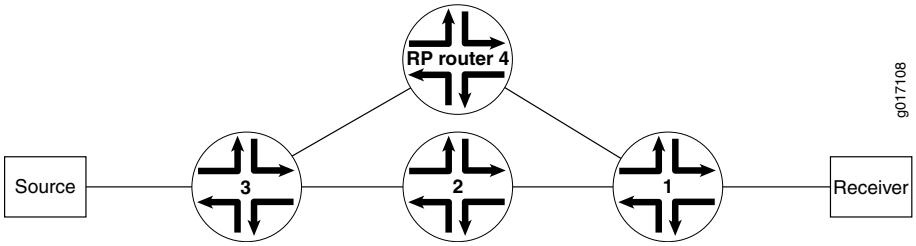
```
[edit]
protocols {
  pim {
    interface all {
      mode sparse;
      version 2;
    }
    interface fxp0.0 {
      disable;
    }
  }
  igmp {
    interface fe-0/1/2 {
      version 3;
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

Example: Configuring PIM SSM on a Network

The following example shows how PIM SSM is configured between a receiver and a source in the network illustrated in Figure 184.

Figure 184: Network on Which to Configure PIM SSM



This example shows how to configure the IGMP version to IGMPv3 on all receiving host interfaces.

1. Enable IGMPv3 on all host-facing interfaces, and disable IGMP on the **fxp0.0** interface on Router 1.

   ```
   user@router1# set protocols igmp interface all version 3
   user@router1# set protocols igmp interface fxp0.0 disable
   ```

   NOTE: When you configure IGMPv3 on a router, hosts on interfaces configured with IGMPv2 cannot join the source tree.

2. After the configuration is committed, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

   ```
   user@router1> show configuration protocol igmp

   [edit protocols igmp]
   interface all {
     version 3;
   }
   interface fxp0.0 {
     disable;
   }
   ```

3. Use the **show igmp interface** command to verify that IGMP interfaces are configured.

   ```
   user@router1> show igmp interface
   Interface      State    Querier      Timeout Version Groups
   fe-0/0/0.0     Up       198.58.3.245     213       3      0
   fe-0/0/1.0     Up       198.58.3.241     220       3      0
   fe-0/0/2.0     Up       198.58.3.237     218       3      0
   Configured Parameters:
   IGMP Query Interval (1/10 secs): 1250
   IGMP Query Response Interval (1/10 secs): 100
   IGMP Last Member Query Interval (1/10 secs): 10
   IGMP Robustness Count: 2
   Derived Parameters:
   IGMP Membership Timeout (1/10 secs): 2600
   IGMP Other Querier Present Timeout (1/10 secs): 2550
   ```

Copyright © 2016, Juniper Networks, Inc.

4. Use the **show pim join extensive** command to verify the PIM join state on Router 2 and Router 3 (the upstream routers).

```
user@router2> show pim join extensive
232.1.1.1       10.4.1.2                        sparse
     Upstream interface: fe-1/1/3.0
     Upstream State: Local Source
     Keepalive timeout: 209
     Downstream Neighbors:
        Interface: so-1/0/2.0
            10.10.71.1       State: Join    Flags: S    Timeout: 209
```

5. Use the **show pim join extensive** command to verify the PIM join state on Router 1 (the router connected to the receiver).

```
user@router1> show pim join extensive
232.1.1.1       10.4.1.2                        sparse
     Upstream interface: so-1/0/2.0
     Upstream State: Join to Source
     Keepalive timeout: 209
     Downstream Neighbors:
        Interface: fe-0/2/3.0
            10.3.1.1         State: Join    Flags: S    Timeout: Infinity
```

NOTE: IP version 6 (IPv6) multicast routers use the Multicast Listener Discovery (MLD) Protocol to manage the membership of hosts and routers in multicast groups and to learn which groups have interested listeners for each attached physical networks. Each routing device maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the routing device does not need to know the address of each listener—just the address of each host. The routing device provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol. MLD is an integral part of IPv6 and must be enabled on all IPv6 routing devices and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

Example: Configuring SSM Mapping

SSM mapping does not require that all hosts support IGMPv3. SSM mapping translates IGMPv1 or IGMPv2 membership reports to an IGMPv3 report. This enables hosts running IGMPv1 or IGMPv2 to participate in SSM until the hosts transition to IGMPv3.

SSM mapping applies to all group addresses that match the policy, not just those that conform to SSM addressing conventions (232/8 for IPv4, ff30::/32 through ff3F::/32 for IPv6).

We recommend separate SSM maps for IPv4 and IPv6 if both address families require SSM support. If you apply an SSM map containing both IPv4 and IPv6 addresses to an interface in an IPv4 context (using IGMP), only the IPv4 addresses in the list are used. If there are no such addresses, no action is taken. Similarly, if you apply an SSM map

Copyright © 2016, Juniper Networks, Inc.

containing both IPv4 and IPv6 addresses to an interface in an IPv6 context (using MLD), only the IPv6 addresses in the list are used. If there are no such addresses, no action is taken.

In this example, you create a policy to match the group addresses that you want to translate to IGMPv3. Then you define the SSM map that associates the policy with the source addresses where these group addresses are found. Finally, you apply the SSM map to one or more IGMP (for IPv4) or MLD (for IPv6) interfaces.

1. Create an SSM policy named **ssm-policy-example**. The policy terms match the IPv4 SSM group address 232.1.1.1/32 and the IPv6 SSM group address ff35::1/128. All other addresses are rejected.

   ```
   user@router1# set policy-options policy-statement ssm-policy-example term A from
     route-filter 232.1.1.1/32 exact
   user@router1# set policy-options policy-statement ssm-policy-example term A then
     accept
   user@router1# set policy-options policy-statement ssm-policy-example term B from
     route-filter ff35::1/128 exact
   user@router1# set policy-options policy-statement ssm-policy-example term B then
     accept
   ```

2. After the configuration is committed, use the **show configuration policy-options** command to verify the policy configuration.

   ```
   user@host> show configuration policy-options

   [edit policy-options]
   policy-statement ssm-policy-example {
     term A {
       from {
         route-filter 232.1.1.1/32 exact;
       }
       then accept;
     }
     term B {
       from {
         route-filter ff35::1/128 exact;
       }
       then accept;
     }
     then reject;
   }
   ```

   The group addresses must match the configured policy for SSM mapping to occur.

3. Define two SSM maps, one called **ssm-map-ipv6-example** and one called **ssm-map-ipv4-example**, by applying the policy and configuring the source addresses as a multicast routing option.

   ```
   user@host# set routing-options multicast ssm-map ssm-map-ipv6-example policy
     ssm-policy-example
   user@host# set routing-options multicast ssm-map ssm-map-ipv6-example source
     fec0::1 fec0::12
   user@host# set routing-options multicast ssm-map ssm-map-ipv4-example policy
     ssm-policy-example
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
  10.10.10.4
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
  192.168.43.66
```

4. After the configuration is committed, use the **show configuration routing-options** command to verify the policy configuration.

```
user@host> show configuration routing-options
```

```
[edit routing-options]
multicast {
  ssm-map ssm-map-ipv6-example {
    policy ssm-policy-example;
    source [ fec0::1 fec0::12 ];
  }
  ssm-map ssm-map-ipv4-example {
    policy ssm-policy-example;
    source [ 10.10.10.4 192.168.43.66 ];
  }
}
```

We recommend separate SSM maps for IPv4 and IPv6.

5. Apply SSM maps for IPv4-to-IGMP interfaces and SSM maps for IPv6-to-MLD interfaces:

```
user@host# set protocols igmp interface fe-0/1/0.0 ssm-map ssm-map-ipv4-example
user@host# set protocols mld interface fe-0/1/1.0 ssm-map ssm-map-ipv6-example
```

6. After the configuration is committed, use the **show configuration protocol** command to verify the IGMP and MLD protocol configuration.

```
user@router1> show configuration protocol
```

```
[edit protocols]
igmp {
  interface fe-0/1/0.0 {
    ssm-map ssm-map-ipv4-example;
  }
}
mld {
  interface fe-/0/1/1.0 {
    ssm-map ssm-map-ipv6-example;
  }
}
```

7. Use the **show igmp interface** and the **show mld interface** commands to verify that the SSM maps are applied to the interfaces.

```
user@host> show igmp interface fe-0/1/0.0
Interface: fe-0/1/0.0
     Querier: 192.168.224.28
     State:         Up Timeout:    None Version:   2 Groups:   2
     SSM Map: ssm-map-ipv4-example
```

```
user@host> show mld interface fe-0/1/1.0
Interface: fe-0/1/1.0
     Querier: fec0:0:0:0:1::12
     State:         Up Timeout:    None Version:   2 Groups:   2
     SSM Map: ssm-map-ipv6-example
```

Multiple SSM Maps and Groups for Interfaces

You can configure multiple source-specific multicast (SSM) maps so that different groups map to different sources, which enables a single multicast group to map to different sources for different interfaces.

Example: Configuring Multiple SSM Maps Per Interface

This example shows how to assign more than one SSM map to an IGMP interface.

- Requirements on page 4195
- Overview on page 4195
- Configuration on page 4195
- Verification on page 4197

Requirements

This example requires Junos OS Release 11.4 or later.

Overview

In this example, you configure a routing policy, POLICY-ipv4-example1, that maps multicast group join messages over an IGMP logical interface to IPv4 multicast source addresses based on destination IP address as follows:

Routing Policy Name	Multicast Group Join Messages for a Route Filter at This Destination Address	Multicast Source Addresses
POLICY-ipv4-example1 term 1	232.1.1.1	10.10.10.4, 192.168.43.66
POLICY-ipv4-example1 term 2	232.1.1.2	10.10.10.5, 192.168.43.67

You apply routing policy POLICY-ipv4-example1 to IGMP logical interface fe-0/1/0.0.

Configuration

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure this example, perform the following task:

Copyright © 2016, Juniper Networks, Inc.

CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement POLICY-ipv4-example1 term 1 from route-filter
  232.1.1.1/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
  10.10.10.4
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
  192.168.43.66
set policy-options policy-statement POLICY-ipv4-example1 term 1 then accept
set policy-options policy-statement POLICY-ipv4-example1 term 2 from route-filter
  232.1.1.2/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
  10.10.10.5
set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
  192.168.43.67
set policy-options policy-statement POLICY-ipv4-example1 term 2 then accept
set protocols igmp interface fe-0/1/0.0 ssm-map-policy POLICY-ipv4-example1
```

Step-by-Step Procedure

To configure multiple SSM maps per interface:

1. Configure protocol-independent routing options for route filter 232.1.1.1, and specify the multicast source addresses to which matching multicast groups are to be mapped.

   ```
   [edit policy-options policy-statement POLICY-ipv4-example1 term 1]
   user@host# set from route-filter 232.1.1.1/32 exact
   user@host# set then ssm-source 10.10.10.4
   user@host# set then ssm-source 192.168.43.66
   user@host# set then accept
   ```

2. Configure protocol-independent routing options for route filter 232.1.1.2, and specify the multicast source addresses to which matching multicast groups are to be mapped.

   ```
   [edit policy-options policy-statement POLICY-ipv4-example1 term 2]
   user@host# set from route-filter 232.1.1.2/32 exact
   user@host# set then ssm-source 10.10.10.5
   user@host# set then ssm-source 192.168.43.67
   user@host# set then accept
   ```

3. Apply the policy map POLICY-ipv4-example1 to IGMP logical interface fe-0/1/1/0.

   ```
   [edit protocols igmp interface fe-0/1/0.0]
   user@host# set ssm-map-policy POLICY-ipv4-example1
   ```

Results

After the configuration is committed, confirm the configuration by entering the **show policy-options** and **show protocols** configuration mode commands. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
user@host# show policy-options
policy-statement POLICY-ipv4-example1 {
  term 1 {
    from {
```

Copyright © 2016, Juniper Networks, Inc.

```
        route-filter 232.1.1.1/32 exact;
      }
      then {
        ssm-source [ 10.10.10.4 192.168.43.66 ];
        accept;
      }
    }
    term 2{
      from {
        route-filter 232.1.1.2/32 exact;
      }
      then {
        ssm-source [ 10.10.10.5 192.168.43.67 ];
        accept;
      }
    }
  }

  user@host# show protocols
  igmp {
    interface fe-0/1/0.0 {
      ssm-map-policy POLICY-ipv4-example1;
    }
  }
```

Verification

Confirm that the configuration is working properly.

- Displaying Information About IGMP-Enabled Interfaces on page 4197
- Displaying the PIM Groups on page 4198
- Displaying the Entries in the IP Multicast Forwarding Table on page 4198

Displaying Information About IGMP-Enabled Interfaces

Purpose Verify that the SSM map policy POLICY-ipv4-example1 is applied to logical interface fe-0/1/0.0.

Action Use the show igmp interface operational mode command for the IGMP logical interface to which you applied the SSM map policy.

```
user@host> show igmp interface
Interface: fe-0/1/0.0
    Querier: 10.111.30.1
    State:         Up Timeout:    None Version:  2 Groups:      2
    SSM Map Policy: POLICY-ipv4-example1;

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0
```

Copyright © 2016, Juniper Networks, Inc.

The command output displays the name of the IGMP logical interface (fe-0/1/0.0), which is the address of the routing device that has been elected to send membership queries and group information.

Displaying the PIM Groups

Purpose Verify the Protocol Independent Multicast (PIM) source and group pair (S,G) entries.

Action Use the **show pim join extensive 232.1.1.1** operational mode command to display the PIM source and group pair (S,G) entries for the 232.1.1.1 group.

Displaying the Entries in the IP Multicast Forwarding Table

Purpose Verify that the IP multicast forwarding table displays the multicast route state.

Action Use the **show multicast route extensive** operational mode command to display the entries in the IP multicast forwarding table to verify that the **Route state** is active and that the **Forwarding state** is forwarding.

CHAPTER 183

Minimizing Routing State Information with Bidirectional PIM

- Example: Configuring Bidirectional PIM on page 4199

Example: Configuring Bidirectional PIM

- Understanding Bidirectional PIM on page 4199
- Example: Configuring Bidirectional PIM on page 4205

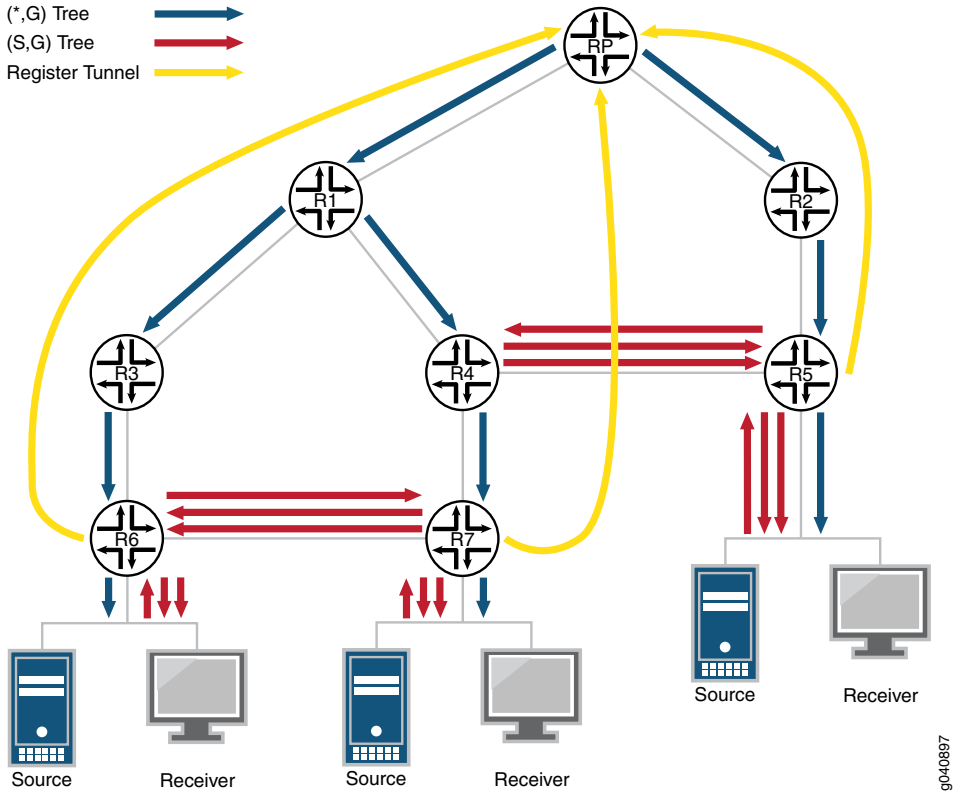
Understanding Bidirectional PIM

Bidirectional PIM (PIM-Bidir) is specified by the IETF in RFC 5015, *Bidirectional Protocol Independent Multicast (BIDIR-PIM)*. It provides an alternative to other PIM modes, such as PIM sparse mode (PIM-SM), PIM dense mode (PIM-DM), and PIM source-specific multicast (SSM). In bidirectional PIM, multicast groups are carried across the network over bidirectional shared trees. This type of tree minimizes the amount of PIM routing state information that must be maintained, which is especially important in networks with numerous and dispersed senders and receivers. For example, one important application for bidirectional PIM is distributed inventory polling. In many-to-many applications, a multicast query from one station generates multicast responses from many stations. For each multicast group, such an application generates a large number of (S,G) routes for each station in PIM-SM, PIM-DM, or SSM. The problem is even worse in applications that use bursty sources, resulting in frequently changing multicast tables and, therefore, performance problems in routers.

Figure 185 shows the traffic flows generated to deliver traffic for one group to and from three stations in a PIM-SM network.

Copyright © 2016, Juniper Networks, Inc.

Figure 185: Example PIM Sparse-Mode Tree

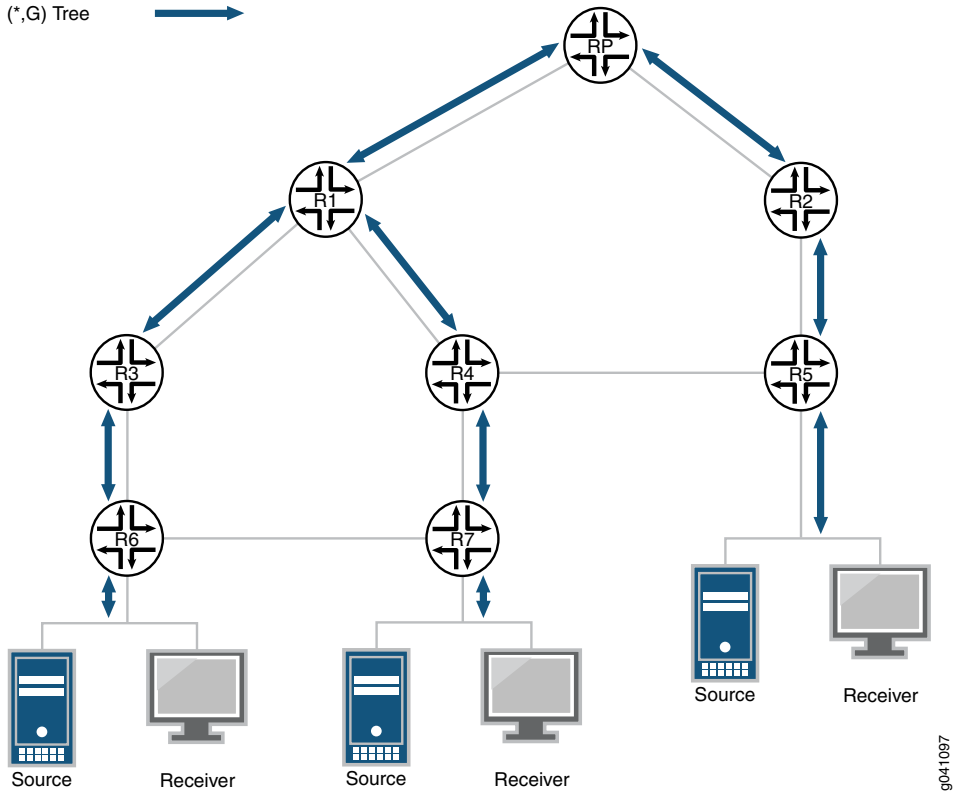


Bidirectional PIM solves this problem by building only group-specific (*,G) state. Thus, only a single (*,G) route is needed for each group to deliver traffic to and from all the sources.

Figure 186 shows the traffic flows generated to deliver traffic for one group to and from three stations in a bidirectional PIM network.

Copyright © 2016, Juniper Networks, Inc.

Figure 186: Example Bidirectional PIM Tree



Bidirectional PIM builds bidirectional shared trees that are rooted at a rendezvous point (RP) address. Bidirectional traffic does not switch to shortest path trees (SPTs) as in PIM-SM and is therefore optimized for routing state size instead of path length. Bidirectional PIM routes are always wildcard-source (*,G) routes. The protocol eliminates the need for (S,G) routes and data-triggered events. The bidirectional (*,G) group trees carry traffic both upstream from senders toward the RP, and downstream from the RP to receivers. As a consequence, the strict reverse path forwarding (RPF)-based rules found in other PIM modes do not apply to bidirectional PIM. Instead, bidirectional PIM routes forward traffic from all sources and the RP. Thus, bidirectional PIM routers must have the ability to accept traffic on many potential incoming interfaces.

Designated Forwarder Election

To prevent forwarding loops, only one router on each link or subnet (including point-to-point links) is a designated forwarder (DF). The responsibilities of the DF are to forward downstream traffic onto the link toward the receivers and to forward upstream traffic from the link toward the RP address. Bidirectional PIM relies on a process called DF election to choose the DF router for each interface and for each RP address. Each bidirectional PIM router in a subnet advertises its interior gateway protocol (IGP) unicast route to the RP address. The router with the best IGP unicast route to the RP address wins the DF election. Each router advertises its IGP route metrics in DF Offer, Winner, Backoff, and Pass messages.

Copyright © 2016, Juniper Networks, Inc.

Junos OS implements the DF election procedures as stated in RFC 5015, except that Junos OS checks RP unicast reachability before accepting incoming DF messages. DF messages for unreachable rendezvous points are ignored.

Bidirectional PIM Modes

In the Junos OS implementation, there are two modes for bidirectional PIM: bidirectional-sparse and bidirectional-sparse-dense. The differences between bidirectional-sparse and bidirectional-sparse-dense modes are the same as the differences between sparse mode and sparse-dense mode. Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as "dense" is not mapped to an RP. Use bidirectional-sparse-dense mode when you have a mix of bidirectional groups, sparse groups, and dense groups in your network. One typical scenario for this is the use of auto-RP, which uses dense-mode flooding to bootstrap itself for sparse mode or bidirectional mode. In general, the dense groups could be for any flows that the network design requires to be flooded.

Each group-to-RP mapping is controlled by the RP **group-ranges** statement and the **ssm-groups** statement.

The choice of PIM mode is closely tied to controlling how groups are mapped to PIM modes, as follows:

- **bidirectional-sparse**—Use if all multicast groups are operating in bidirectional, sparse, or SSM mode.
- **bidirectional-sparse-dense**—Use if multicast groups, except those that are specified in the **dense-groups** statement, are operating in bidirectional, sparse, or SSM mode.

Bidirectional Rendezvous Points

You can configure group-range-to-RP mappings network-wide statically, or only on routers connected to the RP addresses and advertise them dynamically. Unlike rendezvous points for PIM-SM, which must de-encapsulate PIM Register messages and perform other specific protocol actions, bidirectional PIM rendezvous points implement no specific functionality. RP addresses are simply locations in the network to rendezvous toward. In fact, RP addresses need not be loopback interface addresses or even be addresses configured on any router, as long as they are covered by a subnet that is connected to a bidirectional PIM-capable router and advertised to the network.

Thus, for bidirectional PIM, there is no meaningful distinction between static and local RP addresses. Therefore, bidirectional PIM rendezvous points are configured at the **[edit protocols pim rp bidirectional]** hierarchy level, not under **static** or **local**.

The settings at the **[edit protocol pim rp bidirectional]** hierarchy level function like the settings at the **[edit protocols pim rp local]** hierarchy level, except that they create bidirectional PIM RP state instead of PIM-SM RP state.

Where only a single local RP can be configured, multiple bidirectional rendezvous points can be configured having group ranges that are the same, different, or overlapping. It is also permissible for a group range or RP address to be configured as bidirectional and either static or local for sparse-mode.

Copyright © 2016, Juniper Networks, Inc.

If a bidirectional PIM RP is configured without a group range, the default group range is 224/4 for IPv4. For IPv6, the default is ff00::/8. You can configure a bidirectional PIM RP group range to cover an SSM group range, but in that case the SSM or DM group range takes precedence over the bidirectional PIM RP configuration for those groups. In other words, because SSM always takes precedence, it is not permitted to have a bidirectional group range equal to or more specific than an SSM or DM group range.

PIM Bootstrap and Auto-RP Support

Group ranges for the specified RP address are flagged by PIM as bidirectional PIM group-to-RP mappings and, if configured, are advertised using PIM bootstrap or auto-RP. Dynamic advertisement of bidirectional PIM-flagged group-to-RP mappings using PIM bootstrap, and auto-RP is controlled as normal using the **bootstrap** and **auto-rp** statements.

Bidirectional PIM RP addresses configured at the **[edit protocols pim rp bidirectional address]** hierarchy level are advertised by auto-RP or PIM bootstrap if the following prerequisites are met:

- The routing instance must be configured to advertise candidate rendezvous points by way of auto-RP or PIM bootstrap, and an auto-RP mapping agent or bootstrap router, respectively, must be elected.
- The RP address must either be configured locally on an interface in the routing instance, or the RP address must belong to a subnet connected to an interface in the routing instance.

IGMP and MLD Support

Internet Group Management Protocol (IGMP) version 1, version 2, and version 3 are supported with bidirectional PIM. Multicast Listener Discovery (MLD) version 1 and version 2 are supported with bidirectional PIM. However, in all cases, only anysource multicast (ASM) state is supported for bidirectional PIM membership.

The following rules apply to bidirectional PIM:

- IGMP and MLD (*,G) membership reports trigger the PIM DF to originate bidirectional PIM (*,G) join messages.
- IGMP and MLD (S,G) membership reports do not trigger the PIM DF to originate bidirectional PIM (*,G) join messages.

Bidirectional PIM and Graceful Restart

Bidirectional PIM accepts packets for a bidirectional route on multiple interfaces. This means that some topologies might develop multicast routing loops if all PIM neighbors are not synchronized with regard to the identity of the designated forwarder (DF) on each link. If one router is forwarding without actively participating in DF elections, particularly after unicast routing changes, multicast routing loops might occur.

If graceful restart for PIM is enabled and bidirectional PIM is enabled, the default graceful restart behavior is to continue forwarding packets on bidirectional routes. If the gracefully

Copyright © 2016, Juniper Networks, Inc.

restarting router was serving as a DF for some interfaces to rendezvous points, the restarting router sends a DF Winner message with a metric of 0 on each of these RP interfaces. This ensures that a neighbor router does not become the DF due to unicast topology changes that might occur during the graceful restart period. Sending a DF Winner message with a metric of 0 prevents another PIM neighbor from assuming the DF role until after graceful restart completes. When graceful restart completes, the gracefully restarted router sends another DF Winner message with the actual converged unicast metric.

The no-bidirectional-mode statement at the **[edit protocols pim graceful-restart]** hierarchy level overrides the default behavior and disables forwarding for bidirectional PIM routes during graceful restart recovery, both in cases of simple routing protocol process (rpd) restart and graceful Routing Engine switchover. This configuration statement provides a very conservative alternative to the default graceful restart behavior for bidirectional PIM routes. The reason to discontinue forwarding of packets on bidirectional routes is that the continuation of forwarding might lead to short-duration multicast loops in rare double-failure circumstances.

Junos OS Enhancements to Bidirectional PIM

In addition to the functionality specified in RFC 5015, the following functions are included in the Junos OS implementation of bidirectional PIM:

- Source-only branches without PIM join state
- Support for both IPv4 and IPv6 domain and multicast addresses
- Nonstop routing (NSR) for bidirectional PIM routes
- Support for bidirectional PIM in logical systems
- Support for non-forwarding and virtual router instances

Limitations of Bidirectional PIM

The Junos OS implementation of bidirectional PIM does not support the following functionality:

- SNMP for bidirectional PIM.
- Graceful Routing Engine switchover is configurable with bidirectional PIM enabled, but bidirectional routes do not forward packets during the switchover.
- Multicast VPNs (Draft Rosen and NextGen).

The bidirectional PIM protocol does not support the following functionality:

- Embedded RP
- Anycast RP

Copyright © 2016, Juniper Networks, Inc.

Example: Configuring Bidirectional PIM

This example shows how to configure bidirectional PIM, as specified in RFC 5015, *Bidirectional Protocol Independent Multicast (BIDIR-PIM)*.

- Requirements on page 4205
- Overview on page 4205
- Configuration on page 4207
- Verification on page 4211

Requirements

This example uses the following hardware and software components:

- Eight Juniper Networks routers that can be M120, M320, MX Series, or T Series platforms. To support bidirectional PIM, M Series platforms must have I-chip FPCs. M7i, M10i, M40e, and other older M Series routers do not support bidirectional PIM.
- Junos OS Release 12.1 or later running on all eight routers.

Overview

Compared to PIM sparse mode, bidirectional PIM requires less PIM router state information. Because less state information is required, bidirectional PIM scales well and is useful in deployments with many dispersed sources and receivers.

In this example, two rendezvous points are configured statically. One RP is configured as a phantom RP. A phantom RP is an RP address that is a valid address on a subnet, but is not assigned to a PIM router interface. The subnet must be reachable by the bidirectional PIM routers in the network. For the other (non-phantom) RP in this example, the RP address is assigned to a PIM router interface. It can be assigned to either the loopback interface or any physical interface on the router. In this example, it is assigned to a physical interface.

OSPF is used as the interior gateway protocol (IGP) in this example. The OSPF metric determines the designated forwarder (DF) election process. In bidirectional PIM, the DF establishes a loop-free shortest-path tree that is rooted at the RP. On every network segment and point-to-point link, all PIM routers participate in DF election. The procedure selects one router as the DF for every RP of bidirectional groups. This router forwards multicast packets received on that network upstream to the RP. The DF election uses the same tie-break rules used by PIM assert processes.

This example uses the default DF election parameters. Optionally, at the **[edit protocols pim interface (*interface-name* | all)** bidirectional**]** hierarchy level, you can configure the following parameters related to the DF election:

- The robustness-count is the minimum number of DF election messages that must be lost for election to fail.
- The offer period is the interval to wait between repeated DF Offer and Winner messages.

Copyright © 2016, Juniper Networks, Inc.

- The backoff period is the period that the acting DF waits between receiving a better DF Offer and sending the Pass message to transfer DF responsibility.

This example uses bidirectional-sparse-dense mode on the interfaces. The choice of PIM mode is closely tied to controlling how groups are mapped to PIM modes, as follows:

- **bidirectional-sparse**—Use if all multicast groups are operating in bidirectional, sparse, or SSM mode.
- **bidirectional-sparse-dense**—Use if multicast groups, except those that are specified in the **dense-groups** statement, are operating in bidirectional, sparse, or SSM mode.

Topology Diagram

Figure 187 shows the topology used in this example.

Router R1

Step-by-Step Procedure

To configure Router R1:

1. Configure the router interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/1 unit 0 family inet address 10.10.1.1/24
user@R1# set xe-2/1/0 unit 0 family inet address 10.10.2.1/24
user@R1# set lo0 unit 0 family inet address 10.255.11.11/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf area 0.0.0.0]
user@R1# set interface ge-0/0/1.0
user@R1# set interface xe-2/1/0.0
user@R1# set interface lo0.0
user@R1# set interface fxp0.0 disable
```

3. Configure the group-to-RP mappings.

```
[edit protocols pim rp bidirectional]
user@R1# set address 10.10.1.3 group-ranges 224.1.3.0/24
user@R1# set address 10.10.1.3 group-ranges 225.1.3.0/24
user@R1# set address 10.10.13.2 group-ranges 224.1.1.0/24
user@R1# set address 10.10.13.2 group-ranges 225.1.1.0/24
```

Copyright © 2016, Juniper Networks, Inc.

The RP represented by IP address 10.10.1.3 is a phantom RP. The 10.10.1.3 address is not assigned to any interface on any of the routers in the topology. It is, however, a reachable address. It is in the subnet between Routers R1 and R2.

The RP represented by address 10.10.13.2 is assigned to the **ge-2/0/0** interface on Router R6.

4. Enable bidirectional PIM on the interfaces.

```
[edit protocols pim]
user@R1# set interface ge-0/0/1.0 mode bidirectional-sparse-dense
user@R1# set interface xe-2/1/0.0 mode bidirectional-sparse-dense
```

5. (Optional) Configure tracing operations for the DF election process.

```
[edit protocols pim]
user@R1# set traceoptions file df
user@R1# set traceoptions flag bidirectional-df-election detail
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-0/0/1 {
    unit 0 {
        family inet {
            address 10.10.1.1/24;
        }
    }
}
xe-2/1/0 {
    unit 0 {
        family inet {
            address 10.10.2.1/24;
        }
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.11.11/32;
        }
    }
}
```

```
user@R1# show protocols
ospf {
    area 0.0.0.0 {
        interface ge-0/0/1.0;
        interface xe-2/1/0.0;
        interface lo0.0;
        interface fxp0.0 {
            disable;
        }
```

Copyright © 2016, Juniper Networks, Inc.

```
    }
  }
  pim {
    rp {
      bidirectional {
        address 10.10.1.3 { # phantom RP
          group-ranges {
            224.1.3.0/24;
            225.1.3.0/24;
          }
        }
        address 10.10.13.2 {
          group-ranges {
            224.1.1.0/24;
            225.1.1.0/24;
          }
        }
      }
    }
    interface ge-0/0/1.0 {
      mode bidirectional-sparse-dense;
    }
    interface xe-2/1/0.0 {
      mode bidirectional-sparse-dense;
    }
    traceoptions {
      file df;
      flag bidirectional-df-election detail;
    }
  }
```

If you are done configuring the router, enter **commit** from configuration mode.

Repeat the procedure for every Juniper Networks router in the bidirectional PIM network, using the appropriate interface names and addresses for each router.

Verification

Confirm that the configuration is working properly.

Verifying Rendezvous Points

Purpose Verify the group-to-RP mapping information.

Action

```
user@R1> show pim rps
Instance: PIM.master
Address family INET
RP address      Type        Mode   Holdtime Timeout Groups Group prefixes
10.10.1.3       static      bidir       150    None      2 224.1.3.0/24
                                                           225.1.3.0/24
10.10.13.2      static      bidir       150    None      2 224.1.1.0/24
                                                           225.1.1.0/24
```

Verifying Messages

Purpose Check the number of DF election messages sent and received, and check bidirectional join and prune error statistics.

Action

```
user@R1> show pim statistics
PIM Message type        Received       Sent  Rx errors
V2 Hello                      16         34          0
...
V2 DF Election                18         38          0
...

Global Statistics

...
Rx Bidir Join/Prune on non-Bidir if           0
Rx Bidir Join/Prune on non-DF if              0
```

Checking the PIM Join State

Purpose Confirm the upstream interface, neighbor, and state information.

Copyright © 2016, Juniper Networks, Inc.

Action

```
user@R1> show pim join extensive
Instance: PIM.master Family: INET
R = Rendezvous Point Tree, S = Sparse, W = Wildcard

Group: 224.1.1.0
    Bidirectional group prefix length: 24

    Upstream state: None
    Bidirectional accepting interfaces:
        Interface: ge-0/0/1.0    (RPF)
        Interface: lo0.0         (DF Winner)

Group: 225.1.3.0
    Bidirectional group prefix length: 24
    Source: *
    RP: 10.10.1.3
    Flags: bidirectional,rptree,wildcard
    Upstream interface: ge-0/0/1.0 (RP Link)
    Upstream neighbor: Direct
    Upstream state: Local RP
    Bidirectional accepting interfaces:
        Interface: ge-0/0/1.0    (RPF)
        Interface: lo0.0         (DF Winner)
        Interface: xe-2/1/0.0    (DF Winner)
```

Meaning The output shows a (*,G-range) entry for each active bidirectional RP group range. These entries provide a hierarchy from which the individual (*,G) routes inherit RP-derived state (upstream information and accepting interfaces). These entries also provide the control plane basis for the (*, G-range) forwarding routes that implement the sender-only branches of the tree.

Displaying the Designated Forwarder

Purpose Display RP address information and confirm the DF elected.

Action

```
user@R1> show pim bidirectional df-election
Instance: PIM.master Family: INET

RPA: 10.10.1.3
Group ranges: 224.1.3.0/24, 225.1.3.0/24
Interfaces:
    ge-0/0/1.0    (RPL)      DF: none
    lo0.0         (Win)      DF: 10.255.179.246
    xe-2/1/0.0    (Win)      DF: 10.10.2.1

RPA: 10.10.13.2
Group ranges: 224.1.1.0/24, 225.1.1.0/24
Interfaces:
    ge-0/0/1.0    (Lose)     DF: 10.10.1.2
    lo0.0         (Win)      DF: 10.255.179.246
    xe-2/1/0.0    (Lose)     DF: 10.10.2.2
```

Displaying the PIM Interfaces

Purpose Verify that the PIM interfaces have bidirectional-sparse-dense (**SDB**) mode assigned.

Action

```
user@R1> show pim interfaces
Instance: PIM.master

Stat = Status, V = Version, NbrCnt = Neighbor Count,
S = Sparse, D = Dense, B = Bidirectional,
DR = Designated Router, P2P = Point-to-point link,
Active = Bidirectional is active, NotCap = Not Bidirectional Capable

Name               Stat Mode IP V State        NbrCnt JoinCnt(sg/*g) DR address
ge-0/0/1.0          Up   SDB   4 2 NotDR,Active      1 0/0            10.10.1.2
lo0.0              Up   SDB   4 2 DR,Active        0 9901/100      10.255.179.246
xe-2/1/0.0          Up   SDB   4 2 NotDR,Active      1 0/0            10.10.2.2
```

Checking the PIM Neighbors

Purpose Check that the router detects that its neighbors are enabled for bidirectional PIM by verifying that the **B** option is displayed.

Copyright © 2016, Juniper Networks, Inc.

Action

```
user@R1> show pim neighbors
Instance: PIM.master
B = Bidirectional Capable, G = Generation Identifier,
H = Hello Option Holdtime, L = Hello Option LAN Prune Delay,
P = Hello Option DR Priority, T = Tracking Bit

Interface           IP V Mode        Option       Uptime Neighbor addr
ge-0/0/1.0           4 2             HPLGBT     00:06:46 10.10.1.2
xe-2/1/0.0           4 2             HPLGBT     00:06:46 10.10.2.2
```

Checking the Route to the Rendezvous Points

Purpose Check the interface route to the rendezvous points.

Action

```
user@R1> show route 10.10.13.2
inet.0: 56 destinations, 56 routes (55 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.13.0/24      *[OSPF/10] 00:04:35, metric 4
                    > to 10.10.1.2 via ge-0/0/1.0

user@R1> show route 10.10.1.3
inet.0: 56 destinations, 56 routes (55 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.1.0/24       *[Direct/0] 00:06:25
                    > via ge-0/0/1.0
```

Verifying Multicast Routes

Purpose Verify the multicast traffic route for each group.

For bidirectional PIM, the **show multicast route extensive** command shows the (*, G*/prefix*) forwarding routes and the list of interfaces that accept bidirectional PIM traffic.

Copyright © 2016, Juniper Networks, Inc.

Action

```
user@R1> show multicast route extensive
Family: INET

CHAPTER 184

Rapidly Detecting Communication Failures with PIM and the BFD Protocol

- Configuring PIM and the Bidirectional Forwarding Detection (BFD) Protocol on page 4219

Configuring PIM and the Bidirectional Forwarding Detection (BFD) Protocol

- Understanding Bidirectional Forwarding Detection Authentication for PIM on page 4219
- Configuring BFD for PIM on page 4221
- Configuring BFD Authentication for PIM on page 4222

Understanding Bidirectional Forwarding Detection Authentication for PIM

Bidirectional Forwarding Detection (BFD) enables rapid detection of communication failures between adjacent systems. By default, authentication for BFD sessions is disabled. However, when you run BFD over Network Layer protocols, the risk of service attacks can be significant. We strongly recommend using authentication if you are running BFD over multiple hops or through insecure tunnels.

NOTE: **Beginning with Junos OS Release 9.6, Junos OS supports authentication for BFD sessions running over PIM. BFD authentication is only supported in the Canada and United States version of the Junos OS image and is not available in the export version.**

You authenticate BFD sessions by specifying an authentication algorithm and keychain, and then associating that configuration information with a security authentication keychain using the keychain name.

The following sections describe the supported authentication algorithms, security keychains, and level of authentication that can be configured:

- BFD Authentication Algorithms on page 4220
- Security Authentication Keychains on page 4220
- Strict Versus Loose Authentication on page 4221

Copyright © 2016, Juniper Networks, Inc.

BFD Authentication Algorithms

Junos OS supports the following algorithms for BFD authentication:

- **simple-password**—Plain-text password. One to 16 bytes of plain text are used to authenticate the BFD session. One or more passwords can be configured. This method is the least secure and should be used only when BFD sessions are not subject to packet interception.
- **keyed-md5**—Keyed Message Digest 5 hash algorithm for sessions with transmit and receive intervals greater than 100 ms. To authenticate the BFD session, keyed MD5 uses one or more secret keys (generated by the algorithm) and a sequence number that is updated periodically. With this method, packets are accepted at the receiving end of the session if one of the keys matches and the sequence number is greater than or equal to the last sequence number received. Although more secure than a simple password, this method is vulnerable to replay attacks. Increasing the rate at which the sequence number is updated can reduce this risk.
- **meticulous-keyed-md5**—Meticulous keyed Message Digest 5 hash algorithm. This method works in the same manner as keyed MD5, but the sequence number is updated with every packet. Although more secure than keyed MD5 and simple passwords, this method might take additional time to authenticate the session.
- **keyed-sha-1**—Keyed Secure Hash Algorithm I for sessions with transmit and receive intervals greater than 100 ms. To authenticate the BFD session, keyed SHA uses one or more secret keys (generated by the algorithm) and a sequence number that is updated periodically. The key is not carried within the packets. With this method, packets are accepted at the receiving end of the session if one of the keys matches and the sequence number is greater than the last sequence number received.
- **meticulous-keyed-sha-1**—Meticulous keyed Secure Hash Algorithm I. This method works in the same manner as keyed SHA, but the sequence number is updated with every packet. Although more secure than keyed SHA and simple passwords, this method might take additional time to authenticate the session.

NOTE: **Nonstop active routing (NSR) is not supported with meticulous-keyed-md5 and meticulous-keyed-sha-1 authentication algorithms. BFD sessions using these algorithms might go down after a switchover.**

Security Authentication Keychains

The security authentication keychain defines the authentication attributes used for authentication key updates. When the security authentication keychain is configured and associated with a protocol through the keychain name, authentication key updates can occur without interrupting routing and signaling protocols.

The authentication keychain contains one or more keychains. Each keychain contains one or more keys. Each key holds the secret data and the time at which the key becomes valid. The algorithm and keychain must be configured on both ends of the BFD session,

Copyright © 2016, Juniper Networks, Inc.

and they must match. Any mismatch in configuration prevents the BFD session from being created.

BFD allows multiple clients per session, and each client can have its own keychain and algorithm defined. To avoid confusion, we recommend specifying only one security authentication keychain.

Strict Versus Loose Authentication

By default, strict authentication is enabled, and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure *loose checking*. When loose checking is configured, packets are accepted without authentication being checked at each end of the session. This feature is intended for transitional periods only.

Configuring BFD for PIM

The Bidirectional Forwarding Detection (BFD) Protocol is a simple hello mechanism that detects failures in a network. BFD works with a wide variety of network environments and topologies. A pair of routing devices exchanges BFD packets. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply after a specified interval. The BFD failure detection timers have shorter time limits than the Protocol Independent Multicast (PIM) hello hold time, so they provide faster detection.

The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

You must specify the minimum transmit and minimum receive intervals to enable BFD on PIM.

To enable failure detection:

1. Configure the interface globally or in a routing instance.

   This example shows the global configuration.

   ```
   [edit protocols pim]
   user@host# edit interface fe-1/0/0.0 bfd-liveness-detection
   ```

2. Configure the minimum transmit interval.

   This is the minimum interval after which the routing device transmits hello packets to a neighbor with which it has established a BFD session. Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

Copyright © 2016, Juniper Networks, Inc.

```
[edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
user@host# set transmit-interval 350
```

3. Configure the minimum interval after which the routing device expects to receive a reply from a neighbor with which it has established a BFD session.

   Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

   ```
   [edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
   user@host# set minimum-receive-interval 350
   ```

4. (Optional) Configure other BFD settings.

   As an alternative to setting the receive and transmit intervals separately, configure one interval for both.

   ```
   [edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
   user@host# set minimum-interval 350
   ```

5. Configure the threshold for the adaptation of the BFD session detection time.

   When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

   ```
   [edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
   user@host# set detection-time threshold 800
   ```

6. Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down.

   ```
   [edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
   user@host# set multiplier 50
   ```

7. Configure the BFD version.

   ```
   [edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
   user@host# set version 1
   ```

8. Specify that BFD sessions should not adapt to changing network conditions.

   We recommend that you not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

   ```
   [edit protocols pim interface fe-1/0/0.0 bfd-liveness-detection]
   user@host# set no-adaptation
   ```

9. Verify the configuration by checking the output of the **show bfd session** command.

Configuring BFD Authentication for PIM

Beginning with Junos OS Release 9.6, you can configure authentication for Bidirectional Forwarding Detection (BFD) sessions running over Protocol Independent Multicast (PIM). Routing instances are also supported. The following steps are needed to configure authentication on a BFD session:

1. Specify the BFD authentication algorithm for the PIM protocol.
2. Associate the authentication keychain with the PIM protocol.
3. Configure the related security authentication keychain.

Copyright © 2016, Juniper Networks, Inc.

The following sections provide instructions for configuring and viewing BFD authentication on PIM:

- Configuring BFD Authentication Parameters on page 4223
- Viewing Authentication Information for BFD Sessions on page 4224

Configuring BFD Authentication Parameters

BFD authentication is only supported in the Canada and United States version of the Junos OS image and is not available in the export version.

To configure BFD authentication:

1. Specify the algorithm (**keyed-md5**, **keyed-sha-1**, **meticulous-keyed-md5**, **meticulous-keyed-sha-1**, or **simple-password**) to use for BFD authentication on a PIM route or routing instance.

   ```
   [edit protocols pim]
   user@host# set interface if3-pim bfd-liveness-detection authentication algorithm
     keyed-sha-1
   ```

   NOTE: Nonstop active routing (NSR) is not supported with the meticulous-keyed-md5 and meticulous-keyed-sha-1 authentication algorithms. BFD sessions using these algorithms might go down after a switchover.

2. Specify the keychain to be used to associate BFD sessions on the specified PIM route or routing instance with the unique security authentication keychain attributes.

   The keychain you specify must match the keychain name configured at the **[edit security authentication key-chains]** hierarchy level.

   ```
   [edit protocols pim]
   user@host# set interface if3-pim bfd-liveness-detection authentication keychain
     bfd-pim
   ```

   NOTE: The algorithm and keychain must be configured on both ends of the BFD session, and they must match. Any mismatch in configuration prevents the BFD session from being created.

3. Specify the unique security authentication information for BFD sessions:

   - The matching keychain name as specified in Step 2.
   - At least one key, a unique integer between **0** and **63**. Creating multiple keys allows multiple clients to use the BFD session.
   - The secret data used to allow access to the session.
   - The time at which the authentication key becomes active, in the format *yyyy-mm-dd.hh:mm:ss*.

Copyright © 2016, Juniper Networks, Inc.

```
[edit security]
user@host# set authentication-key-chains key-chain bfd-pim key 53 secret "$ABC123/"
  start-time 2009-06-14.10:00:00
```

4. (Optional) Specify loose authentication checking if you are transitioning from nonauthenticated sessions to authenticated sessions.

```
[edit protocols pim]
user@host# set interface if3-pim bfd-liveness-detection authentication loose-check
```

5. (Optional) View your configuration by using the **show bfd session detail** or **show bfd session extensive** command.

6. Repeat these steps to configure the other end of the BFD session.

Viewing Authentication Information for BFD Sessions

You can view the existing BFD authentication configuration by using the **show bfd session detail** and **show bfd session extensive** commands.

The following example shows BFD authentication configured for the **if3-pim** BGP group. It specifies the keyed SHA-1 authentication algorithm and a keychain name of **bfd-pim**. The authentication keychain is configured with two keys. Key **1** contains the secret data "**$ABC123/**" and a start time of June 1, 2009, at 9:46:02 AM PST. Key **2** contains the secret data "**$ABC123/**" and a start time of June 1, 2009, at 3:29:20 PM PST.

```
[edit protocols pim]
interface if3–pim {
  bfd-liveness-detection {
    authentication {
      algorithm keyed-sha-1;
      key-chain bfd-pim;
    }
  }
}
[edit security]
authentication key-chains {
  key-chain bfd-pim {
    key 1 {
      secret "$ABC123/";
      start-time "2009-6-1.09:46:02 -0700";
    }
    key 2 {
      secret "$ABC123/";
      start-time "2009-6-1.15:29:20 -0700";
    }
  }
}
```

If you commit these updates to your configuration, you see output similar to the following example. In the output for the **show bfd session detail** command, **Authenticate** is displayed to indicate that BFD authentication is configured. For more information about the configuration, use the **show bfd session extensive** command. The output for this command provides the keychain name, the authentication algorithm and mode for each client in

Copyright © 2016, Juniper Networks, Inc.

the session, and the overall BFD authentication configuration status, keychain name, and authentication algorithm and mode.

show bfd session detail

```

Understanding Nonstop Active Routing for PIM

Nonstop active routing configurations include two Routing Engines that share information so that routing is not interrupted during Routing Engine failover. When nonstop active routing is configured on a dual Routing Engine platform, the PIM control state is replicated on both Routing Engines.

This PIM state information includes:

- Neighbor relationships
- Join and prune information
- RP-set information
- Synchronization between routes and next hops and the forwarding state between the two Routing Engines

The PIM control state is maintained on the backup Routing Engine by the replication of state information from the master to the backup Routing Engine and having the backup Routing Engine react to route installation and modification in the **[instance].inet.1** routing table on the master Routing Engine. The backup Routing Engine does not send or receive PIM protocol packets directly. In addition, the backup Routing Engine uses the dynamic interfaces created by the master Routing Engine. These dynamic interfaces include PIM encapsulation, de-encapsulation, and multicast tunnel interfaces.

NOTE: **The clear pim join, clear pim register, and clear pim statistics operational mode commands are not supported on the backup Routing Engine when nonstop active routing is enabled.**

Copyright © 2016, Juniper Networks, Inc.

To enable nonstop active routing for PIM (in addition to the PIM configuration on the master Routing Engine), you must include the following statements at the **[edit]** hierarchy level:

- **chassis redundancy graceful-switchover**
- **routing-options nonstop-routing**
- **system commit synchronize**

Example: Configuring Nonstop Active Routing with PIM

This example shows how to configure nonstop active routing for PIM-based multicast IPv4 and IPv6 traffic.

- Requirements on page 4228
- Overview on page 4228
- Configuration on page 4229
- Verification on page 4238

Requirements

Before you begin:

- Configure the router interfaces. See the *Network Interfaces Configuration Guide*.
- Configure an interior gateway protocol or static routing. See the *Routing Protocols Configuration Guide*.
- Configure a multicast group membership protocol (IGMP or MLD). See "Understanding IGMP" on page 4038 and "Understanding MLD" on page 4063.
- For this feature to work with IPv6, the routing device must be running Junos OS Release 10.4 or above.

Overview

Junos OS supports nonstop active routing in the following PIM scenarios:

- Dense mode
- Sparse mode
- SSM
- Static RP
- Auto-RP (for IPv4 only)
- Bootstrap router
- Embedded RP on the non-RP router (for IPv6 only)
- BFD support

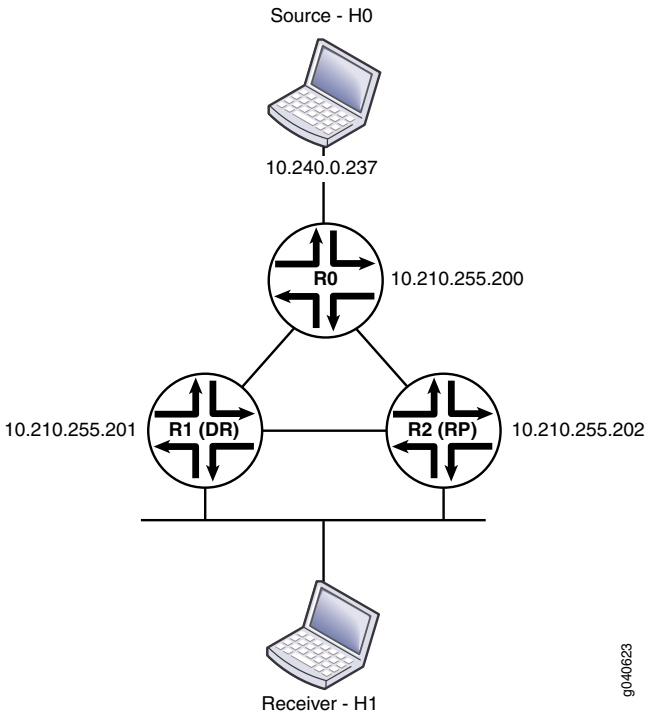
Copyright © 2016, Juniper Networks, Inc.

NOTE: Multicast VPNs are not supported with nonstop active routing. Policy-based features (such as neighbor policy, join policy, BSR policy, scope policy, flow maps, and RPF check policy) are not supported with nonstop active routing.

This example uses static RP. The interfaces are configured to receive both IPv4 and IPv6 traffic. R2 provides RP services as the local RP. Note that nonstop active routing is not supported on the RP router. The configuration shown in this example is on R1.

Figure 188 shows the topology used in this example.

Figure 188: Nonstop Active Routing in PIM Domain



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

R1

```
set system syslog archive size 10m
set system syslog file messages any info
set system commit synchronize
set chassis redundancy graceful-switchover

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure nonstop active routing on R1:

1. Synchronize the Routing Engines.

   ```
   [edit]
   user@host# edit system
   [edit system]
   user@host# set commit synchronize
   user@host# exit
   ```

2. Enable graceful Routing Engine switchover.

   ```
   [edit]
   user@host# set chassis redundancy graceful-switchover
   ```

3. Configure R1's interfaces.

   ```
   [edit]
   user@host# edit interfaces
   ```

Copyright © 2016, Juniper Networks, Inc.

```
[edit interfaces]
user@host# set so-0/0/1 unit 0 description "to R0 so-0/0/1.0"
user@host# set so-0/0/1 unit 0 family inet address 10.210.1.2/30
user@host# set so-0/0/1 unit 0 family inet6 address FDCA:9E34:50CE:0001::2/126
user@host# set fe-0/1/3 unit 0 description "to R2 fe-0/1/3.0"
user@host# set fe-0/1/3 unit 0 family inet address 10.210.12.1/30

```
user@host# edit policy-options policy-statement load-balance
[edit policy-options policy-statement load-balance]
user@host# set then load-balance per-packet
```

8. Apply the load-balance policy on R1.

```
[edit]
user@host# set routing-options forwarding-table export load-balance
```

9. Configure nonstop routing on R1.

```
[edit]
user@host# set routing-options nonstop-routing
user@host# set routing-options router-id 10.210.255.201
```

Step-by-Step Procedure

For troubleshooting, configure system log and tracing operations.

1. Enable system log messages.

```
[edit]
user@host# set system syslog archive size 10m
user@host# set system syslog file messages any info
```

2. Trace interface operations.

```
[edit]
user@host# set interfaces traceoptions file dcd-trace
user@host# set interfaces traceoptions file size 10m
user@host# set interfaces traceoptions file files 10
user@host# set interfaces traceoptions flag all
```

3. Trace IGP operations for IPv4.

```
[edit]
user@host# set protocols ospf traceoptions file r1-nsr-ospf2
user@host# set protocols ospf traceoptions file size 10m
user@host# set protocols ospf traceoptions file files 10
user@host# set protocols ospf traceoptions file world-readable

- show pim rps inet6 detail
- show multicast route inet extensive
- show multicast route inet6 extensive
- show route table inet.1 detail
- show route table inet6.1 detail

Configuring PIM Sparse Mode Graceful Restart

You can configure PIM sparse mode to continue to forward existing multicast packet streams during a routing process failure and restart. Only PIM sparse mode can be configured this way. The routing platform does not forward multicast packets for protocols other than PIM during graceful restart, because all other multicast protocols must restart after a routing process failure. If you configure PIM sparse-dense mode, only sparse multicast groups benefit from a graceful restart.

The routing platform does not forward new streams until after the restart is complete. After restart, the routing platform refreshes the forwarding state with any updates that were received from neighbors during the restart period. For example, the routing platform

Copyright © 2016, Juniper Networks, Inc.

relearns the join and prune states of neighbors during the restart, but it does not apply the changes to the forwarding table until after the restart.

When PIM sparse mode is enabled, the routing platform generates a unique 32-bit random number called a generation identifier. Generation identifiers are included by default in PIM hello messages, as specified in the Internet draft **draft-ietf-pim-sm-v2-new-10.txt**. When a routing platform receives PIM hello messages containing generation identifiers on a point-to-point interface, Junos OS activates an algorithm that optimizes graceful restart.

Before PIM sparse mode graceful restart occurs, each routing platform creates a generation identifier and sends it to its multicast neighbors. If a routing platform with PIM sparse mode restarts, it creates a new generation identifier and sends it to neighbors. When a neighbor receives the new identifier, it resends multicast updates to the restarting router to allow it to exit graceful restart efficiently. The restart phase is complete when the restart duration timer expires.

Multicast forwarding can be interrupted in two ways. First, if the underlying routing protocol is unstable, multicast RPF checks can fail and cause an interruption. Second, because the forwarding table is not updated during the graceful restart period, new multicast streams are not forwarded until graceful restart is complete.

You can configure graceful restart globally or for a routing instance. This example shows how to configure graceful restart globally.

To configure graceful restart for PIM sparse mode:

1. Enable graceful restart.

   ```
   [edit protocols pim]
   user@host# set graceful-restart
   ```

2. (Optional) Configure the amount of time the routing device waits (in seconds) to complete PIM sparse mode graceful restart. By default, the router allows 60 seconds. The range is from 30 through 300 seconds. After this restart time, the Routing Engine resumes normal multicast operation.

   ```
   [edit protocols pim graceful-restart]
   user@host# set restart-duration 120
   ```

3. Monitor the operation of PIM graceful restart by running the show pim neighbors command. In the command output, look for the **G** flag in the **Option** field. The **G** flag stands for generation identifier. Also run the **show task replication** command to verify the status of GRES and NSR.

Configuring PIM-to-IGMP and PIM-to-MLD Message Translation

- Understanding PIM-to-IGMP and PIM-to-MLD Message Translation on page 4240
- Configuring PIM-to-IGMP Message Translation on page 4241
- Configuring PIM-to-MLD Message Translation on page 4242

Understanding PIM-to-IGMP and PIM-to-MLD Message Translation

Routing devices can translate Protocol Independent Multicast (PIM) join and prune messages into corresponding Internet Group Management Protocol (IGMP) or Multicast Listener Discovery (MLD) report or leave messages. You can use this feature to forward multicast traffic across PIM domains in certain network topologies.

In some network configurations, customers are unable to run PIM between the customer edge-facing PIM domain and the core-facing PIM domain, even though PIM is running in sparse mode within each of these domains. Because PIM is not running between the domains, customers with this configuration cannot use PIM to forward multicast traffic across the domains. Instead, they might want to use IGMP to forward IPv4 multicast traffic, or MLD to forward IPv6 multicast traffic across the domains.

To enable the use of IGMP or MLD to forward multicast traffic across the PIM domains in such topologies, you can configure the rendezvous point (RP) router that resides between the edge domain and core domain to translate PIM join or prune messages received from PIM neighbors on downstream interfaces into corresponding IGMP or MLD report or leave messages. The router then transmits the report or leave messages by proxying them to one or two upstream interfaces that you configure on the RP router. As a result, this feature is sometimes referred to as *PIM-to-IGMP proxy* or *PIM-to-MLD proxy*.

To configure the RP router to translate PIM join or prune messages into IGMP report or leave messages, include the **pim-to-igmp-proxy** statement at the **[edit routing-options multicast]** hierarchy level. Similarly, to configure the RP router to translate PIM join or prune messages into MLD report or leave messages, include the **pim-to-mld-proxy** statement at the **[edit routing-options multicast]** hierarchy level. As part of the configuration, you must specify the full name of at least one, but not more than two, upstream interfaces on which to enable the PIM-to-IGMP proxy or PIM-to-MLD proxy feature.

The following guidelines apply when you configure PIM-to-IGMP or PIM-to-MLD message translation:

- Make sure that the router connecting the PIM edge domain and the PIM core domain is the static or elected RP router.
- Make sure that the RP router is using the PIM sparse mode (PIM-SM) multicast routing protocol.
- When you configure an upstream interface, use the full logical interface specification (for example, **ge-0/0/1.0**) and not just the physical interface specification (**ge-0/0/1**).
- When you configure two upstream interfaces, the RP router transmits the same IGMP or MLD report messages and multicast traffic on both upstream interfaces. As a result,

Copyright © 2016, Juniper Networks, Inc.

make sure that reverse-path forwarding (RPF) is running in the PIM-SM core domain to verify that multicast packets are received on the correct incoming interface and to avoid sending duplicate packets.

- The router transmits IGMP or MLD report messages on one or both upstream interfaces only for the first PIM join message that it receives among all of the downstream interfaces. Similarly, the router transmits IGMP or MLD leave messages on one or both upstream interfaces only if it receives a PIM prune message for the last downstream interface.
- Upstream interfaces support both local sources and remote sources.
- Multicast traffic received from an upstream interface is accepted as if it came from a host.

Configuring PIM-to-IGMP Message Translation

You can configure the rendezvous point (RP) routing device to translate PIM join or prune messages into corresponding IGMP report or leave messages. To do so, include the **pim-to-igmp-proxy** statement at the **[edit routing-options multicast]** hierarchy level:

```
[edit routing-options multicast]
pim-to-igmp-proxy {
  upstream-interface [ interface-names ];
}
```

Enabling the routing device to perform PIM-to-IGMP message translation, also referred to as *PIM-to-IGMP proxy*, is useful when you want to use IGMP to forward IPv4 multicast traffic between a PIM sparse mode edge domain and a PIM sparse mode core domain in certain network topologies.

Before you begin configuring PIM-to-IGMP message translation:

- Make sure that the routing device connecting the PIM edge domain and that the PIM core domain is the static or elected RP routing device.
- Make sure that the PIM sparse mode (PIM-SM) routing protocol is running on the RP routing device.
- If you plan to configure two upstream interfaces, make sure that reverse-path forwarding (RPF) is running in the PIM-SM core domain. Because the RP router transmits the same IGMP messages and multicast traffic on both upstream interfaces, you need to run RPF to verify that multicast packets are received on the correct incoming interface and to avoid sending duplicate packets.

To configure the RP routing device to translate PIM join or prune messages into corresponding IGMP report or leave messages:

1. Include the **pim-to-igmp-proxy** statement, specifying the names of one or two logical interfaces to function as the upstream interfaces on which the routing device transmits IGMP report or leave messages.

   The following example configures PIM-to-IGMP message translation on a single upstream interface, **ge-0/1/0.1**.

Copyright © 2016, Juniper Networks, Inc.

```
[edit routing-options multicast]
user@host# set pim-to-igmp-proxy upstream-interface ge-0/1/0.1
```

The following example configures PIM-to-IGMP message translation on two upstream interfaces, **ge-0/1/0.1** and **ge-0/1/0.2**. You must include the logical interface names within square brackets ([ ]) when you configure a set of two upstream interfaces.

```
[edit routing-options multicast]
user@host# set pim-to-igmp-proxy upstream-interface [ge-0/1/0.1 ge-0/1/0.2]
```

2. Use the **show multicast pim-to-igmp-proxy** command to display the PIM-to-IGMP proxy state (enabled or disabled) and the name or names of the configured upstream interfaces.

```
user@host# run show multicast pim-to-igmp-proxy
Proxy state: enabled
ge-0/1/0.1
ge-0/1/0.2
```

Configuring PIM-to-MLD Message Translation

You can configure the rendezvous point (RP) routing device to translate PIM join or prune messages into corresponding MLD report or leave messages. To do so, include the **pim-to-mld-proxy** statement at the **[edit routing-options multicast]** hierarchy level:

```
[edit routing-options multicast]
pim-to-mld-proxy {
  upstream-interface [ interface-names ];
}
```

Enabling the routing device to perform PIM-to-MLD message translation, also referred to as *PIM-to-MLD proxy*, is useful when you want to use MLD to forward IPv6 multicast traffic between a PIM sparse mode edge domain and a PIM sparse mode core domain in certain network topologies.

Before you begin configuring PIM-to-MLD message translation:

- Make sure that the routing device connecting the PIM edge domain and that the PIM core domain is the static or elected RP routing device.
- Make sure that the PIM sparse mode (PIM-SM) routing protocol is running on the RP routing device.
- If you plan to configure two upstream interfaces, make sure that reverse-path forwarding (RPF) is running in the PIM-SM core domain. Because the RP routing device transmits the same MLD messages and multicast traffic on both upstream interfaces, you need to run RPF to verify that multicast packets are received on the correct incoming interface and to avoid sending duplicate packets.

To configure the RP routing device to translate PIM join or prune messages into corresponding MLD report or leave messages:

1. Include the **pim-to-mld-proxy** statement, specifying the names of one or two logical interfaces to function as the upstream interfaces on which the router transmits MLD report or leave messages.

Copyright © 2016, Juniper Networks, Inc.

The following example configures PIM-to-MLD message translation on a single upstream interface, **ge-0/5/0.1**.

```
[edit routing-options multicast]
user@host# set pim-to-mld-proxy upstream-interface ge-0/5/0.1
```

The following example configures PIM-to-MLD message translation on two upstream interfaces, **ge-0/5/0.1** and **ge-0/5/0.2**. You must include the logical interface names within square brackets ([ ]) when you configure a set of two upstream interfaces.

```
[edit routing-options multicast]
user@host# set pim-to-mld-proxy upstream-interface [ge-0/5/0.1 ge-0/5/0.2]
```

2. Use the **show multicast pim-to-mld-proxy** command to display the PIM-to-MLD proxy state (enabled or disabled) and the name or names of the configured upstream interfaces.

```
user@host# run show multicast pim-to-mld-proxy
Proxy state: enabled
ge-0/5/0.1
ge-0/5/0.2
```

Understanding Pragmatic General Multicast

Multicast applications often require real-time operation. These applications cannot take advantage of Transmission Control Protocol (TCP) reliability features such as sequencing, retransmission, and flow control through windowing between sender and receiver. The User Datagram Protocol (UDP), the major transport layer alternative to TCP, is not as reliable as it needs to be for multicast traffic. Pragmatic General Multicast (PGM) is a special protocol layer for multicast traffic that can be used between the IP layer and the multicast application to add reliability to multicast traffic. PGM allows a receiver to detect missing information in all cases and to request replacement information if the receiver application requires it. PGM is Internet Protocol number 113.

Although PGM mainly deals with the operation of multicast source and receiver, PGM-enabled routers (called PGM network elements) play a *router assistance* role in the initial delivery and potential replacement of multicast traffic. PGM routers are not mandatory in PGM, but they can provide the following benefits when placed anywhere between the source and receivers:

- Reduce the load on the multicast source by aggregating duplicate messages to the source. PGM routers are required to perform this function.
- Limit the flooding of repair data (replacement information) to only those downstream receivers that requested the repair data. PGM routers are required to perform this function.

Copyright © 2016, Juniper Networks, Inc.

- Act as designated local repairers (DLRs) by caching the repair data and resending it to receivers that request it later. DLR functions are a PGM option, and PGM routers are not required to perform this role.

PGM adds reliability to multicast traffic streams. It is not a complete multicast protocol like the Distance Vector Routing Multicast Protocol (DVMRP) or Protocol Independent Multicast (PIM). Adding PGM to a router does not enable the router to perform multicast functions. Instead, a PGM router with multicast capabilities and a preconfigured multicast protocol such as PIM can offer more reliable multicast services to PGM sources and receivers. PGM is not an alternative to multicast routing protocols, but an enhancement of the multicast capabilities already present and configured on the router.

PGM Architecture and PGM Routers

PGM is defined in RFC 3208 and forms a reliable transport layer for multicast applications. Almost any multicast application can use PGM. Applications most suitable for PGM include stock market ticker update information, news reports, weather warnings, and other information that must reach multiple listeners in its entirety and in a timely fashion.

The basic PGM architecture consists of a multicast content source, one or more receivers, and zero or more routers between the source and receivers. All end devices must be PGM-enabled, although there can be non-PGM routers between the source and receiver. If all routers are non-PGM routers, then no routers are capable of the PGM router assistance function, and all PGM functions take place directly between the source and receiver.

PGM sources send sequenced content in sessions to receivers, using multicast protocols. Other, non-PGM protocols allow receivers to learn about a particular source, its sessions, and its location. PGM receivers listen to multicast original data (ODATA), detect missing content through the sequence numbers, and send unicast negative acknowledgments (NAKs) back to the source. NAKs are answered by multicast NAK confirmations (NCFs), which suppress any NAKs from receivers on the same subnet that have not yet sent a NAK upstream. The source sends multicast repair data (RDATA) to receivers containing the missing content. PGM routers assist in this process by making sure that the negative acknowledgments follow the same path as the outbound content upstream to the source, and by suppressing duplicate negative acknowledgments and repair information.

PGM sources must maintain a “sliding window” of retransmittable information. There is no concept of group membership in PGM, so receivers never need to communicate with the source unless they request repair data with a negative acknowledgment. However, this means that the PGM source determines the window size for each receiver, in contrast to almost all other protocols, and requires a certain processing power in each receiver. The absence of positive receiver-to-source acknowledgments also means that PGM scales well and cuts down on control message traffic that can easily overwhelm a multicast network.

PGM receivers can start receiving a PGM session from a PGM source at any time and request any missing previous information that the receiving application needs. If the session is not long enough or if the transmit window is too small so that the source does not maintain a long session history, the receiver cannot get all required information.

Copyright © 2016, Juniper Networks, Inc.

PGM-Enabled Source

A PGM-enabled source of multicast content generates sequenced packets of ODATA that are multicast to receivers. Interleaved with the content packets are source path messages (SPMs), which tell PGM routers and receivers about their upstream next-hop PGM device—either another PGM router or the PGM source.

ODATA packets and SPMs are multicast from the source. A PGM router always appends its own IP address to the SPM before it is multicast on the downstream interfaces. The SPMs are sent by the source and upstream PGM routers with the router alert option set in the IP headers so that PGM routers do not have to examine every packet in the session for SPM packets.

The PGM source acknowledges a received NAK by multicasting NAK confirmations (NCFs) downstream to the next PGM device on the path to the receiver. NCFs make sure that PGM routers and receivers do not bombard sources with NAKs. Downstream PGM routers suppress all subsequent NAKs that indicate the same missing information once one NCF is received from the upstream device.

The PGM source also responds to NAKs by multicasting RDATA packets with the same sequence number as the one indicated by the NAK. RDATA packets have the router alert option set in the IP header so that PGM routers can distinguish them from ODATA packets.

PGM sources organize their packets in sessions. PGM sources are not required to retain copies of information older than the current session, although they might. Long sessions are not necessarily kept on the source in their entirety.

PGM sources identify themselves through a global source ID (GSID). This globally unique source identifier is formed from the low-order 48 bits of the Message Digest 5 (MD5) signature of the Domain Name System (DNS) name of the source.

PGM-Enabled Receivers

The PGM architecture requires one or more PGM-enabled receivers of the multicast content generated by a PGM source. PGM receivers accept all types of downstream PGM messages: ODATA, SPMs, NCFs, and RDATA.

Receivers process the ODATA packets as they arrive from the source, constantly checking the 32-bit sequence number in the ODATA PGM header for gaps in the sequence. If the receiver detects missing information, it generates a NAK for that sequence number. The NAK is unicast upstream to the PGM next hop, which is a router or the source, as determined by the last address in the received SPM.

A receiver detects that its NAK was received by the PGM next hop when it receives an NCF in response to its NAK. If several receivers on a subnet are missing the same ODATA packet, receivers getting an NCF for the packet before sending a NAK suppress the NAK. If a receiver does not get an NCF in response to a NAK, the receiving application can send a NAK again or continue, with the certainty that information is missing.

After the NCF, PGM receivers are sent an RDATA packet with the same sequence number indicated in the NAK and a copy of the missing ODATA. NCFs and RDATA can originate

Copyright © 2016, Juniper Networks, Inc.

from the source or a router acting as a designated local repairer (DLR) for a subnet. The receiver now has complete information about what is missing.

PGM receivers can request almost anything from the PGM source. However, because the source determines the window size, there is no guarantee that older information is available.

PGM-Enabled Routers

Multicast-capable routers can implement the PGM router assistance functions, although not all multicast routers must be PGM-enabled routers. Mandatory PGM router assistance functions include aggregating duplicate NAKs sent to the source to reduce the load on the multicast source, generating NCFs in response to NAKs, and flooding RDATA packets to only those downstream receivers that requested it with a NAK. Optionally, a PGM router can be a DLR, caching PGM information and cutting down on network traffic by resending RDATA packets locally.

There can be zero or more PGM-enabled network elements (routers) between the source and receiver. If there are no PGM routers between the source and receiver, then all PGM messages flow directly between the source and receiver, and no router assistance functions are possible. Both PGM and non-PGM routers can be freely mixed on a network because PGM is a transport layer protocol and is not involved with router multicast functions.

PGM routers also receive SPMs from the source or an upstream PGM router and forward them downstream, inserting the router's own downstream IP interface address into the SPM so that receivers always know their upstream PGM next hop.

When a PGM router receives unicast NAKs from a downstream PGM router or receiver, the router unicasts one NAK for each missing sequence number to the next-hop PGM device upstream toward the source. The address of the PGM next-hop device is determined by received SPMs.

The PGM router multicasts NCFs in response to received NAKs on the downstream interfaces that received the NAKs. NCFs are not multicast on interfaces that have not received NAKs.

PGM routers must multicast all ODATA and RDATA packets that they receive from upstream PGM devices. Normal multicast protocols are used to determine downstream interfaces.

If the PGM router is a DLR, it responds to received NAKs with an NCF and with its own RDATA packet. NAKs are not forwarded upstream from a DLR.

Figure 189 shows the overall PGM architecture and the role of PGM-enabled routers.

Copyright © 2016, Juniper Networks, Inc.

Figure 189: PGM Architecture and General Operation

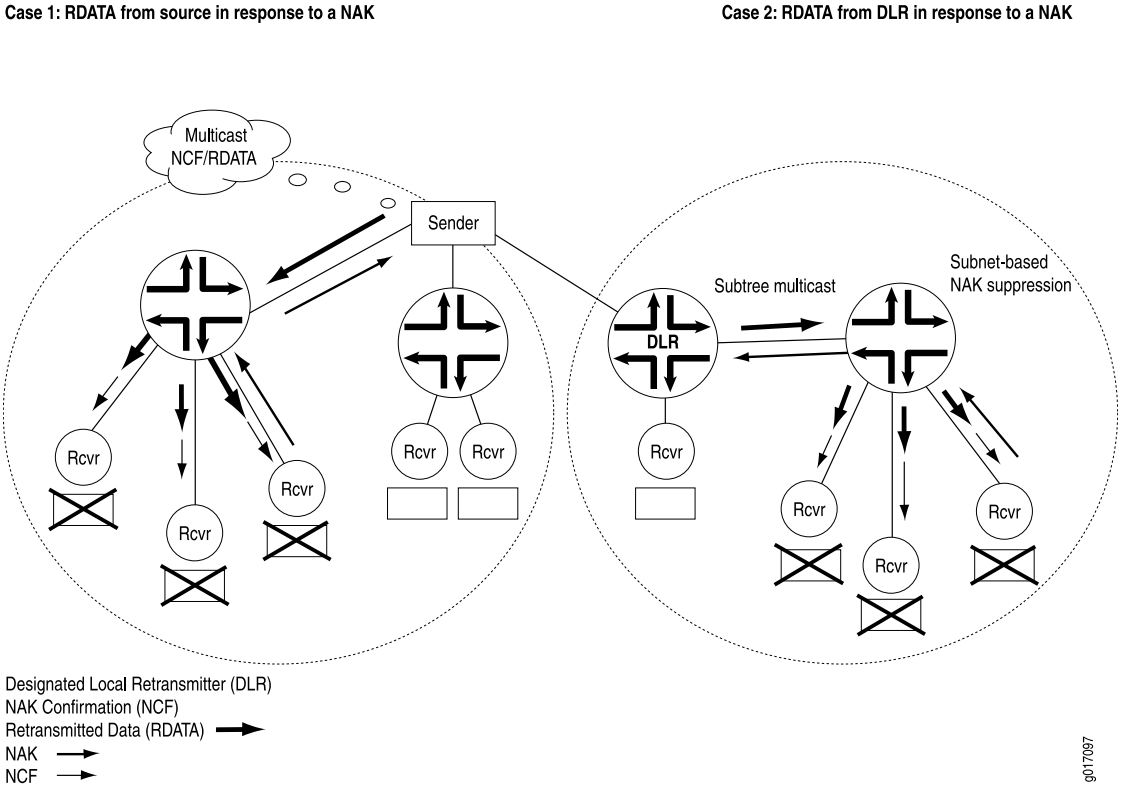

Figure 38 shows only NAKs, NCFs, and RDATA flows. RDATA can come from either the source (left) or a DLR router (right). In both cases, unicast NAKs from a receiver are forwarded upstream by the routers, and multicast NCFs are generated downstream. Subnet NAK suppression is shown, as well as RDATA from the source or DLR sent only to the portions of the network requesting it.

PGM Configuration Guidelines

Pragmatic General Multicast (PGM) allows the router to participate in defined PGM router assistance functions between PGM-enabled sources and receivers. Although PGM is a transport layer protocol and does not do IP packet routing, PGM must be explicitly configured on the router.

To enable PGM globally on the router, include the **pgm** statement:

```
pgm;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems** *logical-system-name* **protocols]**

To trace the operation of PGM, include the **traceoptions** statement:

```
traceoptions {
    flag flag <flag-modifier>;
```

```
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols** pgm**]**
- **[edit logical-systems** *logical-system-name* **protocols** pgm**]**

You can specify the following PGM-specific options in the **flag** statement:

- **all**—Trace all PGM packets.
- **init**—Trace all PGM initialization events.
- **packets**—Trace all PGM packet processing.
- **parser**—Trace all PGM parser processing.
- **route-socket**—Trace all PGM route-socket events.
- **show**—Trace all PGM **show** command servicing.
- **state**—Trace all PGM state transitions.

By default, PGM is enabled on every interface of the router, but global, explicit configuration is required. No options are available for PGM operation.

CHAPTER 187

Connecting Routing Domains Using MSDP

- Examples: Configuring MSDP on page 4253

Examples: Configuring MSDP

- Configuring MSDP on page 4253
- Example: Configuring MSDP in a Routing Instance on page 4254
- Configuring the Interface to Accept Traffic from a Remote Source on page 4262
- Example: Configuring MSDP with Active Source Limits and Mesh Groups on page 4262
- Tracing MSDP Protocol Traffic on page 4268
- Disabling MSDP on page 4269

Configuring MSDP

To configure the Multicast Source Discovery Protocol (MSDP), include the **msdp** statement:

```
msdp {
  disable;
  active-source-limit {
    maximum number;
    threshold number;
  }
  data-encapsulation (disable | enable);
  export [ policy-names ];
  group group-name {
    ... group-configuration ...
  }
  import [ policy-names ];
  local-address address;
  peer address {
    ... peer-configuration ...
  }
  rib-group group-name;
  source ip-prefix</prefix-length> {
    active-source-limit {
      maximum number;
      threshold number;
    }
  }
```

Copyright © 2016, Juniper Networks, Inc.

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier > <disable>;
}
group group-name {
  disable;
  export [ policy-names ];
  import [ policy-names ];
  local-address address;
  mode (mesh-group | standard);
  peer address {
    ... same statements as at the [edit protocols msdp peer address] hierarchy level shown
      just following ...
  }
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
peer address {
  disable;
  active-source-limit {
    maximum number;
    threshold number;
  }
  authentication-key peer-key;
  default-peer;
  export [ policy-names ];
  import [ policy-names ];
  local-address address;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit routing-instances *routing-instance-name* protocols]**
- **[edit logical-systems *logical-system-name* protocols]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]**

By default, MSDP is disabled.

Example: Configuring MSDP in a Routing Instance

This example shows how to configure MSDP in a VRF instance.

- Requirements on page 4255
- Overview on page 4255

Copyright © 2016, Juniper Networks, Inc.

- Configuration on page 4258
- Verification on page 4261

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable PIM. See "PIM Overview" on page 4089.

Overview

You can configure MSDP in the following types of instances:

- Forwarding
- No forwarding
- Virtual router
- VPLS
- VRF

The main use of MSDP in a routing instance is to support anycast RPs in the network, which allows you to configure redundant RPs. Anycast RP addressing requires MSDP support to synchronize the active sources between RPs.

Copyright © 2016, Juniper Networks, Inc.

This example includes the following MSDP settings.

- **authentication-key**—By default, multicast routers accept and process any properly formatted MSDP messages from the configured peer address. This default behavior might violate the security policies in many organizations because MSDP messages by definition come from another routing domain beyond the control of the security practices of the multicast router's organization.

  The router can authenticate MSDP messages using the TCP message digest 5 (MD5) signature option for MSDP peering sessions. This authentication provides protection against spoofed packets being introduced into an MSDP peering session. Two organizations implementing MSDP authentication must decide on a human-readable key on both peers. This key is included in the MD5 signature computation for each MSDP segment sent between the two peers.

  You configure an MSDP authentication key on a per-peer basis, whether the MSDP peer is defined in a group or individually. If you configure different authentication keys for the same peer one in a group and one individually, the individual key is used.

  The peer key can be a text string up to 16 letters and digits long. Strings can include any ASCII characters with the exception of (,), &, and [. If you include spaces in an MSDP authentication key, enclose all characters in quotation marks (“ ”).

  Adding, removing, or changing an MSDP authentication key in a peering session resets the existing MSDP session and establishes a new session between the affected MSDP peers. This immediate session termination prevents excessive retransmissions and eventual session timeouts due to mismatched keys.

- **import** and **export**—All routing protocols use the routing table to store the routes that they learn and to determine which routes they advertise in their protocol packets. Routing policy allows you to control which routes the routing protocols store in, and retrieve from, the routing table.

  You can configure routing policy globally, for a group, or for an individual peer. This example shows how to configure the policy for an individual peer.

  If you configure routing policy at the group level, each peer in a group inherits the group's routing policy.

  The **import** statement applies policies to source-active messages being imported into the source-active cache from MSDP. The **export** statement applies policies to source-active messages being exported from the source-active cache into MSDP. If you specify more than one policy, they are evaluated in the order specified, from first to last, and the first matching policy is applied to the route. If no match is found for the import policy, MSDP shares with the routing table only those routes that were learned from MSDP routers. If no match is found for the export policy, the default MSDP export policy is applied to entries in the source-active cache. See Table 387 for a list of match conditions.

Table 387: MSDP Source-Active Message Filter Match Conditions

Match Condition	Matches On
interface	Router interface or interfaces specified by name or IP address

Copyright © 2016, Juniper Networks, Inc.

Table 387: MSDP Source-Active Message Filter Match Conditions *(continued)*

Match Condition	Matches On
neighbor	Neighbor address (the source address in the IP header of the source-active message)
route-filter	Multicast group address embedded in the source-active message
source-address-filter	Multicast source address embedded in the source-active message

- **local-address**—Identifies the address of the router you are configuring as an MSDP router (the local router). When you configure MSDP, the **local-address** statement is required. The router must also be a Protocol Independent Multicast (PIM) sparse-mode rendezvous point (RP).
- **peer**—An MSDP router must know which routers are its peers. You define the peer relationships explicitly by configuring the neighboring routers that are the MSDP peers of the local router. After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. You must configure at least one peer for MSDP to function. When you configure MSDP, the **peer** statement is required. The router must also be a Protocol Independent Multicast (PIM) sparse-mode rendezvous point (RP).

  You can arrange MSDP peers into groups. Each group must contain at least one peer. Arranging peers into groups is useful if you want to block sources from some peers and accept them from others, or set tracing options on one group and not others. This example shows how to configure the MSDP peers in groups. If you configure MSDP peers in a group, each peer in a group inherits all group-level options.

Figure 190 shows the topology for this example.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement bgp-to-ospf term 1 from protocol bgp
set policy-options policy-statement bgp-to-ospf term 1 then accept
set policy-options policy-statement sa-filter term bad-groups from route-filter 224.0.1.2/32
    exact
set policy-options policy-statement sa-filter term bad-groups from route-filter
    224.77.0.0/16 orlonger
set policy-options policy-statement sa-filter term bad-groups then reject
set policy-options policy-statement sa-filter term bad-sources from source-address-filter
    10.0.0.0/8 orlonger
set policy-options policy-statement sa-filter term bad-sources from source-address-filter
    127.0.0.0/8 orlonger
set policy-options policy-statement sa-filter term bad-sources then reject
set policy-options policy-statement sa-filter term accept-everything-else then accept
set routing-instances VPN-100 instance-type vrf
set routing-instances VPN-100 interface ge-0/0/0.100
set routing-instances VPN-100 interface lo0.100
set routing-instances VPN-100 route-distinguisher 10.255.120.36:100
set routing-instances VPN-100 vrf-target target:100:1
set routing-instances VPN-100 protocols ospf export bgp-to-ospf
set routing-instances VPN-100 protocols ospf area 0.0.0.0 interface lo0.100
set routing-instances VPN-100 protocols ospf area 0.0.0.0 interface ge-0/0/0.100
set routing-instances VPN-100 protocols pim rp static address 11.11.47.100
set routing-instances VPN-100 protocols pim interface lo0.100 mode sparse-dense
set routing-instances VPN-100 protocols pim interface lo0.100 version 2
set routing-instances VPN-100 protocols pim interface ge-0/0/0.100 mode sparse-dense
set routing-instances VPN-100 protocols pim interface ge-0/0/0.100 version 2
```

Copyright © 2016, Juniper Networks, Inc.

```
set routing-instances VPN-100 protocols msdp export sa-filter
set routing-instances VPN-100 protocols msdp import sa-filter
set routing-instances VPN-100 protocols msdp group 100 local-address 10.10.47.100
set routing-instances VPN-100 protocols msdp group 100 peer 10.255.120.39
  authentication-key “New York”
set routing-instances VPN-100 protocols msdp group to_pe local-address 10.10.47.100
set routing-instances VPN-100 protocols msdp group to_pe peer 11.11.47.100
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an MSDP routing instance:

1. Configure the BGP export policy.

   ```
   [edit policy-options]
   user@host# set policy-statement bgp-to-ospf term 1 from protocol bgp
   user@host# set policy-statement bgp-to-ospf term 1 then accept
   ```

2. Configure a policy that filters out certain source and group addresses and accepts all other source and group addresses.

   ```
   [edit policy-options]
   user@host# set policy-statement sa-filter term bad-groups from route-filter
     224.0.1.2/32 exact
   user@host# set policy-statement sa-filter term bad-groups from route-filter
     224.0.1.2/32 exact
   user@host# set policy-statement sa-filter term bad-groups from route-filter
     224.77.0.0/16 orlonger
   user@host# set policy-statement sa-filter term bad-groups then reject
   user@host# set policy-statement sa-filter term bad-sources from
     source-address-filter 10.0.0.0/8 orlonger
   user@host# set policy-statement sa-filter term bad-sources from
     source-address-filter 127.0.0.0/8 orlonger
   user@host# set policy-statement sa-filter term bad-sources then reject
   user@host# set policy-statement sa-filter term accept-everything-else then accept
   ```

3. Configure the routing instance type and interfaces.

   ```
   [edit routing-instances]
   user@host# set VPN-100 instance-type vrf
   user@host# set VPN-100 interface ge-0/0/0.100
   user@host# set VPN-100 interface lo0.100
   ```

4. Configure the routing instance route distinguisher and VRF target.

   ```
   [edit routing-instances]
   user@host# set VPN-100 route-distinguisher 10.255.120.36:100
   user@host# set VPN-100 vrf-target target:100:1
   ```

5. Configure OSPF in the routing instance.

   ```
   [edit routing-instances]
   user@host# set VPN-100 protocols ospf export bgp-to-ospf
   user@host# set VPN-100 protocols ospf area 0.0.0.0 interface lo0.100
   user@host# set VPN-100 protocols ospf area 0.0.0.0 interface ge-0/0/0.100
   ```

6. Configure PIM in the routing instance.

Copyright © 2016, Juniper Networks, Inc.

```
[edit routing-instances]
user@host# set VPN-100 protocols pim rp static address 11.11.47.100
user@host# set VPN-100 protocols pim interface lo0.100 mode sparse-dense
user@host# set VPN-100 protocols pim interface lo0.100 version 2
user@host# set VPN-100 protocols pim interface ge-0/0/0.100 mode sparse-dense
user@host# set VPN-100 protocols pim interface ge-0/0/0.100 version 2
```

7. Configure MSDP in the routing instance.

```
[edit routing-instances]
user@host# set VPN-100 protocols msdp export sa-filter
user@host# set VPN-100 protocols msdp import sa-filter
user@host# set VPN-100 protocols msdp group 100 local-address 10.10.47.100
user@host# set VPN-100 protocols msdp group 100 peer 10.255.120.39
  authentication-key "New York"
[edit routing-instances]
user@host# set VPN-100 protocols msdp group to_pe local-address 10.10.47.100
[edit routing-instances]
user@host# set VPN-100 protocols msdp group to_pe peer 11.11.47.100
```

8. If you are done configuring the device, commit the configuration.

```
[edit routing-instances]
user@host# commit
```

Results

Confirm your configuration by entering the **show policy-options** command and the **show routing-instances** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
policy-statement bgp-to-ospf {
  term 1 {
    from protocol bgp;
    then accept;
  }
}
  policy-statement sa-filter {
    term bad-groups {
      from {
        route-filter 224.0.1.2/32 exact;
        route-filter 224.77.0.0/16 orlonger;
      }
      then reject;
    }
    term bad-sources {
      from {
        source-address-filter 10.0.0.0/8 orlonger;
        source-address-filter 127.0.0.0/8 orlonger;
      }
      then reject;
    }
    term accept-everything-else {
      then accept;
    }
  }
```

            peer 10.255.120.39 {
               authentication-key "$ABC123"; ## SECRET-DATA
            }
         }
         group to_pe {
            local-address 10.10.47.100;
            peer 11.11.47.100;
         }
      }
   }
}
```

Verification

To verify the configuration, run the following commands:

- **show msdp instance VPN-100**
- **show msdp source-active VPN-100**

Copyright © 2016, Juniper Networks, Inc.

- **show multicast usage instance VPN-100**
- **show route table VPN-100.inet.4**

Configuring the Interface to Accept Traffic from a Remote Source

You can configure an incoming interface to accept traffic from a remote source. A remote source is a source that is not on the same subnet as the incoming interface. This enables the remote source to be learned and advertised by MSDP so that receivers in other MSDP areas can join the source. You do not need to disable RPF checking, but you do need to ensure that the best path to reach the remote source is through the incoming interface.

In this sample configuration, the incoming interface (**ge-1/3/0**) is on a provider edge (PE) router on the receiver side of a multicast VPN.

To accept traffic from a remote source:

1. Edit the incoming interface.

   ```
   [edit protocols pim interface ge-1/3/0.0]
   user@host# set accept-remote-source
   ```

2. If the incoming interface is not the only way to reach the remote source, ensure that the best path to reach the remote source is through the incoming interface. One way to do this is to use AS path prepending on the other possible routes.

   ```
   [edit policy-options policy-statement as-path-prepend term prepend]
   user@host# set from route-filter 192.168.0.0/16 orlonger
   user@host# set from route-filter 172.16.0.0/16 orlonger
   user@host# set then as-path-prepend "1111"
   ```

   Another way to do this might be to configure a static route on the receiver side PE router to the source.

4. After the configuration is committed, use the **show pim statistics** and **show msdp source** commands to verify that the interface is accepting traffic from the remote source.

Example: Configuring MSDP with Active Source Limits and Mesh Groups

This example shows how to configure MSDP to filter source-active messages and limit the flooding of source-active messages.

- Requirements on page 4262
- Overview on page 4263
- Configuration on page 4266
- Verification on page 4268

Requirements

Before you begin:

Copyright © 2016, Juniper Networks, Inc.

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Enable PIM sparse mode. See "PIM Overview" on page 4089.
- Configure the router as a PIM sparse-mode RP. See "Configuring Local PIM RPs" on page 4136.

Overview

A router interested in MSDP messages, such as an RP, might have to process a large number of MSDP messages, especially source-active messages, arriving from other routers. Because of the potential need for a router to examine, process, and create state tables for many MSDP packets, there is a possibility of an MSDP-based denial-of-service (DoS) attack on a router running MSDP. To minimize this possibility, you can configure the router to limit the number of source active messages the router accepts. Also, you can configure a threshold for applying random early detection (RED) to drop some but not all MSDP active source messages.

By default, the router accepts 25,000 source active messages before ignoring the rest. The limit can be from 1 through 1,000,000. The limit is applied to both the number of messages and the number of MSDP peers.

By default, the router accepts 24,000 source-active messages before applying the RED profile to prevent a possible DoS attack. This number can also range from 1 through 1,000,000. The next 1000 messages are screened by the RED profile and the accepted messages processed. If you configure no drop profiles (as this example does not), RED is still in effect and functions as the primary mechanism for managing congestion. In the default RED drop profile, when the packet queue fill-level is 0 percent, the drop probability is 0 percent. When the fill-level is 100 percent, the drop probability is 100 percent.

NOTE: **The router ignores source-active messages with encapsulated TCP packets. Multicast does not use TCP; segments inside source-active messages are most likely the result of worm activity.**

The number configured for the threshold must be less than the number configured for the maximum number of active MSDP sources.

You can configure an active source limit globally, for a group, or for a peer. If active source limits are configured at multiple levels of the hierarchy (as shown in this example), all are applied.

You can configure an active source limit for an address range as well as for a specific peer. A per-source active source limit uses an IP prefix and prefix length instead of a specific address. You can configure more than one per-source active source limit. The longest match determines the limit.

Copyright © 2016, Juniper Networks, Inc.

Per-source active source limits can be combined with active source limits at the peer, group, and global (instance) hierarchy level. Per-source limits are applied before any other type of active source limit. Limits are tested in the following order:

- Per-source
- Per-peer or group
- Per-instance

An active source message must "pass" all limits established before being accepted. For example, if a source is configured with an active source limit of 10,000 active multicast groups and the instance is configured with a limit of 5000 (and there are no other sources or limits configured), only 5000 active source messages are accepted from this source.

MSDP mesh groups are groups of peers configured in a full-mesh topology that limits the flooding of source-active messages to neighboring peers. Every mesh group member must have a peer connection with every other mesh group member. When a source-active message is received from a mesh group member, the source-active message is always accepted but is not flooded to other members of the same mesh group. However, the source-active message is flooded to non-mesh group peers or members of other mesh groups. By default, standard flooding rules apply if **mesh-group** is not specified.

CAUTION: When configuring MSDP mesh groups, you must configure all members the same way. If you do not configure a full mesh, excessive flooding of source-active messages can occur.

A common application for MSDP mesh groups is peer-reverse-path-forwarding (peer-RPF) check bypass. For example, if there are two MSDP peers inside an autonomous system (AS), and only one of them has an external MSDP session to another AS, the internal MSDP peer often rejects incoming source-active messages relayed by the peer with the external link. Rejection occurs because the external MSDP peer must be reachable by the internal MSDP peer through the next hop toward the source in another AS, and this next-hop condition is not certain. To prevent rejections, configure an MSDP mesh group on the internal MSDP peer so it always accepts source-active messages.

NOTE: An alternative way to bypass the peer-RPF check is to configure a default peer. In networks with only one MSDP peer, especially stub networks, the source-active message always needs to be accepted. An MSDP default peer is an MSDP peer from which all source-active messages are accepted without performing the peer-RPF check. You can establish a default peer at the peer or group level by including the default-peer statement.

Table 388 explains how flooding is handled by peers in this example. .

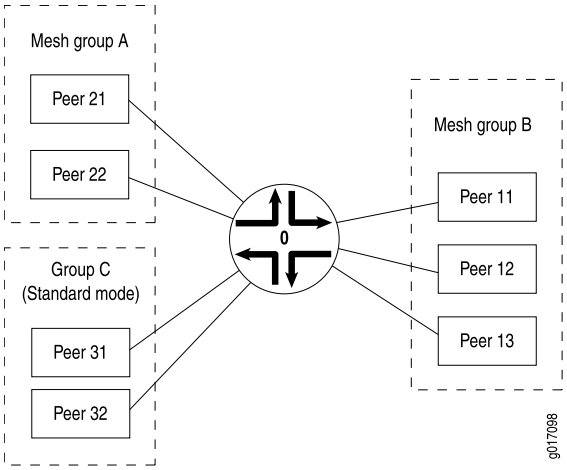
Copyright © 2016, Juniper Networks, Inc.

Table 388: Source-Active Message Flooding Explanation

Source-Active Message Received From	Source-Active Message Flooded To	Source-Active Message Not Flooded To
Peer 21	Peer 11, Peer 12, Peer 13, Peer 31, Peer 32	Peer 22
Peer 11	Peer 21, Peer 22, Peer 31, Peer 32	Peer 12, Peer 13
Peer 31	Peer 21, Peer 22, Peer 11, Peer 12, Peer 13, Peer 32	–

Figure 191 illustrates source-active message flooding between different mesh groups and peers within the same mesh group.

Figure 191: Source-Active Message Flooding



This example includes the following settings:

- **active-source-limit maximum 10000**—Applies a limit of 10,000 active sources to all other peers.
- **data-encapsulation disable**—On an RP router using MSDP, disables the default encapsulation of multicast data received in MSDP register messages inside MSDP source-active messages.

  MSDP data encapsulation mainly concerns bursty sources of multicast traffic. Sources that send only one packet every few minutes have trouble with the timeout of state relationships between sources and their multicast groups (S,G). Routers lose data while they attempt to reestablish (S,G) state tables. As a result, multicast register messages contain data, and this data encapsulation in MSDP source-active messages can be turned on or off through configuration.

  By default, MSDP data encapsulation is enabled. An RP running MSDP takes the data packets arriving in the source's register message and encapsulates the data inside an MSDP source-active message.

Copyright © 2016, Juniper Networks, Inc.

However, data encapsulation creates both a multicast forwarding cache entry in the **inet.1** table (this is also the forwarding table) and a routing table entry in the **inet.4** table. Without data encapsulation, MSDP creates only a routing table entry in the **inet.4** table. In some circumstances, such as the presence of Internet worms or other forms of DoS attack, the router's forwarding table might fill up with these entries. To prevent the forwarding table from filling up with MSDP entries, you can configure the router not to use MSDP data encapsulation. However, if you disable data encapsulation, the router ignores and discards the encapsulated data. Without data encapsulation, multicast applications with bursty sources having transmit intervals greater than about 3 minutes might not work well.

- **group MSDP-group local-address 10.1.2.3**—Specifies the address of the local router (this router).
- **group MSDP-group mode mesh-group**—Specifies that all peers belonging to the **MSDP-group** group are mesh group members.
- **group MSDP-group peer 10.10.10.10**—Prevents the sending of source-active messages to neighboring peer 10.10.10.10.
- **group MSDP-group peer 10.10.10.10 active-source-limit maximum 7500**—Applies a limit of 7500 active sources to MSDP peer 10.10.10.10 in group **MSDP-group**.
- **peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000**—Applies a threshhold of 4000 active sources and a limit of 5000 active sources to MSDP peer 10.0.0.1.
- **source 10.1.0.0/16 active-source-limit maximum 500**—Applies a limit of 500 active sources to any source on the 10.1.0.0/16 network.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols msdp data-encapsulation disable
set protocols msdp active-source-limit maximum 10000
set protocols msdp peer 10.0.0.1 active-source-limit maximum 5000
set protocols msdp peer 10.0.0.1 active-source-limit threshold 4000
set protocols msdp source 10.1.0.0/16 active-source-limit maximum 500
set protocols msdp group MSDP-group mode mesh-group
set protocols msdp group MSDP-group local-address 10.1.2.3
set protocols msdp group MSDP-group peer 10.10.10.10 active-source-limit maximum
  7500
```

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure MSDP source active routes and mesh groups:

1. (Optional) Disable data encapsulation.

   ```
   [edit protocols msdp]
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set data-encapsulation disable
```

2. Configure the active source limits.

```
[edit protocols msdp]
user@host# set peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000
user@host# set group MSDP-group peer 10.10.10.10 active-source-limit maximum
  7500
user@host# set active-source-limit maximum 10000
user@host# set source 10.1.0.0/16 active-source-limit maximum 500
```

3. Configure the mesh group.

```
[edit protocols msdp]
user@host# set group MSDP-group mode mesh-group
user@host# set group MSDP-group peer 10.10.10.10
user@host# set group MSDP-group local-address 10.1.2.3
```

4. If you are done configuring the device, commit the configuration.

```
[edit routing-instances]
user@host# commit
```

Results

Confirm your configuration by entering the **show protocols** command.

```
user@host# show protocols
msdp {
  data-encapsulation disable;
  active-source-limit {
    maximum 10000;
  }
  peer 10.0.0.1 {
    active-source-limit {
      maximum 5000;
      threshold 4000;
    }
  }
  source 10.1.0.0/16 {
    active-source-limit {
      maximum 500;
    }
  }
  group MSDP-group {
    mode mesh-group;
    local-address 10.1.2.3;
    peer 10.10.10.10 {
      active-source-limit {
        maximum 7500;
      }
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

Verification

To verify the configuration, run the following commands:

- show msdp source-active
- show msdp statistics

Tracing MSDP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
all	Trace all operations.
general	Trace general events.
keepalive	Trace keepalive messages.
normal	Trace normal events.
packets	Trace all MSDP packets.
policy	Trace policy processing.
route	Trace MSDP changes to the routing table.
source-active	Trace source-active packets.
source-active-request	Trace source-active request packets.
source-active-response	Trace source-active response packets.
state	Trace state transitions.
task	Trace task processing.
timer	Trace timer processing.

Copyright © 2016, Juniper Networks, Inc.

You can configure MSDP tracing for all peers, for all peers in a particular group, or for a particular peer.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on MSDP peers in a particular group. To configure tracing operations for MSDP:

1. (Optional) Configure tracing by including the **traceoptions** statement at the **[edit routing-options]** hierarchy level and set the **all-packets-trace** and **all** flags to trace all protocol packets.

   ```
   [edit routing-options traceoptions]
   user@host# set file all-packets-trace
   user@host# set flag all
   ```

2. Configure the filename for the MSDP trace file.

   ```
   [edit protocols msdp group groupa traceoptions]
   user@host# set file msdp-trace
   ```

3. (Optional) Configure the maximum number of trace files.

   ```
   [edit protocols msdp group groupa traceoptions]
   user@host# set file files 5
   ```

4. (Optional) Configure the maximum size of each trace file.

   ```
   [edit protocols msdp group groupa traceoptions]
   user@host# set file size 1m
   ```

5. (Optional) Enable unrestricted file access.

   ```
   [edit protocols msdp group groupa traceoptions]
   user@host# set file world-readable
   ```

6. Configure tracing flags. Suppose you are troubleshooting issues with the source-active cache for **groupa**. The following example shows how to trace messages associated with the group address.

   ```
   [edit protocols msdp group groupa traceoptions]
   user@host# set flag source-active | match 230.0.0.3
   ```

7. View the trace file.

   ```
   user@host> file list /var/log
   user@host> file show /var/log/msdp-trace
   ```

Disabling MSDP

To disable MSDP on the router, include the **disable** statement:

```
disable;
```

You can disable MSDP globally for all peers, for all peers in a group, or for an individual peer.

- Globally for all MSDP peers at the following hierarchy levels:

Copyright © 2016, Juniper Networks, Inc.

- [edit protocols msdp]
- [edit logical-systems *logical-system-name* protocols msdp]
- [edit routing-instances *routing-instance-name* protocols msdp]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp]

- For all peers in a group at the following hierarchy levels:
  - [edit protocols msdp group *group-name*]
  - [edit logical-systems *logical-system-name* protocols msdp group *group-name*]
  - [edit routing-instances *routing-instance-name* protocols msdp group *group-name*]
  - [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp group *group-name*]
- For an individual peer at the following hierarchy levels:
  - [edit protocols msdp peer *address*]
  - [edit protocols msdp group *group-name* peer *address*]
  - [edit logical-systems *logical-system-name* protocols msdp peer *address*]
  - [edit logical-systems *logical-system-name* protocols msdp group *group-name* peer *address*]
  - [edit routing-instances *routing-instance-name* protocols msdp peer *address*]
  - [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp peer *address*]
  - [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp group *group-name* peer *address*]

If you disable MSDP at the group level, each peer in the group is disabled.

Copyright © 2016, Juniper Networks, Inc.

CHAPTER 188

Handling Session Announcements with SAP

- Configuring the Session Announcement Protocol on page 4271

Configuring the Session Announcement Protocol

The SAP and SDP protocols associate multicast session names with multicast traffic addresses. Only SAP has configuration parameters that users can change. Enabling SAP allows the router to receive announcements about multimedia and other multicast sessions.

Junos OS supports the following SAP and SDP standards:

- RFC 2327, *SDP Session Description Protocol*
- RFC 2974, *Session Announcement Protocol*

Before you begin:

1. Determine whether the router is directly attached to any multicast sources. Receivers must be able to locate these sources.
2. Determine whether the router is directly attached to any multicast group receivers. If receivers are present, IGMP is needed.
3. Determine whether to configure multicast to use sparse, dense, or sparse-dense mode. Each mode has different configuration considerations.
4. Determine the address of the RP if sparse or sparse-dense mode is used.
5. Determine whether to locate the RP with the static configuration, BSR, or auto-RP method.
6. Determine whether to configure multicast to use its own RPF routing table when configuring PIM in sparse, dense, or sparse-dense mode.

To enable SAP and the receipt of session announcements, include the **sap** statement:

```
sap {
  disable;
  listen address <port port>;
}
```

Copyright © 2016, Juniper Networks, Inc.

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

By default, SAP listens to the address and port 224.2.127.254:9875 for session advertisements. To add other addresses or pairs of address and port, include one or more **listen** statements.

Sessions established by SDP, SAP's higher-layer protocol, time out after 60 minutes.

To monitor the operation, use the show sap listen command.

Related Documentation

- show sap listen on page 4834

CHAPTER 189

Facilitating Multicast Delivery Across Unicast-Only Networks with AMT

- Example: Configuring Automatic IP Multicast Without Explicit Tunnels on page 4273

Example: Configuring Automatic IP Multicast Without Explicit Tunnels

- Understanding AMT on page 4273
- AMT Applications on page 4274
- AMT Operation on page 4276
- Configuring the AMT Protocol on page 4277
- Configuring Default IGMP Parameters for AMT Interfaces on page 4279
- Example: Configuring the AMT Protocol on page 4281

Understanding AMT

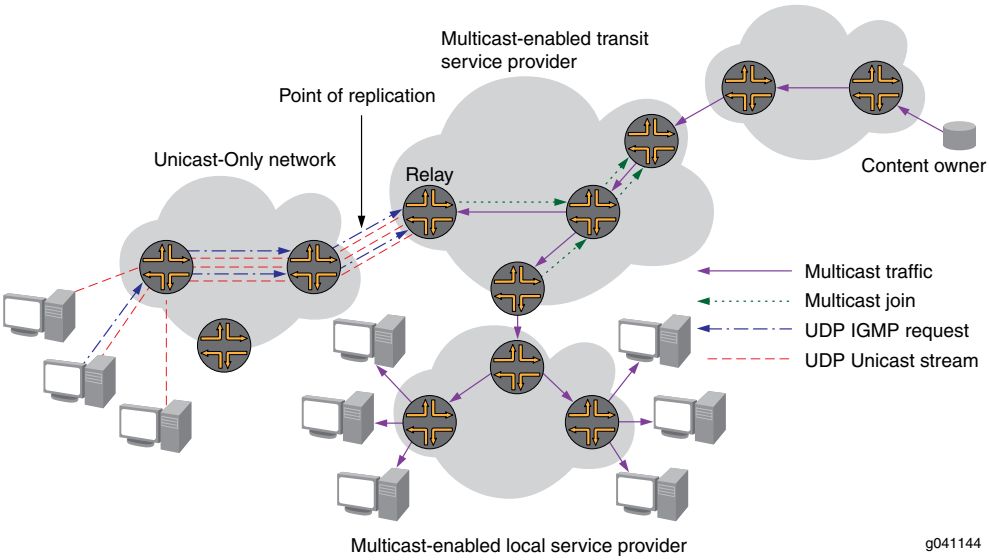
Automatic Multicast Tunneling (AMT) facilitates dynamic multicast connectivity between multicast-enabled networks across islands of unicast-only networks. Such connectivity enables service providers, content providers, and their customers to participate in delivering multicast traffic even if they lack end-to-end multicast connectivity.

AMT is supported on MX Series Ethernet Services Routers except the MX80 router and all Modular Port Concentrators (MPCs) that use the Junos Trio chipset. AMT supports graceful restart (GR) but does not support Graceful Routing Engine switchover (GRES).

AMT dynamically establishes unicast-encapsulated tunnels between well-known multicast-enabled relay points (AMT relays) and network points reachable only through unicast (AMT gateways). Figure 192 shows the Automatic Multicast Tunneling Connectivity.

Copyright © 2016, Juniper Networks, Inc.

Figure 192: Automatic Multicast Tunneling Connectivity



The AMT protocol provides discovery and handshaking between relays and gateways to establish tunnels dynamically without requiring explicit per-tunnel configuration.

AMT relays are typically routers with native IP multicast connectivity that aggregate a potentially large number of AMT tunnels.

The Junos OS implementation supports the following AMT relay functions:

- IPv4 multicast traffic and IPv4 encapsulation
- Well-known sources located on the multicast network
- Prevention of denial-of-service attacks by quickly discarding multicast packets that are sourced through a gateway.
- Per-route replication to the full fan-out of all AMT tunnels desired
- The ability to collect normal interface statistics on AMT tunnels

Multicast sources located behind AMT gateways are not supported."Example: Configuring the AMT Protocol" on page 4281"Example: Configuring the AMT Protocol" on page 4281

AMT supports PIM sparse mode. AMT does not support dense mode operation.

AMT Applications

Transit service providers have a challenge in the Internet because many local service providers are not multicast-enabled. The challenge is how to entice content owners to transmit video and other multicast traffic across their backbones. The cost model for the content owners might be prohibitively high if they have to pay for unicast streams for the majority of their subscribers.

Until more local providers are multicast-enabled, there is a transition strategy proposed by the Internet Engineering Task Force (IETF) and implemented in open source software. This strategy is called Automatic IP Multicast Without Explicit Tunnels (AMT). AMT

Copyright © 2016, Juniper Networks, Inc.

involves setting up relays at peering points in multicast networks that can be reached from gateways installed on hosts connected to unicast networks.

Without AMT, when a user who is connected to a unicast-only network wants to receive multicast content, the content owner can allow the user to join through unicast. However, the content owner incurs an added cost because the owner needs extra bandwidth to support the unicast subscribers.

AMT allows any host to receive multicast. On the client end is an AMT gateway that is a single host. Once the gateway has located an AMT relay, which might be a host but is more typically a router, the gateway periodically sends Internet Group Management Protocol (IGMP) messages over a dynamically created UDP tunnel to the relay. AMT relays and gateways cooperate to transmit multicast traffic sourced within the multicast network to end-user sites. AMT relays receive the traffic natively and unicast-encapsulate it to gateways. This allows anyone on the Internet to create a dynamic tunnel to download multicast data streams.

With AMT, a multicast-enabled service provider can offer multicast services to a content owner. When a customer of the unicast-only local provider wants to receive the content and subscribes using an AMT join, the multicast-enabled transit provider can then efficiently transport the content to the unicast-only local provider, which sends it on to the end user.

AMT is an excellent way for transit service providers (who can get access to the content, but do not have many end users) to provide multicast service to content owners, where it would not otherwise be economically feasible. It is also a useful transition strategy for local service providers who do not yet have multicast support on all downstream equipment.

AMT is also useful for connecting two multicast-enabled service providers that are separated by a unicast-only service provider.

Similarly, AMT can be used by local service providers whose networks are multicast-enabled to tunnel multicast traffic over legacy edge devices such as digital subscriber line access multiplexers (DSLAMs) that have limited multicast capabilities.

Technical details of the implementation of AMT are as follows:

- A three-way handshake is used to join groups from unicast receivers to prevent spoofing and denial-of-service (DoS) attacks.
- An AMT relay acting as a replication server joins the multicast group and translates multicast traffic into multiple unicast streams.
- The discovery mechanism uses anycast, enabling the discovery of the relay that is closest to the gateway in the network topology.
- An AMT gateway acting as a client is a host that joins the multicast group.
- Tunnel count limits on relays can limit bandwidth usage and avoid degradation of service.

Copyright © 2016, Juniper Networks, Inc.

AMT is described in detail in Internet draft draft-ietf-mboned-auto-multicast-10.txt, *Automatic IP Multicast Without Explicit Tunnels (AMT)*.

AMT Operation

AMT is used to create multicast tunnels dynamically between multicast-enabled networks across islands of unicast-only networks. To do this, several steps occur sequentially.

1. The AMT relay (typically a router) advertises an anycast address prefix and route into the unicast routing infrastructure.
2. The AMT gateway (a host) sends AMT relay discovery messages to the nearest AMT relay reachable across the unicast-only infrastructure. To reduce the possibility of replay attacks or dictionary attacks, the relay discovery messages contain a cryptographic nonce. A cryptographic nonce is a random number used only once.
3. The closest relay in the topology receives the AMT relay discovery message and returns the nonce from the discovery message in an AMT relay advertisement message. This enables the gateway to learn the relay's unique IP address. The AMT relay now has an address to use for all subsequent (S,G), entries it will join.
4. The AMT gateway sends an AMT request message to the AMT relay's unique IP address to begin the process of joining the (S,G).
5. The AMT relay sends an AMT membership query back to the gateway.
6. The AMT gateway receives the AMT query message and sends an AMT membership update message containing the IGMP join messages.
7. The AMT relay sends a join message toward the source to build a native multicast tree in the native multicast infrastructure.
8. As packets are received from the source, the AMT relay replicates the packets to all interfaces in the outgoing interface list, including the AMT tunnel. The multicast traffic is then encapsulated in unicast AMT multicast data messages.
9. To maintain state in the AMT relay, the AMT gateway sends periodic AMT membership updates.
10. After the tunnel is established, the AMT tunnel state is refreshed with each membership update message sent. The timeout for the refresh messages is 240 seconds.
11. When the AMT gateway leaves the group, the AMT relay can free resources associated with the tunnel.

Note the following operational details:

- The AMT relay creates an AMT pseudo interface (tunnel interface). AMT tunnel interfaces are implemented as generic UDP encapsulation (**ud**) logical interfaces. These logical interfaces have the identifier format **ud-fpc/pic/port.unit**.
- All multicast packets (data and control) are encapsulated in unicast packets. UDP encapsulation is used for all AMT control and data packets using the IANA reserved UDP port number (2268) for AMT.

Copyright © 2016, Juniper Networks, Inc.

- The AMT relay maintains a receiver list for each multicast session. The relay maintains the multicast state for each gateway that has joined a particular group or (S,G) pair.

Configuring the AMT Protocol

To configure the AMT protocol, include the **amt** statement:

```
amt {
  relay {
    family {
      inet {
        anycast-prefix ip-prefix</prefix-length>;
        local-address ip-address;
      }
    }
    secret-key-timeout minutes;
    tunnel-limit number;
  }
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**
- **[edit routing-instances *routing-instance-name* protocols]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]**

NOTE: In the following example, only the **[edit protocols]** hierarchy is identified.

The minimum configuration to enable AMT is to specify the AMT local address and the AMT anycast prefix.

1. To enable the MX Series router to create the UDP encapsulation (**ud**) logical interfaces, include the **bandwidth** statement and specify the bandwidth in gigabits per second.

   ```
   [edit chassis fpc 0 pic 1]
   user@host# set tunnel-services bandwidth 1g
   ```

2. Specify the local address by including the **local-address** statement at the **[edit protocols amt relay family inet]** hierarchy level.

   ```
   [edit protocols amt relay family inet]
   user@host# set local-address 192.168.7.1
   ```

   The local address is used as the IP source of AMT control messages and the source of AMT data tunnel encapsulation. The local address can be configured on any active

Copyright © 2016, Juniper Networks, Inc.

interface. Typically, the IP address of the router's **lo0.0** loopback interface is used for configuring the AMT local address in the default routing instance, and the IP address of the router's **lo0.*n*** loopback interface is used for configuring the AMT local address in VPN routing instances.

3. Specify the AMT anycast address by including the **anycast-prefix** statement at the **[edit protocols amt relay family inet]** hierarchy level.

   ```
   [edit protocols amt relay family inet]
   user@host# set anycast-prefix 192.168.0.0/16
   ```

   The AMT anycast prefix is advertised by unicast routing protocols to route AMT discovery messages to the router from nearby AMT gateways. Typically, the router's **lo0.0** interface loopback address is used for configuring the AMT anycast prefix in the default routing instance, and the router's **lo0.*n*** loopback address is used for configuring the AMT anycast prefix in VPN routing instances. However, the anycast address can be either the primary or secondary **lo0.0** loopback address.

   Ensure that your unicast routing protocol advertises the AMT anycast prefix in the route advertisements. If the AMT anycast prefix is advertised by BGP, ensure that the local autonomous system (AS) number for the AMT relay router is in the AS path leading to the AMT anycast prefix.

4. (Optional) Specify the AMT secret key timeout by including the **secret-key-timeout** statement at the **[edit protocols amt relay]** hierarchy level. In the following example, the secret key timeout is configured to be 120 minutes.

   ```
   [edit protocols amt relay]
   user@host# set secret-key-timeout 120
   ```

   The secret key is used to generate the AMT Message Authentication Code (MAC). Setting the secret key timeout shorter might improve security, but it consumes more CPU resources. The default is 60 minutes.

5. (Optional) Specify an AMT tunnel limit by including the **tunnel-limit** statement at the **[edit protocols amt relay]** hierarchy level. In the following example, the AMT tunnel limit is 12.

   ```
   [edit protocols amt relay]
   user@host# set tunnel-limit 12
   ```

   The tunnel limit configures the static upper limit to the number of AMT tunnels that can be established. When the limit is reached, new AMT relay discovery messages are ignored.

6. Trace AMT protocol traffic by specifying options to the **traceoptions** statement at the **[edit protocols amt]** hierarchy level. Options applied at the AMT protocol level trace only AMT traffic. In the following example, all AMT packets are logged to the file **amt-log**.

   ```
   [edit protocols amt]
   user@host# set traceoptions file amt-log
   user@host# set traceoptions flag packets
   ```

Copyright © 2016, Juniper Networks, Inc.

NOTE: For AMT operation, configure the PIM rendezvous point address as the primary loopback address of the AMT relay.

Configuring Default IGMP Parameters for AMT Interfaces

You can optionally configure default IGMP parameters for all AMT tunnel interfaces. Although, typically you do not need to change the values. To configure default IGMP attributes of all AMT relay tunnels, include the **amt** statement:

```
amt {
  relay {
    defaults {
      (accounting (Protocols IGMP AMT Interface) | no-accounting (Protocols IGMP AMT
        Interface));
      group-policy [ policy-names ];
      query-interval seconds;
      query-response-interval seconds;
      robust-count number;
      ssm-map ssm-map-name;
      version version;
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols igmp]**
- **[edit logical-systems *logical-system-name* protocols igmp]**
- **[edit routing-instances *routing-instance-name* protocols igmp]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp]**

The IGMP statements included at the **[edit protocols igmp amt relay defaults]** hierarchy level have the same syntax and purpose as IGMP statements included at the **[edit protocols igmp]** or **[edit protocols igmp interface *interface-name*]** hierarchy levels. These statements are as follows:

- You can collect IGMP join and leave event statistics. To enable the collection of IGMP join and leave event statistics for all AMT interfaces, include the **accounting** statement:

  user@host# **set protocols igmp amt relay defaults accounting**

- After enabling IGMP accounting, you must configure the router to filter the recorded information to a file or display it to a terminal. You can archive the events file.
- To disable the collection of IGMP join and leave event statistics for all AMT interfaces, include the **no-accounting** statement:

  user@host# **set protocols igmp amt relay defaults no-accounting**

Copyright © 2016, Juniper Networks, Inc.

- You can filter unwanted IGMP reports at the interface level. To filter unwanted IGMP reports, define a policy to match only IGMP group addresses (for IGMPv2) by using the policy's **route-filter** statement to match the group address. Define the policy to match IGMP (S,G) addresses (for IGMPv3) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address. In the following example, the **amt_reject** policy is created to match both the group and source addresses.

  ```
  user@host# set policy-options policy-statement amt_reject from route-filter 224.1.1.1/32
    exact
  user@host# set policy-options policy-statement amt_reject from source-address-filter
    192.168.0.0/16 orlonger
  user@host# set policy-options policy-statement amt_reject then reject
  ```

- To apply the IGMP report filtering on the interface where you prefer not to receive specific group or (S,G) reports, include the **group-policy** statement. The following example applies the **amt_reject** policy to all AMT interfaces.

  ```
  user@host# set protocols igmp amt relay defaults group-policy amt_reject
  ```

- You can change the IGMP query interval for all AMT interfaces to reduce or increase the number of host query messages sent. In AMT, host query messages are sent in response to membership request messages from the gateway. The query interval configured on the relay must be compatible with the membership request timer configured on the gateway. To modify this interval, include the **query-interval** statement. The following example sets the host query interval to 250 seconds.

  ```
  user@host# set protocols igmp amt relay defaults query-interval 250
  ```

  The IGMP querier router periodically sends general host-query messages. These messages solicit group membership information and are sent to the all-systems multicast group address, 224.0.0.1.

- You can change the IGMP query response interval. The query response interval multiplied by the robust count is the maximum amount of time that can elapse between the sending of a host query message by the querier router and the receipt of a response from a host. Varying this interval allows you to adjust the number of IGMP messages on the AMT interfaces. To modify this interval, include the **query-response-interval** statement. The following example configures the query response interval to 20 seconds.

  ```
  user@host# set protocols igmp amt relay defaults query-response-interval 20
  ```

- You can change the IGMP robust count. The robust count is used to adjust for the expected packet loss on the AMT interfaces. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork. To modify the robust count, include the **robust-count** statement. The following example configures the robust count to **3**.

  ```
  user@host# set protocols igmp amt relay defaults robust-count 3
  ```

  The robust count automatically changes certain IGMP message intervals for IGMPv2 and IGMPv3.

  - On a shared network running IGMPv2, when the query router receives an IGMP leave message, it must send an IGMP group query message for a specified number of times. The number of IGMP group query messages sent is determined by the robust count.

Copyright © 2016, Juniper Networks, Inc.

The interval between query messages is determined by the last member query interval. Also, the IGMPv2 query response interval is multiplied by the robust count to determine the maximum amount of time between the sending of a host query message and receipt of a response from a host.

For more information about the IGMPv2 robust count, see RFC 2236, *Internet Group Management Protocol, Version 2*.

- In IGMPv3 a change of interface state causes the system to immediately transmit a state-change report from that interface. If the state-change report is missed by one or more multicast routers, it is retransmitted. The number of times it is retransmitted is the robust count minus one. In IGMPv3 the robust count is also a factor in determining the group membership interval, the older version querier interval, and the other querier present interval.

  For more information about the IGMPv3 robust count, see RFC 3376, *Internet Group Management Protocol, Version 3*.

- You can apply a source-specific multicast (SSM) map to an AMT interface. SSM mapping translates IGMPv1 or IGMPv2 membership reports to an IGMPv3 report, which allows hosts running IGMPv1 or IGMPv2 to participate in SSM until the hosts transition to IGMPv3.

  SSM mapping applies to all group addresses that match the policy, not just those that conform to SSM addressing conventions (232/8 for IPv4).

  In this example, you create a policy to match the 232.1.1.1/32 group address for translation to IGMPv3. Then you define the SSM map that associates the policy with the 192.168.43.66 source address where these group addresses are found. Finally, you apply the SSM map to all AMT interfaces.

  ```
  user@host# set policy-options policy-statement ssm-policy-example term A from
    route-filter 232.1.1.1/32 exact
  user@host# set policy-options policy-statement ssm-policy-example term A then
    accept
  user@host# set routing-options multicast ssm-map ssm-map-example policy
    ssm-policy-example
  user@host# set routing-options multicast ssm-map ssm-map-example source
    192.168.43.66
  user@host# set protocols igmp amt relay defaults ssm-map ssm-map-example
  ```

Example: Configuring the AMT Protocol

This example shows how to configure the Automatic Multicast Tunneling (AMT) Protocol to facilitate dynamic multicast connectivity between multicast-enabled networks across islands of unicast-only networks.

- Requirements on page 4282
- Overview on page 4282
- Configuration on page 4282
- Verification on page 4284

Copyright © 2016, Juniper Networks, Inc.

Requirements

Before you begin:

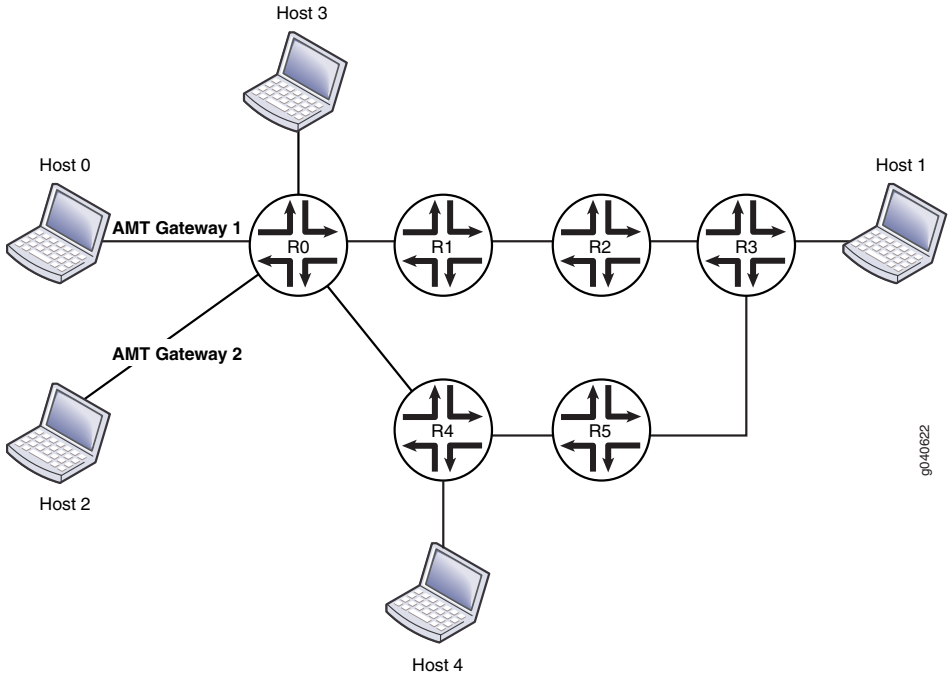
- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure a multicast group membership protocol (IGMP or MLD). See "Understanding IGMP" on page 4038 and "Understanding MLD" on page 4063.

Overview

In this example, Host 0 and Host 2 are multicast receivers in a unicast cloud. Their default gateway devices are AMT gateways. R0 and R4 are configured with unicast protocols only. R1, R2, R3, and R5 are configured with PIM multicast. Host 1 is a source in a multicast cloud. R0 and R5 are configured to perform AMT relay. Host 3 and Host 4 are multicast receivers (or sources that are directly connected to receivers). This example shows R1 configured with an AMT relay local address and an anycast prefix as its own loopback address. The example also shows R0 configured with tunnel services enabled.

Figure 193 shows the topology used in this example.

Figure 193: AMT Gateway Topology



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

Copyright © 2016, Juniper Networks, Inc.

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols amt traceoptions file amt.log
set protocols amt traceoptions flag errors
set protocols amt traceoptions flag packets detail
set protocols amt traceoptions flag route detail
set protocols amt traceoptions flag state detail
set protocols amt traceoptions flag tunnels detail
set protocols amt relay family inet anycast-prefix 10.10.10.10/32
set protocols amt relay family inet local-address 10.255.112.201
set protocols amt relay tunnel-limit 10
set protocols pim interface all mode sparse-dense
set protocols pim interface all version 2
set protocols pim interface fxp0.0 disable
set chassis fpc 0 pic 0 tunnel-services bandwidth 1g
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the AMT protocol on R1:

1. Configure AMT tracing operations.

   ```
   [edit protocols amt traceoptions]
   user@host# set file amt.log
   user@host# set flag errors
   user@host# set flag packets detail
   user@host# set flag route detail
   user@host# set flag state detail
   user@host# set flag tunnels detail
   ```

2. Configure the AMT relay settings.

   ```
   [edit protocols amt relay]
   user@host# set relay family inet anycast-prefix 10.10.10.10/32
   user@host# set family inet local-address 10.255.112.201
   user@host# set tunnel-limit 10
   ```

3. Configure PIM on R1's interfaces.

   ```
   [edit protocols pim]
   set interface all mode sparse-dense
   set interface all version 2
   set interface fxp0.0 disable
   ```

4. Enable tunnel functionality.

   ```
   [edit chassis]
   set fpc 0 pic 0 tunnel-services bandwidth 1g
   ```

5. If you are done configuring the device, commit the configuration.

   ```
   user@host# commit
   ```

Copyright © 2016, Juniper Networks, Inc.

Results

From configuration mode, confirm your configuration by entering the **show chassis** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show chassis
fpc 0 {
  pic 0 {
    tunnel-services {
      bandwidth 1g;
    }
  }
}
```

```
user@host# show protocols
amt {
  traceoptions {
    file amt.log;
    flag errors;
    flag packets detail;
    flag route detail;
    flag state detail;
    flag tunnels detail;
  }
  relay {
    family {
      inet {
        anycast-prefix 10.10.10.10/32;
        local-address 10.255.112.201;
      }
    }
    tunnel-limit 10;
  }
}
pim {
  interface all {
    mode sparse-dense;
    version 2;
  }
  interface fxp0.0 {
    disable;
  }
}
```

Verification

To verify the configuration, run the following commands:

- show amt statistics
- show amt summary
- show amt tunnel

CHAPTER 190

Routing Content to Densely Clustered Receivers with DVMRP

- Examples: Configuring DVMRP on page 4287

Examples: Configuring DVMRP

- Understanding DVMRP on page 4287
- Configuring DVMRP on page 4288
- Example: Configuring DVMRP on page 4288
- Example: Configuring DVMRP to Announce Unicast Routes on page 4292
- Tracing DVMRP Protocol Traffic on page 4295

Understanding DVMRP

The Distance Vector Multicast Routing Protocol (DVMRP) is a distance-vector routing protocol that provides connectionless datagram delivery to a group of hosts across an internetwork. DVMRP is a distributed protocol that dynamically generates IP multicast delivery trees by using a technique called reverse-path multicasting (RPM) to forward multicast traffic to downstream interfaces. These mechanisms allow the formation of shortest-path trees, which are used to reach all group members from each network source of multicast traffic.

DVMRP is designed to be used as an interior gateway protocol (IGP) within a multicast domain.

Because not all IP routers support native multicast routing, DVMRP includes direct support for tunneling IP multicast datagrams through routers. The IP multicast datagrams are encapsulated in unicast IP packets and addressed to the routers that do support native multicast routing. DVMRP treats tunnel interfaces and physical network interfaces the same way.

DVMRP routers dynamically discover their neighbors by sending neighbor probe messages periodically to an IP multicast group address that is reserved for all DVMRP routers.

Copyright © 2016, Juniper Networks, Inc.

Configuring DVMRP

Distance Vector Multicast Routing Protocol (DVMRP) is the first of the multicast routing protocols and has a number of limitations that make this method unattractive for large-scale Internet use. DVMRP is a dense-mode-only protocol, and uses the flood-and-prune or implicit join method to deliver traffic everywhere and then determine where the uninterested receivers are. DVMRP uses source-based distribution trees in the form (S,G).

To configure the Distance Vector Multicast Routing Protocol (DVMRP), include the **dvmrp** statement:

```
dvmrp {
    disable;
    export [ policy-names ];
    import [ policy-names ];
    interface interface-name {
        disable;
        hold-time seconds;
        metric metric;
        mode (forwarding | unicast-routing);
    }
    rib-group group-name;
    traceoptions {
        file filename <files number> <size size> <world-readable | no-world-readable>;
        flag flag <flag-modifier> <disable>;
    }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

By default, DVMRP is disabled.

Example: Configuring DVMRP

This example shows how to use DVMRP to announce routes used for multicast routing as well as multicast data forwarding.

- Requirements on page 4288
- Overview on page 4289
- Configuration on page 4290
- Verification on page 4291

Requirements

Before you begin:

- Configure the router interfaces.

Copyright © 2016, Juniper Networks, Inc.

- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.

Overview

DVMRP is a distance vector protocol for multicast. It is similar to RIP, in that both RIP and DVMRP have issues with scalability and robustness. PIM domains are more commonly used than DVMRP domains. In some environments, you might need to configure interoperability with DVMRP.

This example includes the following DVMRP settings:

- **protocols dvmrp rib-group**—Associates the **dvmrp-rib** routing table group with the DVMRP protocol to enable multicast RPF lookup.
- **protocols dvmrp interface**—Configures the DVMRP interface. The interface of a DVMRP router can be either a physical interface to a directly attached subnetwork or a tunnel interface to another multicast-capable area of the Multicast Backbone (*MBone*). The DVMRP hold-time period is the amount of time that a neighbor is to consider the sending router (this router) to be operative (up). The default hold-time period is 35 seconds.
- **protocols dvmrp interface hold-time**—The DVMRP hold-time period is the amount of time that a neighbor is to consider the sending router (this router) to be operative (up). The default hold-time period is 35 seconds.
- **protocols dvmrp interface metric**—All interfaces can be configured with a metric specifying cost for receiving packets on a given interface. The default metric is 1.

  For each source network reported, a route metric is associated with the unicast route being reported. The metric is the sum of the interface metrics between the router originating the report and the source network. A metric of 32 marks the source network as unreachable, thus limiting the breadth of the DVMRP network and placing an upper bound on the DVMRP convergence time.
- **routing-options rib-groups**—Enables DVMRP to access route information from the unicast routing table, **inet.0**, and from a separate routing table that is reserved for DVMRP. In this example, the first routing table group named **ifrg** contains local interface routes. This ensures that local interface routes get added to both the **inet.0** table for use by unicast protocols and the **inet.2** table for multicast RPF check. The second routing table group named **dvmrp-rib** contains **inet.2** routes.

  DVMRP needs to access route information from the unicast routing table, **inet.0**, and from a separate routing table that is reserved for DVMRP. You need to create the routing table for DVMRP and to create groups of routing tables so that the routing protocol process imports and exports routes properly. We recommend that you use routing table **inet.2** for DVMRP routing information.
- **routing-options interface-routes**— After defining the **ifrg** routing table group, use the **interface-routes** statement to insert interface routes into the **ifrg** group—in other words,

Copyright © 2016, Juniper Networks, Inc.

into both **inet.0** and **inet.2**. By default, interface routes are imported into routing table **inet.0** only.

- **sap**—Enables the Session Directory Announcement Protocol (SAP) and the Session Directory Protocol (SDP). Enabling SAP allows the router to receive announcements about multimedia and other multicast sessions.

  SAP always listens to the address and port 224.2.127.254:9875 for session advertisements. To add other addresses or pairs of address and port, include one or more **listen** statements.

  Sessions learned by SDP, SAP's higher-layer protocol, time out after 60 minutes.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-options interface-routes rib-group inet ifrg
set routing-options rib-groups ifrg import-rib inet.0
set routing-options rib-groups ifrg import-rib inet.2
set routing-options rib-groups dvmrp-rib export-rib inet.2
set routing-options rib-groups dvmrp-rib import-rib inet.2
set protocols sap
set protocols dvmrp rib-group dvmrp-rib
set protocols dvmrp interface ip-0/0/0.0 metric 5
set protocols dvmrp interface ip-0/0/0.0 hold-time 40
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an MSDP routing instance:

1. Create the routing tables for DVMRP routes.

   ```
   [edit routing-options]
   user@host# set interface-routes rib-group inet ifrg
   user@host# set rib-groups ifrg import-rib [ inet.0 inet.2 ]
   user@host# set rib-groups dvmrp-rib import-rib inet.2
   user@host# set rib-groups dvmrp-rib export-rib inet.2
   ```

2. Configure SAP and SDP.

   ```
   [edit protocols]
   user@host# set sap
   ```

3. Enable DVMRP on the router and associate the **dvmrp-rib** routing table group with DVMRP to enable multicast RPF checks.

   ```
   [edit protocols]
   user@host# set dvmrp rib-group dvmrp-rib
   ```

Copyright © 2016, Juniper Networks, Inc.

4. Configure the DVMRP interface with a hold-time value and a metric. This example shows an IP-over-IP encapsulation tunnel interface.

```
[edit protocols]
user@host# set dvmrp interface ip–0/0/0.0
user@host# set dvmrp interface ip–0/0/0.0 hold-time 40
user@host# set dvmrp interface ip–0/0/0.0 metric 5
```

5. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show routing-options** command and the **show protocols** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show routing-options
interface-routes {
   rib-group inet ifrg;
}
   rib-groups {
      ifrg {
         import-rib [ inet.0 inet.2 ];
      }
      dvmrp-rib {
         export-rib inet.2;
         import-rib inet.2;
      }
   }
user@host# show protocols
sap;
dvmrp {
   rib-group dvmrp-rib;
   interface ip-0/0/0.0 {
      metric 5;
      hold-time 40;
   }
}
```

Verification

To verify the configuration, run the following commands:

- show dvmrp interfaces
- show dvmrp neighbors

Copyright © 2016, Juniper Networks, Inc.

Example: Configuring DVMRP to Announce Unicast Routes

This example shows how to use DVMRP to announce unicast routes used solely for multicast reverse-path forwarding (RPF) to set up the multicast control plane.

- Requirements on page 4292
- Overview on page 4292
- Configuration on page 4293
- Verification on page 4295

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.

Overview

DVMRP has two modes. Forwarding mode is the default mode. In forwarding mode, DVMRP is responsible for the multicast control plane and multicast data forwarding. In the nondefault mode (which is shown in this example), DVMRP does not forward multicast data traffic. This mode is called unicast routing mode because in this mode DVMRP is only responsible for announcing unicast routes used for multicast RPF—in other words, for establishing the control plane. To forward multicast data, enable Protocol Independent Multicast (PIM) on the interface. If you have configured PIM on the interface, as shown in this example, you can configure DVMRP in unicast-routing mode only. You cannot configure PIM and DVMRP in forwarding mode at the same time.

This example includes the following settings:

- **policy-statement dvmrp-export**—Accepts static default routes.
- **protocols dvmrp export dvmrp-export**—Associates the **dvmrp-export** policy with the DVMRP protocol.

  All routing protocols use the routing table to store the routes that they learn and to determine which routes they advertise in their protocol packets. Routing policy allows you to control which routes the routing protocols store in and retrieve from the routing table. Import and export policies are always from the point of view of the routing table. So the **dvmrp-export** policy exports static default routes from the routing table and accepts them into DVMRP.
- **protocols dvmrp interface all mode unicast-routing**—Enables all interfaces to announce unicast routes used solely for multicast RPF.
- **protocols dvmrp rib-group inet dvmrp-rg**—Associates the **dvmrp-rib** routing table group with the DVMRP protocol to enable multicast RPF checks.
- **protocols pim rib-group inet pim-rg**—Associates the **pim-rg** routing table group with the PIM protocol to enable multicast RPF checks.

Copyright © 2016, Juniper Networks, Inc.

- **routing-options rib inet.2 static route 0.0.0.0/0 discard**—Redistributes static routes to all DVMRP neighbors. The **inet.2** routing table stores unicast IPv4 routes for multicast RPF lookup. The **discard** statement silently drops packets without notice.
- **routing-options rib-groups dvmrp-rg import-rib inet.2**—Creates the routing table for DVMRP to ensure that the routing protocol process imports routes properly.
- **routing-options rib-groups dvmrp-rg export-rib inet.2**—Creates the routing table for DVMRP to ensure that the routing protocol process exports routes properly.
- **routing-options rib-groups pim-rg import-rib inet.2**—Enables access to route information from the routing table that stores unicast IPv4 routes for multicast RPF lookup. In this example, the first routing table group named **pim-rg** contains local interface routes. This ensures that local interface routes get added to the **inet.2** table.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement dvmrp-export term 10 from protocol static
set policy-options policy-statement dvmrp-export term 10 from route-filter 0.0.0.0/0
  exact
set policy-options policy-statement dvmrp-export term 10 then accept
set protocols dvmrp rib-group inet
set protocols dvmrp rib-group dvmrp-rg
set protocols dvmrp export dvmrp-export
set protocols dvmrp interface all mode unicast-routing
set protocols dvmrp interface fxp0.0 disable
set protocols pim rib-group inet pim-rg
set protocols pim interface all
set routing-options rib inet.2 static route 0.0.0.0/0 discard
set routing-options rib-groups pim-rg import-rib inet.2
set routing-options rib-groups dvmrp-rg export-rib inet.2
set routing-options rib-groups dvmrp-rg import-rib inet.2
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an MSDP routing instance:

1. Configure the routing options.

```
[edit routing-options]
[edit routing -options]
user@host# set rib inet.2 static route 0.0.0.0/0 discard
user@host# set rib-groups pim-rg import-rib inet.2
user@host# set rib-groups dvmrp-rg import-rib inet.2
user@host# set rib-groups dvmrp-rg export-rib inet.2
```

2. Configure DVMRP.

Copyright © 2016, Juniper Networks, Inc.

```
[edit protocols]
user@host# set dvmrp rib-group inet dvmrp-rg
user@host# set dvmrp export dvmrp-export
user@host# set dvmrp interface all mode unicast-routing
user@host# set dvmrp interface fxp0 disable
```

3. Configure PIM so that PIM performs multicast data forwarding.

```
[edit protocols]
user@host# set pim rib-group inet pim-rg
user@host# set pim interface all
```

4. Configure the DVMRP routing policy.

```
[edit policy-options policy-statement dvmrp-export term 10]
user@host# set from protocol static
user@host# set from route-filter 0.0.0.0/0 exact
user@host# set then accept
```

5. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show policy-options** command, the **show protocols** command, and the **show routing-options** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
policy-statement dvmrp-export {
    term 10 {
        from {
            protocol static;
            route-filter 0.0.0.0/0 exact;
        }
        then accept;
    }
}

user@host# show protocols
dvmrp {
    rib-group inet dvmrp-rg;
    export dvmrp-export;

        mode unicast-routing;
    }
    interface fxp0.0 {
        disable;
    }
}
pim {
    rib-group inet pim-rg;
    interface all;
}

user@host# show routing-options
```

Copyright © 2016, Juniper Networks, Inc.

```
rib inet.2 {
  static {
    route 0.0.0.0/0 discard;
  }
}
  rib-groups {
    pim-rg {
      import-rib inet.2;
    }
    dvmrp-rg {
      export-rib inet.2;
      import-rib inet.2;
    }
  }
```

Verification

To verify the configuration, run the following commands:

- show dvmrp interfaces
- show pim statistics

Tracing DVMRP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
all	Trace all operations.
general	Trace general flow.
graft	Trace graft messages.
neighbor	Trace neighbor probe packets.
normal	Trace normal events.
packets	Trace all DVMRP packets.
poison	Trace poison-route-reverse packets.
policy	Trace policy processing.
probe	Trace probe packets.
prune	Trace prune messages.

Copyright © 2016, Juniper Networks, Inc.

Flag	Description
report	Trace membership report messages.
route	Trace routing information.
state	Trace state transitions.
task	Trace task processing.
timer	Trace timer processing.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on DVMRP packets of a particular type. To configure tracing operations for DVMRP:

1. (Optional) Configure tracing at the routing options level to trace all protocol packets.

   ```
   [edit routing-options traceoptions]
   user@host# set file all-packets-trace
   user@host# set flag all
   ```

2. Configure the filename for the DVMRP trace file.

   ```
   [edit protocols dvmrp traceoptions]
   user@host# set file dvmrp-trace
   ```

3. (Optional) Configure the maximum number of trace files.

   ```
   [edit protocols dvmrp traceoptions]
   user@host# set file files 5
   ```

4. (Optional) Configure the maximum size of each trace file.

   ```
   [edit protocols dvmrp traceoptions]
   user@host# set file size 1m
   ```

5. (Optional) Enable unrestricted file access.

   ```
   [edit protocols dvmrp traceoptions]
   user@host# set file world-readable
   ```

6. Configure tracing flags. Suppose you are troubleshooting issues with a particular DVMRP neighbor. The following example shows how to trace neighbor probe packets that match the neighbor's IP address.

   ```
   [edit protocols dvmrp traceoptions]
   user@host# set flag neighbor | match 192.168.1.1
   ```

7. View the trace file.

   ```
   user@host> file list /var/log
   user@host> file show /var/log/dvmrp-trace
   ```

CHAPTER 191

Configuring PIM Join Load Balancing

- PIM Join Load Balancing on Multipath MVPN Routes Overview on page 4299

PIM Join Load Balancing on Multipath MVPN Routes Overview

A multicast virtual private network (MVPN) is a technology to deploy the multicast service in an existing MPLS/BGP VPN.

The two main MVPN services are:

- Dual PIM MVPNs (also referred to as Draft-Rosen)
- Multiprotocol BGP-based MVPNs (also referred to as next-generation)

Next-generation MVPNs constitute the next evolution after the Draft-Rosen MVPN and provide a simpler solution for administrators who want to configure multicast over Layer 3 VPNs. A Draft-Rosen MVPN uses Protocol Independent Multicast (PIM) for customer multicast (C-multicast) signaling, and a next-generation MVPN uses BGP for C-multicast signaling.

Multipath routing in an MVPN is applied to make data forwarding more robust against network failures and to minimize shared backup capacities when resilience against network failures is required.

By default, PIM join messages are sent toward a source based on the reverse path forwarding (RPF) routing table check. If there is more than one equal-cost path toward the source [S, G] or rendezvous point (RP) [*, G], then one upstream interface is used to send the join messages. The upstream path can be:

- A single active external BGP (EBGP) path when both EBGP and internal BGP (IBGP) paths are present.
- A single active IBGP path when there is no EBGP path present.

With the introduction of the multipath PIM join load-balancing feature, customer PIM (C-PIM) join messages are load-balanced in the following ways:

- In the case of a Draft-Rosen MVPN, unequal EBGP and IBGP paths are utilized.
- In the case of next-generation MVPN:
  - Available IBGP paths are utilized when no EBGP path is present.

Copyright © 2016, Juniper Networks, Inc.

- Available EBGP paths are utilized when both EBGP and IBGP paths are present.

This feature is applicable to IPv4 C-PIM join messages over the Layer 3 MVPN service.

By default, a customer source (C-S) or a customer RP (C-RP) is considered remote if the active **rt_entry** is a secondary route and the primary route is present in a different routing instance. Such determination is being done without taking into consideration the (C-*,G) or (C-S,G) state for which the check is being performed. The multipath PIM join load-balancing feature determines if a source (or RP) is remote by taking into account the associated (C-*,G) or (C-S,G) state.

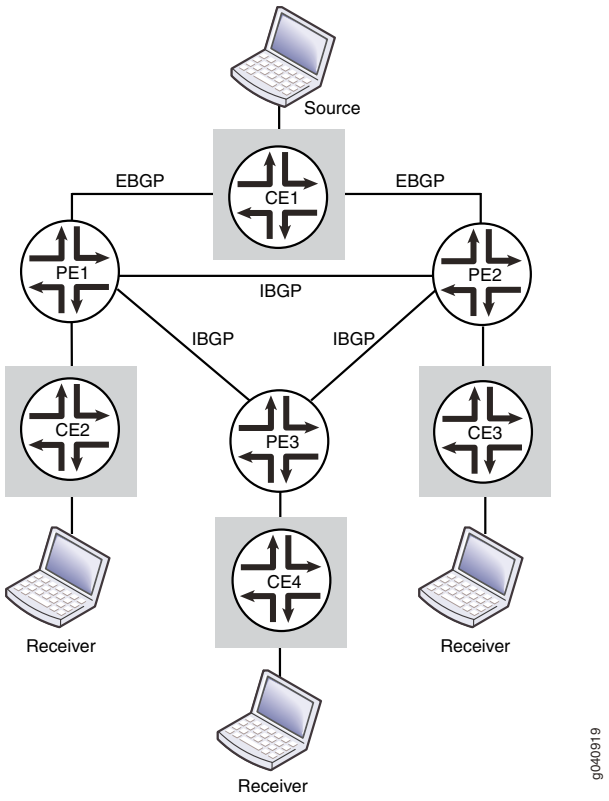
When the provider network does not have provider edge (PE) routers with the multipath PIM join load-balancing feature enabled, hash-based join load balancing is used. Although the decision to configure this feature does not impact PIM or overall system performance, network performance can be affected temporarily, if the feature is not enabled.

With hash-based join load balancing, adding new PE routers to the candidate upstream toward the C-S or C-RP results in C-PIM join messages being redistributed to new upstream paths. If the number of join messages is large, network performance is impacted because of join messages being sent to the new RPF neighbor and prune messages being sent to the old RPF neighbor. In next-generation MVPN, this results in BGP C-multicast data messages being withdrawn from old upstream paths and advertised on new upstream paths, impacting network performance.

Copyright © 2016, Juniper Networks, Inc.

In Figure 194, PE1 and PE2 are the upstream PE routers. Router PE1 learns route Source from EBGP and IBGP peers—the customer edge CE1 router and the PE2 router, respectively.

Figure 194: PIM Join Load Balancing



- If the PE routers run the Draft-Rosen MVPN, the PE1 router distributes C-PIM join messages between the EBGP path to the CE1 router and the IBGP path to the PE2 router. The join messages on the IBGP path are sent over a multicast tunnel interface through which the PE routers establish C-PIM adjacency with each other.

  If a PE router loses one or all EBGP paths toward the source (or RP), the C-PIM join messages that were previously using the EBGP path are moved to a multicast tunnel interface, and the RPF neighbor on the multicast tunnel interface is selected based on a hash mechanism.

  On discovering the first EBGP path toward the source (or RP), only new join messages get load-balanced across EBGP and IBGP paths, whereas the existing join messages on the multicast tunnel interface remain unaffected.

- If the PE routers run the next-generation MVPN, the PE1 router sends C-PIM join messages directly to the CE1 router over the EBGP path. There is no C-PIM adjacency between the PE1 and PE2 routers. Router PE3 distributes the C-PIM join messages between the two IBGP paths to PE1 and PE2. The Bytewise-XOR hash algorithm is used to send the C-multicast data according to Internet draft draft-ietf-l3vpn-2547bis-mcast-bgp, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*.

Copyright © 2016, Juniper Networks, Inc.

Because the multipath PIM join load-balancing feature in a Draft-Rosen MVPN utilizes unequal EBGP and IBGP paths to the destination, loops can be created when forwarding unicast packets to the destination. To avoid or break such loops:

- Traffic arriving from a core or master instance should not be forwarded back to the core facing interfaces.
- A single multicast tunnel interface should either be selected as the upstream interface or the downstream interface.
- An upstream or downstream multicast tunnel interface should point to a non-multicast tunnel interface.

As a result of the loop avoidance mechanism, join messages arriving from an EBGP path get load-balanced across EIBGP paths as expected, whereas join messages from an IBGP path are constrained to choose the EBGP path only.

In Figure 194, if the CE2 host sends unicast data traffic to the CE1 host, the PE1 router could send the multicast flow to the PE2 router over the MPLS core due to traffic load balancing. A data forwarding loop is prevented by ensuring that PE2 does not forward traffic back on the MPLS core because of the load-balancing algorithm.

In the case of C-PIM join messages, assuming that both the CE2 host and the CE3 host are interested in receiving traffic from the source (S, G), and if both PE1 and PE2 choose each other as the RPF neighbor toward the source, then a multicast tree cannot be formed completely. This feature implements mechanisms to prevent such join loops in the multicast control plane in a Draft-Rosen MVPN scenario.

NOTE:

Disruption of multicast traffic or creation of join loops can occur, resulting in a multicast distribution tree (MDT) not being formed properly due to one of the following reasons:

- During a graceful Routing Engine switchover (GRES), the EIBGP path selection for C-PIM join messages can vary, because the upstream interface selection is performed again for the new Routing Engine based on the join messages it receives from the CE and PE neighbors. This can lead to disruption of multicast traffic depending on the number of join messages received and the load on the network at the time of the graceful restart. However, nonstop active routing (NSR) is not supported and has no impact on the multicast traffic in a Draft-Rosen MVPN scenario.
- Any PE router in the provider network is running another vendor's implementation that does not apply the same hashing algorithm implemented in this feature.
- The multipath PIM join load-balancing feature has not been configured properly.

CHAPTER 192

Configuring Next-Generation Multicast VPNs

- Example: Configuring PIM Join Load Balancing on Next-Generation Multicast VPN on page 4303

Example: Configuring PIM Join Load Balancing on Next-Generation Multicast VPN

This example shows how to configure multipath routing for external and internal virtual private network (VPN) routes with unequal interior gateway protocol (IGP) metrics and Protocol Independent Multicast (PIM) join load balancing on provider edge (PE) routers running next-generation multicast VPN (MVPN). This feature allows customer PIM (C-PIM) join messages to be load-balanced across available internal BGP (IBGP) upstream paths when there is no external BGP (EBGP) path present, and across available EBGP upstream paths when external and internal BGP (EIBGP) paths are present toward the source or rendezvous point (RP).

- Requirements on page 4303
- Overview and Topology on page 4304
- Configuration on page 4306
- Verification on page 4310

Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of M Series, MX Series, or T Series routers.
- Junos OS Release 12.1 running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure the following routing protocols on all PE routers:
   - OSPF
   - MPLS
   - LDP

Copyright © 2016, Juniper Networks, Inc.

- PIM
- BGP

3. Configure a multicast VPN.

Overview and Topology

Junos OS Release 12.1 and later support multipath configuration along with PIM join load balancing. This allows C-PIM join messages to be load-balanced across all available IBGP paths when there are only IBGP paths present, and across all available upstream EBGP paths when EIBGP paths are present toward the source (or RP). Unlike Draft-Rosen MVPN, next-generation MVPN does not utilize unequal EIBGP paths to send C-PIM join messages. This feature is applicable to IPv4 C-PIM join messages.

By default, only one active IBGP path is used to send the C-PIM join messages for a PE router having only IBGP paths toward the source (or RP). When there are EIBGP upstream paths present, only one active EBGP path is used to send the join messages.

In a next-generation MVPN, C-PIM join messages are translated into (or encoded as) BGP customer multicast (C-multicast) MVPN routes and advertised with the BGP MCAST-VPN address family toward the sender PE routers. A PE router originates a C-multicast MVPN route in response to receiving a C-PIM join message through its PE router to customer edge (CE) router interface. The two types of C-multicast MVPN routes are:

- Shared tree join route (C-*, C-G)
  - Originated by receiver PE routers.
  - Originated when a PE router receives a shared tree C-PIM join message through its PE-CE router interface.
- Source tree join route (C-S, C-G)
  - Originated by receiver PE routers.
  - Originated when a PE router receives a source tree C-PIM join message (C-S, C-G), or originated by the PE router that already has a shared tree join route and receives a source active autodiscovery route.

  The upstream path in a next-generation MVPN is selected using the Bytewise-XOR hash algorithm as specified in Internet draft draft-ietf-l3vpn-2547bis-mcast, *Multicast in MPLS/BGP IP VPNs*. The hash algorithm is performed as follows:

  1. The PE routers in the candidate set are numbered from lower to higher IP address, starting from **0**.
  2. A bytewise exclusive-or of all the bytes is performed on the C-root (source) and the C-G (group) address.

Copyright © 2016, Juniper Networks, Inc.

3. The result is taken modulo *n*, where *n* is the number of PE routers in the candidate set. The result is **N**.

4. **N** represents the IP address of the upstream PE router as numbered in Step 1.

During load balancing, if a PE router with one or more upstream IBGP paths toward the source (or RP) discovers a new IBGP path toward the same source (or RP), the C-PIM join messages distributed among previously existing IBGP paths get redistributed due to the change in the candidate PE router set.

In this example, PE1, PE2, and PE3 are the PE routers that have the multipath PIM join load-balancing feature configured. Router PE1 has two EBGP paths and one IBGP upstream path, PE2 has one EBGP path and one IBGP upstream path, and PE3 has two IBGP upstream paths toward the Source. Router CE4 is the customer edge (CE) router attached to PE3. Source and Receiver are the Free BSD hosts.

On PE routers that have EIBGP paths toward the source (or RP), such as PE1 and PE2, PIM join load balancing is performed as follows:

1. The C-PIM join messages are sent using EBGP paths only. IBGP paths are not used to propagate the join messages.

   In Figure 195, the PE1 router distributes the join messages between the two EBGP paths to the CE1 router, and PE2 uses the EBGP path to CE1 to send the join messages.

2. If a PE router loses one or more EBGP paths toward the source (or RP), the RPF neighbor on the multicast tunnel interface is selected based on a hash mechanism.

   On discovering the first EBGP path, only new join messages get load-balanced across available EBGP paths, whereas the existing join messages on the multicast tunnel interface are not redistributed.

   If the EBGP path from the PE2 router to the CE1 router goes down, PE2 sends the join messages to PE1 using the IBGP path. When the EBGP path to CE1 is restored, only new join messages that arrive on PE2 use the restored EBGP path, whereas join messages already sent on the IBGP path are not redistributed.

On PE routers that have only IBGP paths toward the source (or RP), such as the PE3 router, PIM join load balancing is performed as follows:

1. The C-PIM join messages from CE routers get load-balanced only as BGP C-multicast data messages among IBGP paths.

   In Figure 195, assuming that the CE4 host is interested in receiving traffic from the Source, and CE4 initiates source join messages for different groups (Group 1 [C-S,C-G1] and Group 2 [C-S,C-G2]), the source join messages arrive on the PE3 router.

   Router PE3 then uses the Bytewise-XOR hash algorithm to select the upstream PE router to send the C-multicast data for each group. The algorithm first numbers the upstream PE routers from lower to higher IP address starting from **0**.

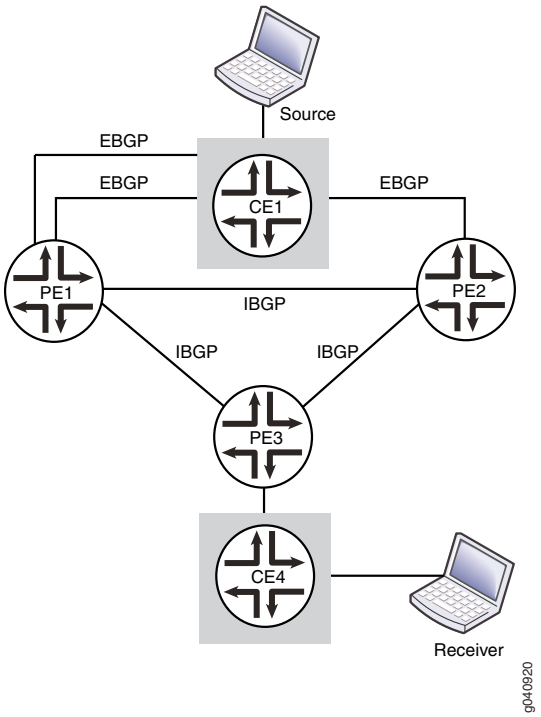
   Assuming that Router PE1 router is numbered **0** and Router PE2 is **1**, and the hash result for Group 1 and Group 2 join messages is **0** and **1**, respectively, the PE3 router

Copyright © 2016, Juniper Networks, Inc.

selects PE1 as the upstream PE router to send Group 1 join messages, and PE2 as the upstream PE router to send the Group 2 join messages to the Source.

2. The shared join messages for different groups [C-*,C-G] are also treated in a similar way to reach the destination.

Figure 195: PIM Join Load Balancing on Next-Generation MVPN



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

PE1

```
set routing-instances vpn1 instance-type vrf
set routing-instances vpn1 interface ge-3/0/1.0
set routing-instances vpn1 interface ge-3/3/2.0

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*. To configure the PE1 router:

NOTE: Repeat this procedure for every Juniper Networks router in the MVPN domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure a VPN routing forwarding (VRF) routing instance.

```
[edit routing-instances vpn1]
user@PE1# set instance-type vrf
user@PE1# set interface ge-3/0/1.0
user@PE1# set interface ge-3/3/2.0
user@PE1# set interface lo0.1
user@PE1# set route-distinguisher 1:1
user@PE1# set provider-tunnel rsvp-te label-switched-path-template
  default-template
user@PE1# set vrf-target target:1:1
user@PE1# set vrf-table-label
```

2. Enable protocol-independent load balancing for the VRF instance.

```
[edit routing-instances vpn1]
user@PE1# set routing-options multipath vpn-unequal-cost equal-external-internal
```

3. Configure BGP groups and neighbors to enable PE to CE routing.

```
[edit routing-instances vpn1 protocols]
user@PE1# set bgp export direct
user@PE1# set bgp group bgp type external
user@PE1# set bgp group bgp local-address 10.40.10.1
user@PE1# set bgp group bgp family inet unicast
user@PE1# set bgp group bgp neighbor 10.40.10.2 peer-as 3
user@PE1# set bgp group bgp1 type external
user@PE1# set bgp group bgp1 local-address 10.10.10.1
user@PE1# set bgp group bgp1 family inet unicast
user@PE1# set bgp group bgp1 neighbor 10.10.10.2 peer-as 3
```

4. Configure PIM to enable PE to CE multicast routing.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim rp static address 10.255.10.119
```

5. Enable PIM on all network interfaces.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim interface all
```

6. Enable PIM join load balancing for the VRF instance.

```
[edit routing-instances vpn1 protocols]
user@PE1# set pim join-load-balance
```

7. Configure the mode for C-PIM join messages to use rendezvous-point trees, and switch to the shortest-path tree after the source is known.

Copyright © 2016, Juniper Networks, Inc.

```
[edit routing-instances vpn1 protocols]
user@PE1# set mvpn mvpn-mode rpt-spt
```

8. Configure the VRF instance to use the Bytewise-XOR hash algorithm.

```
[edit routing-instances vpn1 protocols]
user@PE1# set mvpn mvpn-join-load-balance bytewise-xor-hash
```

Results

From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show routing-instances
routing-instances {
  vpn1 {
    instance-type vrf;
    interface ge-3/0/1.0;
    interface ge-3/3/2.0;

      }
    }
    protocols {
      bgp {
        export direct;
        group bgp {
          type external;
          local-address 10.40.10.1;
          family inet {
            unicast;
          }
          neighbor 10.40.10.2 {
            peer-as 3;
          }
        }
        group bgp1 {
          type external;
          local-address 10.10.10.1;
          family inet {
            unicast;
          }
          neighbor 10.10.10.2 {
```

Copyright © 2016, Juniper Networks, Inc.

```
            peer-as 3;
          }
        }
      }
      pim {
        rp {
          static {
            address 10.255.10.119;
          }
        }
        interface all;
        join-load-balance;
      }
      mvpn {
        mvpn-mode {
          rpt-spt;
        }
        mvpn-join-load-balance {
          bytewise-xor-hash;
        }
      }
    }
  }
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- Verifying MVPN C-Multicast Route Information for Different Groups of Join Messages on page 4310

Verifying MVPN C-Multicast Route Information for Different Groups of Join Messages

Purpose Verify MVPN C-multicast route information for different groups of join messages received on the PE3 router.

Action From operational mode, run the **show mvpn c-multicast** command.

```
user@PE3>

Understanding Multicast Reverse Path Forwarding

Unicast forwarding decisions are typically based on the destination address of the packet arriving at a router. The unicast routing table is organized by destination subnet and mainly set up to forward the packet toward the destination.

In multicast, the router forwards the packet away from the source to make progress along the distribution tree and prevent routing loops. The router's multicast forwarding state runs more logically by organizing tables based on the reverse path, from the receiver back to the root of the distribution tree. This process is known as *reverse-path forwarding* (*RPF*).

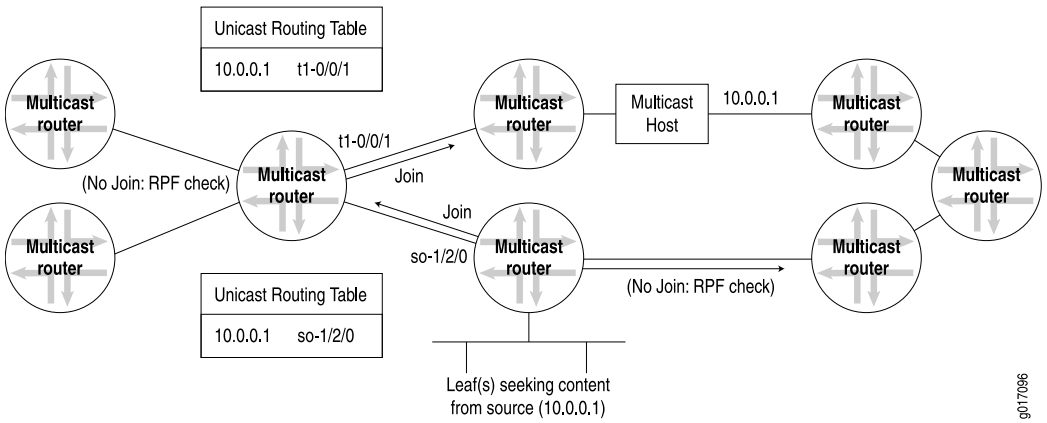
The router adds a branch to a distribution tree depending on whether the request for traffic from a multicast group passes the reverse-path-forwarding check (RPF check). Every multicast packet received must pass an RPF check before it is eligible to be replicated or forwarded on any interface.

The RPF check is essential for every router's multicast implementation. When a multicast packet is received on an interface, the router interprets the source address in the multicast IP packet as the destination address for a unicast IP packet. The source multicast address is found in the unicast routing table, and the outgoing interface is determined. If the outgoing interface found in the unicast routing table is the same as the interface that the multicast packet was received on, the packet passes the RPF check. Multicast packets that fail the RPF check are dropped because the incoming interface is not on the *shortest path* back to the source.

Copyright © 2016, Juniper Networks, Inc.

Figure 196 shows how multicast routers can use the unicast routing table to perform an RPF check and how the results obtained at each router determine where join messages are sent.

Figure 196: Multicast Routers and the RPF Check



Routers can build and maintain separate tables for RPF purposes. The router must have some way to determine its RPF interface for the group, which is the interface topologically closest to the root. For greatest efficiency, the distribution tree follows the shortest-path tree topology. The RPF check helps to construct this tree.

RPF Table

The RPF table plays the key role in the multicast router. The RPF table is consulted for every RPF check, which is performed at intervals on multicast packets entering the multicast router. Distribution trees of all types rely on the RPF table to form properly, and the multicast forwarding state also depends on the RPF table.

RPF checks are performed only on unicast addresses to find the upstream interface for the multicast source or RP.

The routing table used for RPF checks can be the same routing table used to forward unicast IP packets, or it can be a separate routing table used only for multicast RPF checks. In either case, the RPF table contains only unicast routes, because the RPF check is performed on the source address of the multicast packet, not the multicast group destination address, and a multicast address is forbidden from appearing in the source address field of an IP packet header. The unicast address can be used for RPF checks because there is only one source host for a particular stream of IP multicast content for a multicast group address, although the same content could be available from multiple sources.

If the same routing table used to forward unicast packets is also used for the RPF checks, the routing table is populated and maintained by the traditional unicast routing protocols such as BGP, IS-IS, OSPF, and the Routing Information Protocol (RIP). If a dedicated multicast RPF table is used, this table must be populated by some other method. Some multicast routing protocols (such as the Distance Vector Multicast Routing Protocol [DVMRP]) essentially duplicate the operation of a unicast routing protocol and populate a dedicated RPF table. Others, such as PIM, do not duplicate routing protocol functions

Copyright © 2016, Juniper Networks, Inc.

and must rely on some other routing protocol to set up this table, which is why PIM is *protocol independent*.

Some traditional routing protocols such as BGP and IS-IS now have extensions to differentiate between different sets of routing information sent between routers for unicast and multicast. For example, there is multiprotocol BGP (MBGP) and multitopology routing in IS-IS (M-IS-IS). IS-IS routes can be added to the RPF table even when special features such as traffic engineering and "shortcuts" are turned on. Multicast Open Shortest Path First (MOSPF) also extends OSPF for multicast use, but goes further than MBGP or M-IS-IS and makes MOSPF into a complete multicast routing protocol on its own. When these routing protocols are used, routes can be tagged as multicast RPF routers and used by the receiving router differently than the unicast routing information.

Using the main unicast routing table for RPF checks provides simplicity. A dedicated routing table for RPF checks allows a network administrator to set up separate paths and routing policies for unicast and multicast traffic, allowing the multicast network to function more independently of the unicast network.

Multicast RPF Configuration Guidelines

You use multicast RPF checks to prevent multicast routing loops. Routing loops are particularly debilitating in multicast applications because packets are replicated with each pass around the routing loop.

In general, a router is to forward a multicast packet only if it arrives on the interface closest (as defined by a unicast routing protocol) to the origin of the packet, whether source host or rendezvous point (RP). In other words, if a unicast packet would be sent to the "destination" (the reverse path) on the interface that the multicast packet arrived on, the packet passes the RPF check and is processed. Multicast (or unicast) packets that fail the RPF check are not forwarded (this is the default behavior). For an overview of how a Juniper Networks router implements RPF checks with tables, see "Understanding Multicast Reverse Path Forwarding" on page 4315.

However, there are network router configurations where multicast packets that fail the RPF check need to be forwarded. For example, when point-to-multipoint label-switched paths (LSPs) are used for distributing multicast traffic to PIM "islands" downstream from the egress router, the interface on which the multicast traffic arrives is not always the RPF interface. This is because LSPs do not follow the normal next-hop rules of independent packet routing.

In cases such as these, you can configure policies on the PE router to decide which multicast groups and sources are exempt from the default RPF check.

Example: Configuring a Dedicated PIM RPF Routing Table

This example explains how to configure a dedicated Protocol Independent Multicast (PIM) reverse path forwarding (RPF) routing table.

- Requirements on page 4318
- Overview on page 4318
- Configuration on page 4319

Copyright © 2016, Juniper Networks, Inc.

Requirements

Before you begin:

- Configure the router interfaces. See the *Interfaces Feature Guide for Security Devices*.
- Enable PIM. See "PIM Overview" on page 4089.

This example uses the following software components:

- Junos OS Release 7.4 or later

Overview

By default, PIM uses the **inet.0** routing table as its RPF routing table. PIM uses an RPF routing table to resolve its RPF neighbor for a particular multicast source address and to resolve the RPF neighbor for the rendezvous point (RP) address. PIM can optionally use **inet.2** as its RPF routing table. The **inet.2** routing table is dedicated to this purpose.

PIM uses a single routing table for its RPF check, this ensures that the route with the longest matching prefix is chosen as the RPF route.

If multicast routes are exchanged by Multiprotocol Border Gateway Protocol MP-BGP or multitopology IS-IS, they are placed in **inet.2** by default.

Using **inet.2** as the RPF routing table enables you to have a control plane for multicast, which is independent of the normal unicast routing table. You might want to use **inet.2** as the RPF routing table for any of the following reasons:

- If you use traffic engineering or have an interior gateway protocol (IGP) configured for shortcuts, the router has label-switched paths (LSPs) installed as the next hops in **inet.2**. By applying policy, you can have the router install the routes with non-MPLS next-hops in the **inet.2** routing table.
- If you have an MPLS network that does not support multicast traffic over LSP tunnels, you need to configure the router to use a routing table other than **inet.0**. You can have the **inet.2** routing table populated with native IGP, BGP, and interface routes that can be used for RPF.

To populate the PIM RPF table, you use rib groups. A rib group is defined with the **rib-groups** statement at the **[edit routing-options]** hierarchy level. The rib group is applied to the PIM protocol by including the **rib-group** statement at the **[edit pim]** hierarchy level. A rib group is most frequently used to place routes in multiple routing tables.

When you configure rib groups for PIM, keep the following in mind:

- The **import-rib** statement copies routes from the protocol to the routing table.
- The **export-rib** statement has no effect on PIM.
- Only the first rib routing table specified in the **import-rib** statement is used by PIM for RPF checks.

Copyright © 2016, Juniper Networks, Inc.

You can also configure IS-IS or OSPF to populate **inet.2** with routes that have regular IP next hops. This allows RPF to work properly even when MPLS is configured for traffic engineering, or when IS-IS or OSPF are configured to use “shortcuts” for local traffic.

You can also configure the PIM protocol to use a rib group for RPF checks under a virtual private network (VPN) routing instance. In this case the rib group is still defined at the **[edit routing-options]** hierarchy level.

Configuration

Configuring a PIM RPF Routing Table Group Using Interface Routes

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-options rib-groups mcast-rpf-rib import-rib inet.2
set protocols pim rib-group mcast-rpf-rib
set routing-options interface-routes rib-group inet if-rib
set routing-options rib-groups if-rib import-rib [ inet.0 inet.2 ]
```

Step-by-Step Procedure

In this example, the network administrator has decided to use the **inet.2** routing table for RPF checks. In this process, local routes are copied into this table by using an interface rib group.

To define an interface routing table group and use it to populate **inet.2** for RPF checks:

1. Use the **show multicast rpf** command to verify that the multicast RPF table is not populated with routes.

   ```
   user@host> show multicast rpf
   instance is not running
   ```

2. Create a multicast routing table group named **mcast-rpf-rib**.

   Each routing table group must contain one or more routing tables that Junos OS uses when importing routes (specified in the **import-rib** statement).

   Include the **import-rib** statement and specify the **inet.2** routing table at the **[edit routing-options rib-groups]** hierarchy level.

   ```
   [edit routing-options rib-groups]
   user@host# set mcast-rpf-rib import-rib inet.2
   ```

3. Configure PIM to use the **mcast-rpf-rib** rib group.

   The rib group for PIM can be applied globally or in a routing instance. In this example, the global configuration is shown.

   Include the **rib-group** statement and specify the **mcast-rpf-rib** rib group at the **[edit protocols pim]** hierarchy level.

   ```
   [edit protocols pim]
   user@host# set rib-group mcast-rpf-rib
   ```

4. Create an interface rib group named **if-rib**.

Copyright © 2016, Juniper Networks, Inc.

Include the **rib-group** statement and specify the **inet** address family at the **[edit routing-options interface-routes]** hierarchy level.

```
[edit routing-options interface-routes]
user@host# set rib-group inet if-rib
```

5. Configure the **if-rib** rib group to import routes from the **inet.0** and **inet.2** routing tables.

   Include the **import-rib** statement and specify the **inet.0** and **inet.2** routing tables at the **[edit routing-options rib-groups]** hierarchy level.

```
[edit routing-options rib-groups]
user@host# set if-rib import-rib [ inet.0 inet.2 ]
```

6. Commit the configuration.

```
user@host# commit
```

Verifying Multicast RPF Table

Purpose Verify that the multicast RPF table is now populated with routes.

Action Use the **show multicast rpf** command.

```
user@host> show multicast rpf
Multicast RPF table: inet.2 , 10 entries

10.0.24.12/30
    Protocol: Direct
    Interface: fe-0/1/2.0

10.0.24.13/32
    Protocol: Local

10.0.27.12/30
    Protocol: Direct
    Interface: fe-0/1/3.0

10.0.27.13/32
    Protocol: Local

10.0.224.8/30
    Protocol: Direct
    Interface: ge-1/3/3.0

10.0.224.9/32
    Protocol: Local

127.0.0.1/32
    Inactive

192.168.2.1/32
    Protocol: Direct
    Interface: lo0.0

192.168.187.0/25
    Protocol: Direct
    Interface: fxp0.0
```

Copyright © 2016, Juniper Networks, Inc.

```
192.168.187.12/32
    Protocol: Local
```

Meaning The first line of the sample output shows that the **inet.2** table is being used and that there are 10 routes in the table. The remainder of the sample output lists the routes that populate the **inet.2** routing table.

Example: Configuring RPF Policies

A multicast RPF policy disables RPF checks for a particular multicast (S,G) pair. You usually disable RPF checks on egress routing devices of a point-to-multipoint label-switched path (LSP), because the interface receiving the multicast traffic on a point-to-multipoint LSP egress router might not always be the RPF interface.

This example shows how to configure an RPF check policy named **disable-RPF-on-PE**. The **disable-RPF-on-PE** policy disables RPF checks on packets arriving for group 228.0.0.0/8 or from source address 196.168.25.6.

- Requirements on page 4321
- Overview on page 4321
- Configuration on page 4322
- Verification on page 4323

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.

Overview

An RPF policy behaves like an import policy. If no policy term matches the input packet, the default action is to accept (that is, to perform the RPF check). The **route-filter** statement filters group addresses, and the **source-address-filter** statement filters source addresses.

This example shows how to configure each condition as a separate policy and references both policies in the **rpf-check-policy** statement. This allows you to associate groups in one policy and sources in the other.

NOTE: **Be careful when disabling RPF checks on multicast traffic. If you disable RPF checks in some configurations, multicast loops can result.**

Changes to an RPF check policy take effect immediately:

Copyright © 2016, Juniper Networks, Inc.

- If no policy was previously configured, the policy takes effect immediately.
- If the policy name is changed, the new policy takes effect immediately and any packets no longer filtered are subjected to the RPF check.
- If the policy is deleted, all packets formerly filtered are subjected to the RPF check.
- If the underlying policy is changed, but retains the same name, the new conditions take effect immediately and any packets no longer filtered are subjected to the RPF check.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement disable-RPF-from-group term first from route-filter
  228.0.0.0/8 orlonger
set policy-options policy-statement disable-RPF-from-group term first then reject
set policy-options policy-statement disable-RPF-from-source term first from
  source-address-filter 192.168.25.6/32 exact
set policy-options policy-statement disable-RPF-from-source term first then reject
set routing-options multicast rpf-check-policy [ disable-RPF-from-group
  disable-RPF-from-source ]
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an RPF policy:

1. Configure a policy for group addresses.

   ```
   [edit policy-options]
   user@host# set policy-statement disable-RPF-for-group term first from route-filter
     228.0.0.0/8 orlonger
   user@host# set policy-statement disable-RPF-for-group term first then reject
   ```

2. Configure a policy for a source address.

   ```
   [edit policy-options]
   user@host# set policy-statement disable-RPF-for-source term first from
     source-address-filter 192.168.25.6/32 exact
   user@host# set policy-statement disable-RPF-for-source term first then reject
   ```

3. Apply the policies.

   ```
   [edit routing-options]
   user@host# set multicast rpf-check-policy [ disable-RPF-for-group
     disable-RPF-for-source ]
   ```

4. If you are done configuring the device, commit the configuration.

   ```
   user@host# commit
   ```

Copyright © 2016, Juniper Networks, Inc.

Results

Confirm your configuration by entering the **show policy-options** and **show routing-options** commands.

```
user@host# show policy-options
policy-statement disable-RPF-from-group {
   term first {
      from {
         route-filter 228.0.0.0/8 orlonger;
      }
      then reject;
   }
}
policy-statement disable-RPF-from-source {
   term first {
      from {
         source-address-filter 192.168.25.6/32 exact;
      }
      then reject;
   }
}
```

```
user@host# show routing-options
multicast {
   rpf-check-policy [ disable-RPF-from-group disable-RPF-from-source ];
}
```

Verification

To verify the configuration, run the show multicast rpf command.

Example: Configuring PIM RPF Selection

This example shows how to configure and verify the multicast PIM RPF next-hop neighbor selection for a group or (S,G) pair.

- Requirements on page 4323
- Overview on page 4324
- Configuration on page 4325
- Verification on page 4327

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Security Devices*.
- Make sure that the RPF next-hop neighbor you want to specify is operating.

Copyright © 2016, Juniper Networks, Inc.

Overview

Multicast PIM RPF neighbor selection allows you to specify the RPF neighbor (next hop) and source address for a single group or multiple groups using a prefix list. RPF neighbor selection can only be configured for VPN routing and forwarding (VRF) instances.

If you have multiple service VRFs through which a receiver VRF can learn the same source or rendevous point (RP) address, PIM RPF checks typically choose the best path determined by the unicast protocol for all multicast flows. However, if RPF neighbor selection is configured, RPF checks are based on your configuration instead of the unicast routing protocols.

You can use this static RPF selection as a building block for particular applications. For example, an extranet. Suppose you want to split the multicast flows among parallel PIM links or assign one multicast flow to a specific PIM link. With static RPF selection configured, the router sends join and prune messages based on the configuration.

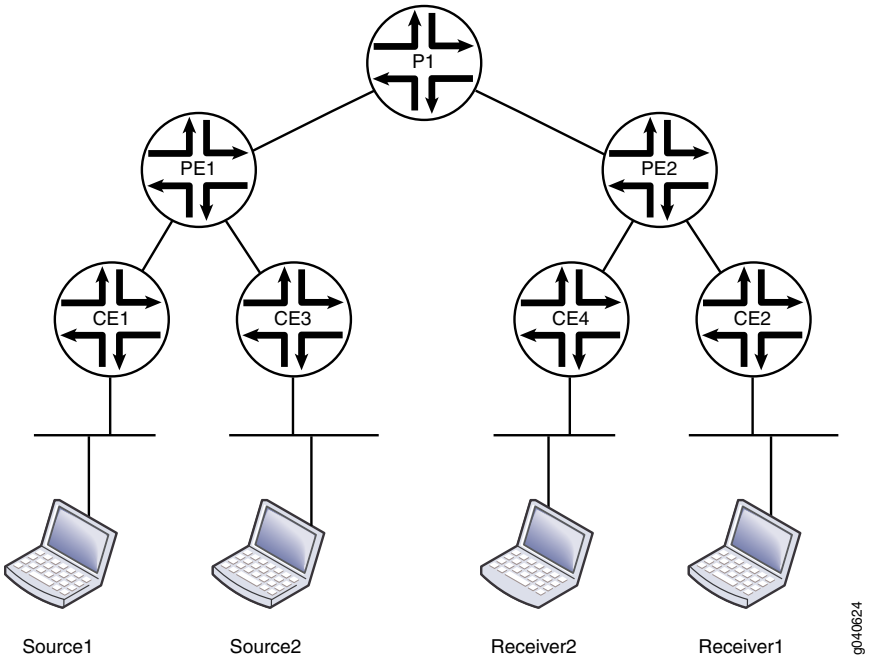
You can use wildcards to designate the source address. Whether or not you use wildcards affects how the PIM joins work:

- If you configure only a source prefix for a group, all (*,G) joins are sent to the next-hop neighbor selected by the unicast protocol, while (S,G) joins are sent to the next-hop neighbor specified for the source.
- If you configure only a wildcard source for a group, all (*,G) and (S,G) joins are sent to the upstream interface pointing to the wildcard source next-hop neighbor.
- If you configure both a source prefix and a wildcard source for a group, all (S,G) joins are sent to the next-hop neighbor defined for the source prefix, while (*,G) joins are sent to the next-hop neighbor specified for the wildcard source.

Figure 197 shows the topology used in this example.

Copyright © 2016, Juniper Networks, Inc.

Figure 197: PIM RPF Selection



In this example, the RPF selection is configured on the receiver provider edge router (PE2).

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set routing-instance vpn-a protocols pim rpf-selection group 225.5.0.0/16 wildcard-source
    next-hop 10.12.5.2
set routing-instance vpn-a protocols pim rpf-selection prefix-list group12 wildcard-source
    next-hop 10.12.31.2
set routing-instance vpn-a protocols pim rpf-selection prefix-list group34 source
    22.1.12.0/24 next-hop 10.12.32.2
set policy-options prefix-list group12 225.1.1.0/24
set policy-options prefix-list group12 225.2.0.0/16
set policy-options prefix-list group34 225.3.3.3/32
set policy-options prefix-list group34 225.4.4.0/24
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PIM RPF selection:

1. On PE2, configure RFP selection in a routing instance.

```
[edit routing-instance vpn-a protocols pim]
user@host# set rpf-selection group 225.5.0.0/16 wildcard-source next-hop 10.12.5.2
user@host# set rpf-selection prefix-list group12 wildcard-source next-hop 10.12.31.2
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set rpf-selection prefix-list group34 source 22.1.12.0/24 next-hop
  10.12.32.2
user@host# exit
```

2. On PE2, configure the policy.

```
[edit policy-options]
set prefix-list group12 225.1.1.0/24
set prefix-list group12 225.2.0.0/16
set prefix-list group34 225.3.3.3/32
set prefix-list group34 225.4.4.0/24
```

3. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results From configuration mode, confirm your configuration by entering the **show policy-options** and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
prefix-list group12 {
  225.1.1.0/24;
  225.2.0.0/16;
}
prefix-list group34 {
  225.3.3.3/32;
  225.4.4.0/24;
}
```

```
user@host# show routing-instances
vpn-a{
  protocols {
    pim {
      rpf-selection {
        group 225.5.0.0/16 {
          wildcard-source {
            next-hop 10.12.5.2;
          }
        }
        prefix-list group12 {
          wildcard-source {
            next-hop 10.12.31.2;
          }
        }
        prefix-list group34 {
          source 22.1.12.0/24 {
            next-hop 10.12.32.2;
          }
        }
      }
    }
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

Verification

To verify the configuration, run the following commands, checking the upstream interface and the upstream neighbor:

- show pim join **extensive**
- show multicast route

- Configuring IGMP Snooping Trace Operations on page 4341

Understanding Multicast Snooping

Network devices such as routers operate mainly at the packet level, or Layer 3. Other network devices such as bridges or LAN switches operate mainly at the frame level, or Layer 2. Multicasting functions mainly at the packet level, Layer 3, but there is a way to map Layer 3 IP multicast group addresses to Layer 2 MAC multicast group addresses at the frame level.

Routers can handle both Layer 2 and Layer 3 addressing information because the frame and its addresses must be processed to access the encapsulated packet inside. Routers can run Layer 3 multicast protocols such as PIM or IGMP and determine where to forward multicast content or when a host on an interface joins or leaves a group. However, bridges and LAN switches, as Layer 2 devices, are not supposed to have access to the multicast information inside the packets that their frames carry.

Copyright © 2016, Juniper Networks, Inc.

How then are bridges and other Layer 2 devices to determine when a device on an interface joins or leaves a multicast tree, or whether a host on an attached LAN wants to receive the content of a particular multicast group?

The answer is for the Layer 2 device to implement multicast snooping. Multicast snooping is a general term and applies to the process of a Layer 2 device "snooping" at the Layer 3 packet content to determine which actions are taken to process or forward a frame. There are more specific forms of snooping, such as IGMP snooping or PIM snooping. In all cases, snooping involves a device configured to function at Layer 2 having access to normally "forbidden" Layer 3 (packet) information. Snooping makes multicasting more efficient in these devices.

Understanding IGMP Snooping

Snooping is a general way for Layer 2 devices, such as Juniper Networks MX Series Ethernet Services Routers, to implement a series of procedures to "snoop" at the Layer 3 packet content to determine which actions are to be taken to process or forward a frame. More specific forms of snooping, such as Internet Group Membership Protocol (IGMP) snooping or Protocol Independent Multicast (PIM) snooping, are used with multicast.

Layer 2 devices (LAN switches or bridges) handle multicast packets and the frames that contain them much in the same way the Layer 3 devices (routers) handle broadcasts. So, a Layer 2 switch processes an arriving frame having a multicast destination media access control (MAC) address by forwarding a copy of the packet (frame) onto each of the other network interfaces of the switch that are in a forwarding state.

However, this approach (sending multicast frames everywhere the device can) is not the most efficient use of network bandwidth, particularly for IPTV applications. IGMP snooping functions by "snooping" at the IGMP packets received by the switch interfaces and building a multicast database similar to that a multicast router builds in a Layer 3 network. Using this database, the switch can forward multicast traffic only onto downstream interfaces with interested receivers, and this technique allows more efficient use of network bandwidth.

You configure IGMP snooping for each bridge on the router. A bridge instance without qualified learning has just one learning domain. For a bridge instance with qualified learning, snooping will function separately within each learning domain in the bridge. That is, IGMP snooping and multicast forwarding will proceed independently in each learning domain in the bridge.

This discussion focuses on bridge instances without qualified learning (those forming one learning domain on the device). Therefore, all the interfaces mentioned are logical interfaces of the bridge or VPLS instance.

Several related concepts are important when discussing IGMP snooping:

- Bridge or VPLS instance interfaces are either multicast-router interfaces or host-side interfaces.
- IGMP snooping supports proxy mode or without-proxy mode.

Copyright © 2016, Juniper Networks, Inc.

NOTE: When integrated routing and bridging (IRB) is used, if the router is an IGMP querier, any leave message received on any Layer 2 interface will cause a group-specific query on all Layer 2 interfaces (as a result of this practice, some corresponding reports might be received on all Layer 2 interfaces). However, if some of the Layer 2 interfaces are also router (Layer 3) interfaces, reports and leaves from other Layer 2 interfaces will not be forwarded on those interfaces.

If an IRB interface is used as an outgoing interface in a multicast forwarding cache entry (as determined by the routing process), then the output interface list is expanded into a subset of the Layer 2 interface in the corresponding bridge. The subset is based on the snooped multicast membership information, according to the multicast forwarding cache entry installed by the snooping process for the bridge.

If no snooping is configured, the IRB output interface list is expanded to all Layer 2 interfaces in the bridge.

The Junos OS does not support IGMP snooping in a VPLS configuration on a virtual switch. This configuration is disallowed in the CLI.

IGMP Snooping Interfaces and Forwarding

IGMP snooping divides the device interfaces into multicast-router interfaces and host-side interfaces. A multicast-router interface is an interface in the direction of a multicasting router. An interface on the bridge is considered a multicast-router interface if it meets at least one of the following criteria:

- It is statically configured as a multicast-router interface in the bridge instance.
- IGMP queries are being received on the interface.

All other interfaces that are not multicast-router interfaces are considered host-side interfaces.

Any multicast traffic received on a bridge interface with IGMP snooping configured will be forwarded according to following rules:

- Any IGMP packet is sent to the Routing Engine for snooping processing.
- Other multicast traffic with destination address 224.0.0/24 is flooded onto all other interfaces of the bridge.
- Other multicast traffic is sent to all the multicast-router interfaces but only to those host-side interfaces that have hosts interested in receiving that multicast group.

IGMP Snooping and Proxies

Without a proxy arrangement, IGMP snooping does not generate or introduce queries and reports. It will only “snoop” reports received from all of its interfaces (including multicast-router interfaces) to build its state and group (S,G) database.

Copyright © 2016, Juniper Networks, Inc.

Without a proxy, IGMP messages are processed as follows:

- Query—All general and group-specific IGMP query messages received on a multicast-router interface are forwarded to all other interfaces (both multicast-router interfaces and host-side interfaces) on the bridge.
- Report—IGMP reports received on any interface of the bridge are forwarded toward other multicast-router interfaces. The receiving interface is added as an interface for that group if a multicast routing entry exists for this group. Also, a group timer is set for the group on that interface. If this timer expires (that is, there was no report for this group during the IGMP group timer period), then the interface is removed as an interface for that group.
- Leave—Any IGMP leave message received on any interface of the bridge. The Leave Group message reduces the time it takes for the multicast router to stop forwarding multicast traffic when there are no longer any members in the host group.

Proxy snooping reduces the number of IGMP reports sent toward an IGMP router.

NOTE: With proxy snooping configured, an IGMP router is not able to perform host tracking.

As proxy for its host-side interfaces, IGMP snooping in proxy mode replies to the queries it receives from an IGMP router on a multicast-router interface. On the host-side interfaces, IGMP snooping in proxy mode behaves as an IGMP router and sends general and group-specific queries on those interfaces.

NOTE: Only group-specific queries are generated by IGMP snooping directly. General queries received from the multicast-router interfaces are flooded to host-side interfaces.

All the queries generated by IGMP snooping are sent using 0.0.0.0 as the source address. Also, all reports generated by IGMP snooping are sent with 0.0.0.0 as the source address unless there is a configured source address to use.

Proxy mode functions differently on multicast-router interfaces than it does on host-side interfaces.

Multicast-Router Interfaces and IGMP Snooping Proxy Mode

On multicast-router interfaces, in response to IGMP queries, IGMP snooping in proxy mode sends reports containing aggregate information on groups learned on all host-side interfaces of the bridge.

Besides replying to queries, IGMP snooping in proxy mode forwards all queries, reports, and leaves received on a multicast-router interface to other multicast-router interfaces. IGMP snooping keeps the membership information learned on this interface but does not send a group-specific query for leave messages received on this interface. It simply

Copyright © 2016, Juniper Networks, Inc.

times out the groups learned on this interface if there are no reports for the same group within the timer duration.

NOTE: For the hosts on all the multicast-router interfaces, it is the IGMP router, not the IGMP snooping proxy, that generates general and group-specific queries.

Host-Side Interfaces and IGMP Snooping Proxy Mode

No reports are sent on host-side interfaces by IGMP snooping in proxy mode. IGMP snooping processes reports received on these interfaces and sends group-specific queries onto host-side interfaces when it receives a leave message on the interface. Host-side interfaces do not generate periodic general queries, but forwards or floods general queries received from multicast-router interfaces.

If a group is removed from a host-side interface and this was the last host-side interface for that group, a leave is sent to the multicast-router interfaces. If a group report is received on a host-side interface and this was the first host-side interface for that group, a report is sent to all multicast-router interfaces.

IGMP Snooping and Bridge Domains

IGMP snooping on a VLAN is only allowed for the legacy **vlan-id all** case. In other cases, there is a specific bridge domain configuration that determines the VLAN-specific configuration for IGMP snooping.

Configuring IGMP Snooping

To configure Internet Group Management Protocol (IGMP) snooping, include the **igmp-snooping** statement:

```
igmp-snooping {
    immediate-leave;
    interface interface-name {
        group-limit limit;
        host-only-interface;
        immediate-leave;
        multicast-router-interface;
        static {
            group ip-address {
                source ip-address;
            }
        }
    }
    proxy {
        source-address ip-address;
    }
    query-interval seconds;
    query-last-member-interval seconds;
    query-response-interval seconds;
    robust-count number;
    vlan vlan-id {
```

Copyright © 2016, Juniper Networks, Inc.

```
        immediate-leave;
        interface interface-name {
          group-limit limit;
          host-only-interface;
          immediate-leave;
          multicast-router-interface;
          static {
            group ip-address {
              source ip-address;
            }
          }
        }
        proxy {
          source-address ip-address;
        }
        query-interval seconds;
        query-last-member-interval seconds;
        query-response-interval seconds;
        robust-count number;
      }
    }
```

You can include this statement at the following hierarchy levels:

- **[edit bridge-domains *bridge-domain-name* protocols]**
- **[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols]**

By default, IGMP snooping is not enabled. Statements configured at the VLAN level apply only to that particular VLAN.

Configuring VLAN-Specific IGMP Snooping Parameters

All of the IGMP snooping statements configured with the **igmp-snooping** statement, with the exception of the **traceoptions** statement, can be qualified with the same statement at the VLAN level. To configure IGMP snooping parameters at the VLAN level, include the **vlan** statement:

```
vlan vlan-id;
  immediate-leave;
  interface interface-name {
    group-limit limit;
    host-only-interface;
    multicast-router-interface;
    static {
      group ip-address {
        source ip-address;
      }
    }
  }
  proxy {
    source-address ip-address;
  }
  query-interval seconds;
  query-last-member-interval seconds;
```

Copyright © 2016, Juniper Networks, Inc.

```
    query-response-interval seconds;
    robust-count number;
}
```

You can include this statement at the following hierarchy levels:

- **[edit bridge-domains *bridge-domain-name* protocols igmp-snooping]**
- **[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping]**

Example: Configuring IGMP Snooping

This example shows how to configure IGMP snooping. IGMP snooping can reduce unnecessary traffic from IP multicast applications.

- Requirements on page 4335
- Overview and Topology on page 4335
- Configuration on page 4339
- Verification on page 4341

Requirements

This example uses the following hardware components:

- One MX Series router
- One Layer 3 device functioning as a multicast router

Before you begin:

- Configure the interfaces. See the *Interfaces Feature Guide for Security Devices*.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure a multicast protocol. This feature works with the following multicast protocols:
  - DVMRP
  - PIM-DM
  - PIM-SM
  - PIM-SSM

Overview and Topology

IGMP snooping controls multicast traffic in a switched network. When IGMP snooping is not enabled, the Layer 2 device broadcasts multicast traffic out of all of its ports, even if the hosts on the network do not want the multicast traffic. With IGMP snooping enabled, a Layer 2 device monitors the IGMP join and leave messages sent from each connected host to a multicast router. This enables the Layer 2 device to keep track of the multicast groups and associated member ports. The Layer 2 device uses this information to make

Copyright © 2016, Juniper Networks, Inc.

intelligent decisions and to forward multicast traffic to only the intended destination hosts.

This example includes the following statements:

- **proxy**—Enables the Layer 2 device to actively filter IGMP packets to reduce load on the multicast router. Joins and leaves heading upstream to the multicast router are filtered so that the multicast router has a single entry for the group, regardless of how many active listeners have joined the group. When a listener leaves a group but other listeners remain in the group, the leave message is filtered because the multicast router does not need this information. The status of the group remains the same from the router's point of view.
- **immediate-leave**—When only one IGMP host is connected, the **immediate-leave** statement enables the multicast router to immediately remove the group membership from the interface and suppress the sending of any group-specific queries for the multicast group.

  When you configure this feature on IGMPv2 interfaces, ensure that the IGMP interface has only one IGMP host connected. If more than one IGMPv2 host is connected to a LAN through the same interface, and one host sends a leave message, the router removes all hosts on the interface from the multicast group. The router loses contact with the hosts that properly remain in the multicast group until they send join requests in response to the next general multicast listener query from the router.

  When IGMP snooping is enabled on a router running IGMP version 3 (IGMPv3) snooping, after the router receives a report with the type BLOCK_OLD_SOURCES, the router suppresses the sending of group-and-source queries but relies on the Junos OS host-tracking mechanism to determine whether or not it removes a particular source group membership from the interface.
- **query-interval**—Enables you to change the number of IGMP messages sent on the subnet by configuring the interval at which the IGMP querier router sends general host-query messages to solicit membership information.

  By default, the query interval is 125 seconds. You can configure any value in the range 1 through 1024 seconds.
- **query-last-member-interval**—Enables you to change the amount of time it takes a device to detect the loss of the last member of a group.

  The last-member query interval is the maximum amount of time between group-specific query messages, including those sent in response to leave-group messages.

  By default, the last-member query interval is 1 second. You can configure any value in the range 0.1 through 0.9 seconds, and then 1-second intervals from 1 through 1024 seconds.
- **query-response-interval**—Configures how long the router waits to receive a response from its host-query messages.

  By default, the query response interval is 10 seconds. You can configure any value in the range 1 through 1024 seconds. This interval should be less than the interval set in the **query-interval** statement.

Copyright © 2016, Juniper Networks, Inc.

- **robust-count**—Provides fine-tuning to allow for expected packet loss on a subnet. It is basically the number of intervals to wait before timing out a group. You can wait more intervals if subnet packet loss is high and IGMP report messages might be lost.

  By default, the robust count is 2. You can configure any value in the range 2 through 10 intervals.

- **group-limit**—Configures a limit for the number of multicast groups (or [S,G] channels in IGMPv3) that can join an interface. After this limit is reached, new reports are ignored and all related flows are discarded, not flooded.

  By default, there is no limit to the number of groups that can join an interface. You can configure a limit in the range 0 through a 32-bit number.

- **host-only-interface**—Configure an IGMP snooping interface to be an exclusively host-side interface. On a host-side interface, received IGMP queries are dropped.

  By default, an interface can face either other multicast routers or hosts.

- **multicast-router-interface**—Configures an IGMP snooping interface to be an exclusively router-facing interface.

  By default, an interface can face either other multicast routers or hosts.

- **static**—Configures an IGMP snooping interface with multicast groups statically.

  By default, the router learns about multicast groups on the interface dynamically.

Figure 198 shows networks without IGMP snooping. Suppose host A is an IP multicast sender and hosts B and C are multicast receivers. The router forwards IP multicast traffic only to those segments with registered receivers (hosts B and C). However, the Layer 2 devices flood the traffic to all hosts on all interfaces.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set bridge-domains domain1 domain-type bridge
set bridge-domains domain1 interface ge-0/0/1.1
set bridge-domains domain1 interface ge-0/0/2.1
set bridge-domains domain1 interface ge-0/0/3.1
set bridge-domains domain1 protocols igmp-snooping query-interval 200
set bridge-domains domain1 protocols igmp-snooping query-response-interval 0.4
set bridge-domains domain1 protocols igmp-snooping query-last-member-interval 0.1
set bridge-domains domain1 protocols igmp-snooping robust-count 4
set bridge-domains domain1 protocols igmp-snooping immediate-leave
set bridge-domains domain1 protocols igmp-snooping proxy
set bridge-domains domain1 protocols igmp-snooping interface ge-0/0/1.1
  host-only-interface
set bridge-domains domain1 protocols igmp-snooping interface ge-0/0/1.1 group-limit
  50
set bridge-domains domain1 protocols igmp-snooping interface ge-0/0/3.1 static group
  225.100.100.100
set bridge-domains domain1 protocols igmp-snooping interface ge-0/0/2.1
  multicast-router-interface
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure IGMP snooping:

1. Configure the bridge domain.

```
[edit bridge-domains domain1]
user@host# set domain-type bridge
user@host# set interface ge-0/0/1.1
user@host# set interface ge-0/0/2.1
user@host# set interface ge-0/0/3.1
```

2. Enable IGMP snooping and configure the router to serve as a proxy.

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping proxy
```

3. Configure the limit for the number of multicast groups allowed on the **ge-0/0/1.1** interface to 50.

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping interface ge-0/0/1.1group-limit 50
```

4. Configure the router to immediately remove a group membership from an interface when it receives a leave message from that interface without waiting for any other IGMP messages to be exchanged.

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping immediate-leave
```

5. Statically configure IGMP group membership on a port.

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping interface ge-0/0/3.1 static group
  225.100.100.100
```

6. Configure an interface to be an exclusively router-facing interface (to receive multicast traffic).

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping interface ge-0/0/2.1
  multicast-router-interface
```

7. Configure an interface to be an exclusively host-facing interface (to drop IGMP query messages).

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snooping interface ge-0/0/1.1 host-only-interface
```

8. Configure the IGMP message intervals and robustness count.

```
[edit bridge-domains domain1]
user@host# set protocols igmp-snoopingrobust-count 4
user@host# set protocols igmp-snooping query-last-member-interval 0.1
user@host# set protocols igmp-snooping query-interval 200
user@host# set protocols igmp-snooping query-response-interval 0.4
```

Copyright © 2016, Juniper Networks, Inc.

9. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results Confirm your configuration by entering the **show bridge-domains** command.

```
user@host# show bridge-domains
domain1 {
  domain-type bridge;
  interface ge-0/0/1.1;
  interface ge-0/0/2.1;
  interface ge-0/0/3.1;
  protocols {
    igmp-snooping {
      query-interval 200;
      query-response-interval 0.4;
      query-last-member-interval 0.1;
      robust-count 4;
      immediate-leave;
      proxy;
      interface ge-0/0/1.1 {
        host-only-interface;
        group-limit 50;
      }
      interface ge-0/0/3.1 {
        static {
          group 225.100.100.100;
        }
      }
      interface ge-0/0/2.1 {
        multicast-router-interface;
      }
    }
  }
}
```

Verification

To verify the configuration, run the following commands:

- show igmp snooping interface
- show igmp snooping membership
- show igmp snooping statistics

Configuring IGMP Snooping Trace Operations

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy

Copyright © 2016, Juniper Networks, Inc.

actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
all	Trace all operations.
client-notification	Trace notifications.
general	Trace general flow.
group	Trace group operations.
host-notification	Trace host notifications.
leave	Trace leave group messages (IGMPv2 only).
normal	Trace normal events.
packets	Trace all IGMP packets.
policy	Trace policy processing.
query	Trace IGMP membership query messages.
report	Trace membership report messages.
route	Trace routing information.
state	Trace state transitions.
task	Trace routing protocol task processing.
timer	Trace timer processing.

You can configure tracing operations for IGMP snooping globally or in a routing instance. The following example shows the global configuration.

To configure tracing operations for IGMP snooping:

1. Configure the filename for the trace file.

   [edit bridge-domains domain1 protocols igmp-snooping traceoptions]
   user@host# **set file igmp-snoop-trace**

2. (Optional) Configure the maximum number of trace files.

   [edit bridge-domains domain1 protocols igmp-snooping traceoptions]
   user@host# **set file files 5**

3. (Optional) Configure the maximum size of each trace file.

   [edit bridge-domains domain1 protocols igmp-snooping traceoptions]

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set file size 1m
```

4. (Optional) Enable unrestricted file access.

```
[edit bridge-domains domain1 protocols igmp-snooping traceoptions]
user@host# set file world-readable
```

5. Configure tracing flags. Suppose you are troubleshooting issues with a policy related to received packets on a particular logical interface with an IP address of 192.168.0.1. The following example shows how to flag all policy events for received packets associated with the IP address.

```
[edit bridge-domains domain1 protocols igmp-snooping traceoptions]
user@host# set flag policy receive | match 192.168.0.1
```

6. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/igmp-snoop-trace
```

Understanding Multicast Snooping

Network devices such as routers operate mainly at the packet level, or Layer 3. Other network devices such as bridges or LAN switches operate mainly at the frame level, or Layer 2. Multicasting functions mainly at the packet level, Layer 3, but there is a way to map Layer 3 IP multicast group addresses to Layer 2 MAC multicast group addresses at the frame level.

Routers can handle both Layer 2 and Layer 3 addressing information because the frame and its addresses must be processed to access the encapsulated packet inside. Routers can run Layer 3 multicast protocols such as PIM or IGMP and determine where to forward multicast content or when a host on an interface joins or leaves a group. However, bridges and LAN switches, as Layer 2 devices, are not supposed to have access to the multicast information inside the packets that their frames carry.

How then are bridges and other Layer 2 devices to determine when a device on an interface joins or leaves a multicast tree, or whether a host on an attached LAN wants to receive the content of a particular multicast group?

Copyright © 2016, Juniper Networks, Inc.

The answer is for the Layer 2 device to implement multicast snooping. Multicast snooping is a general term and applies to the process of a Layer 2 device "snooping" at the Layer 3 packet content to determine which actions are taken to process or forward a frame. There are more specific forms of snooping, such as IGMP snooping or PIM snooping. In all cases, snooping involves a device configured to function at Layer 2 having access to normally "forbidden" Layer 3 (packet) information. Snooping makes multicasting more efficient in these devices.

Understanding Multicast Snooping and VPLS Root Protection

Snooping occurs when a Layer 2 protocol such as a spanning-tree protocol is aware of the operational details of a Layer 3 protocol such as the Internet Group Management Protocol (IGMP) or other multicast protocol. Snooping is necessary when Layer 2 devices such as VLAN switches must be aware of Layer 3 information such as the media access control (MAC) addresses of members of a multicast group.

VPLS root protection is a spanning-tree protocol process in which only one interface in a multihomed environment is actively forwarding spanning-tree protocol frames. This protects the root of the spanning tree against bridging loops, but also prevents both devices in the multihomed topology from snooped information, such as IGMP membership reports.

For example, consider a collection of multicast-capable hosts connected to two customer edge (CE) routers (CE1 and CE2) which are connected to each other (a CE1–CE2 link is configured) and multihomed to two provider edge (PE) routers (PE1 and PE2, respectively). The active PE only receives forwarded spanning-tree protocol information on the active PE-CE link, due to root protection operation. As long as the CE1–CE2 link is operational, this is not a problem. However, if the link between CE1 and CE2 fails, and the other PE becomes the active spanning-tree protocol link, no multicast snooping information is available on the new active PE. The new active PE will not forward multicast traffic to the CE and the hosts serviced by this CE router.

The service outage is corrected once the hosts send new group membership IGMP reports to the CE routers. However, the service outage can be avoided if multicast snooping information is available to both PEs in spite of normal spanning-tree protocol root protection operation.

NOTE: **You can configure multicast snooping to ignore messages about spanning tree topology changes for the virtual-switch routing-instance type only.**

Configuring Multicast Snooping

To configure the general multicast snooping parameters for MX Series routers, include the **multicast-snooping-options** statement:

```
multicast-snooping-options {
  flood-groups [ ip-addresses ];
  forwarding-cache {
    threshold suppress value <reuse value>;
```

Copyright © 2016, Juniper Networks, Inc.

```
    }
    graceful-restart <restart-duration seconds>;
    ignore-stp-topology-change;
    multichassis-lag-replicate-state;
    nexthop-hold-time milliseconds;
    traceoptions {
      file filename <files number> <size size> <world-readable | no-world-readable>;
      flag flag <flag-modifier> <disable>;
    }
  }
```

You can include this statement at the following hierarchy levels:

- **[edit bridge-domains *bridge-domain-name*]**
- **[edit routing-instances *routing-instance-name*]**
- **[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name*]**

By default, multicast snooping is disabled. You can enable multicast snooping in VPLS or virtual switch instance types in the instance hierarchy or in one or more bridge domains.

If there are multiple bridge domains configured under a VPLS or virtual switch instance, the multicast snooping options configured at the instance level apply to all the bridge domains. Multicast snooping options configured at the bridge domain level only apply to that particular bridge domain. The options configured at the bridge domain take precedence over the options configured at the instance level.

NOTE: The **ignore-stp-topology-change** statement is supported for the **virtual-switch** routing instance type only and is not supported under the **[edit logical-systems]** hierarchy.

NOTE: The **nexthop-hold-time** statement is supported only at the **[edit routing-instances *routing-instance-name*]** hierarchy, and only for an instance type of **virtual-switch** or **vpls**.

Example: Configuring Multicast Snooping

This example shows how to configure multicast snooping in a bridge or VPLS routing-instance scenario.

- Requirements on page 4346
- Overview and Topology on page 4346
- Configuration on page 4348
- Verification on page 4350

Requirements

This example uses the following hardware components:

- One MX Series router
- One Layer 3 device functioning as a multicast router

Before you begin:

- Configure the interfaces.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure a multicast protocol. This feature works with the following multicast protocols:
  - DVMRP
  - PIM-DM
  - PIM-SM
  - PIM-SSM

Overview and Topology

IGMP snooping prevents Layer 2 devices from indiscriminately flooding multicast traffic out all interfaces. The settings that you configure for multicast snooping help manage the behavior of IGMP snooping.

You can configure multicast snooping options on the default master instance and on individual bridge or VPLS instances. The default master instance configuration is global and applies to all individual bridge or VPLS instances in the logical router. The configuration for the individual instances overrides the global configuration.

This example includes the following statements:

- **flood-groups**—Enables you to list multicast group addresses for which traffic must be flooded. This setting if useful for making sure that IGMP snooping does not prevent necessary multicast flooding. The block of multicast addresses from 224.0.0.1 through 224.0.0.255 is reserved for local wire use. Groups in this range are assigned for various uses, including routing protocols and local discovery mechanisms. For example, OSPF uses 224.0.0.5 for all OSPF routers.
- **forwarding-cache**—Specifies how forwarding entries are aged out and how the number of entries is controlled.

  You can configure threshold values on the forwarding cache to suppress (suspend) snooping when the cache entries reach a certain maximum and reuse the cache when the number falls to another threshold value. By default, no threshold values are enabled on the router.

Copyright © 2016, Juniper Networks, Inc.

The suppress threshold suppresses new multicast forwarding cache entries. An optional reuse threshold specifies the point at which the router begins to create new multicast forwarding cache entries. The range for both thresholds is from 1 through 200,000. If configured, the reuse value must be less than the suppression value. The suppression value is mandatory. If you do not specify the optional reuse value, then the number of multicast forwarding cache entries is limited to the suppression value. A new entry is created as soon as the number of multicast forwarding cache entries falls below the suppression value.

- **graceful-restart**—Configures the time after which routes learned before a restart are replaced with routes relearned. If graceful restart for multicast snooping is disabled, snooping information is lost after a Routing Engine restart.

  By default, the graceful restart duration is 180 seconds (3 minutes). You can set this value between 0 and 300 seconds. If you set the duration to 0, graceful restart is effectively disabled. Set this value slightly larger than the IGMP query response interval.

- **ignore-stp-topology-change**—Configures the MX Series router to ignore messages about the spanning-tree topology state change.

  By default the IGMP snooping process on an MX Series router detects interface state changes made by any of the spanning tree protocols (STPs).

  In a VPLS multihoming environment where two PE routers are connected to two interconnected CE routers and STP root protection is enabled on the PE routers, one of the PE router interfaces is in forwarding state and the other is in blocking state.

  If the link interconnecting the two CE routers fails, the PE router interface in blocking state transitions to the forwarding state.

  The PE router interface does not wait to receive membership reports in response to the next general or group-specific query. Instead, the IGMP snooping process sends a general query message toward the CE router. The hosts connected to the CE router reply with reports for all groups they are interested in.

  When the link interconnecting the two CE routers is restored, the original spanning-tree state on both PE routers is restored. The forwarding PE receives a spanning-tree topology change message and sends a general query message toward the CE router to immediately reconstruct the group membership state.

NOTE: **The ignore-stp-topology-change statement is supported for the virtual-switch routing instance type only.**

Figure 200 shows a VPLS multihoming topology in which a customer network has two CE devices with a link between them. Each CE is connected to one PE.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set bridge-domains domain1 multicast-snooping-options forwarding-cache threshold
  suppress 100
set bridge-domains domain1 multicast-snooping-options forwarding-cache threshold
  reuse 50
set bridge-domains domain1 multicast-snooping-options graceful-restart restart-duration
  120
set routing-instances ce1 instance-type virtual-switch
set routing-instances ce1 bridge-domains domain1 domain-type bridge
set routing-instances ce1 bridge-domains domain1 vlan-id 100
set routing-instances ce1 bridge-domains domain1 interface ge-0/3/9.0
set routing-instances ce1 bridge-domains domain1 interface ge-0/0/6.0
set routing-instances ce1 bridge-domains domain1 multicast-snooping-options
  flood-groups 224.0.0.5
set routing-instances ce1 bridge-domains domain1 multicast-snooping-options
  ignore-stp-topology-change
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure IGMP snooping:

1. Configure multicast snooping settings in the master routing instance.

```
[edit bridge-domains domain1]
user@host# set multicast-snooping-options forwarding-cache threshold suppress
  100 reuse 50
user@host# set multicast-snooping-options graceful-restart 120
```

Copyright © 2016, Juniper Networks, Inc.

2. Configure the routing instance.

```
[edit routing-instances ce1]
user@host# set instance-type virtual-switch
```

3. Configure the bridge domain in the routing instance.

```
[edit routing-instances ce1 bridge-domains domain1]
user@host# set domain-type bridge
user@host# set interface ge-0/0/6.0
user@host# set interface ge-0/3/9.0
user@host# set vlan-id 100
```

4. Configure flood groups.

```
[edit routing-instances ce1 bridge-domains domain1]
user@host# set multicast-snooping-options flood-groups 224.0.0.5
```

5. Configure the router to ignore messages about spanning-tree topology state changes.

```
[edit routing-instances ce1 bridge-domains domain1]
user@host# set multicast-snooping-options ignore-stp-topology-change
```

6. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results Confirm your configuration by entering the **show bridge-domains** and **show routing-instances** commands.

```
user@host# show bridge-domains
domain1 {
  multicast-snooping-options {
    forwarding-cache {
      threshold {
        suppress 100;
        reuse 50;
      }
    }
    graceful-restart {
      restart-duration 120;
    }
  }
}
```

```
user@host# show routing-instances
ce1 {
  instance-type virtual-switch;
  bridge-domains {
    domain1 {
      domain-type bridge;
      vlan-id 100;
      interface ge-0/3/9.0; ## 'ge-0/3/9.0' is not defined
      interface ge-0/0/6.0; ## 'ge-0/0/6.0' is not defined
      multicast-snooping-options {
        flood-groups 224.0.0.5;
        ignore-stp-topology-change;
```

Copyright © 2016, Juniper Networks, Inc.

```
        }
      }
    }
  }
```

Verification

To verify the configuration, run the following commands:

- show igmp snooping interface
- show igmp snooping membership
- show igmp snooping statistics
- show multicast snooping route
- show multicast snooping statistics
- show route table

Enabling Bulk Updates for Multicast Snooping

Whenever an individual interface joins or leaves a multicast group, a new next hop entry is installed in the routing table and the forwarding table. You can use the **nexthop-hold-time** statement to specify a time, from 1 through 1000 milliseconds (ms), during which outgoing interface changes are accumulated and then updated in bulk to the routing table and forwarding table. Bulk updating reduces the processing time and memory overhead required to process join and leave messages. This is useful for applications such as Internet Potocol television (IPTV), in which users changing channels can create thousands of interfaces joining or leaving a group in a short period. In IPTV scenarios, typically there is a relatively small and controlled number of streams and a high number of outgoing interfaces. Using bulk updates can reduce the join delay.

In this example, you configure a hold-time of 20 milliseconds for **instance-type virtual-switch**, using the **nexthop-hold-time** statement:

1. Enable the **nexthop-hold-time** statement by configuring it under **multicast-snooping-options**, using 20 milliseconds for the time value.

   ```
   [edit routing-instances vs]
   multicast-snooping-options {
     nexthop-hold-time 20;
   }
   ```

2. Use the **show multicast snooping route** command to verify that the bulk updates feature is turned on.

   ```
   user@host> show multicast snooping route instance vs
   Nexthop Bulking: ON
   Family: INET
   Group: 224.0.0.0
   ```

You can include the **nexthop-hold-time** statement only for routing-instance types of **virtual-switch** or **vpls** at the following hierarchy level.

Copyright © 2016, Juniper Networks, Inc.

- **[edit routing-instances** *routing-instance-name* **multicast-snooping-options]**

If the **nexthop-hold-time** statement is deleted from the router configuration, bulk updates are disabled.

Enabling Multicast Snooping for Multichassis Link Aggregation Group Interfaces

Include the **multichassis-lag-replicate-state** statement at the **[edit multicast-snooping-options]** hierarchy level to enable IGMP snooping and state replication for multichassis link aggregation group (MC-LAG) interfaces.

```
[edit]
multicast-snooping-options {
  multichassis-lag-replicate-state;
}
```

Replicating join and leave messages between links of a dual-link MC-LAG interface enables faster recovery of membership information for MC-LAG interfaces that experience service interruption.

Without state replication, if a dual-link MC-LAG interface experiences a service interruption (for example, if an active link switches to standby), the membership information for the interface is recovered by generating an IGMP query to the network. This method can take from 1 through 10 seconds to complete, which might be too long for some applications.

When state replication is provided for MC-LAG interfaces, IGMP join or leave messages received on an MC-LAG device are replicated from the active MC-LAG link to the standby link through an Interchassis Communication Protocol (ICCP) connection. The standby link processes the messages as if they were received from the corresponding active MC-LAG link, except it does not add itself as a next hop and it does not flood the message to the network. After a failover, the multicast membership status of the link can be recovered within a few seconds or less by retrieving the replicated messages.

This example enables state replication for MC-LAG interfaces in a bridge domain named bridge1:

1. Enable state replication for MC-LAG interfaces.

   ```
   user@host# set multicast-snooping-options multicast-lag-replicate-state
   ```

   After you commit the configuration, multicast snooping automatically identifies the active link during initialization or after failover, and replicates data between the active and standby links without administrator intervention.

2. Use the **show igmp snooping interface** command to display the state for MC-LAG interfaces.

   ```
   user@host> show igmp snooping interface

   Instance: bridge-domain bridge1
   Learning-Domain: default
   Interface: ae0.1
     State: Up Groups: 1
     mc-lag state: standby
     Immediate leave: Off
   ```

Copyright © 2016, Juniper Networks, Inc.

```
    Router interface: no
Interface: ge-0/1/3.100
    State: Up Groups: 1
    Immediate leave: Off
    Router interface: no
Interface: ae1.2
    State: Up Groups: 1
    mc-lag state: standby
    Immediate leave: Off
    Router interface: no
```

NOTE: You can use the **show igmp snooping membership** command to display group membership information for the links of MC-LAG interfaces.

If you delete the **multicast-lag-replicate-state** statement or the configuration of IGMP snooping, replication between MC-LAG links stops within the hierarchy level from which the configuration was deleted. Then, multicast membership is recovered as needed by generating standard IGMP queries over the network.

Understanding Bandwidth Management for Multicast

Bandwidth management enables you to control the multicast flows that leave a multicast interface. This control enables you to better manage your multicast traffic and reduce or eliminate the chances of interface oversubscription or congestion.

Bandwidth management ensures that multicast traffic oversubscription does not occur on an interface. When managing multicast bandwidth, you define the maximum amount of multicast bandwidth that an individual interface can use as well as the bandwidth individual multicast flows use.

For example, the routing software cannot add a flow to an interface if doing so exceeds the allowed bandwidth for that interface. Under these circumstances, the interface is rejected. This rejection, however, does not prevent a multicast protocol (for example, PIM) from sending a join message upstream. Traffic continues to arrive on the router, even though the router is not sending the flow from the expected outgoing interfaces.

You can configure the flow bandwidth statically by specifying a bandwidth value for the flow in bits per second, or you can enable the flow bandwidth to be measured and adaptively changed. When using the adaptive bandwidth option, the routing software

Copyright © 2016, Juniper Networks, Inc.

queries the statistics for the flows to be measured at 5-second intervals and calculates the bandwidth based on the queries. The routing software uses the maximum value measured within the last minute (that is, the last 12 measuring points) as the flow bandwidth.

For more information, see the following sections:

- Bandwidth Management and PIM Graceful Restart on page 4354
- Bandwidth Management and Source Redundancy on page 4354
- Logical Systems and Bandwidth Oversubscription on page 4354

Bandwidth Management and PIM Graceful Restart

When using PIM graceful restart, after the routing process restarts on the Routing Engine, previously admitted interfaces are always readmitted and the available bandwidth is adjusted on the interfaces. When using the adaptive bandwidth option, the bandwidth measurement is initially based on the configured or default starting bandwidth, which might be inaccurate during the first minute. This means that new flows might be incorrectly rejected or admitted temporarily. You can correct this problem by issuing the **clear multicast bandwidth-admission** operational command.

If PIM graceful restart is not configured, after the routing process restarts, previously admitted or rejected interfaces might be rejected or admitted in an unpredictable manner.

Bandwidth Management and Source Redundancy

When using source redundancy, multiple sources (for example, s1 and s2) might exist for the same destination group (g). However, only one of the sources can actively transmit at any time. In this case, multiple forwarding entries—(s1,g) and (s2,g)—are created after each goes through the admission process.

With redundant sources, unlike unrelated entries, an OIF that is already admitted for one entry—for example, (s1,g)—is automatically admitted for other redundancy entries—for example, (s2,g). The remaining bandwidth on the interface is deducted each time an outbound interface is added, even though only one sender actively transmits. By measuring bandwidth, the bandwidth deducted for the inactive entries is credited back when the router detects no traffic is being transmitted.

For more information about defining redundant sources, see "Example: Configuring a Multicast Flow Map" on page 4377.

Logical Systems and Bandwidth Oversubscription

You can manage bandwidth at both the physical and logical interface level. However, if more than one logical system shares the same physical interface, the interface might become oversubscribed. Oversubscription occurs if the total bandwidth of all separately configured maximum bandwidth values for the interfaces on each logical system exceeds the bandwidth of the physical interface.

When displaying interface bandwidth information, a negative available bandwidth value indicates oversubscription on the interface.

Copyright © 2016, Juniper Networks, Inc.

Interface bandwidth can become oversubscribed when the configured maximum bandwidth decreases or when some flow bandwidths increase because of a configuration change or an actual increase in the traffic rate.

Interface bandwidth can become available again if one of the following occurs:

- The configured maximum bandwidth increases.
- Some flows are no longer transmitted from interfaces, and bandwidth reserves for them are now available to other flows.
- Some flow bandwidths decrease because of a configuration change or an actual decrease in the traffic rate.

Interfaces that are rejected for a flow because of insufficient bandwidth are not automatically readmitted, even when bandwidth becomes available again. Rejected interfaces have an opportunity to be readmitted when one of the following occurs:

- The multicast routing protocol updates the forwarding entry for the flow after receiving a join, leave, or prune message or after a topology change occurs.
- The multicast routing protocol updates the forwarding entry for the flow due to configuration changes.
- You manually reapply bandwidth management to a specific flow or to all flows using the **clear multicast bandwidth-admission** operational command.

In addition, even if previously available bandwidth is no longer available, already admitted interfaces are not removed until one of the following occurs:

- The multicast routing protocol explicitly removes the interfaces after receiving a leave or prune message or after a topology change occurs.
- You manually reapply bandwidth management to a specific flow or to all flows using the **clear multicast bandwidth-admission** operational command.

Example: Defining Interface Bandwidth Maximums

This example shows you how to configure the maximum bandwidth for a physical or logical interface.

- Requirements on page 4355
- Overview on page 4356
- Configuration on page 4356
- Verification on page 4358

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.

Copyright © 2016, Juniper Networks, Inc.

- Configure a multicast protocol. This feature works with the following multicast protocols:
  - DVMRP
  - PIM-DM
  - PIM-SM
  - PIM-SSM

Overview

The maximum bandwidth setting applies admission control either against the configured interface bandwidth or against the native speed of the underlying interface (when there is no configured bandwidth for the interface).

If you configure several logical interfaces (for example, to support VLANs or PVCs) on the same underlying physical interface, and no bandwidth is configured for the logical interfaces, it is assumed that the logical interfaces all have the same bandwidth as the underlying interface. This can cause oversubscription. To prevent oversubscription, configure bandwidth for the logical interfaces, or configure admission control at the physical interface level.

You only need to define the maximum bandwidth for an interface on which you want to apply bandwidth management. An interface that does not have a defined maximum bandwidth transmits all multicast flows as determined by the multicast protocol that is running on the interface (for example, PIM).

If you specify **maximum-bandwidth** without including a bits-per-second value, admission control is enabled based on the bandwidth configured for the interface. In the following example, admission control is enabled for logical interface unit **200**, and the maximum bandwidth is 20 Mbps. If the bandwidth is not configured on the interface, the maximum bandwidth is the link speed.

```
routing-options {
   multicast {
      interface fe-0/2/0.200 {
         maximum-bandwidth;
      }
interfaces {
   fe-0/2/0 {
      unit 200 {
         bandwidth 20m;
      }
   }
}
```

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Copyright © 2016, Juniper Networks, Inc.

```
set interfaces fe-0/2/0 unit 200 bandwidth 20m
set routing-options multicast interface fe-0/2/0.200 maximum-bandwidth
set routing-options multicast interface fe-0/2/1 maximum-bandwidth 60m
set routing-options multicast interface fe-0/2/1.200 maximum-bandwidth 10m
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a bandwidth maximum:

1. Configure the a logical interface bandwidth.

   ```
   [edit interfaces]
   user@host# set fe-0/2/0 unit 200 bandwidth 20m
   ```

2. Enable admission control on the logical interface.

   ```
   [edit routing-options]
   user@host# set multicast interface fe-0/2/0.200 maximum-bandwidth
   ```

3. On a physical interface, enable admission control and set the maximum bandwidth to 60 Mbps.

   ```
   [edit routing-options]
   user@host# set multicast interface fe-0/2/1 maximum-bandwidth 60m
   ```

4. For a logical interface on the same physical interface shown in Step 3, set a smaller maximum bandwidth.

   ```
   [edit routing-options]
   user@host# set multicast interface fe-0/2/1.200 maximum-bandwidth 10m
   ```

Results

Confirm your configuration by entering the **show interfaces** and **show routing-options** commands.

```
user@host# show interfaces
fe-0/2/0 {
  unit 200 {
    bandwidth 20m;
  }
}
user@host# show routing-options
multicast {
  interface fe-0/2/0.200 {
    maximum-bandwidth;
  }
  interface fe-0/2/1 {
    maximum-bandwidth 60m;
  }
  interface fe-0/2/1.200 {
    maximum-bandwidth 10m;
  }
}
```

Copyright © 2016, Juniper Networks, Inc.

Verification

To verify the configuration, run the show multicast interface command.

Example: Configuring Multicast with Subscriber VLANs

This example shows how to configure an MX Series router to function as a broadband service router (BSR).

- Requirements on page 4358
- Overview and Topology on page 4358
- Configuration on page 4362
- Verification on page 4370

Requirements

This example uses the following hardware components:

- One MX Series router or EX Series switch with a PIC that supports traffic control profile queuing
- One DSLAM

Before you begin:

- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure PIM and IGMP or MLD on the interfaces.

Overview and Topology

When multiple BSR interfaces receive IGMP and MLD join and leave requests for the same multicast stream, the BSR sends a copy of the multicast stream on each interface. Both the multicast control packets (IGMP and MLD) and the multicast data packets flow on the same BSR interface, along with the unicast data. Because all per-customer traffic has its own interface on the BSR, per-customer accounting, call admission control (CAC), and quality-of-service (QoS) adjustment are supported. The QoS bandwidth used by multicast reduces the unicast bandwidth.

Multiple interfaces on the BSR might connect to a shared device (for example, a DSLAM). The BSR sends the same multicast stream multiple times to the shared device, thus wasting bandwidth. It is more efficient to send the multicast stream one time to the DSLAM and replicate the multicast streams in the DSLAM. There are two approaches that you can use.

The first approach is to continue to send unicast data on the per-customer interfaces, but have the DSLAM route all the per-customer IGMP and MLD join and leave requests to the BSR on a single dedicated interface (a multicast VLAN). The DSLAM receives the multicast streams from the BSR on the dedicated interface with no unnecessary replication and performs the necessary replication to the customers. Because all multicast control and data packets use only one interface, only one copy of a stream is sent even

Copyright © 2016, Juniper Networks, Inc.

if there are multiple requests. This approach is called reverse outgoing interface (OIF) mapping. Reverse OIF mapping enables the BSR to propagate the multicast state of the shared interface to the customer interfaces, which enables per-customer accounting and QoS adjustment to work. When a customer changes the TV channel, the router gateway (RG) sends an IGMP or MLD join and leave messages to the DSLAM. The DSLAM transparently passes the request to the BSR through the multicast VLAN. The BSR maps the IGMP or MLD request to one of the subscriber VLANs based on the IP source address or the source MAC address. When the subscriber VLAN is found, QoS adjustment and accounting are perfomed on that VLAN or interface.

The second approach is for the DSLAM to continue to send unicast data and all the per-customer IGMP and MLD join and leave requests to the BSR on the individual customer interfaces, but to have the multicast streams arrive on a single dedicated interface. If multiple customers request the same multicast stream, the BSR sends one copy of the data on the dedicated interface. The DSLAM receives the multicast streams from the BSR on the dedicated interface and performs the necessary replication to the customers. Because the multicast control packets use many customer interfaces, configuration on the BSR must specify how to map each customer's multicast data packets to the single dedicated output interface. QoS adjustment is supported on the customer interfaces. CAC is supported on the shared interface. This second approach is called multicast OIF mapping.

OIF mapping and reverse OIF mapping are not supported on the same customer interface or shared interface. This example shows how to configure the two different approaches. Both approaches support QoS adjustment, and both approaches support MLD/IPv6. The reverse OIF mapping example focuses on IGMP/IPv4 and enables QoS adjustment. The OIF mapping example focuses on MLD/IPv6 and disables QoS adjustment.

The first approach (reverse OIF mapping) includes the following statements:

- **flow-map**—Defines a flow map that controls the bandwidth for each flow.
- **maximum-bandwidth**—Enables CAC.
- **reverse-oif-mapping**—Enables the routing device to identify a subscriber VLAN or interface based on an IGMP or MLD join or leave request that it receives over the multicast VLAN.

  After the subscriber VLAN is identified, the routing device immediately adjusts the QoS (in this case, the bandwidth) on that VLAN based on the addition or removal of a subscriber.

  The routing device uses IGMP and MLD join or leave reports to obtain the subscriber VLAN information. This means that the connecting equipment (for example, the DSLAM) must forward all IGMP and MLD reports to the routing device for this feature to function properly. Using report suppression or an IGMP proxy can result in reverse OIF mapping not working properly.
- **subscriber-leave-timer**—Introduces a delay to the QoS update. After receiving an IGMP or MLD leave request, this statement defines a time delay (between 1 and 30 seconds) that the routing device waits before updating the QoS for the remaining subscriber interfaces. You might use this delay to decrease how often the routing device adjusts

Copyright © 2016, Juniper Networks, Inc.

the overall QoS bandwidth on the VLAN when a subscriber sends rapid leave and join messages (for example, when changing channels in an IPTV network).

- **traffic-control-profile**—Configures a shaping rate on the logical interface. The configured shaping rate must be configured as an absolute value, not as a percentage.

The second approach (OIF mapping) includes the following statements:

- **map-to-interface**—In a policy statement, enables you to build the OIF map.

  The OIF map is a routing policy statement that can contain multiple terms. When creating OIF maps, keep the following in mind:

  - If you specify a physical interface (for example, **ge-0/0/0**), a ".0" is appended to the interface to create a logical interface (for example, **ge-0/0/0.0**).
  - Configure a routing policy for each logical system. You cannot configure routing policies dynamically.
  - The interface must also have IGMP, MLD, or PIM configured.
  - You cannot map to a mapped interface.
  - We recommend that you configure policy statements for IGMP and MLD separately.
  - Specify either a logical interface or the keyword **self**. The **self** keyword specifies that multicast data packets be sent on the same interface as the control packets and that no mapping occur. If no term matches, then no multicast data packets are sent.

- **no-qos-adjust**—Disables QoS adjustment.

  QoS adjustment decreases the available bandwidth on the client interface by the amount of bandwidth consumed by the multicast streams that are mapped from the client interface to the shared interface. This action always occurs unless it is explicitly disabled.

  If you disable QoS adjustment, available bandwidth is not reduced on the customer interface when multicast streams are added to the shared interface.

  NOTE: You can dynamically disable QoS adjustment for IGMP and MLD interfaces using dynamic profiles.

- **oif-map**—Associate a map with an IGMP or MLD interface. The OIF map is then applied to all IGMP or MLD requests received on the configured interface. In this example, subscriber VLANs 1 and 2 have MLD configured, and each VLAN points to an OIF map that directs some traffic to **ge-2/3/9.4000**, some traffic to **ge-2/3/9.4001**, and some traffic to **self**.

  NOTE: You can dynamically associate OIF maps with IGMP interfaces using dynamic profiles.

- **passive**—Defines either IGMP or MLD to use passive mode.

Copyright © 2016, Juniper Networks, Inc.

The OIF map interface should not typically pass IGMP or MLD control traffic and should be configured as passive. However, the OIF map implementation does support running IGMP or MLD on an interface (control and data) in addition to mapping data streams to the same interface. In this case, you should configure IGMP or MLD normally (that is, not in passive mode) on the mapped interface. In this example, the OIF map interfaces (**ge-2/3/9.4000** and **ge-2/3/9.4001**) are configured as MLD passive.

By default, specifying the **passive** statement means that no general queries, group-specific queries, or group-source-specific queries are sent over the interface and that all received control traffic is ignored by the interface. However, you can selectively activate up to two out of the three available options for the **passive** statement while keeping the other functions passive (inactive).

These options include the following:

- **send-general-query**—When specified, the interface sends general queries.
- **send-group-query**—When specified, the interface sends group-specific and group-source-specific queries.
- **allow-receive**—When specified, the interface receives control traffic.

Figure 201 shows the scenario.

In both approaches, if multiple customers request the same multicast stream, the BSR sends one copy of the stream on the shared multicast VLAN interface. The DSLAM receives the multicast stream from the BSR on the shared interface and performs the necessary replication to the customers.

In the first approach (reverse OIF mapping), the DSLAM uses the per-customer subscriber VLANs for unicast data only. IGMP and MLD join and leave requests are sent on the multicast VLAN.

In the second approach (OIF mapping), the DSLAM uses the per-customer subscriber VLANs for unicast data and for IGMP and MLD join and leave requests. The multicast VLAN is used only for multicast streams, not for join and leave requests.

Configuration

Configuring a Reverse OIF Map

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode. .

```
set class-of-service traffic-control-profiles tcp-ifl shaping-rate 20m
set class-of-service interfaces ge-2/2/0 shaping-rate 240m
set class-of-service interfaces ge-2/2/0 unit 50 output-traffic-control-profile tcp-ifl
set class-of-service interfaces ge-2/2/0 unit 51 output-traffic-control-profile tcp-ifl
set interfaces ge-2/0/0 unit 0 family inet address 30.0.0.2/24
set interfaces ge-2/2/0 hierarchical-scheduler
set interfaces ge-2/2/0 vlan-tagging
set interfaces ge-2/2/0 unit 10 vlan-id 10
set interfaces ge-2/2/0 unit 10 family inet address 40.0.0.2/24
set interfaces ge-2/2/0 unit 50 vlan-id 50
set interfaces ge-2/2/0 unit 50 family inet address 50.0.0.2/24
set interfaces ge-2/2/0 unit 51 vlan-id 51
set interfaces ge-2/2/0 unit 51 family inet address 50.0.1.2/24
set policy-options policy-statement all-mcast-groups from source-address-filter
  30.0.0.0/8 orlonger
set policy-options policy-statement all-mcast-groups then accept
set protocols igmp interface all
set protocols igmp interface fxp0.0 disable
set protocols pim rp local address 20.0.0.2
set protocols pim interface all
set protocols pim interface fxp0.0 disable
set protocols pim interface ge-2/2/0.10 disable
set routing-options multicast flow-map map1 policy all-mcast-groups
set routing-options multicast flow-map map1 bandwidth 10m
set routing-options multicast flow-map map1 bandwidth adaptive
set routing-options multicast interface ge-2/2/0.10 maximum-bandwidth 500m
```

Copyright © 2016, Juniper Networks, Inc.

```
set routing-options multicast interface ge-2/2/0.10 reverse-oif-mapping
set routing-options multicast interface ge-2/2/0.10 subscriber-leave-timer 20
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure reverse OIF mapping:

1. Configure a logical interface for unicast data traffic.

   ```
   [edit interfaces ge-2/0/0]
   user@host# set unit 0 family inet address 30.0.0.2/24
   ```

2. Configure a logical interface for subscriber control traffic.

   ```
   [edit interfaces ge-2/2/0]
   user@host# set hierarchical-scheduler
   user@host# set vlan-tagging
   user@host# set unit 10 vlan-id 10
   user@host# set unit 10 family inet address 40.0.0.2/24
   ```

3. Configure two logical interfaces on which QoS adjustments are made.

   ```
   [edit interfaces ge-2/2/0]
   user@host# set unit 50 vlan-id 50
   user@host# set unit 50 family inet address 50.0.0.2/24
   user@host# set unit 51 vlan-id 51
   user@host# set unit 51 family inet address 50.0.1.2/24
   ```

4. Configure a policy.

   ```
   [edit policy-options policy-statement all-mcast-groups]
   user@host# set from source-address-filter 30.0.0.0/8 orlonger
   user@host# set then accept
   ```

5. Enable a flow map that references the policy.

   ```
   [edit routing-options multicast]
   user@host# set flow-map map1 policy all-mcast-groups
   user@host# set flow-map map1 bandwidth 10m adaptive
   ```

6. Enable OIF mapping on the logical interface that receives subscriber control traffic.

   ```
   [edit routing-options multicast]
   user@host# set interface ge-2/2/0.10 maximum-bandwidth 500m
   user@host# set interface ge-2/2/0.10 reverse-oif-mapping
   user@host# set interface ge-2/2/0.10 subscriber-leave-timer 20
   ```

7. Configure PIM and IGMP.

   ```
   [edit protocols]
   user@host# set igmp interface all
   user@host# set igmp interface fxp0.0 disable
   user@host# set pim rp local address 20.0.0.2
   user@host# set pim interface all
   user@host# set pim interface fxp0.0 disable
   user@host# set pim interface ge-2/2/0.10 disable
   ```

Copyright © 2016, Juniper Networks, Inc.

8. Configure the hierarchical scheduler by configuring a shaping rate for the physical interface and a slower shaping rate for the logical interfaces on which QoS adjustments are made.

```
[edit class-of-service interfaces ge-2/2/0]
user@host# set shaping-rate 240m
user@host# set unit 50 output-traffic-control-profile tcp-ifl
user@host# set unit 51 output-traffic-control-profile tcp-ifl

[edit class-of-service traffic-control-profiles tcp-30m-no-smap]
user@host# set shaping-rate 20m
```

Results From configuration mode, confirm your configuration by entering the **show class-of-service**, **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show class-of-service
traffic-control-profiles {
    tcp-ifl {
        shaping-rate 20m;
    }
}
interfaces {
    ge-2/2/0 {
        shaping-rate 240m;
        unit 50 {
            output-traffic-control-profile tcp-ifl;
        }
        unit 51 {
            output-traffic-control-profile tcp-ifl;
        }
    }
}
```

```
user@host# show interfaces
ge-2/0/0 {
    unit 0 {
        family inet {
            address 30.0.0.2/24;
        }
    }
}
ge-2/2/0 {
    hierarchical-scheduler;
    vlan-tagging;
    unit 10 {
        vlan-id 10;
        family inet {
            address 40.0.0.2/24;
        }
    }
    unit 50 {
        vlan-id 50;
        family inet {
```

Copyright © 2016, Juniper Networks, Inc.

```
        address 50.0.0.2/24;
      }
    }
    unit 51 {
      vlan-id 51;
      family inet {
        address 50.0.1.2/24;
      }
    }
}
```

```
user@host# show policy-options
policy-statement all-mcast-groups {
  from {
    source-address-filter 30.0.0.0/8 orlonger;
  }
  then accept;
}
```

```
user@host# show protocols
igmp {
  interface all;
  interface fxp0.0 {
    disable;
  }
}
pim {
  rp {
    local {
      address 20.0.0.2;
    }
  }
  interface all;
  interface fxp0.0 {
    disable;
  }
  interface ge-2/2/0.10 {
    disable;
  }
}
```

```
user@host# show routing-options
multicast {
  flow-map map1 {
    policy all-mcast-groups;
    bandwidth 10m adaptive;
  }
  interface ge-2/2/0.10 {
    maximum-bandwidth 500m;
    reverse-oif-mapping;
    subscriber-leave-timer 20;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

set routing-options multicast interface ge-2/3/9.2 no-qos-adjust
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure reverse OIF mapping:

1. Configure a logical interface for unicast data traffic.

Copyright © 2016, Juniper Networks, Inc.

```
[edit interfaces ge-2/3/8 ]
user@host# set unit 0 family inet6 address C300:0101::/24
```

2. Configure logical interfaces for subscriber VLANs.

```
[edit interfaces ge-2/3/9]
user@host# set vlan-tagging
user@host# set unit 1 vlan-id 1
user@host# set unit 1 family inet6 address C400:0101::/24
user@host# set unit 2 vlan-id 2
user@host# set unit 2 family inet6 address C400:0201::/24 lo0 unit 0 family inet6
  address C000::1/128
user@host# set unit 2 family inet6 address C400:0201::/24
```

3. Configure two map-to logical interfaces.

```
[edit interfaces ge-2/2/0]
user@host# set unit 4000 vlan-id 4000
user@host# set unit 4000 family inet6 address C40F:A001::/24
user@host# set unit 4001 vlan-id 4001
user@host# set unit 4001 family inet6 address C40F:A101::/24
```

4. Configure the OIF map.

```
[edit policy-options policy-statement g539-v6]
user@host# set term g539-4000 from route-filter FF05:0101:0000::/39 orlonger
user@host# set then map-to-interface ge-2/3/9.4000
user@host# set then accept
user@host# set term g539-4001 from route-filter FF05:0101:0200::/39 orlonger
user@host# set then map-to-interface ge-2/3/9.4001
user@host# set then accept
user@host# set term self from route-filter FF05:0101:0700::/40 orlonger
user@host# set then map-to-interface self
user@host# set then accept

[edit policy-options policy-statement g539-v6-all]
user@host# set term g539 from route-filter 0::/0 orlonger
user@host# set then map-to-interface ge-2/3/9.4000
user@host# set then accept
```

5. Disable QoS adjustment on the subscriber VLANs.

```
[edit routing-options multicast]
user@host# set interface ge-2/3/9.1 no-qos-adjust
user@host# set interface ge-2/3/9.2 no-qos-adjust
```

6. Configure PIM and MLD. Point the MLD subscriber VLANs to the OIF map.

```
[edit protocols]
user@host# set pim rp local address 20.0.0.4
user@host# set pim rp local family inet6 address C000::1 #C000::1 is the address
  of lo0
user@host# set pim interface ge-2/3/8.0 mode sparse
user@host# set pim interface ge-2/3/8.0 version 2
user@host# set mld interface fxp0.0 disable
user@host# set interface ge-2/3/9.4000 passive
user@host# set interface ge-2/3/9.4001 passive
user@host# set interface ge-2/3/9.1 version 1
user@host# set interface ge-2/3/9.1 oif-map g539-v6
```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set interface ge-2/3/9.2 version 2
user@host# set interface ge-2/3/9.2 oif-map g539-v6
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces
ge-2/3/8 {
  unit 0 {
    family inet6 {
      address C300:0101::/24;
    }
  }
}
ge-2/3/9 {

        version 2;
      }
    }
```

```
user@host# show routing-options
multicast {
  interface ge-2/3/9.1 no-qos-adjust;
  interface ge-2/3/9.2 no-qos-adjust;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

To verify the configuration, run the following commands:

- **show igmp statistics**
- **show class-of-service interface**
- **show interfaces statistics**
- **show mld statistics**
- **show multicast interface**
- **show policy**

Copyright © 2016, Juniper Networks, Inc.

Configuring Multicast Routing over IP Demux Interfaces

In a subscriber management network, fields in packets sent from IP demux interfaces are intended to correspond to a specific client that resides on the other side of an aggregation device (for example, a Multiservice Access Node [MSAN]). However, packets sent from a Broadband Services Router (BSR) to an MSAN do not identify the demux interface. Once it obtains a packet, it is up to the MSAN device to determine which client receives the packet.

Depending on the intelligence of the MSAN device, determining which client receives the packet can occur in an inefficient manner. For example, when it receives IGMP control traffic, an MSAN might forward the control traffic to all clients instead of the one intended client. In addition, once a data stream destination is established, though an MSAN can use IGMP snooping to determine which hosts reside in a particular group and limit data streams to only that group, the MSAN still must send multiple copies of the data stream to each group member, even if that data stream is intended for only one client in the group.

Various multicast features, when combined, enable you to avoid the inefficiencies mentioned above. These features include the following:

- The ability to configure the IP demux interface **family** statement to use **inet** for either the numbered or unnumbered primary interface.
- The ability to configure IGMP on the primary interface to send general queries for all clients. The demux configuration prevents the primary IGMP interface from receiving any client IGMP control packets. Instead, all IGMP control packets go to the demux interfaces. However, to guarantee that no joins occur on the primary interface:
  - For static IGMP interfaces—Include the **passive send-general-query** statement in the IGMP configuration at the **[edit protocols igmp interface *interface-name*]** hierarchy level.
  - For dynamic IGMP demux interfaces—Include the **passive send-general-query** statement at the **[edit dynamic-profiles *profile-name* protocols igmp interface *interface-name*]** hierarchy level.
- The ability to map all multicast groups to the primary interface as follows:
  - For static IGMP interfaces—Include the **oif-map** statement at the **[edit protocols igmp interface *interface-name*]** hierarchy level.
  - For dynamic IGMP demux interfaces—Include the **oif-map** statement at the **[edit dynamic-profiles *profile-name* protocols igmp interface *interface-name*]** hierarchy level.

Copyright © 2016, Juniper Networks, Inc.

Using the **oif-map** statement, you can map the same IGMP group to the same output interface and send only one copy of the multicast stream from the interface.

- The ability to configure IGMP on each demux interface. To prevent duplicate general queries:
  - For static IGMP interfaces—Include the **passive allow-receive send-group-query** statement at the **[edit protocols igmp interface *interface-name*]** hierarchy level.
  - For dynamic demux interfaces—Include the **passive allow-receive send-group-query** statement at the **[edit dynamic-profiles *profile-name* protocols igmp interface *interface-name*]** hierarchy level.

NOTE: To send only one copy of each group, regardless of how many customers join, use the oif-map statement as previously mentioned.

Classifying Packets by Egress Interface

For Juniper Networks M320 Multiservice Edge Routers and T Series Core Routers with the Intelligent Queuing (IQ), IQ2, Enhanced IQ (IQE), Multiservices link services intelligent queuing (LSQ) interfaces, or ATM2 PICs, you can classify unicast and multicast packets based on the egress interface. For unicast traffic, you can also use a multifield filter, but only egress interface classification applies to multicast traffic as well as unicast traffic. If you configure egress classification of an interface, you cannot perform Differentiated Services code point (DSCP) rewrites on the interface. By default, the system will not perform any classification based on the egress interface.

To enable packet classification by the egress interface, you first configure a forwarding class map and one or more queue numbers for the egress interface at the **[edit class-of-service forwarding-classes-interface-specific *forwarding-class-map-name*]** hierarchy level:

```
[edit class-of-service]
forwarding-classes-interface-specific  forwarding-class-map-name {
   class class-name queue-num queue-number [ restricted-queue queue-number ];
}
```

For T Series routers that are restricted to only four queues, you can control the queue assignment with the **restricted-queue** option, or you can allow the system to automatically determine the queue in a modular fashion. For example, a map assigning packets to queue 6 would map to queue 2 on a four-queue system.

NOTE: If you configure an output forwarding class map associating a forwarding class with a queue number, this map is not supported on multiservices link services intelligent queuing (lsq-) interfaces.

Copyright © 2016, Juniper Networks, Inc.

Once the forwarding class map has been configured, you apply the map to the logical interface by using the **output-forwarding-class-map** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
output-forwarding-class-map forwarding-class-map-name;
```

All parameters relating to the queues and forwarding class must be configured as well. For more information about configuring forwarding classes and queues, see Configuring Forwarding Classes.

This example shows how to configure an interface-specific forwarding-class map named **FCMAP1** that restricts queues 5 and 6 to different queues on four-queue systems and then applies **FCMAP1** to **unit 0** of interface **ge-6/0/0**:

```
[edit class-of-service]
forwarding-classes-interface-specific FCMAP1 {
  class FC1 queue-num 6 restricted-queue 3;
  class FC2 queue-num 5 restricted-queue 2;
  class FC3 queue-num 3;
  class FC4 queue-num 0;
  class FC3 queue-num 0;
  class FC4 queue-num 1;
}

[edit class-of-service]
interfaces {
  ge-6/0/0 unit 0 {
    output-forwarding-class-map FCMAP1;
  }
}
```

Note that without the **restricted-queue** option in **FCMAP1**, the example would assign **FC1** and **FC2** to queues 2 and 1, respectively, on a system restricted to four queues.

Use the **show class-of-service forwarding-class *forwarding-class-map-name*** command to display the forwarding-class map queue configuration:

```
user@host> show class-of-service forwarding-class FCMAP2

Forwarding class                          ID      Queue  Restricted queue
  FC1                                      0       6          3
  FC2                                      1       5          2
  FC3                                      2       3          3
  FC4                                      3       0          0
  FC5                                      4       0          0
  FC6                                      5       1          1
  FC7                                      6       6          2
  FC8                                      7       7          3
```

Use the **show class-of-service interface *interface-name*** command to display the forwarding-class maps (and other information) assigned to a logical interface:

```
user@host> show class-of-service interface ge-6/0/0

Physical interface: ge-6/0/0, Index: 128
Queues supported: 8, Queues in use: 8
```

Understanding the Multicast Forwarding Cache

IP multicast protocols can create numerous entries in the multicast forwarding cache. If the forwarding cache fills up with entries that prevent the addition of higher-priority entries, applications and protocols might not function properly. You can manage the multicast forwarding cache properties by limiting the size of the cache and by controlling the length of time that entries remain in the cache. By managing timeout values, you can give preference to more important forwarding cache entries while removing other less important entries.

Example: Configuring the Multicast Forwarding Cache

When a routing device receives multicast traffic, it places the (S,G) route information in the multicast forwarding cache, **inet.1**. This example shows how to configure multicast forwarding cache limits to prevent the cache from filling up with entries.

- Requirements on page 4375

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure a multicast protocol. This feature works with the following multicast protocols:
  - DVMRP
  - PIM-DM
  - PIM-SM
  - PIM-SSM

Overview

This example includes the following statements:

- **forwarding-cache**—Specifies how forwarding entries are aged out and how the number of entries is controlled.
- **timeout**—Specifies an idle period after which entries are aged out and removed from **inet.1**. You can specify a timeout in the range from 1 through 720 minutes.
- **threshold**—Enables you to specify threshold values on the forwarding cache to suppress (suspend) entries from being added when the cache entries reach a certain maximum and begin adding entries to the cache when the number falls to another threshold value. By default, no threshold values are enabled on the routing device.

  The suppress threshold suspends the addition of new multicast forwarding cache entries. If you do not specify a suppress value, multicast forwarding cache entries are created as necessary. If you specify a suppress threshold, you can optionally specify a reuse threshold, which sets the point at which the device resumes adding new multicast forwarding cache entries. During suspension, forwarding cache entries time out. After a certain number of entries time out, the reuse threshold is reached, and new entries are added. The range for both thresholds is from 1 through 200,000. If configured, the reuse value must be less than the suppression value. If you do not specify a reuse value, the number of multicast forwarding cache entries is limited to the suppression value. A new entry is created as soon as the number of multicast forwarding cache entries falls below the suppression value.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

Copyright © 2016, Juniper Networks, Inc.

```
set routing-options multicast forwarding-cache threshold suppress 150000
set routing-options multicast forwarding-cache threshold reuse 34
set routing-options multicast forwarding-cache timeout 60
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the multicast forwarding cache:

1. Configure the maximum size of the forwarding cache.

   ```
   [edit routing-options multicast forwarding-cache]
   user@host# set threshold suppress 150000
   ```

2. Configure the amount of time (in minutes) entries can remain idle before being removed.

   ```
   [edit routing-options multicast forwarding-cache]
   user@host# set timeout 60
   ```

3. Configure the size of the forwarding cache when suppression stops and new entries can be added.

   ```
   [edit routing-options multicast forwarding-cache]
   user@host# set threshold reuse 70000
   ```

Results

Confirm your configuration by entering the **show routing-options** command.

```
user@host# show routing-options
multicast {
  forwarding-cache {
    threshold {
      suppress 150000;
      reuse 70000;
    }
    timeout 60;
  }
}
```

Verification

To verify the configuration, run the **show multicast route extensive** command.

```
user@host> show multicast route extensive
Family: INET
Group: 232.0.0.1
    Source: 11.11.11.11/32
    Upstream interface: fe-0/2/0.200
    Downstream interface list:
        fe-0/2/1.210
    Downstream interface list rejected by CAC:
        fe-0/2/1.220
    Session description: Source specific multicast
    Statistics: 0 kBps, 0 pps, 0 packets
    Next-hop ID: 337
```

Copyright © 2016, Juniper Networks, Inc.

```
    Upstream protocol: PIM
    Route state: Active
    Forwarding state: Forwarding
    Cache lifetime/timeout: 60 minutes
Wrong incoming interface notifications: 0
```

Example: Configuring a Multicast Flow Map

This example shows how to configure a flow map to prevent certain forwarding cache entries from aging out, thus allowing for faster failover from one source to another. Flow maps enable you to configure bandwidth variables and multicast forwarding cache timeout values for entries defined by the flow map policy.

- Requirements on page 4377
- Overview on page 4377
- Configuration on page 4379
- Verification on page 4380

Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol. See the *Junos OS Routing Protocols Library for Security Devices*.
- Configure a multicast protocol. This feature works with the following multicast protocols:
  - DVMRP
  - PIM-DM
  - PIM-SM
  - PIM-SSM

Overview

Flow maps are typically used for fast multicast source failover when there are multiple sources for the same group. For example, when one video source is actively sending the traffic, the forwarding states for other video sources are timed out after a few minutes. Later, when a new source starts sending the traffic again, it takes time to install a new forwarding state for the new source if the forwarding state is not already there. This switchover delay is worsened when there are many video streams. Using flow maps with longer timeout values or permanent cache entries helps reduce this switchover delay.

NOTE: The permanent forwarding state must exist on all routing devices in the path for fast source switchover to function properly.

Copyright © 2016, Juniper Networks, Inc.

This example includes the following statements:

- **bandwidth**—Specifies the bandwidth for each flow that is defined by a flow map to ensure that an interface is not oversubscribed for multicast traffic. If adding one more flow would cause overall bandwidth to exceed the allowed bandwidth for the interface, the request is rejected. A rejected request means that traffic might not be delivered out of some or all of the expected outgoing interfaces. You can define the bandwidth associated with multicast flows that match a flow map by specifying a bandwidth in bits per second or by specifying that the bandwidth is measured and adaptively modified.

  When you use the **adaptive** option, the bandwidth adjusts based on measurements made at 5-second intervals. The flow uses the maximum bandwidth value from the last 12 measured values (1 minute).

  When you configure a bandwidth value with the **adaptive** option, the bandwidth value acts as the starting bandwidth for the flow. The bandwidth then changes based on subsequent measured bandwidth values. If you do not specify a bandwidth value with the **adaptive** option, the starting bandwidth defaults to 2 megabits per second (Mbps).

  For example, the **bandwidth 2m adaptive** statement is equivalent to the **bandwidth adaptive** statement because they both use the same starting bandwidth (2 Mbps, the default). If the actual flow bandwidth is 4 Mbps, the measured flow bandwidth changes to 4 Mbps after reaching the first measuring point (5 seconds). However, if the actual flow bandwidth rate is 1 Mbps, the measured flow bandwidth remains at 2 Mbps for the first 12 measurement cycles (1 minute) and then changes to the measured 1 Mbps value.

- **flow-map**—Defines a flow map that controls the forwarding cache timeout of specified source and group addresses, controls the bandwidth for each flow, and specifies redundant sources. If a flow can match multiple flow maps, the first flow map applies.

- **forwarding-cache**—Enables you to configure the forwarding cache properties of entries defined by a flow map. You can specify a timeout of **never** to make the forwarding entries permanent, or you can specify a timeout in the range from 1 through 720 minutes. If you set the value to **never**, you can specify the **non-discard-entry-only** option to make an exception for entries that are in the pruned state. In other words, the **never non-discard-entry-only** statement allows entries in the pruned state to time out, while entries in the forwarding state never time out.

- **policy**—Specifies source and group addresses to which the flow map applies. This example creates a flow map policy called **policyForFlow1**. The policy matches the source address using the **source-address-filter** statement and matches the group address using the **prefix-list-filter** statement.

  NOTE: The addresses must match the configured policy for flow mapping to occur.

- **redundant-sources**—Specify redundant (backup) sources for flows identified by a flow map.

Copyright © 2016, Juniper Networks, Inc.

Outbound interfaces that are admitted for one of the forwarding entries are automatically admitted for any other entries identified by the redundant source configuration.

In this example, forwarding entries (10.11.11.11, g1) and (10.11.11.12, g1) match the flow map **flowMap1**. In this case, if a particular outbound interface is admitted for entry (10.11.11.11, g1), it is automatically admitted for entry (10.11.11.12, g1), even if there is no longer enough remaining bandwidth available after creating entry (10.11.11.11, g1). The interface is added because only one of the two sources can send traffic at any time.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options prefix-list permanentEntries1 232.1.1.0/24
set policy-options policy-statement policyForFlow1 from source-address-filter 11.11.11.11/32
    exact
set policy-options policy-statement policyForFlow1 from prefix-list-filter
    permanentEntries1 orlonger
set policy-options policy-statement policyForFlow1 then accept
set routing-options multicast flow-map flowMap1 policy policyForFlow1
set routing-options multicast flow-map flowMap1 bandwidth 2m
set routing-options multicast flow-map flowMap1 bandwidth adaptive
set routing-options multicast flow-map flowMap1 redundant-sources 10.11.11.11
set routing-options multicast flow-map flowMap1 redundant-sources 10.11.11.12
set routing-options multicast flow-map flowMap1 forwarding-cache timeout never
    non-discard-entry-only
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a flow map:

1. Configure the flow map policy.

   ```
   [edit policy-options]
   user@host# set prefix-list permanentEntries1 232.1.1.0/24
   user@host# set policy policyForFlow1 from source-address-filter 11.11.11.11/32 exact
   user@host# set policy policyForFlow1 from prefix-list-filter permanentEntries1
     orlonger
   user@host# set policy policyForFlow1 then accept
   ```

2. Apply the flow map policy.

   ```
   [edit routing-options]
   user@host# set multicast flow-map flowMap1 policy policyForFlow1
   ```

3. Configure permanent forwarding entries (that is, entries that never time out), and enable entries in the pruned state to time out.

   ```
   [edit routing-options]
   ```

Copyright © 2016, Juniper Networks, Inc.

```
user@host# set multicast flow-map flowMap1 forwarding-cache timeout never
  non-discard-entry-only
```

4. Configure the flow map bandwidth to be adaptive with a default starting bandwidth of 2 Mbps.

```
[edit routing-options]
user@host# set multicast flow-map flowMap1 bandwidth 2m adaptive
```

5. Specify backup sources.

```
[edit routing-options]
user@host# set multicast flow-map flowMap1 redundant-sources [ 10.11.11.11 10.11.11.12
  ]
```

6. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show policy-options** and **show routing-options** commands.

```
user@host# show policy-options
prefix-list permanentEntries1 {
   232.1.1.0/24;
}
policy-statement policyForFlow1 {
   from {
      source-address-filter 11.11.11.11/32 exact;
      prefix-list-filter permanentEntries1 orlonger;
   }
   then accept;
}
```

```
user@host# show routing-options
multicast {
   flow-map flowMap1 {
      policy policyForFlow1;
      bandwidth 2m adaptive;
      redundant-sources [ 10.11.11.11 10.11.11.12 ];
      forwarding-cache {
         timeout never non-discard-entry-only;
      }
   }
}
```

Verification

To verify the configuration, run the following commands:

- show multicast flow-map
- show multicast route **extensive**

Understanding Ingress PE Redundancy

In many network topologies, point-to-multipoint label-switched paths (LSPs) are used to distribute multicast traffic over a virtual private network (VPN). When traffic engineering is added to the provider edge (PE) routers, a popular deployment option has been to use traffic-engineered point-to-multipoint LSPs at the origin PE. In these network deployments, the PE is a single point of failure. Network operators have previously provided redundancy by broadcasting duplicate streams of multicast traffic from multiple PEs, a practice which at least doubles the bandwidth required for each stream.

Ingress PE redundancy eliminates the bandwidth duplication requirement by configuring one or more ingress PEs as a group. Within a group, one PE is designated as the primary PE and one or more others become backup PEs for the configured traffic stream. The solution depends on a full mesh of point-to-point (P2P) LSPs among the primary and backup PEs. Also, you must configure a full set of point-to-multipoint LSPs at the backup PEs, even though these point-to-multipoint LSPs at the backup PEs are not sending any traffic or using any bandwidth. The P2P LSPs are configured with bidirectional forwarding detection (BFD). When BFD detects a failure on the primary PE, a new designated forwarder is elected for the stream.

Example: Configuring Ingress PE Redundancy

This example shows how to configure one PE as part of a backup PE group to enable ingress PE redundancy for multicast traffic streams.

- Requirements on page 4381
- Overview on page 4382
- Configuration on page 4383
- Verification on page 4386

Requirements

Before you begin:

- Configure the router interfaces.
- Configure a full mesh of P2P LSPs between the PEs in the backup group.

Copyright © 2016, Juniper Networks, Inc.

Overview

Ingress PE redundancy provides a backup resource when point-to-multipoint LSPs are configured for multicast distribution. When point-to-multipoint LSPs are used for multicast traffic, the PE device can become a single point of failure. One way to provide redundancy is by broadcasting duplicate streams from multiple PEs, thus doubling the bandwidth requirements for each stream. This feature implements redundancy between two or more PEs by designating a primary and one or more backup PEs for each configured stream. The solution depends on the configuration of a full mesh of P2P LSPs between the primary and backup PEs. These LSPs are configured with Bidirectional Forwarding Detection (BFD) running on top of them. BFD is used on the backup PEs to detect failure on the primary PE routing device and to elect a new designated forwarder for the stream.

A full mesh is required so that each member of the group can make an independent decision about the health of the other PEs and determine the designated forwarder for the group. The key concept in a backup PE group is that of a designated PE. A designated PE is a PE that forwards data on the static route. All other PEs in the backup PE group do not forward any data on the static route. This allows you to have one designated forwarder. If the designated forwarder fails, another PE takes over as the designated forwarder, thus allowing the traffic flow to continue uninterrupted.

Each PE in the backup PE group makes its own local decision regarding the designated forwarder. Thus, there is no inter-PE communication regarding designated forwarder. A PE computes the designated forwarder based on the IP address of all PEs and the connectivity status of other PEs. Connectivity status is determined based on the state of the BFD session on the P2P LSP to a PE.

A PE chosen is as the designated forwarder if it satisfies the following conditions:

- The PE is in the UP state. Either it is the local PE, or the BFD session on the P2P LSP to that PE is in the UP state.
- The PE has the lowest IP address among all PEs that are in the UP state.

Because all PEs have P2P LSPs to each other, each PE can determine the UP state of each other PE, and all PEs converge to the same designated forwarder.

If the designated forwarder PE fails, then all other PEs lose connectivity with the designated forwarder, and their BFD session ends. Consequently, other PEs then choose another designated forwarder. The new forwarder starts forwarding traffic. Thus, the traffic loss is limited to the failure detection time, which is the BFD session detection time.

When a PE that was the designated forwarder fails and then resumes operating, all other PEs recognize this fact, rerun the designated forwarder algorithm, and choose the PE as the designated forwarder. Consequently, the backup designated forwarder stops forwarding traffic. Thus, traffic switches back to the most eligible designated forwarder.

This example includes the following statements:

Copyright © 2016, Juniper Networks, Inc.

- **associate-backup-pe-groups**—Monitors the health of the routing device at the other end of the LSP. You can configure multiple backup PE groups that contain the same routing device's address. Failure of this LSP indicates to all of these groups that the destination PE routing device is down. So, the **associate-backup-pe-groups** statement is not tied to any specific group but applies to all groups that are monitoring the health of the LSP to the remote address.

  If there are multiple LSPs with the **associate-backup-pe-groups** statement to the same destination PE, then the local routing device picks the first LSP to that PE for detection purposes.

  We do not recommend configuring multiple LSPs to the same destination. If you do, make sure that the LSP parameters (for example, liveliness detection) are similar to avoid false failure notification even when the remote PE is up.

- **backup-pe-group**—Configures ingress PE redundancy for multicast traffic streams.
- **bfd-liveness-detection**—Enables BFD for each LSP.
- **label-switched-path**—Configures an LSP. You must configure a full mesh of P2P LSPs between the primary and backup PEs.

  NOTE: We recommend that you configure the P2P LSPs with fast reroute and node link protection so that link failures do not result in the LSP failure. For the purpose of PE redundancy, a failure in the P2P LSP is treated as a PE failure. Redundancy in the inter-PE path is also encouraged.

- **p2mp-lsp-next-hop**—Enables you to associate a backup PE group with a static route.
- **static**—Applies the backup group to a static route on the PE. This ensures that the static route is active (installed in the forwarding table) when the local PE is the designated forwarder for the configured backup PE group.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement no-rpf from route-filter 225.1.1.1/32 exact
set policy-options policy-statement no-rpf then reject
set protocols mpls label-switched-path backup_PE1 to 10.255.16.61
set protocols mpls label-switched-path backup_PE1 oam bfd-liveness-detection
  minimum-interval 500
set protocols mpls label-switched-path backup_PE1 oam bfd-liveness-detection multiplier
  3
set protocols mpls label-switched-path backup_PE1 associate-backup-pe-groups
set protocols mpls label-switched-path dest1 to 10.255.16.57

set routing-options static route 1.1.1.1/32 backup-pe-group g1
set routing-options static route 225.1.1.1/32 p2mp-lsp-next-hop p2mp-lsp
set routing-options static route 225.1.1.1/32 backup-pe-group g1
set routing-options multicast rpf-check-policy no-rpf
set routing-options multicast interface fe-1/3/3.0 enable
set routing-options multicast backup-pe-group g1 backups 10.255.16.61
set routing-options multicast backup-pe-group g1 local-address 10.255.16.59
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure ingress PE redundancy:

1. Configure the multicast settings.

   ```
   [edit routing-options multicast]
   user@host# set rpf-check-policy no-rpf
   user@host# set interface fe-1/3/3.0 enable
   ```

2. Configure the RPF policy.

   ```
   [edit policy-options policy-statement no-rpf]
   user@host# set from route-filter 225.1.1.1/32 exact
   user@host# set then reject
   ```

3. Configure the backup PE group.

   ```
   [edit routing-options multicast]
   user@host# set backup-pe-group g1 backups 10.255.16.61
   user@host# set backup-pe-group g1 local-address 10.255.16.59
   ```

4. Configure the static routes for the point-to-multipoint LSPs backup PE group.

   ```
   [edit routing-options static]
   user@host# set route 1.1.1.1/32 p2mp-lsp-next-hop p2mp-lsp
   user@host# set route 1.1.1.1/32 backup-pe-group g1
   user@host# set route 225.1.1.1/32 p2mp-lsp-next-hop p2mp-lsp
   user@host# set route 225.1.1.1/32 backup-pe-group g1
   ```

5. Configure the MPLS interfaces.

   ```
   [edit protocols mpls]
   user@host# set interface all
   user@host# set interface fxp0.0 disable
   ```

6. Configure the LSP to the redundant router.

   ```
   [edit protocols mpls]
   user@host# set label-switched-path backup_PE1 to 10.255.16.61
   user@host# set label-switched-path backup_PE1 oam bfd-liveness-detection
     minimum-interval 500
   user@host# set label-switched-path backup_PE1 oam bfd-liveness-detection
     multiplier 3
   user@host# set label-switched-path backup_PE1 associate-backup-pe-groups
   ```

Copyright © 2016, Juniper Networks, Inc.

7. Configure LSPs to two traffic destinations.

```
[edit protocols mpls]
user@host# set label-switched-path dest1 to 10.255.16.57
user@host# set label-switched-path dest1 p2mp p2mp-lsp
user@host# set label-switched-path dest2 to 10.255.16.55
user@host# set label-switched-path dest2 p2mp p2mp-lsp
```

8. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

Results

Confirm your configuration by entering the **show policy**, **show protocols**, and **show routing-options** commands.

```
user@host# show policy
policy-statement no-rpf {
  from {
    route-filter 225.1.1.1/32 exact;
  }
  then reject;
}
```

```
user@host# show protocols
mpls {
  label-switched-path backup_PE1 {
    to 10.255.16.61;
    oam {
      bfd-liveness-detection {
        minimum-interval 500;
        multiplier 3;
      }
    }
    associate-backup-pe-groups;
  }
  label-switched-path dest1 {
    to 10.255.16.57;
    p2mp p2mp-lsp;
  }
  label-switched-path dest2 {
    to 10.255.16.55;
    p2mp p2mp-lsp;
  }
  interface all;
  interface fxp0.0 {
    disable;
  }
}
```

```
user@host# show routing-options
static {
  route 1.1.1.1/32 {
    p2mp-lsp-next-hop p2mp-lsp;
    backup-pe-group g1;
  }
```

Copyright © 2016, Juniper Networks, Inc.

```
    route 225.1.1.1/32 {
      p2mp-lsp-next-hop p2mp-lsp;
      backup-pe-group g1;
    }
  }
  multicast {
    rpf-check-policy no-rpf;
    interface fe-1/3/3.0 enable;
    backup-pe-group g1 {
      backups 10.255.16.61;
      local-address 10.255.16.59;
    }
  }
```

Verification

To verify the configuration, run the following commands:

- **show mpls lsp**
- **show multicast backup-pe-groups**
- **show multicast rpf**

accept-remote-source

Syntax accept-remote-source;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 9.6 for EX Series switches.

Description Accept traffic from a remote source. A remote source is a source that is not on the same subnet as the incoming interface. This statement enables the remote source to be learned and advertised by MSDP so that receivers in other MSDP areas can join the source. You do not need to disable RPF checking, but you do need to ensure that the best path to reach the remote source is through the incoming interface.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring the Interface to Accept Traffic from a Remote Source on page 4262

accounting (Protocols IGMP)

Syntax accounting;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp],
[edit protocols igmp]

Release Information Statement introduced in Junos OS Release 8.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Enable the collection of IGMP join and leave event statistics on the system.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Recording IGMP Join and Leave Events on page 4056

Copyright © 2016, Juniper Networks, Inc.

accounting (Protocols IGMP AMT Interface)

Syntax (accounting | no-accounting);

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description Enable or disable the collection of IGMP join and leave event statistics for an Automatic Multicast Tunneling (AMT) interface.

Default Disabled

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Default IGMP Parameters for AMT Interfaces on page 4279

accounting (Protocols IGMP Interface)

Syntax (accounting | no-accounting);

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Enable or disable the collection of IGMP join and leave event statistics for an interface.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Recording IGMP Join and Leave Events on page 4056

Copyright © 2016, Juniper Networks, Inc.

accounting (Protocols MLD)

Syntax accounting;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld],
[edit protocols mld]

Release Information Statement introduced in Junos OS Release 9.1.

Description Enable the collection of MLD join and leave event statistics on the system.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Recording MLD Join and Leave Events on page 4082

accounting (Protocols MLD Interface)

Syntax (accounting | no-accounting);

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*],
[edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 9.1.

Description Enable or disable the collection of MLD join and leave event statistics for an interface.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Recording MLD Join and Leave Events on page 4082

[edit routing-instances *routing-instance-name* protocols msdp peer *address*],
[edit routing-instances *routing-instance-name* protocols msdp source *ip-address/prefix-length*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Limit the number of active source messages the routing device accepts.

Default

If you do not include this statement, the router accepts any number of MSDP active source messages.

Options

The options are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring MSDP with Active Source Limits and Mesh Groups on page 4262

address (Anycast RPs)

Syntax address *address* <forward-msdp-sa>;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim rp local (inet | inet6) anycast-pim rp-set],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp local (inet | inet6) anycast-pim rp-set],
[edit protocols pim rp local (inet | inet6) anycast-pim rp-set],
[edit routing-instances *routing-instance-name* protocols pim rp local (inet | inet6) anycast-pim rp-set]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the anycast rendezvous point (RP) addresses in the RP set. Multiple addresses can be configured in an RP set. If the RP has peer Multicast Source Discovery Protocol (MSDP) connections, then the RP must forward MSDP source active (SA) messages.

Options ***address***—RP address in an RP set.

forward-msdp-sa—(Optional) Forward MSDP SAs to this address.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Copyright © 2016, Juniper Networks, Inc.

address (Bidirectional Rendezvous Points)

Syntax

```
address address {
  group-ranges {
    destination-ip-prefix</prefix-length>;
  }
  hold-time seconds;
  priority number;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp bidirectional],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp bidirectional],
[edit protocols pim rp bidirectional],
[edit routing-instances *routing-instance-name* protocols pim rp bidirectional]

Release Information

Statement introduced in Junos OS Release 12.1.

Description

Configure bidirectional rendezvous point (RP) addresses. The address can be a loopback interface address, an address of a link interface, or an address that is not assigned to an interface but belongs to a subnet that is reachable by the bidirectional PIM routers in the network.

Options

address—Bidirectional RP address.

Default: 232.0.0.0/8

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

address (Static RPs)

Syntax

```
address address {
  group-ranges {
    destination-ip-prefix</prefix-length>;
  }
  override;
  version version;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp static],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp static],
[edit protocols pim static],
[edit routing-instances *routing-instance-name* protocols pim rp static]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Configure static rendezvous point (RP) addresses. You can configure a static RP in a logical system only if the logical system is not directly connected to a source.

For each static RP address, you can optionally specify the PIM version and the groups for which this address can be the RP. The default PIM version is version 1.

Options

address—Static RP address.

Default: 224.0.0.0/4

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

algorithm

Syntax algorithm *algorithm-name*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection authentication],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection authentication]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the algorithm to use for BFD authentication.

Options ***algorithm-name***—Name of algorithm to use for BFD authentication:

- **simple-password**—Plain-text password. One to 16 bytes of plain text. One or more passwords can be configured.
- **keyed-md5**—Keyed Message Digest 5 hash algorithm for sessions with transmit and receive rates greater than 100 ms.
- **meticulous-keyed-md5**—Meticulous keyed Message Digest 5 hash algorithm.
- **keyed-sha-1**—Keyed Secure Hash Algorithm I for sessions with transmit and receive rates greater than 100 ms.
- **meticulous-keyed-sha-1**—Meticulous keyed Secure Hash Algorithm I.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

anycast-prefix

Syntax anycast-prefix *ip-prefix/<prefix-length>*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols amt relay family inet],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt relay family inet],
[edit protocols amt relay family inet],
[edit routing-instances *routing-instance-name* protocols amt relay family inet]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify an IP address prefix to use for the Automatic Multicast Tunneling (AMT) relay anycast address. The prefix is advertised by unicast routing protocols to route AMT discovery messages to the router from nearby AMT gateways. The IP address that the prefix is derived from can be configured on any interface in the system. Typically, the router's **lo0.0** loopback address prefix is used for configuring the AMT anycast prefix in the default routing instance, and the router's **lo0.*n*** loopback address prefix is used for configuring the AMT anycast prefix in VPN routing instances. However, the anycast address can be either the primary or secondary **lo0.0** loopback address.

Default None. The anycast prefix must be configured.

Options ***ip-prefix/<prefix-length>***—IP address prefix.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

assert-timeout

Syntax assert-timeout *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Multicast routing devices running PIM sparse mode often forward the same stream of multicast packets onto the same LAN through the rendezvous-point tree (RPT) and shortest-path tree (SPT). PIM assert messages help routing devices determine which routing device forwards the traffic and prunes the RPT for this group. By default, routing devices enter an assert cycle every 180 seconds. You can configure this assert timeout to be between 5 and 210 seconds.

Options ***seconds***—Time for routing device to wait before another assert message cycle.

Range: 5 through 210 seconds

Default: 180 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring the PIM Assert Timeout on page 4175

authentication

Syntax

```
authentication {
  algorithm algorithm-name;
  key-chain key-chain-name;
  loose-check;
}
```

Hierarchy Level

[edit protocols pim interface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information

Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure the algorithm, security keychain, and level of authentication for BFD sessions running on PIM interfaces.

Options

The statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

auto-rp

Syntax

```
auto-rp {
  (announce | discovery | mapping);
  (mapping-agent-election | no-mapping-agent-election);
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp],
[edit protocols pim rp],
[edit routing-instances *routing-instance-name* protocols pim rp]

Release Information

Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure automatic RP announcement and discovery.

Options

announce—Configure the routing device to listen only for mapping packets and also to advertise itself if it is an RP.

discovery—Configure the routing device to listen only for mapping packets.

mapping—Configures the routing device to announce, listen for and generate mapping packets, and announce that the routing device is eligible to be an RP.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

backoff-period

Syntax backoff-period *milliseconds*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim interface *interface-name* bidirectional df-election],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election],
[edit protocols pim interface *interface-name* bidirectional df-election],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election]

Release Information Statement introduced in Junos OS Release 12.1.

Description Configure the designated forwarder (DF) election backoff period for bidirectional PIM. The **backoff-period** statement configures the period that the acting DF waits between receiving a better DF Offer and sending the Pass message to transfer DF responsibility.

NOTE: Junos OS checks rendezvous point (RP) unicast reachability before accepting incoming DF messages. DF messages for unreachable rendezvous points are ignored. This is needed to prevent the following example scenario. Routers A and B are downstream routers on the same LAN, and both are supposed to send DF election messages with an infinite metric on their upstream interfaces (reverse-path forwarding [RPF] interfaces). Router A has a higher IP address than Router B. When both routers lose the path to the RP, both send an Offer message with the infinite metric onto the LAN. Router A wins the election because it has a higher IP address, and Router B backs off as a result. After three Offer messages, according to RFC 5015, Router A looks up the RP and finds no path to the RP. As a result, Router A transitions to the Lose state and sends nothing. On the other hand, after backing off for an interval of 3 x the Offer period, Router B does not receive any messages, and resumes the DF election by sending a new Offer message. Hence, the pattern repeats indefinitely.

Options *milliseconds*—Period that the acting DF waits between receiving a better DF Offer and sending the Pass message to transfer DF responsibility.

Range: 100 through 65,535 milliseconds

Default: 1000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols msdp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure a rendezvous point (RP) using MSDP to encapsulate multicast data received in MSDP register messages inside forwarded MSDP source-active messages.

Default If you do not include this statement, the RP encapsulates multicast data.

Options **disable**—(Optional) Do not use MSDP data encapsulation.

enable—Use MSDP data encapsulation.

Default: **enable**

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols msdp group *group-name* peer *address*],
[edit routing-instances *routing-instance-name* protocols msdp peer *address*]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Establish this peer as the default MSDP peer and accept source-active messages from the peer without the usual peer-reverse-path-forwarding (peer-RPF) check.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

defaults

Syntax

```
defaults {
  (accounting (Protocols IGMP AMT Interface) | no-accounting (Protocols IGMP AMT
    Interface));
  group-policy [ policy-names ];
  query-interval seconds;
  query-response-interval seconds;
  robust-count number;
  ssm-map ssm-map-name;
  version version;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* statement-name protocols igmp amt relay],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* statement-name protocols igmp amt relay],
[edit protocols igmp amt relay],
[edit routing-instances *routing-instance-name* statement-name protocols igmp amt relay]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

Configure default IGMP attributes for all Automatic Multicast Tunneling (AMT) interfaces.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the AMT Protocol on page 4277

dense-groups

Syntax

```
dense-groups {
  addresses;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure which groups are operating in dense mode.

Options

addresses—Address of groups operating in dense mode.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring PIM Sparse-Dense Mode Properties on page 4111

detection-time (BFD for PIM)

Syntax

```
detection-time {
  threshold milliseconds;
}
```

Hierarchy Level

[edit protocols pim interface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information

Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

df-election

Syntax

```
df-election {
  backoff-period milliseconds;
  offer-period milliseconds;
  robustness-count number;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim interface *interface-name* bidirectional],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional],
[edit protocols pim interface *interface-name* bidirectional],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional]

Release Information

Statement introduced in Junos OS Release 12.1.

Description

Optionally, configure the designated forwarder (DF) election parameters for bidirectional PIM.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

disable (Protocols SAP)

Syntax disable;

Hierarchy Level [edit logical-systems *logical-system-name* protocols sap],
[edit protocols sap]

Release Information Statement introduced before Junos OS Release 7.4.

Description Explicitly disable SAP.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring the Session Announcement Protocol on page 4271

dr-election-on-p2p

Syntax dr-election-on-p2p;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information Statement introduced in Junos OS Release 9.1.
Statement introduced in Junos OS Release 9.1 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Enable PIM designated router (DR) election on point-to-point (P2P) links.

Default No PIM DR election is performed on point-to-point links.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring PIM Designated Router Election on Point-to-Point Links on page 4104

dr-register-policy

Syntax dr-register-policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp],
[edit protocols pim rp],
[edit routing-instances *routing-instance-name* protocols pim rp]

Release Information Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Apply one or more policies to control outgoing PIM register messages.

Options ***policy-names***—Name of one or more import policies.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

dvmrp

Syntax

```
dvmrp {
  disable;
  export [ policy-names ];
  import [ policy-names ];
  interface interface-name {
    disable;
    hold-time seconds;
    metric metric;
    mode (forwarding | unicast-routing);
  }
  rib-group group-name;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols],
[edit protocols]

Release Information Statement introduced before Junos OS Release 7.4.

Description Enable DVMRP on the router.

Default DVMRP is disabled on the router.

Options The statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring DVMRP on page 4288

embedded-rp

Syntax

```
embedded-rp {
  group-ranges {
    destination-ip-prefix</prefix-length>;
  }
  maximum-rps limit;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp],
[edit protocols pim rp],
[edit routing-instances *routing-instance-name* protocols pim rp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure properties for embedded IP version 6 (IPv6) RPs.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring PIM Embedded RP for IPv6 on page 4158

exclude (Protocols IGMP)

Syntax

```
exclude;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address*],
[edit protocols igmp interface *interface-name* static group *multicast-group-address*]

Release Information

Statement introduced in Junos OS Release 9.3.

Description

Configure the static group to operate in exclude mode. In exclude mode all sources except the address configured are accepted for the group. If this statement is not included, the group operates in include mode.

Required Privilege Level

view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

Related Documentation

- Enabling IGMP Static Group Membership on page 4050

Copyright © 2016, Juniper Networks, Inc.

exclude (Protocols MLD)

Syntax exclude;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address*],
[edit protocols mld interface *interface-name* static group *multicast-group-address*]

Release Information Statement introduced in Junos OS Release 9.3.

Description Configure the static group to operate in exclude mode. In exclude mode all sources except the address configured are accepted for the group. By default, the group operates in include mode.

Required Privilege Level view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

Related Documentation
- Enabling MLD Static Group Membership on page 4075

export (Protocols DVMRP)

Syntax export [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* protocols dvmrp],
[edit protocols dvmrp]

Release Information Statement introduced before Junos OS Release 7.4.

Description Apply one or more policies to routes being exported from the routing table into DVMRP. If you specify more than one policy, they are evaluated in the order specified, from first to last, and the first matching policy is applied to the route. If no match is found, the routing table exports into DVMRP only the routes that it learned from DVMRP and direct routes.

Options ***policy-names***—Name of one or more policies.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- import (Protocols DVMRP) on page 4476
- Example: Configuring DVMRP to Announce Unicast Routes on page 4292

flood-groups

Syntax flood-groups [*ip-addresses*];

Hierarchy Level [edit bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* multicast-snooping-options]

Release Information Statement introduced in Junos OS Release 8.5.

Description Establish a list of flood group addresses for multicast snooping.

Options ***ip-addresses***—List of IP addresses subject to flooding.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

flow-map

Syntax

```
flow-map flow-map-name {
  bandwidth (bps | adaptive);
  forwarding-cache {
    timeout (never non-discard-entry-only | minutes);
  }
  policy [ policy-names ];
  redundant-sources [ addresses ];
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information

Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure multicast flow maps.

Options

flow-map-name—Name of the flow-map.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

forwarding-cache (Bridge Domains)

Syntax

```
forwarding-cache {
    threshold suppress value <reuse value>;
}
```

Hierarchy Level

[edit bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* multicast-snooping-options]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Establish multicast snooping forwarding cache parameter values.

Options

The statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Multicast Snooping on page 4345

forwarding-cache (Flow Maps)

Syntax

```
forwarding-cache {
    timeout (minutes | never non-discard-entry-only );
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-options multicast flow-map *flow-map-name*]

Release Information

Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure multicast forwarding cache properties for the flow map.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring a Multicast Flow Map on page 4377

forwarding-cache (Multicast)

Syntax

```
forwarding-cache {
    threshold suppress value <reuse value>;
    timeout minutes;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure multicast forwarding cache properties. These properties include threshold suppression and reuse limits and timeout values.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

graceful-restart (Multicast Snooping)

Syntax graceful-restart <restart-duration *seconds*>;

Hierarchy Level [edit bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options],
[edit routing-instances *routing-instance-name* multicast-snooping-options]

Release Information Statement introduced in Junos OS Release 9.2.

Description Establish the graceful restart duration for multicast snooping. You can set this value between 0 and 300 seconds. If you set the duration to 0, graceful restart is effectively disabled. Set this value slightly larger than the IGMP query response interval.

Default 180 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Multicast Snooping on page 4345
- query-response-interval (Bridge Domains) on page 4548

group (Bridge Domains)

Syntax

```
group ip-address {
    source-address ip-address;
}
```

Hierarchy Level

[edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name* static],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name* static],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name* static],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols vlan *vlan-id* igmp-snooping interface *interface-name* static]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Configure the IGMP multicast group address that receives data on an interface and (optionally) a source address for certain packets.

Options

ip-address—Group address.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring IGMP Snooping on page 4335

group (Protocols IGMP)

Syntax

```
group multicast-group-address {
  exclude;
  group-count number;
  group-increment increment;
  source ip-address {
    source-count number;
    source-increment increment;
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static], [edit protocols igmp interface *interface-name* static]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the IGMP multicast group address and (optionally) the source address for the multicast group being statically configured on an interface.

NOTE: You must specify a unique address for each group.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

group (Protocols MLD)

Syntax

```
group multicast-group-address {
  exclude;
  group-count number;
  group-increment increment;
  source ip-address {
    source-count number;
    source-increment increment;
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static], [edit protocols mld interface *interface-name* static]

Release Information Statement introduced before Junos OS Release 7.4.

Description The MLD multicast group address and (optionally) the source address for the multicast group being statically configured on an interface.

Options ***multicast-group-address***—Address of the group.

NOTE: You must specify a unique address for each group.

The remaining statements are explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

group (Protocols MSDP)

Syntax

```
group group-name {
  disable;
  export [ policy-names ];
  import [ policy-names ];
  local-address address;
  mode (mesh-group | standard);
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
  peer address; {
    disable;
    active-source-limit {
      maximum number;
      threshold number;
    }
    authentication-key peer-key;
    default-peer;
    export [ policy-names ];
    import [ policy-names ];
    local-address address;
    traceoptions {
      file filename <files number> <size size> <world-readable | no-world-readable>;
      flag flag <flag-modifier> <disable>;
    }
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols msdp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp],
[edit protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Define an MSDP peer group. MSDP peers within groups share common tracing options, if present and not overridden for an individual peer with the peer statement. To configure multiple MSDP groups, include multiple **group** statements.

By default, the group's options are identical to the global MSDP options. To override the global options, include group-specific options within the **group** statement.

The group must contain at least one peer.

Options

group-name—Name of the MSDP group.

The remaining statements are explained separately.

Copyright © 2016, Juniper Networks, Inc.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring MSDP in a Routing Instance on page 4254

group (RPF Selection)

Syntax

```
group group-address{
  sourcesource-address{
    next-hop next-hop-address;
  }
  wildcard-source {
    next-hop next-hop-address;
  }
}
```

Hierarchy Level
[edit routing-instances *routing-instance-name* edit protocols pim rpf-selection]

Release Information
Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description
Configure the PIM group address for which you configure RPF selectiongroup (RPF Selection).

Default
By default, PIM RPF selection is not configured.

Options
group-address—PIM group address for which you configure RPF selection.

Required Privilege Level
view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

Related Documentation
- Example: Configuring PIM RPF Selection on page 4323

group-count

Syntax group-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address*],
[edit protocols igmp interface *interface-name* static group *multicast-group-address*]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the number of static groups to be created.

Options *number*—Number of static groups.

Default:

Range: 1 through 512

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Enabling IGMP Static Group Membership on page 4050

group-count (Protocols MLD)

Syntax group-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address*],
[edit protocols mld interface *interface-name* static group *multicast-group-address*]

Release Information Statement introduced in Junos OS Release 9.6.

Description Configure the number of static groups to be created.

Options *number*—Number of static groups.

Default: 1

Range: 1 through 512

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Enabling MLD Static Group Membership on page 4075

Copyright © 2016, Juniper Networks, Inc.

group-increment (Protocols IGMP)

Syntax group-increment *increment*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address*],
[edit protocols igmp interface *interface-name* static group *multicast-group-address*]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the number of times the address should be incremented for each static group created. The increment is specified in dotted decimal notation similar to an IPv4 address.

Options *increment*—Number of times the address should be incremented.

Default: 0.0.0.1

Range: 0.0.0.1 through 255.255.255.255

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Enabling IGMP Static Group Membership on page 4050

group-increment (Protocols MLD)

Syntax group-increment *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address*],
[edit protocols mld interface *interface-name* static group *multicast-group-address*]

Release Information Statement introduced in Junos OS Release 9.6.

Description Configure the number of times the address should be incremented for each static group created. The increment is specified in a format similar to an IPv6 address.

Options *increment*—Number of times the address should be incremented.

Default: ::1

Range: ::1 through ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff:

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Enabling MLD Static Group Membership on page 4075

Copyright © 2016, Juniper Networks, Inc.

group-limit (Protocols IGMP)

Syntax group-limit *limit*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure a limit for the number of multicast groups (or [S,G] channels in IGMPv3) allowed on an interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.

Default By default, there is no limit to the number of multicast groups that can join the interface.

Options *limit*—group limit value for the interface.

Range: 1 through 32767

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Limiting the Number of IGMP Multicast Group Joins on Logical Interfaces on page 4057

Copyright © 2016, Juniper Networks, Inc.

group-limit (IGMP and MLD Snooping)

Syntax group-limit *limit*;

Hierarchy Level
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols vlan *vlan-id* igmp-snooping interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.5.

Description Configure a limit for the number of multicast groups (or [S,G] channels in IGMPv3) allowed on an interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.

Default By default, there is no limit to the number of multicast groups joining an interface.

Options ***limit***—a 32-bit number for the limit on the interface.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring IGMP Snooping on page 4335

group-limit (Protocols MLD)

Syntax group-limit *limit*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*],
[edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 10.4.

Description Configure a limit for the number of multicast groups (or [S,G] channels in MLDv2) allowed on a logical interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.

Default By default, there is no limit to the number of multicast groups that can join the interface.

Options *limit*—group value limit for the interface.
Range: 1 through 32767

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Examples: Configuring MLD on page 4063

group-policy (Protocols IGMP)

Syntax group-policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 9.1.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), after the routing device receives an IGMP report, the routing device compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report).

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Filtering Unwanted IGMP Reports at the IGMP Interface Level on page 4045

Copyright © 2016, Juniper Networks, Inc.

group-policy (Protocols IGMP AMT Interface)

Syntax group-policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description When this statement is enabled on the Automatic Multicast Tunneling (AMT) interfaces running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), after the router receives an IGMP report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report).

Options ***policy-names***—Name of the policy.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Default IGMP Parameters for AMT Interfaces on page 4279

group-policy (Protocols MLD)

Syntax group-policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*],
[edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 9.1.

Description When a router running MLD version 1 or version 2 (MLDv1 or MLDv2), receives an MLD report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report).

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit routing-instances *routing-instance-name* protocols pim rp static address *address*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
Support for bidirectional RP addresses introduced in Junos OS Release 12.1.
Statement introduced in Junos OS Release 13.3 for the PTX5000 router.

Description

Configure the address ranges of the multicast groups for which this routing device can be a rendezvous point (RP).

Default

The routing device is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12).

Options

destination-ip-prefix</prefix-length>—Addresses or address ranges for which this routing device can be an RP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Enable IGMP on the router. IGMP must be enabled for the router to receive multicast packets.

The remaining statements are explained separately.

Default IGMP is disabled on the router. IGMP is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP).

Release Information Statement introduced in Junos OS Release 8.5.

Description The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

immediate-leave (Protocols MLD)

Syntax immediate-leave;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*], [edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.3.

Description The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

Release Information Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the timeout for the join state. If the periodic join refresh message is not received before the timeout expires, the join state is removed.

Options **seconds**—Number of seconds to wait for the periodic join message to arrive.

Range: 210 through 240 seconds

Default: 210 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Modifying the Join State Timeout on page 4122

key-chain

Syntax key-chain *key-chain-name*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection authentication],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection authentication]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the security keychain to use for BFD authentication.

Options ***key-chain-name***—Name of the security keychain to use for BFD authentication. The name is a unique integer between **0** and **63**. This must match one of the keychains in the **authentication-key-chains** statement at the **[edit security]** hierarchy level.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

listen

Syntax listen *address* <port *port*>;

Hierarchy Level [edit logical-systems *logical-system-name* protocols sap],
[edit protocols sap]

Release Information Statement introduced before Junos OS Release 7.4.

Description Specify an address and optionally a port on which SAP and SDP listen, in addition to the default SAP address and port on which they always listen, 224.2.127.254:9875. To specify multiple additional addresses or pairs of address and port, include multiple **listen** statements.

Options ***address***—(Optional) Address on which SAP listens for session advertisements.

Default: 224.2.127.254

port *port*—(Optional) Port on which SAP listens for session advertisements.

Default: 9875

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

local

Syntax

```
local {
  disable;
  address address;
  family (inet | inet6) {
    disable;
    address address;
    anycast-pim {
      local-address address;
        rp-set {
        address address <forward-msdp-sa>;
      }
    }
    group-ranges {
      destination-ip-prefix</prefix-length>;
    }
    hold-time seconds;
    override;
    priority number;
  }
  group-ranges {
    destination-ip-prefix</prefix-length>;
  }
  hold-time seconds;
  override;
  priority number;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp],
[edit protocols pim rp],
[edit routing-instances *routing-instance-name* protocols pim rp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
The remaining statements are explained separately.

Description

Configure the routing device's RP properties.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

local-address (Protocols AMT)

Syntax local-address *ip-address*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols amt relay family inet],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt relay family inet],
[edit protocols amt relay family inet],
[edit routing-instances *routing-instance-name* protocols amt relay family inet]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify the local unique IP address to send in Automatic Multicast Tunneling (AMT) relay advertisement messages, for use as the IP source of AMT control messages, and as the source of the data tunnel encapsulation. The address can be configured on any interface in the system. Typically, the router's **lo0.0** loopback address is used for configuring the AMT local address in the default routing instance, and the router's **lo0.*n*** loopback address is used for configuring the AMT local address in VPN routing instances.

Default None. The local address must be configured.

Options ***ip-address***—Unique unicast IP address.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

[edit protocols msdp peer *address*],
[edit routing-instances *routing-instance-name* protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp group *group-name*],
[edit routing-instances *routing-instance-name* protocols msdp group *group-name* peer *address*],
[edit routing-instances *routing-instance-name* protocols msdp peer *address*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the local end of an MSDP session. You must configure at least one peer for MSDP to function. When configuring a peer, you must include this statement. This address is used to accept incoming connections to the peer and to establish connections to the remote peer.

Options ***address***—IP address of the local end of the connection.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

local-address (Protocols PIM)

Syntax local-address *address*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim rp local family (inet | inet6) anycast-pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp local family (inet | inet6) anycast-pim],
[edit protocols pim rp local family (inet | inet6) anycast-pim],
[edit routing-instances *routing-instance-name* protocols pim rp local family (inet | inet6) anycast-pim]

Release Information
Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the routing device local address for the anycast rendezvous point (RP). If this statement is omitted, the router ID is used as this address.

Options ***address***—Anycast RP IPv4 or IPv6 address, depending on **family** configuration.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring PIM Anycast With or Without MSDP on page 4142

local-address (Routing Options)

Syntax local-address *address*;

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast backup-pe-group *group-name*],
[edit logical-systems *logical-system-name* routing-options multicast backup-pe-group *group-name*],
[edit routing-instances *routing-instance-name* routing-options multicast backup-pe-group *group-name*],
[edit routing-options multicast backup-pe-group *group-name*]

Release Information
Statement introduced in Junos OS Release 9.0.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Configure the address of the local PE for ingress PE redundancy when point-to-multipoint LSPs are used for multicast distribution.

Options ***address***—Address of local PEs in the backup group.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring Ingress PE Redundancy on page 4381

loose-check

Syntax loose-check;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection authentication],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection authentication]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify loose authentication checking on the BFD session. Use loose authentication for transitional periods only when authentication might not be configured at both ends of the BFD session.

By default, strict authentication is enabled and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure *loose checking*. When loose checking is configured, packets are accepted without authentication being checked at each end of the session.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

mapping-agent-election

Syntax (mapping-agent-election | no-mapping-agent-election);

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim rp auto-rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp auto-rp],
[edit protocols pim rp auto-rp],
[edit routing-instances *routing-instance-name* protocols pim rp auto-rp]

Release Information Statement introduced in Junos OS Release 7.5.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the routing device mapping announcements as a mapping agent.

Options

mapping-agent-election—Mapping agents do not announce mappings when receiving mapping messages from a higher-addressed mapping agent.

no-mapping-agent-election—Mapping agents always announce mappings and do not perform mapping agent election.

Default: **mapping-agent-election**

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

maximum (MSDP Active Source Messages)

Syntax maximum *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols msdp active-source-limit],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp active-source-limit],
[edit protocols msdp active-source-limit],
[edit routing-instances *routing-instance-name* protocols msdp active-source-limit]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the maximum number of MSDP active source messages the router accepts.

Options *number*—Maximum number of active source messages.

Range: 1 through 1,000,000

Default: 25,000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

maximum-bandwidth

Syntax maximum-bandwidth *bps*;

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit logical-systems *logical-system-name* routing-options multicast interface *interface-name*],
[edit routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit routing-options multicast interface *interface-name*]

Release Information
Statement introduced in Junos OS Release 8.3.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the multicast bandwidth for the interface.

Options *bps*—Bandwidth rate, in bits per second, for the multicast interface.

Range: 0 through any amount of bandwidth

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Defining Interface Bandwidth Maximums on page 4355

Copyright © 2016, Juniper Networks, Inc.

maximum-rps

Syntax maximum-rps *limit*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim rp embedded-rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp embedded-rp],
[edit protocols pim rp embedded-rp],
[edit routing-instances *routing-instance-name* protocols pim rp embedded-rp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Limit the number of RPs that the routing device acknowledges.

Options *limit*—Number of RPs.

Range: 1 through 500

Default: 100

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring PIM Embedded RP for IPv6 on page 4158

maximum-transmit-rate (Protocols IGMP)

Syntax maximum-transmit-rate *packets-per-second*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp],
[edit protocols igmp]

Release Information Statement introduced in Junos OS Release 9.3.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Limit the transmission rate of IGMP packets

Options **packets-per-second**—Maximum number of IGMP packets transmitted in one second by the router.

Range: 1 through 10000

Default: 500 packets

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Limiting the Maximum IGMP Message Rate on page 4049

metric (Protocols DVMRP)

Syntax metric *metric*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols dvmrp interface *interface-name*],
[edit protocols dvmrp interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.

Description Define the DVMRP metric value.

Options *metric*—Metric value.

Range: 1 through 31

Default: 1

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring DVMRP on page 4288

minimum-interval (PIM BFD Liveness Detection)

Syntax minimum-interval *milliseconds*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the minimum interval after which the local routing device transmits hello packets and then expects to receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can specify the minimum transmit and receive intervals separately using the **transmit-interval minimum-interval** and **minimum-receive-interval** statements.

Options *milliseconds*—Minimum transmit and receive interval.

Range: 1 through 255,000 milliseconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring BFD for PIM on page 4221

Copyright © 2016, Juniper Networks, Inc.

minimum-interval (PIM BFD Transmit Interval)

Syntax minimum-interval *milliseconds*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection transmit-interval],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection transmit-interval]

Release Information Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the minimum interval after which the local routing device transmits hello packets to a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can configure the minimum transmit interval using the **minimum-interval** statement at the **[edit protocols pim interface *interface-name* bfd-liveness-detection]** hierarchy level.

Options ***milliseconds***—Minimum transmit interval value.

Range: 1 through 255,000

NOTE: The threshold value specified in the **threshold** statement must be greater than the value specified in the **minimum-interval** statement for the **transmit-interval** statement.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

minimum-receive-interval

Syntax minimum-receive-interval *milliseconds*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the minimum interval after which the local routing device must receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can configure the minimum receive interval using the **minimum-interval** statement at the **[edit protocols pim interface *interface-name* bfd-liveness-detection]** hierarchy level.

Options ***milliseconds***—Minimum receive interval.

Range: 1 through 255,000 milliseconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring BFD for PIM on page 4221

mld

Syntax

```
mld {
  accounting;
  interface interface-name {
    (accounting | no-accounting);
    disable;
    group-limit limit;
    group-policy [ policy-names ];
    immediate-leave;
    oif-map [ map-names ];
    passive;
    ssm-map ssm-map-name;
    ssm-map-policy ssm-map-policy-name;
    static {
      group multicast-group-address {
        exclude;
        group-count number;
        group-increment increment;
        source ip-address {
          source-count number;
          source-increment increment;
        }
      }
    }
    version version;
  }
  maximum-transmit-rate packets-per-second;
  query-interval seconds;
  query-last-member-interval seconds;
  query-response-interval seconds;
  robust-count number;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols],
[edit protocols]

Release Information Statement introduced before Junos OS Release 7.4.

Description Enable MLD on the router. MLD must be enabled for the router to receive multicast packets.

Default MLD is disabled on the router. MLD is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP).

Options The statements are explained separately.

Copyright © 2016, Juniper Networks, Inc.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Enabling MLD on page 4067

mode (Protocols DVMRP)

Syntax
```
mode (forwarding | unicast-routing);
```

Hierarchy Level
[edit logical-systems *logical-system-name* protocols dvmrp interface *interface-name*],
[edit protocols dvmrp interface *interface-name*]

Release Information
Statement introduced before Junos OS Release 7.4.

Description
Configure DVMRP for multicast traffic forwarding or unicast routing.

Options
forwarding—DVMRP performs unicast routing as well as multicast data forwarding.

unicast-routing—DVMRP performs unicast routing only. To forward multicast data, you must configure Protocol Independent Multicast (PIM) on the interface.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring DVMRP to Announce Unicast Routes on page 4292

Copyright © 2016, Juniper Networks, Inc.

mode (Protocols MSDP)

Syntax mode (mesh-group | standard);

Hierarchy Level [edit logical-systems *logical-system-name* protocols msdp group *group-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp group *group-name*],
[edit protocols msdp group *group-name*],
[edit routing-instances *routing-instance-name* protocols msdp group *group-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure groups of peers in a full mesh topology to limit excessive flooding of source-active messages to neighboring peers. The default flooding mode is **standard**.

Default If you do not include this statement, default flooding is applied.

Options **mesh-group**—Group of peers that are mesh group members.

standard—Use standard MSDP source-active flooding rules.

Default: standard

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring MSDP with Active Source Limits and Mesh Groups on page 4262

Copyright © 2016, Juniper Networks, Inc.

mode (Protocols PIM)

Syntax mode (bidirectional-sparse | bidirectional-sparse-dense | dense | sparse | sparse-dense);

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
bidirectional-sparse and **bidirectional-sparse-dense** options introduced in Junos OS Release 12.1.

Description Configure the PIM mode on the interface.

Options The choice of PIM mode is closely tied to controlling how groups are mapped to PIM modes, as follows:

- **bidirectional-sparse**—Use if all multicast groups are operating in bidirectional, sparse, or SSM mode.
- **bidirectional-sparse-dense**—Use if multicast groups, except those that are specified in the **dense-groups** statement, are operating in bidirectional, sparse, or SSM mode.
- **dense**—Use if all multicast groups are operating in dense mode.
- **sparse**—Use if all multicast groups are operating in sparse mode or SSM mode.
- **sparse-dense**—Use if multicast groups, except those that are specified in the **dense-groups** statement, are operating in sparse mode or SSM mode.

Default: Sparse mode

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols],
[edit protocols],
[edit routing-instances *routing-instance-name* protocols]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.4 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Enable MSDP on the router or switch. You must also configure at least one peer for MSDP to function.

Default

MSDP is disabled on the router or switch.

Options

The statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

no-bidirectional-mode

Syntax no-birectional-mode;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim graceful-restart],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim graceful-restart],
[edit protocols pim graceful-restart],
[edit routing-instances *routing-instance-name* protocols pim graceful-restart]

Release Information Statement introduced in Junos OS Release 12.1.

Description Disable forwarding for bidirectional PIM routes during graceful restart recovery, both in cases of a routing protocol process (rpd) restart and graceful Routing Engine switchover.

Bidirectional PIM accepts packets for a bidirectional route on multiple interfaces. This means that some topologies might develop multicast routing loops if all PIM neighbors are not synchronized with regard to the identity of the designated forwarder (DF) on each link. If one router is forwarding without actively participating in DF elections, particularly after unicast routing changes, multicast routing loops might occur.

If graceful restart for PIM is enabled and the forwarding of packets on bidirectional routes is disallowed (by including the **no-bidirectional-mode** statement in the configuration), PIM behaves conservatively to avoid multicast routing loops during the recovery period. When the routing protocol process (rpd) restarts, all bidirectional routes are deleted. After graceful restart has completed, the routes are re-added, based on the converged unicast and bidirectional PIM state. While graceful restart is active, bidirectional multicast flows drop packets.

Default If graceful restart for PIM is enabled and the bidirectional PIM is enabled, the default graceful restart behavior is to continue forwarding packets on bidirectional routes. If the gracefully restarting router was serving as a DF for some interfaces to rendezvous points, the restarting router sends a DF Winner message with a metric of 0 on each of these RP interfaces. This ensures that a neighbor router does not become the DF due to unicast topology changes that might occur during the graceful restart period. Sending a DF Winner message with a metric of 0 prevents another PIM neighbor from assuming the DF role until after graceful restart completes. When graceful restart completes, the gracefully restarted router sends another DF Winner message with the actual converged unicast metric.

NOTE: Graceful Routing Engine switchover operates independently of the graceful restart behavior. If graceful Routing Engine switchover is configured without graceful restart, all PIM routes for all modes are deleted when the rpd process restarts. If graceful Routing Engine switchover is configured with graceful restart, the behavior is the same as described here, except that the recovery happens on the Routing Engine that assumes mastership.

offer-period

Syntax offer-period *milliseconds*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim interface *interface-name* bidirectional df-election],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election],
[edit protocols pim interface *interface-name* bidirectional df-election],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election]

Release Information Statement introduced in Junos OS Release 12.1.

Description Configure the designated forwarder (DF) election offer period for bidirectional PIM. When a DF election Offer or Winner message fails to be received, the message is retransmitted. The **offer-period** statement modifies the interval between repeated DF election messages. The robustness-count statement determines the minimum number of DF election messages that must fail to be received for DF election to fail. To prevent routing loops, all routers on the link must have a consistent view of the DF. When the DF election fails because DF election messages are not received, forwarding on bidirectional PIM routes is suspended.

If a router receives from a neighbor a better offer than its own, the router stops participating in the election for a period of robustness-count * **offer-period**. Eventually, all routers except the best candidate stop sending Offer messages.

Options *milliseconds*—Interval to wait before retransmitting DF Offer and Winner messages.

Range: 100 through 10,000 milliseconds

Default: 100

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

[edit routing-instances *routing-instance-name* protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp group *group-name*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Define an MSDP peering relationship. An MSDP router must know which routers are its peers. You define the peer relationships explicitly by configuring the neighboring routers that are the MSDP peers of the local router. After peer relationships are established, the MSDP peers exchange messages to advertise active multicast sources. To configure multiple MSDP peers, include multiple **peer** statements.

By default, the peer's options are identical to the global or group-level MSDP options. To override the global or group-level options, include peer-specific options within the peer statement.

At least one peer must be configured for MSDP to function. You must configure ***address*** and **local-address**.

Options

address—Name of the MSDP peer.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Copyright © 2016, Juniper Networks, Inc.

Related Documentation
- Example: Configuring MSDP in a Routing Instance on page 4254

pgm

Syntax

```
pgm {
  traceoptions {
    flag flag <flag-modifier>;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols],
[edit protocols]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure PGM globally and set tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

The remaining statement is explained separately.

Default

The default PGM trace options are inherited from the routing protocol **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

pim-to-igmp-proxy

Syntax
```
pim-to-igmp-proxy {
  upstream-interface [ interface-names ];
}
```

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 9.6 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the rendezvous point (RP) routing device that resides between a customer edge-facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain to translate PIM join or prune messages into corresponding Internet Group Management Protocol (IGMP) report or leave messages. The routing device then transmits the report or leave messages by proxying them to one or two upstream interfaces that you configure on the RP routing device. Including the **pim-to-igmp-proxy** statement enables you to use IGMP to forward IPv4 multicast traffic across the PIM sparse mode domains.

The remaining statement is explained separately.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

pim-to-mld-proxy

Syntax

```
pim-to-mld-proxy {
  upstream-interface [ interface-names ];
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information

Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 9.6 for EX Series switches.

Description

Configure the rendezvous point (RP) routing device that resides between a customer edge–facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain to translate PIM join or prune messages into corresponding Multicast Listener Discovery (MLD) report or leave messages. The routing device then transmits the report or leave messages by proxying them to one or two upstream interfaces that you configure on the RP routing device. Including the **pim-to-mld-proxy** statement enables you to use MLD to forward IPv6 multicast traffic across the PIM sparse mode domains.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

policy (Flow Maps)

Syntax policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-options multicast flow-map *flow-map-name*]

Release Information Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure a flow map policy.

Options ***policy-names***—Name of one or more policies for flow mapping.

Required Privilege Level routing—To view this statement in the configuration.

policy (SSM Maps)

Syntax policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-options multicast ssm-map *ssm-map-name*]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.

Description Apply one or more policies to an SSM map.

Options ***policy-names***—Name of one or more policies for SSM mapping.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To view this statement in the configuration.

prefix-list (PIM RPF Selection)

Syntax

```
prefix-list prefix-list-addresses {
  source source-address {
    next-hop next-hop-address;
  }
  wildcard-source {
    next-hop next-hop-address;
  }
}
```

Hierarchy Level

[edit routing-instances *routing-instance-name* protocols pim rpf-selection group *group-address* source *source-address*],
[edit routing-instances *routing-instance-name* protocols pim rpf-selection group *group-address* wildcard-source],
[edit routing-instances *routing-instance-name* protocols pim rpf-selection prefix-list *prefix-list-addresses* source *source-address*],
[edit routing-instances *routing-instance-name* protocols pim rpf-selection prefix-list *prefix-list-addresses* wildcard-source]

Release Information

Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

(Optional) Configure a list of prefixes (addresses) for multiple PIM groups.

Options

prefix-list-addresses—List of prefixes (addresses) for multiple PIM groups.

The remaining statements are explained separately.

Required Privilege Level

view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

priority (Bootstrap)

Syntax priority *number*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim rp bootstrap (inet | inet6)],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp bootstrap (inet | inet6)],
[edit protocols pim rp bootstrap (inet | inet6)],
[edit routing-instances *routing-instance-name* protocols pim rp bootstrap (inet | inet6)]

Release Information
Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the routing device's likelihood to be elected as the bootstrap router.

Options
number—Routing device's priority for becoming the bootstrap router. A higher value corresponds to a higher priority.

Range: 0 through a 32-bit number

Default: 0 (The routing device has the least likelihood of becoming the bootstrap router and sends packets with a priority of 0.)

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

priority (PIM Interfaces)

Syntax priority *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the routing device's likelihood to be elected as the designated router.

Options *number*—Routing device's priority for becoming the designated router. A higher value corresponds to a higher priority.

Range: 0 through 4294967295

Default: 1 (Each routing device has an equal probability of becoming the DR.)

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

priority (PIM RPs)

Syntax priority *number*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim rp bidirectional address *address*],
[edit logical-systems *logical-system-name* routing-instances *instance-name* protocols pim rp bidirectional address *address*],
[edit protocols pim rp bidirectional address *address*],
[edit protocols pim rp local family (inet | inet6)],
[edit routing-instances *instance-name* protocols pim rp bidirectional address *address*],
[edit routing-instances *routing-instance-name* protocols pim rp local family (inet | inet6)]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional RP addresses introduced in Junos OS Release 12.1.

Description For PIM-SM, configure this routing device's priority for becoming an RP.

For bidirectional PIM, configure this RP address' priority for becoming an RP.

The bootstrap router uses this field when selecting the list of candidate rendezvous points to send in the bootstrap message. A smaller number increases the likelihood that the routing device or RP address becomes the RP. A priority value of 0 means that bootstrap router can override the group range being advertised by the candidate RP.

Options *number*—Priority for becoming an RP. A lower value corresponds to a higher priority.

Range: 0 through 255

Default: 1

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

propagation-delay

Syntax propagation-delay *milliseconds*;

Hierarchy Level
[edit protocols pim],
[edit protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*]

Release Information
Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Set a delay for implementing a PIM prune message on the upstream router on a multicast network for which join suppression has been enabled. The router waits for the prune pending period to detect whether a join message is currently being suppressed by another router.

Options ***milliseconds***—Interval for the prune pending timer, which is the sum of the **propagation-delay** value and the **override-interval** value.

Range: 250 through 2000 milliseconds

Default: 500 milliseconds

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Enabling Join Suppression on page 4122
- override-interval on page 4525
- reset-tracking-bit on page 4555

proxy

Syntax

```
proxy {
    source-address ip-address;
}
```

Hierarchy Level

[edit bridge-domains *bridge-domain-name* protocols igmp-snooping],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols vlan *vlan-id* igmp-snooping]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Configure proxy mode and options, including source address. All the queries generated by IGMP snooping are sent using 0.0.0.0 as the source address in order to avoid participating in IGMP querier election. Also, all reports generated by IGMP snooping are sent with 0.0.0.0 as the source address unless there is a configured source address to use.

Default

By default, IGMP snooping does not employ proxy mode.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring IGMP Snooping on page 4335

[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.5.

Description Specify how long to wait to receive a response to a specific query message from a host.

Options ***seconds***—Time interval. This interval should be less than the host-query interval.

Range: 1 through 1024

Default: 10 seconds

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

query-response-interval (Protocols IGMP)

Syntax query-response-interval *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp],
[edit protocols igmp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify how long the querier router waits to receive a response to a host-query message from a host.

Options ***seconds***—The query response interval must be less than the query interval.

Range: 1 through 1024

Default: 10 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

query-response-interval (Protocols IGMP AMT)

Syntax query-response-interval *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify how long the IGMP querier router waits to receive a response to a host query message from a host through an Automatic Multicast Tunneling (AMT) interface. The query response interval must be less than the query interval.

Options ***seconds***—Time to wait to receive a response to a host query message.

Range: 1 through 1024

Default: 10 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

query-response-interval (Protocols MLD)

Syntax query-response-interval *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld],
[edit protocols mld]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description Specify how long the querier router waits to receive a response to a host-query message from a host.

Options ***seconds***—Time interval. This interval must be less than the interval between general host-query messages.

Range: 1 through 1024

Default: 10 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

redundant-sources

Syntax redundant-sources [*addresses*];

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-options multicast flow-map *flow-map-name*]

Release Information
Statement introduced in Junos OS Release 8.3.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure a list of redundant sources for multicast flows defined by a flow map.

Options ***addresses***—List of IPv4 or IPv6 addresses for use as redundant (backup) sources for multicast flows defined by a flow map.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring a Multicast Flow Map on page 4377

relay (AMT Protocol)

Syntax

```
relay {
  accounting;
  family {
    inet {
      anycast-prefix ip-prefix/<prefix-length>;
      local-address ip-address;
    }
  }
  secret-key-timeout minutes;
  tunnel-limit number;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols amt],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt],
[edit protocols amt],
[edit routing-instances *routing-instance-name* protocols amt]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

Configure the protocol address family, secret key timeout, and tunnel limit for Automatic Multicast Tunneling (AMT) relay functions.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the AMT Protocol on page 4277

Copyright © 2016, Juniper Networks, Inc.

relay (IGMP)

Syntax

```
relay {
  defaults {
    (accounting (Protocols IGMP AMT Interface) | no-accounting (Protocols IGMP AMT
      Interface));
    group-policy [ policy-names ];
    query-interval seconds;
    query-response-interval seconds;
    robust-count number;
    ssm-map ssm-map-name;
    version version;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* statement-name protocols igmp amt],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* statement-name protocols igmp amt],
[edit protocols igmp amt],
[edit routing-instances *routing-instance-name* statement-name protocols igmp amt]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

Configure default Automatic Multicast Tunneling (AMT) interface attributes.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring Default IGMP Parameters for AMT Interfaces on page 4279

reset-tracking-bit

Syntax reset-tracking-bit;

Hierarchy Level
[edit protocols pim],
[edit protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*]

Release Information
Statement introduced in Junos OS Release 10.1.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds (1.1 × periodic through 1.4 × periodic, where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join.

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Enabling Join Suppression on page 4122
- override-interval on page 4525
- propagation-delay on page 4541

restart-duration

Syntax restart-duration *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols pim graceful-restart],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim graceful-restart],
[edit protocols pim graceful-restart],
[edit routing-instances *routing-instance-name* protocols pim graceful-restart]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the duration of the graceful restart interval.

Options *seconds*—Time that the routing device waits (in seconds) to complete PIM sparse mode graceful restart.

Range: 30 through 300

Default: 60

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

reverse-oif-mapping

Syntax

```
reverse-oif-mapping {
    no-qos-adjust;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit logical-systems *logical-system-name* routing-options multicast interface *interface-name*],
[edit routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit routing-options multicast interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 9.2.
Statement introduced in Junos OS Release 9.2 for EX Series switches.
The **no-qos-adjust** statement added in Junos OS Release 9.5.
The **no-qos-adjust** statement introduced in Junos OS Release 9.5 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Enable the routing device to identify a subscriber VLAN or interface based on an IGMP or MLD request it receives over the multicast VLAN.

The remaining statement is explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Multicast with Subscriber VLANs on page 4358

rib-group (Protocol DVMRP)

Syntax

rib-group *group-name*;

Hierarchy Level

[edit logical-systems *logical-system-name* protocols dvmrp],
[edit protocols dvmrp]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Associate a routing table group with DVMRP.

Options

group-name—Name of the routing table group. The name must be one that you defined with the **rib-groups** statement at the **[edit routing-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring DVMRP on page 4288

Copyright © 2016, Juniper Networks, Inc.

rib-group (Protocols MSDP)

Syntax rib-group *group-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols msdp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp],
[edit protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Associate a routing table group with MSDP.

Options *group-name*—Name of the routing table group. The name must be one that you defined with the **rib-groups** statement at the **[edit routing-options]** hierarchy level.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring MSDP in a Routing Instance on page 4254

Copyright © 2016, Juniper Networks, Inc.

rib-group (Protocols PIM)

Syntax

```
rib-group {
    inet group-name;
    inet6 group-name;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Associate a routing table group with PIM.

Options

table-name—Name of the routing table. The name must be one that you defined with the **rib-groups** statement at the **[edit routing-options]** hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Copyright © 2016, Juniper Networks, Inc.

robust-count (Bridge Domains)

Syntax robust-count *number*;

Hierarchy Level
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.5.

Description Provide fine-tuning to allow for expected packet loss on a subnet. You can wait more intervals if subnet packet loss is high and IGMP report messages might be lost.

Options *number*—Robust interval.

Range: 2 through 10

Default: 2

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring IGMP Snooping on page 4335

Copyright © 2016, Juniper Networks, Inc.

robust-count (Protocols IGMP)

Syntax robust-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp],
[edit protocols igmp]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Tune the expected packet loss on a subnet. This factor is used to calculate the group member interval, other querier present interval, and last-member query count.

Options *number*—Robustness variable.

Range: 2 through 10

Default: 2

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Modifying the IGMP Robustness Variable on page 4047

robust-count (Protocols IGMP AMT)

Syntax robust-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description Configure the expected IGMP packet loss on an Automatic Multicast Tunneling (AMT) tunnel. If a tunnel is expected to have packet loss, increase the robust count.

Options *number*—Number of packets that can be lost before the AMT protocol deletes the multicast state.

Range: 2 through 10

Default: 2

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Default IGMP Parameters for AMT Interfaces on page 4279

Copyright © 2016, Juniper Networks, Inc.

robust-count (Protocols MLD)

Syntax robust-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld],
[edit protocols mld]

Release Information Statement introduced before Junos OS Release 7.4.

Description Tune for the expected packet loss on a subnet.

Options *number*—Time interval. This interval must be less than the interval between general host-query messages.

Range: 2 through 10

Default: 2 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Modifying the MLD Robustness Variable on page 4073

Copyright © 2016, Juniper Networks, Inc.

robustness-count

Syntax robustness-count *number*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim interface *interface-name* bidirectional df-election],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election],
[edit protocols pim interface *interface-name* bidirectional df-election],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bidirectional df-election]

Release Information Statement introduced in Junos OS Release 12.1.

Description Configure the designated forwarder (DF) election robustness count for bidirectional PIM. When a DF election Offer or Winner message fails to be received, the message is retransmitted. The **robustness-count** statement sets the minimum number of DF election messages that must fail to be received for DF election to fail. To prevent routing loops, all routers on the link must have a consistent view of the DF. When the DF election fails because DF election messages are not received, forwarding on bidirectional PIM routes is suspended.

If a router receives from a neighbor a better offer than its own, the router stops participating in the election for a period of **robustness-count** * offer-period. Eventually, all routers except the best candidate stop sending Offer messages.

Options *number*—Number of transmission attempts for DF election messages.

Range: 1 through 10

Default: 3

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure the routing device as an actual or potential RP. A routing device can be an RP for more than one group.

The remaining statements are explained separately.

Default

If you do not include the **rp** statement, the routing device can never become the RP.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

rp-set

Syntax

```
rp-set {
    address address <forward-msdp-sa>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim local family (inet | inet6) anycast-pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim local family (inet | inet6) anycast-pim],
[edit protocols pim local family (inet | inet6) anycast-pim],
[edit routing-instances *routing-instance-name* protocols pim local family (inet | inet6) anycast-pim]

Release Information

Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure a set of rendezvous point (RP) addresses for anycast RP. You can configure up to 15 RPs.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

rpf-selection

Syntax

```
rpf-selection {
  group group-address {
    sourcesource-address {
      next-hop next-hop-address;
    }
    wildcard-source {
      next-hop next-hop-address;
    }
  }
  prefix-list prefix-list-addresses {
    source source-address {
      next-hop next-hop-address;
    }
    wildcard-source {
      next-hop next-hop-address;
    }
  }
```

Hierarchy Level [edit routing-instances *routing-instance-name* protocols pim]

Release Information Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the PIM RPF next-hop neighbor for a specific group and source for a VRF routing instance.

The remaining statements are explained separately.

Default If you omit the **rpf-selection** statement, PIM RPF checks typically choose the best path determined by the unicast protocol for all multicast flows.

Options ***source-address***—Specific source address for the PIM group.

Required Privilege Level view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

Related Documentation

sap

Syntax

```
sap {
  disable;
  listen address <port port>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols],
[edit protocols]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Enable the router to listen to session directory announcements for multimedia and other multicast sessions.

SAP and SDP always listen on the default SAP address and port, 224.2.127.254:9875. To have SAP listen on additional addresses or pairs of address and port, include a **listen** statement for each address or pair.

Options

The statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

scope-policy

Syntax scope-policy [*policy-names*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-options multicast]

NOTE: You can configure a scope policy at these two hierarchy levels only. You cannot apply a scope policy to a specific routing instance, because all scoping policies are applied to all routing instances. However, you can apply the **scope** statement to a specific routing instance at the **[edit routing-instances *routing-instance-name* routing-options multicast]** or **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast]** hierarchy level.

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Apply policies for scoping. The policy must be correctly configured at the **edit policy-options policy-statement** hierarchy level.

Options ***policy-names***—Name of one or more multicast scope policies.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- scope on page 4571

secret-key-timeout

Syntax secret-key-timeout *minutes*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols amt relay],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt relay],
[edit protocols amt relay],
[edit routing-instances *routing-instance-name* protocols amt relay]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify the period in minutes after which the local opaque secret key used in the Automatic Multicast Tunneling (AMT) Message Authentication Code (MAC) times out and is regenerated.

Default 60 minutes

Options ***minutes***—Number of minutes to wait before generating a new MAC opaque secret key.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring the AMT Protocol on page 4277

source (Bridge Domains)

Syntax source *ip-address*;

Hierarchy Level [edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name* static group],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name* static group],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name* static group],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols vlan *vlan-id* igmp-snooping interface *interface-name* static group]

Release Information Statement introduced in Junos OS Release 8.5.

Description Statically define multicast group source addresses on an interface.

Options ***ip-address***—IP address to use as the source for the group.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

source (PIM RPF Selection)

Syntax

```
source source-address {
    next-hop next-hop-address;
}
```

Hierarchy Level

[edit routing-instances *routing-instance-name* protocols pim rpf-selection group *group-address*],
[edit routing-instances *routing-instance-name* protocols pim rpf-selection prefix-list *prefix-list-addresses*]

Release Information

Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure the source address for the PIM group.

Options

source-address—Specific source address for the PIM group.

The remaining statements are explained separately.

Required Privilege Level

view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

Related Documentation

- Example: Configuring PIM RPF Selection on page 4323

Copyright © 2016, Juniper Networks, Inc.

source (Protocols IGMP)

Syntax

```
source ip-address {
    source-count number;
    source-increment increment;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address*],
[edit protocols igmp interface *interface-name* static group *multicast-group-address*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Specify the IP version 4 (IPv4) unicast source address for the multicast group being statically configured on an interface.

Options

ip-address—IPv4 unicast address.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling IGMP Static Group Membership on page 4050

source (Protocols MLD)

Syntax

```
source ip-address {
    source-count number;
    source-increment increment;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address*],
[edit protocols mld interface *interface-name* static group *multicast-group-address*]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

IP version 6 (IPv6) unicast source address for the multicast group being statically configured on an interface.

Options

ip-address — One or more IPv6 unicast addresses.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling MLD Static Group Membership on page 4075

source (Protocols MSDP)

Syntax

```
source ip-address</prefix-length> {
  active-source-limit {
    maximum number;
    threshold number;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols msdp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp],
[edit protocols msdp],
[edit routing-instances *routing-instance-name* protocols msdp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Limit the number of active source messages the routing device accepts from sources in this address range.

Default

If you do not include this statement, the routing device accepts any number of MSDP active source messages.

Options

The other statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring MSDP with Active Source Limits and Mesh Groups on page 4262

Copyright © 2016, Juniper Networks, Inc.

source (Routing Instances)

Syntax source [*addresses*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast ssm-map *ssm-map-name*],
[edit routing-options multicast ssm-map *ssm-map-name*]

Release Information Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description Specify IPv4 or IPv6 source addresses for an SSM map.

Options ***addresses***—IPv4 or IPv6 source addresses.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To view this statement in the configuration.

Related Documentation
- Example: Configuring SSM Mapping on page 4192

source-address

Syntax source-address *ip-address*;

Hierarchy Level [edit bridge-domains *bridge-domain-name* protocols igmp-snooping proxy],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* proxy],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping proxy],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* proxy]

Release Information Statement introduced in Junos OS Release 8.5.

Description Specify the IP address to use as the source for IGMP snooping reports in proxy mode. Reports are sent with address 0.0.0.0 as the source address unless there is a source address configured.

Options ***ip-address***—IP address to use as the source for proxy-mode IGMP snooping reports.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring IGMP Snooping on page 4335

Copyright © 2016, Juniper Networks, Inc.

source-count (Protocols IGMP)

Syntax source-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address* source],
[edit protocols igmp interface *interface-name* static group *multicast-group-address* source]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the number of multicast source addresses that should be accepted for each static group created.

Options *number*—Number of source addresses.

Default: 1

Range: 1 through 1024

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling IGMP Static Group Membership on page 4050

source-count (Protocols MLD)

Syntax source-count *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address* source],
[edit protocols mld interface *interface-name* static group *multicast-group-address* source]

Release Information Statement introduced in Junos OS Release 9.6.

Description Configure the number of multicast source addresses that should be accepted for each static group created.

Options *number*—Number of source addresses.

Default: 1

Range: 1 through 1024

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling MLD Static Group Membership on page 4075

Copyright © 2016, Juniper Networks, Inc.

source-increment (Protocols IGMP)

Syntax source-increment *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name* static group *multicast-group-address* source],
[edit protocols igmp interface *interface-name* static group *multicast-group-address* source]

Release Information Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the number of times the multicast source address should be incremented for each static group created. The increment is specified in dotted decimal notation similar to an IPv4 address.

Options *increment*—Number of times the source address should be incremented.

Default: 0.0.0.1

Range: 0.0.0.1 through 255.255.255.255

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling IGMP Static Group Membership on page 4050

source-increment (Protocols MLD)

Syntax source-increment *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name* static group *multicast-group-address* source],
[edit protocols mld interface *interface-name* static group *multicast-group-address* source]

Release Information Statement introduced in Junos OS Release 9.6.

Description Configure the number of times the address should be incremented for each static group created. The increment is specified in a format similar to an IPv6 address.

Options *increment*—Number of times the source address should be incremented.

Default: ::1

Range: ::1 through ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff:

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Enabling MLD Static Group Membership on page 4075

spt-threshold

Syntax

```
spt-threshold {
  infinity [ policy-names ];
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information

Statement introduced in Junos OS Release 8.0.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Set the SPT threshold to infinity for a source-group address pair. Last-hop multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or an SPT rooted at the source. By default, last-hop routing devices transition to a direct SPT to the source. You can configure this routing device to set the SPT transition value to infinity to prevent this transition for any source-group address pair.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring the PIM SPT Threshold Policy on page 4177

Copyright © 2016, Juniper Networks, Inc.

ssm-groups

Syntax ssm-groups [*ip-addresses*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 12.3 for ACX Series routers.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Configure source-specific multicast (SSM) groups.

By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the **ssm-groups** statement in the configuration. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the **ssm-groups** statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.

IGMPv3 supports SSM groups. By utilizing inclusion lists, only sources that are specified send to the SSM group.

Options ***ip-addresses***—List of one or more additional SSM group addresses separated by a space.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Source-Specific Multicast Groups with Any-Source Override on page 4187

Copyright © 2016, Juniper Networks, Inc.

ssm-map (Protocols IGMP AMT)

Syntax ssm-map *ssm-map-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description Apply a source-specific multicast (SSM) map to all Automatic Multicast Tunneling (AMT) interfaces.

Options ***ssm-map-name***—Name of the SSM map.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Configuring Default IGMP Parameters for AMT Interfaces on page 4279

ssm-map (Protocols MLD)

Syntax ssm-map *ssm-map-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*],
[edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 7.4.

Description Apply an SSM map to an MLD interface.

Options ***ssm-map-name***—Name of SSM map.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring SSM Mapping on page 4192

Copyright © 2016, Juniper Networks, Inc.

ssm-map (Multicast Routing Options)

Syntax

```
ssm-map ssm-map-name {
    policy [ policy-names ];
    source [ addresses ];
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast],
[edit logical-systems *logical-system-name* routing-options multicast],
[edit routing-instances *routing-instance-name* routing-options multicast],
[edit routing-options multicast]

Release Information

Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure SSM mapping.

Options

ssm-map-name—Name of the SSM map.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SSM Mapping on page 4192

ssm-map (Protocols IGMP)

Syntax

```
ssm-map ssm-map-name;
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Apply an SSM map to an IGMP interface.

Options

ssm-map-name—Name of SSM map.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring SSM Mapping on page 4192

Copyright © 2016, Juniper Networks, Inc.

ssm-map-policy (IGMP)

Syntax ssm-map-policy *ssm-map-policy-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Apply an SSM map policy to an IGMP interface.

Options ***ssm-map-policy-name***—Name of SSM map policy.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring SSM Maps for Different Groups to Different Sources on page 4195

ssm-map-policy (MLD)

Syntax ssm-map-policy *ssm-map-policy-name*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*],
[edit protocols mld interface *interface-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Apply an SSM map policy to an MLD interface.

Options ***ssm-map-policy-name***—Name of SSM map policy.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Example: Configuring SSM Maps for Different Groups to Different Sources on page 4195

Copyright © 2016, Juniper Networks, Inc.

static (Bridge Domains)

Syntax

```
static {
  group multicast-group-address {
    source ip-address;
  }
}
```

Hierarchy Level

[edit bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping interface *interface-name*],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id* interface *interface-name*]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Define static multicast groups on an interface.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring IGMP Snooping on page 4335

Copyright © 2016, Juniper Networks, Inc.

static (Protocols MLD)

Syntax

```
static {
  group multicast-group-address {
    exclude;
    group-count number;
    group-increment increment;
    source ip-address {
      source-count number;
      source-increment increment;
    }
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*], [edit protocols mld interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.

Description Test multicast forwarding on an interface.

The **static** statement simulates MLD joins on a routing device statically on an interface without any MLD hosts. It is supported for both MLDv1 and MLDv2 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

NOTE: To prevent joining too many groups accidentally, the static statement is not supported with the interface all statement.

The remaining statements are explained separately.

Required Privilege Level routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

Related Documentation

- Enabling MLD Static Group Membership on page 4075

Copyright © 2016, Juniper Networks, Inc.

static (Protocols IGMP)

Syntax

```
static {
  group multicast-group-address {
    exclude;
    group-count number;
    group-increment increment;
    source ip-address {
      source-count number;
      source-increment increment;
    }
  }
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*], [edit protocols igmp interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Test multicast forwarding on an interface without a receiver host.

The **static** statement simulates IGMP joins on a routing device statically on an interface without any IGMP hosts. It is supported for both IGMPv2 and IGMPv3 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.

NOTE: To prevent joining too many groups accidentally, the **static** statement is not supported with the **interface all** statement.

The remaining statements are explained separately.

Required Privilege Level routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

static (Protocols PIM)

Syntax

```
static {
  address address {
    group-ranges {
      destination-ip-prefix</prefix-length>;
    }
    override;
    version version;
  }
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim rp],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp],
[edit protocols pim rp],
[edit routing-instances *routing-instance-name* protocols pim rp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure static RP addresses. The default static RP address is 224.0.0.0/4. To configure other addresses, include one or more **address** statements. You can configure a static RP in a logical system only if the logical system is not directly connected to a source.

For each static RP address, you can optionally specify the PIM version and the groups for which this address can be the RP. The default PIM version is version 1.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the Static PIM RP Address on the Non-RP Routing Device on page 4137

subscriber-leave-timer

Syntax subscriber-leave-timer *seconds*;

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit logical-systems *logical-system-name* routing-options multicast interface *interface-name*],
[edit routing-instances *routing-instance-name* routing-options multicast interface *interface-name*],
[edit routing-options multicast interface *interface-name*]

Release Information Statement introduced in Junos OS Release 9.2.
Statement introduced in Junos OS Release 9.2 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Length of time before the multicast VLAN updates QoS data (for example, available bandwidth) for subscriber interfaces after it receives an IGMP leave message.

Options ***seconds***—Length of time before the multicast VLAN updates QoS data (for example, available bandwidth) for subscriber interfaces after it receives an IGMP leave message. Specifying a value of 0 results in an immediate update. This is the same as if the statement were not configured.

Range: 0 through 30

Default: 0 seconds

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Multicast with Subscriber VLANs on page 4358

threshold (Bridge Domains)

Syntax threshold suppress *value* <reuse *value*>;

Hierarchy Level [edit bridge-domains *bridge-domain-name* multicast-snooping-options forwarding-cache],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* multicast-snooping-options forwarding-cache],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options forwarding-cache],
[edit routing-instances *routing-instance-name* multicast-snooping-options forwarding-cache],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* multicast-snooping-options forwarding-cache]

Release Information Statement introduced in Junos OS Release 8.5.

Description Configure the suppression and reuse thresholds for multicast snooping forwarding cache limits.

Options

suppress *value*—Value to begin suppressing new multicast forwarding cache entries. This value is mandatory. This number must be greater than the reuse value.

Range: 1 through 200,000

reuse *value*—(Optional) Value to begin creating new multicast forwarding cache entries. If configured, this number must be less than the suppress value.

Range: 1 through 200,000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Example: Configuring Multicast Snooping on page 4345

Copyright © 2016, Juniper Networks, Inc.

threshold (Protocols MSDP)

Syntax threshold *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols msdp active-source-limit],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols msdp active-source-limit],
[edit protocols msdp active-source-limit],
[edit routing-instances *routing-instance-name* protocols msdp active-source-limit]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Configure the random early detection (RED) threshold for MSDP active source messages. This number must be less than the configured or default maximum.

Options *number*—RED threshold for active source messages.

Range: 1 through 1,000,000

Default: 24,000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

threshold (PIM BFD Detection Time)

Syntax threshold *milliseconds*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection detection-time],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection detection-time]

Release Information Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the threshold for the adaptation of the BFD session detection time. When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

NOTE: The threshold value must be equal to or greater than the transmit interval.

The threshold time must be equal to or greater than the value specified in the minimum-interval or the minimum-receive-interval statement.

Options *milliseconds*—Value for the detection time adaptation threshold.

Range: 1 through 255,000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

threshold (PIM BFD Transmit Interval)

Syntax threshold *milliseconds*;

Hierarchy Level [edit protocols pim interface *interface-name* bfd-liveness-detection transmit-interval],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection transmit-interval]

Release Information Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the threshold for the adaptation of the BFD session transmit interval. When the transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent.

Options ***milliseconds***—Value for the transmit interval adaptation threshold.

Range: 0 through 4,294,967,295 ($2^{32} - 1$)

NOTE: The threshold value specified in the threshold statement must be greater than the value specified in the minimum-interval statement for the transmit-interval statement.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

timeout (Flow Maps)

Syntax timeout (never non-discard-entry-only | *minutes*);

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit logical-systems *logical-system-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-instances *routing-instance-name* routing-options multicast flow-map *flow-map-name*],
[edit routing-options multicast flow-map *flow-map-name*]

Release Information Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure the timeout value for multicast forwarding cache entries associated with the flow map.

Options *minutes*—Length of time that the forwarding cache entry remains active.

Range: 1 through 720

never non-discard-entry-only—Specify that the forwarding cache entry always remain active. If you omit the **non-discard-entry-only** option, all multicast forwarding entries, including those in forwarding and pruned states, are kept forever. If you include the **non-discard-entry-only** option, entries with forwarding states are kept forever, and entries with pruned states time out.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Copyright © 2016, Juniper Networks, Inc.

timeout (Multicast)

Syntax timeout *minutes*;

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast forwarding-cache],
[edit logical-systems *logical-system-name* routing-options multicast forwarding-cache],
[edit routing-instances *routing-instance-name* routing-options multicast forwarding-cache],

traceoptions (Multicast Snooping Options)

Syntax

```
traceoptions {
  file filename<files number> <size size> <world-readable | no-world-readable>;
  flag flag <disable>;
}
```

Hierarchy Level [edit multicast-snooping-options]

Release Information Statement introduced in Junos OS Release 8.5.

Description Set multicast snooping tracing options.

Default Tracing operations are disabled.

Options

disable—(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *name*—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place multicast snooping tracing output in the file **/var/log/multicast-snooping-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten.

If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

Range: 2 through 1000 files

Default: 1 trace file only

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

The following are the tracing options:

- **all**—All tracing operations
- **config-internal**—Trace configuration internals.
- **general**—Trace general events.
- **normal**—All normal events.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **policy**—Trace policy operations and actions.

Copyright © 2016, Juniper Networks, Inc.

- **route**—Trace routing table changes.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

no-world-readable—(Optional) Prevent any user from reading the log file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When the ***trace-file*** again reaches its maximum size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols AMT)

Syntax

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols amt],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt],
[edit protocols amt],
[edit routing-instances *routing-instance-name* protocols amt]

Release Information

Statement introduced in Junos OS Release 10.2.

Description

Configure Automatic Multicast Tunneling (AMT) tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the file **igmp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

AMT Tracing Flags

- **errors**—All error conditions
- **packets**—All AMT packets
- **tunnels**—All AMT tunnel-related information

Global Tracing Flags

- **all**—All tracing operations

Copyright © 2016, Juniper Networks, Inc.

- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols DVMRP)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols dvmrp],
[edit protocols dvmrp]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure DVMRP tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Default The default DVMRP trace options are those inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the **dvmrp-log** file.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

DVMRP Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **graft**—Graft messages
- **neighbor**—Neighbor probe messages
- **normal**—All normal operations

Copyright © 2016, Juniper Networks, Inc.

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **packets**—All DVMRP packets
- **poison**—Poison-route-reverse packets
- **probe**—Probe packets
- **prune**—Prune messages
- **report**—DVMRP route report packets
- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Copyright © 2016, Juniper Networks, Inc.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols IGMP)

Syntax

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols igmp],
[edit protocols igmp]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure IGMP tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

To trace the paths of multicast packets, use the **mtrace** command.

Default

The default IGMP trace options are those inherited from the routing protocols **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the file **igmp-log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

IGMP Tracing Flags

- **leave**—Leave group messages (for IGMP version 2 only).
- **mtrace**—Mtrace packets. Use the **mtrace** command to troubleshoot the software.
- **packets**—All IGMP packets.

Copyright © 2016, Juniper Networks, Inc.

- **query**—IGMP membership query messages, including general and group-specific queries.
- **report**—Membership report messages.

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Copyright © 2016, Juniper Networks, Inc.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols IGMP Snooping)

Syntax

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable> ;
    flag flag (detail | disable | receive | send);
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* bridge-domains *domain-name* protocols igmp-snooping],
[edit logical-systems *logical-system-name* routing-instances instance-name bridge-domains *domain-name* protocols igmp-snooping],
[edit logical-systems *logical-system-name* routing-instances *instance-name* protocols igmp-snooping],
[edit bridge-domains *domain-name* protocols igmp-snooping],
[edit routing-instances *instance-name* bridge-domains *domain-name* protocols igmp-snooping],
[edit routing-instances *instance-name* protocols igmp-snooping]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Define tracing operations for IGMP snooping.

Default

The **traceoptions** feature is disabled by default.

Options

file *filename*—Name of the file to receive the output of the tracing operation. All files are placed in the directory **/var/log**.

files *number*—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached (***x***k to specify KB, ***x***m to specify MB, or ***x***g to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

Range: 2 through 1000

Default: 3 files

flag *flag* —Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:

- **all**—All tracing operations.
- **client-notification**—Trace notifications.
- **general**—Trace general IGMP snooping protocol events.
- **group**—Trace group operations.
- **host-notification**—Trace host notifications.
- **leave**—Trace leave group messages (IGMPv2 only).
- **normal**—Trace normal IGMP snooping protocol events.
- **packets**—Trace all IGMP packets.

Copyright © 2016, Juniper Networks, Inc.

- **policy**—Trace policy processing.
- **query**—Trace IGMP membership query messages.
- **report**—Trace membership report messages.
- **route**—Trace routing information.
- **state**—Trace IGMP state transitions.
- **task**—Trace routing protocol task processing.
- **timer**—Trace routing protocol timer processing.

no-world-readable—(Optional) Restrict file access to the user who created the file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify gigabytes

Range: 10 KB through 1 gigabytes

Default: 128 KB

world-readable—(Optional) Enable unrestricted file access.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

traceoptions (Protocols MLD)

Syntax

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld],
[edit protocols mld]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure MLD tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

To trace the paths of multicast packets, use the **mtrace** command.

Default The default MLD trace options are those inherited from the **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options **disable**—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file ***filename***—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the file **mld-log**.

files ***number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MLD Tracing Flags

- **leave**—Leave group messages.
- **mtrace**—Mtrace packets. Use the **mtrace** command to troubleshoot the software.
- **packets**—All MLD packets.
- **query**—MLD membership query messages, including general and group-specific queries.

Copyright © 2016, Juniper Networks, Inc.

- **report**—Membership report messages.

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—Traces errors and significant events during normal packet processing

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Copyright © 2016, Juniper Networks, Inc.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Configure MSDP tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default MSDP trace options are those inherited from the routing protocol's **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the **msdp-log** file.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

Copyright © 2016, Juniper Networks, Inc.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

MSDP Tracing Flags

- **keepalive**—Keepalive messages
- **packets**—All MSDP packets
- **route**—MSDP changes to the routing table
- **source-active**—Source-active packets
- **source-active-request**—Source-active request packets
- **source-active-response**—Source-active response packets

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

Copyright © 2016, Juniper Networks, Inc.

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

no-world-readable—(Optional) Do not allow any user to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size ***size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*****.0**. When ***trace-file*** again reaches this size, ***trace-file*****.0** is renamed ***trace-file*****.1** and ***trace-file*** is renamed ***trace-file*****.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*****k** to specify KB, ***x*****m** to specify MB, or ***x*****g** to specify GB

Range: 10 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols PGM)

Syntax

```
traceoptions {
  flag flag <flag-modifier>;
}
```

Hierarchy Level [edit logical-systems *logical-system-name* protocols pgm],
[edit protocols pgm]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure PGM tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Default The default PGM trace options are those inherited from the routing protocol **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options **disable**—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

PGM Tracing Flags

- **all**—Trace all PGM packets.
- **init**—Trace all PGM initialization events.
- **packets**—Trace all PGM packet processing.
- **parser**—Trace all PGM parser processing.
- **route-socket**—Trace all PGM route-socket events.
- **show**—Trace all PGM **show** command servicing.
- **state**—Trace all PGM state transitions.

Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions

Copyright © 2016, Juniper Networks, Inc.

- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of the following modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

traceoptions (Protocols PIM)

Syntax

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

Hierarchy Level

[edit logical-systems *logical-system-name* protocols pim],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description

Configure PIM tracing options.

To specify more than one tracing operation, include multiple **flag** statements.

Default

The default PIM trace options are those inherited from the routing protocol's **traceoptions** statement included at the **[edit routing-options]** hierarchy level.

Options

disable—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

file *filename*—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. We recommend that you place tracing output in the **pim-log** file.

files *number*—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file*.0**, then ***trace-file*.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you must also include the **size** statement to specify the maximum file size.

Range: 2 through 1000 files

Default: 2 files

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

PIM Tracing Flags

- **assert**—Assert messages
- **bidirectional-df-election**—Bidirectional PIM designated-forwarder (DF) election events

Copyright © 2016, Juniper Networks, Inc.

- **bootstrap**—Bootstrap messages
- **cache**—Packets in the PIM sparse mode routing cache
- **graft**—Graft and graft acknowledgment messages
- **hello**—Hello packets
- **join**—Join messages
- **mt**—Multicast tunnel messages
- **nsr-synchronization**—Nonstop active routing (NSR) synchronization messages
- **packets**—All PIM packets
- **prune**—Prune messages
- **register**—Register and register stop messages
- **rp**—Candidate RP advertisements
- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

Default: If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

flag-modifier—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

no-stamp—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

Default: If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

Copyright © 2016, Juniper Networks, Inc.

no-world-readable—(Optional) Do not allow users to read the log file.

replace—(Optional) Replace an existing trace file if there is one.

Default: If you do not include this option, tracing output is appended to an existing trace file.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file*.0**. When ***trace-file*** again reaches this size, ***trace-file*.0** is renamed ***trace-file*.1** and ***trace-file*** is renamed ***trace-file*.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

Syntax: ***x*k** to specify KB, ***x*m** to specify MB, or ***x*g** to specify GB

Range: 0 KB through the maximum file size supported on your system

Default: 1 MB

world-readable—(Optional) Allow any user to read the log file.

Required Privilege Level

routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

transmit-interval (PIM BFD Liveness Detection)

Syntax

```
transmit-interval {
  minimum-interval milliseconds;
  threshold milliseconds;
}
```

Hierarchy Level

[edit protocols pim interface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information

Statement introduced in Junos OS Release 8.2.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Support for BFD authentication introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description

Specify the transmit interval for the **bfd-liveness-detection** statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum interval between receiving packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

tunnel-devices (Routing Instances)

Syntax tunnel-devices [mt-*fpc/pic/port*];

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *instance-name* protocols pim], [edit routing-instances *instance-name* protocols pim]

Release Information Statement introduced in Junos OS Release 10.2.
Statement introduced in Junos OS Release 10.2 for EX Series switches.

Description List one or more tunnel-capable PICs to be used for creating multicast tunnel (**mt**) interfaces. Creating a PIC list enables you to control the load-balancing implementation.

Tunnel-capable PICs include:

- Adaptive Services PIC
- Multiservices PIC or Multiservices DPC
- Tunnel Services PIC
- On MX Series routers, a PIC created with the **tunnel-services** statement at the **[edit chassis fpc *slot-number* pic *number*]** hierarchy level.

The physical position of the PIC in the routing device determines the multicast tunnel interface name. For example, if you have an Adaptive Services PIC installed in FPC slot 0 and PIC slot 0, the corresponding multicast tunnel interface name is **mt-0/0/0**. The same is true for Tunnel Services PICs, Multiservices PICs, and Multiservices DPCs.

Default Multicast tunnel interfaces are created on all available tunnel-capable PICs, based on a round-robin algorithm.

Options **mt-*fpc/pic/port***—Interface that is automatically generated when a tunnel-capable PIC is installed in the routing device.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Copyright © 2016, Juniper Networks, Inc.

tunnel-limit (Protocols AMT)

Syntax tunnel-limit *number*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols amt relay],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols amt relay],
[edit protocols amt relay],
[edit routing-instances *routing-instance-name* protocols amt relay]

Release Information Statement introduced in Junos OS Release 10.2.

Description Limit the number of Automatic Multicast Tunneling (AMT) data tunnels created. The system might reach a dynamic upper limit of tunnels of all types before the static AMT limit is reached.

Options *number*—Maximum number of data AMTs that can be created on the system.

Range: 0 through 4294967295

Default: 1 tunnel

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

- Configuring the AMT Protocol on page 4277

upstream-interface

Syntax upstream-interface [*interface-names*];

Hierarchy Level
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast pim-to-igmp-proxy],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast pim-to-mld-proxy],
[edit logical-systems *logical-system-name* routing-options multicast pim-to-igmp-proxy],
[edit logical-systems *logical-system-name* routing-options multicast pim-to-mld-proxy],
[edit routing-instances *routing-instance-name* routing-options multicast pim-to-igmp-proxy],
[edit routing-instances *routing-instance-name* routing-options multicast pim-to-mld-proxy],
[edit routing-options multicast pim-to-igmp-proxy],
[edit routing-options multicast pim-to-mld-proxy]

Release Information
Statement introduced in Junos OS Release 9.6.
Statement introduced in Junos OS Release 9.6 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Configure at least one, but not more than two, upstream interfaces on the rendezvous point (RP) routing device that resides between a customer edge–facing Protocol Independent Multicast (PIM) domain and a core-facing PIM domain. The RP routing device translates PIM join or prune messages into corresponding IGMP report or leave messages (if you include the **pim-to-igmp-proxy** statement), or into corresponding MLD report or leave messages (if you include the **pim-to-mld-proxy** statement). The routing device then proxies the IGMP or MLD report or leave messages to one or both upstream interfaces to forward IPv4 multicast traffic (for IGMP) or IPv6 multicast traffic (for MLD) across the PIM domains.

Options
interface-names—Names of one or two upstream interfaces to which the RP routing device proxies IGMP or MLD report or leave messages for transmission of multicast traffic across PIM domains. You can specify a maximum of two upstream interfaces on the RP routing device. To configure a set of two upstream interfaces, specify the full interface names, including all physical and logical address components, within square brackets ([ ]).

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

version (BFD)

Syntax version (0 | 1 | automatic);

Hierarchy Level [edit protocols piminterface *interface-name* bfd-liveness-detection],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name* bfd-liveness-detection]

Release Information Statement introduced in Junos OS Release 8.1.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the bidirectional forwarding detection (BFD) protocol version that you want to detect.

Options Configure the BFD version to detect: **1** (BFD version 1) or **automatic** (autodetect the BFD version)

Default: automatic

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

version (PIM)

Syntax version *version*;

Hierarchy Level
[edit logical-systems *logical-system-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* protocols pim rp static address *address*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim rp static address *address*],
[edit protocols pim interface *interface-name*],
[edit protocols pim rp static address *address*],
[edit routing-instances *routing-instance-name* protocols pim interface *interface-name*],
[edit routing-instances *routing-instance-name* protocols pim rp static address *address*]

Release Information
Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Specify the version of PIM.

Options *version*—PIM version number.

Range: 1 or 2

Default: PIMv1 for rendezvous point (RP) mode (at the **[edit protocols pim rp static address *address*]** hierarchy level). PIMv2 for interface mode (at the **[edit protocols pim interface *interface-name*]** hierarchy level).

Required Privilege Level
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

version (Protocols IGMP)

Syntax version *version*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*],
[edit protocols igmp interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.1 for the QFX Series.

Description Specify the version of IGMP.

Options *version*—IGMP version number.

Range: 1, 2, or 3

Default: IGMP version 2

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- Changing the IGMP Version on page 4049

version (Protocols IGMP AMT)

Syntax version *version*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols igmp amt relay defaults],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols igmp amt relay defaults],
[edit protocols igmp amt relay defaults],
[edit routing-instances *routing-instance-name* protocols igmp amt relay defaults]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify the version of IGMP used through an Automatic Multicast Tunneling (AMT) interface.

Options *version*—IGMP version number.

Range: 1, 2, or 3

Default: IGMP version 3

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

version (Protocols MLD)

Syntax version *version*;

Hierarchy Level [edit logical-systems *logical-system-name* protocols mld interface *interface-name*], [edit protocols mld interface *interface-name*]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure the MLD version explicitly. MLD version 2 (MLDv2) is used only to support source-specific multicast (SSM).

Options ***version***—MLD version to run on the interface.

Range: 1 or 2

Default: 1 (MLDv1)

Required Privilege Level routing and trace—To view this statement in the configuration.
routing-control and trace-control—To add this statement to the configuration.

Related Documentation

vlan (Bridge Domains)

Syntax

```
vlan vlan-id {
  immediate-leave;
  interface interface-name {
    group-limit limit;
    host-only-interface;
    multicast-router-interface;
    static {
      group multicast-group-address {
        source ip-address;
      }
    }
  }
  proxy {
    source-address ip-address;
  }
  query-interval seconds;
  query-last-member-interval seconds;
  query-response-interval seconds;
  robust-count number;
}
```

Hierarchy Level

[edit bridge-domains *bridge-domain-name* protocols igmp-snooping],
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping]

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Configure IGMP snooping parameters for a particular VLAN.

Default

By default, IGMP snooping options apply to all VLANs.

Options

vlan-id—Apply the parameters to this VLAN.

The remaining statements are explained separately.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

vpn-group-address

Syntax vpn-group-address *address*;

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols pim],
[edit routing-instances *routing-instance-name* protocols pim]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure the group address for the Layer 3 VPN in the service provider's network.

Options ***address***—Address for the Layer 3 VPN in the service provider's network.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation
- *Multicast Feature Guide for Security Devices*

wildcard-source (PIM RPF Selection)

Syntax
```
wildcard-source {
    next-hop next-hop-address;
}
```

Hierarchy Level [edit routing-instances *routing-instance-name* protocols pim rpf-selection group *group-address*],
[edit routing-instances *routing-instance-name* protocols pim rpf-selection prefix-list *prefix-list-addresses*]

Release Information Statement introduced in Junos OS Release 10.4.
Statement introduced in Junos OS Release 11.3 for the QFX Series.

Description Use a wildcard for the multicast source instead of (or in addition to) a specific multicast source.

The remaining statements are explained separately.

Required Privilege Level view-level—To view this statement in the configuration.
control-level—To add this statement to the configuration.

clear amt statistics

Syntax
clear amt statistics
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced in Junos OS Release 10.2.

Description
Clear Automatic Multicast Tunneling (AMT) statistics.

Options
none—Clear the multicast statistics for all AMT tunnel interfaces.

instance *instance-name*—(Optional) Clear AMT multicast statistics for the specified instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
clear

clear amt tunnel

Syntax

clear amt tunnel
<gateway *gateway-ip-addr*> <port *port-number*>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<statistics>
<tunnel-interface *interface-name*>

Release Information

Command introduced in Junos OS Release 10.2.

Description

Clear the Automatic Multicast Tunneling (AMT) multicast state. Optionally, clear AMT protocol statistics.

Options

none—Clear multicast state for all AMT tunnel interfaces.

gateway *gateway-ip-addr* port *port-number*—(Optional) Clear the AMT multicast state for the specified gateway address. If no port is specified, clear the AMT multicast state for all AMT gateways with the given IP address.

instance *instance-name*—(Optional) Clear the AMT multicast state for the specified instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

statistics—(Optional) Clear multicast statistics for all AMT tunnels or for specified tunnels.

tunnel-interface *interface-name*—(Optional) Clear the AMT multicast state for the specified AMT tunnel interface.

Required Privilege Level

clear

clear igmp membership

List of Syntax
Syntax on page 4635
Syntax (EX Series Switch and the QFX Series) on page 4635

Syntax
clear igmp membership
<group *address-range*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)
clear igmp membership
<group *address-range*>
<interface *interface-name*>

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description
Clear Internet Group Management Protocol (IGMP) group members.

Options
none—Clear all IGMP members on all interfaces and for all address ranges.

group *address-range*—(Optional) Clear all IGMP members that are in a particular address range. An example of a range is **224.2/16**. If you omit the destination prefix length, the default is **/32**.

interface *interface-name*—(Optional) Clear all IGMP group members on an interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
clear

clear igmp snooping membership

Syntax

clear igmp snooping membership
<group | source *address*>
<instance *instance-name*>
<interface *interface-name*>
<learning-domain *learning-domain-name*>
<vlan-id *vlan-identifier*>

Release Information

Command introduced in Junos OS Release 8.5.

Description

Clear IP IGMP snooping membership information.

Options

none—Clear IGMP snooping membership for all supported address families on all interfaces.

group | source *address*—(Optional) Clear IGMP snooping membership for the specified multicast group or source address.

instance *instance-name*—(Optional) Clear IGMP snooping membership for the specified instance.

interface *interface-name*—(Optional) Clear IGMP snooping membership on a specific interface.

learning-domain *learning-domain-name*—(Optional) Perform this operation on all learning domains or on a particular learning domain.

vlan-id *vlan-identifier*—(Optional) Perform this operation on a particular VLAN.

Required Privilege Level

clear

clear pim join

List of Syntax
Syntax on page 4648
Syntax (EX Series Switch and the QFX Series) on page 4648

Syntax

clear pim join
<*group-address*>
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

clear pim join
<*group-address*>
<inet | inet6>
<instance *instance-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear the Protocol Independent Multicast (PIM) join and prune states.

Options

none—Clear the PIM join and prune states for all groups, family addresses, and instances.

group-address—(Optional) Clear the PIM join and prune states for a group address.

inet | inet6—(Optional) Clear the PIM join and prune states for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Clear the join and prune states for a specific PIM-enabled routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

The **clear pim join** command cannot be used to clear the PIM join and prune state on a backup Routing Engine when nonstop active routing is enabled.

Required Privilege Level

clear

clear pim join-distribution

Syntax

clear pim join-distribution
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Release Information

Command introduced in Junos OS Release 10.0.

Description

Redistribute the Protocol Independent Multicast (PIM) join states.

You can find out if there are multiple paths available for a source (for example, an RP) with the output of the **show pim source** command.

When you include the **join-load-balance** statement in the configuration, the PIM join states are distributed evenly on available equal-cost multipath links. When an upstream neighbor link fails, Junos OS redistributes the PIM join states to the remaining links. However, when new links are added or the failed link is restored, the existing PIM joins are not redistributed to the new link. New flows will be distributed to the new links. However, in a network without new joins and prunes, the new link is not used for multicast traffic. The **clear pim join-distribution** command redistributes the existing flows to the new upstream neighbors. Redistributing the existing flows causes traffic to be disrupted, so we recommend that you run the **clear pim join-distribution** command during a maintenance window.

Options

none—Redistribute the PIM join states for the default master instance.

instance *instance-name*—(Optional) Redistribute the join states for a specific PIM-enabled routing instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

The **clear pim join-distribution** command cannot be used to redistribute the PIM join states on a backup Routing Engine when nonstop active routing is enabled.

Required Privilege Level

clear

<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)
clear pim register
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>

Syntax (PTX Series)
clear pim register
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced in Junos OS Release 7.6.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description
Clear Protocol Independent Multicast (PIM) register message counters.

Options
none—Clear PIM register message counters for all family addresses, instances, and interfaces.

inet | inet6—(Optional) Clear PIM register message counters for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Clear register message counters for a specific PIM-enabled routing instance.

interface *interface-name*—(Optional) Clear PIM register message counters for a specific interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information
The **clear pim register** command cannot be used to clear the PIM register state on a backup Routing Engine when nonstop active routing is enabled.

Required Privilege Level
clear

clear pim statistics

List of Syntax
Syntax on page 4654
Syntax (EX Series Switch and the QFX Series) on page 4654

Syntax

clear pim statistics
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

clear pim statistics
<inet | inet6>
<instance *instance-name*>
<interface *interface-name*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Clear Protocol Independent Multicast (PIM) statistics.

Options

none—Clear PIM statistics for all family addresses, instances, and interfaces.

inet | inet6—(Optional) Clear PIM statistics for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Clear statistics for a specific PIM-enabled routing instance.

interface *interface-name*—(Optional) Clear PIM statistics for a specific interface.

logical-system (all | *logical-system-name)*—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information

The **clear pim statistics** command cannot be used to clear the PIM statistics on a backup Routing Engine when nonstop active routing is enabled.

Required Privilege Level

clear

request pim multicast-tunnel rebalance

List of Syntax
Syntax on page 4657
Syntax (EX Series Switches) on page 4657

Syntax
request pim multicast-tunnel rebalance
<instance *instance-name*>
<logical-system (all | *logical-system-name*>

Syntax (EX Series Switches)
request pim multicast-tunnel rebalance
<instance *instance-name*>

Release Information
Command introduced in Junos OS Release 10.2.
Command introduced in Junos OS Release 10.2 for EX Series switches.

Description
Rebalance the assignment of multicast tunnel encapsulation interfaces across available tunnel-capable PICs or across a configured list of tunnel-capable PICs. You can determine whether a rebalance is necessary by running the **show pim interfaces instance** ***instance-name*** command.

Options
none—Re-create and rebalance all tunnel interfaces for all routing instances.

instance ***instance-name***—Re-create and rebalance all tunnel interfaces for a specific instance.

logical-system (all | ***logical-system-name*****)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
maintenance

Related Documentation
- show pim interfaces on page 4763

Output Fields
This command produces no output. To verify the operation of the command, run the **show pim interface instance** ***instance-name*** before and after running the **request pim multicast-tunnel rebalance** command.

show amt statistics on page 4659

Output Fields
Table 59 describes the output fields for the **show amt statistics** command. Output fields are listed in the approximate order in which they appear.

Table 389: show amt statistics Output Fields

Field Name	Field Description
AMT receive message count	Summary of AMT statistics for messages received on all interfaces. • **AMT relay discovery**—Number of AMT relay discovery messages received. • **AMT membership request**—Number of AMT membership request messages received. • **AMT membership update**—Number of AMT membership update messages received.
AMT send message count	Summary of AMT statistics for messages sent on all interfaces. • **AMT relay advertisement**—Number of AMT relay advertisement messages sent. • **AMT membership query**—Number of AMT membership query messages sent.

Copyright © 2016, Juniper Networks, Inc.

Table 389: show amt statistics Output Fields *(continued)*

Field Name	Field Description
AMT error message count	Summary of AMT statistics for error messages received on all interfaces. • **AMT incomplete packet**—Number of messages received with length errors so severe that further classification could not occur. • **AMT invalid mac**—Number of messages received with an invalid message authentication code (MAC). • **AMT unexpected type**—Number of messages received with an unknown message type specified. • **AMT invalid relay discovery address**—Number of AMT relay discovery messages received with an address other than the configured anycast address. • **AMT invalid membership request address**—Number of AMT membership request messages received with an address other than the configured AMT local address. • **AMT invalid membership update address**—Number of AMT membership update messages received with an address other than the configured AMT local address. • **AMT incomplete relay discovery messages**—Number of AMT relay discovery messages received that are not fully formed. • **AMT incomplete membership request messages**—Number of AMT membership request messages received that are not fully formed. • **AMT incomplete membership update messages**—Number of AMT membership update messages received that are not fully formed. • **AMT no active gateway**—Number of AMT membership update messages received for a tunnel that does not exist for the gateway that sent the message. • **AMT invalid inner header checksum**—Number of AMT membership update messages received with an invalid IP checksum. • **AMT gateways timed out**—Number of gateways that timed out because of inactivity.

Sample Output

show amt statistics

```
user@host> show amt statistics

AMT receive message count
AMT relay advertisement                 :          2
AMT membership request                  :          5
AMT membership update                   :          5

AMT send message count
AMT relay advertisement                 :          2
AMT membership query                    :          5

AMT error message count
AMT incomplete packet                   :          0
AMT invalid mac                         :          0
AMT unexpected type                     :          0
AMT invalid relay discovery address     :          0
AMT invalid membership request address  :          0
AMT invalid membership update address   :          0
AMT incomplete relay discovery messages :          0
AMT incomplete membership request messages :       0
AMT incomplete membership update messages  :       0
AMT no active gateway                   :          0
```

Output Fields
Table 390 describes the output fields for the **show amt summary** command. Output fields are listed in the approximate order in which they appear.

Table 390: show amt summary Output Fields

Field Name	Field Description	Level of Output
AMT anycast prefix	Prefix advertised by unicast routing protocols to route AMT discovery messages to the router from nearby AMT gateways.	All levels
AMT anycast address	Anycast address configured from which the anycast prefix is derived.	All levels
AMT local address	Local unique AMT relay IP address configured. Used to send AMT relay advertisement messages, it is the IP source address of AMT control messages and the source address of the data tunnel encapsulation.	All levels
AMT tunnel limit	Maximum number of AMT tunnels that can be created.	All levels
active tunnels	Number of active AMT tunnel interfaces.	All levels

Copyright © 2016, Juniper Networks, Inc.

Sample Output

show amt summary

```
user@host> show amt summary
 AMT anycast prefix : 20.0.0.4/32
 AMT anycast address : 20.0.0.4
 AMT local address : 20.0.0.4
 AMT tunnel limit : 1000, active tunnels : 2
```

show amt tunnel

Syntax

show amt tunnel
<brief | detail>
<gateway-address *gateway-ip-address*> <port *port-number*>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<tunnel-interface *interface-name*>

Release Information

Command introduced in Junos OS Release 10.2.

Description

Display information about the Automatic Multicast Tunneling (AMT) dynamic tunnels.

Options

none—Display summary information about all AMT protocol instances.

brief | detail—(Optional) Display the specified level of detail.

gateway-address *gateway-ip-address* port *port-number*—(Optional) Display information for the specified AMT gateway only. If no port is specified, display information for all AMT gateways with the given IP address.

instance *instance-name*—(Optional) Display information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

tunnel-interface *interface-name*—(Optional) Display information for the specified AMT tunnel interface only.

Output Fields

Table 391 describes the output fields for the **show amt tunnel** command. Output fields are listed in the approximate order in which they appear.

Table 391: show amt tunnel Output Fields

Field Name	Field Description	Level of Output
AMT gateway address	Address of the AMT gateway that is being connected by the AMT tunnel.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 391: show amt tunnel Output Fields *(continued)*

Field Name	Field Description	Level of Output
port	Client port used by the AMT tunnel.	All levels
AMT tunnel interface	Dynamically created AMT logical interfaces used by the AMT tunnel in the format **ud-FPC/PIC/Port.unit**.	All levels
AMT tunnel state	State of the AMT tunnel. The state is normally **Active**. • **Active**—The tunnel is active. • **Pending**—The tunnel creation is pending. This is a transient state. • **Down**—The tunnel is in the down state. • **Graceful restart pending**—Graceful restart is in progress. • **Reviving**—The routing protocol daemon or Routing Engine was restarted (not gracefully). The tunnel remains in the reviving state until the AMT gateway sends a control message. When the message is received the tunnel is moved to the **Active** state. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.	All levels
AMT tunnel inactivity timeout	Number of seconds since the most recent control message was received from an AMT gateway. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.	All levels
Number of groups	Number of multicast groups using the tunnel.	All levels
Group	Multicast group address or addresses using the tunnel.	**detail**
Include Source	Multicast source address for each IGMPv3 group using the tunnel.	**detail**
AMT message count	Statistics for AMT messages: • **AMT Request**—Number of AMT relay tunnel request messages received. • **AMT membership update**—Number of AMT membership update messages received.	All levels

Sample Output

show amt tunnel

show dvmrp interfaces

Syntax
show dvmrp interfaces
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced before Junos OS Release 7.4.

Description
Display information about Distance Vector Multicast Routing Protocol (DVMRP)–enabled interfaces.

Options
none—(Same as **logical-system all**) Display information about DVMRP-enabled interfaces.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

List of Sample Output
show dvmrp interfaces on page 4667

Output Fields
Table 392 describes the output fields for the **show dvmrp interfaces** command. Output fields are listed in the approximate order in which they appear.

Table 392: show dvmrp interfaces Output Fields

Field Name	Field Description
Interface	Name of the interface.
State	State of the interface: **up** or **down**.
Leaf	Whether the interface is a leaf (that is, whether it has no neighbors) or whether it has neighbors.
Metric	Interface metric: a value from **1** through **31**.
Announce	Number of routes the interface is announcing.
Mode	DVMRP mode: • **Forwarding**—DVMRP does both the routing and the multicast data forwarding. • **Unicast-routing**—DVMRP does only the routing. Forwarding of the multicast data packets can be done by enabling PIM on the interface.

Copyright © 2016, Juniper Networks, Inc.

Sample Output

show dvmrp interfaces

```
user@host> show dvmrp interfaces
Interface State Leaf Metric Announce Mode
fxp0.0    Up    N    1      4 Forwarding
fxp1.0    Up    N    1      4 Forwarding
fxp2.0    Up    N    1      3 Forwarding
lo0.0     Up    Y    1      0 Unicast-routing
```

show dvmrp neighbors

Syntax show dvmrp neighbors
<logical-system (all | *logical-system-name*)>

Release Information Command introduced before Junos OS Release 7.4.

Description Display information about Distance Vector Multicast Routing Protocol (DVMRP) neighbors.

Options **none**—(Same as **logical-system all**) Display information about DVMRP neighbors.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level view

List of Sample Output show dvmrp neighbors on page 4669

Output Fields Table 393 describes the output fields for the **show dvmrp neighbors** command. Output fields are listed in the approximate order in which they appear.

Table 393: show dvmrp neighbors Output Fields

Field Name	Field Description
Neighbor	Address of the neighboring DVMRP router.
Interface	Interface through which the neighbor is reachable.
Version	Version of DVMRP that the neighbor is running, in the format ***majorminor***.
Flags	Information about the neighbor: • **1**—One way. The local router has seen the neighbor, but the neighbor has not seen the local router. • **G**—Neighbor supports generation ID. • **L**—Neighbor is a leaf router. • **M**—Neighbor supports mtrace. • **N**—Neighbor supports netmask in prune messages and graft messages. • **P**—Neighbor supports pruning. • **S**—Neighbor supports SNMP.
Routes	Number of routes learned from the neighbor.
Timeout	How long until the DVMRP neighbor information times out, in seconds.
Transitions	Number of generation ID changes that have occurred since the local router learned about the neighbor.

Copyright © 2016, Juniper Networks, Inc.

Sample Output

show dvmrp neighbors

```
user@host> show dvmrp neighbors
Neighbor        Interface        Version Flags   Routes Timeout Transitions
192.168.1.1    ipip.0            3.255  PGM         3      28           1
```

show dvmrp prefix

Syntax
show dvmrp prefix
<brief | detail>
<logical-system (all | *logical-system-name*)>
<*prefix*>

Release Information
Command introduced before Junos OS Release 7.4.

Description
Display information about Distance Vector Multicast Routing Protocol (DVMRP) prefixes.

Options
none—Display standard information about all DVMRP prefixes.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

prefix—(Optional) Display information about specific prefixes.

Required Privilege Level
view

List of Sample Output
show dvmrp prefix on page 4671
show dvmrp prefix brief on page 4671
show dvmrp prefix detail on page 4671

Output Fields
Table 394 describes the output fields for the **show dvmrp prefix** command. Output fields are listed in the approximate order in which they appear.

Table 394: show dvmrp prefix Output Fields

Field Name	Field Description	Level of Output
Prefix	DVMRP route.	All levels
Next hop	Next hop from which the route was learned.	All levels
Age	Last time that the route was refreshed.	All levels
multicast-group	Multicast group address.	**detail**
Prunes sent	Number of prune messages sent to the multicast group.	**detail**
Grafts sent	Number of grafts sent to the multicast group.	**detail**
Cache lifetime	Lifetime of the group in the multicast cache, in seconds.	**detail**
Prune lifetime	Lifetime remaining and total lifetime of prune messages, in seconds.	**detail**

Copyright © 2016, Juniper Networks, Inc.

Sample Output

show dvmrp prefix

```
user@host> show dvmrp prefix
Prefix              Next hop         Age
10.38.0.0      /30 10.38.0.1        00:06:17
10.38.0.4      /30 10.38.0.5        00:06:13
10.38.0.8      /30 10.38.0.2        00:00:04

show dvmrp prunes

Syntax
show dvmrp prunes
<all | rx | tx>
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced before Junos OS Release 7.4.

Description
Display information about active Distance Vector Multicast Routing Protocol (DVMRP) prune messages.

Options
none—Display received and transmitted DVMRP prune information.

all—(Optional) Display information about all received and transmitted prune messages.

rx—(Optional) Display information about received prune messages.

tx—(Optional) Display information about transmitted prune messages.

logical-system (all | *logical-system-name)*—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

List of Sample Output
show dvmrp prunes on page 4672

Output Fields
Table 395 describes the output fields for the **show dvmrp prunes** command. Output fields are listed in the approximate order in which they appear.

Table 395: show dvmrp prunes Output Fields

Field Name	Field Description
Group	Group address.
Source prefix	Prefix for the prune.
Timeout	How long until the prune message expires, in seconds.
Neighbor	Neighbor to which the prune was sent or from which the prune was received.

Sample Output

show dvmrp prunes

```
user@host> show dvmrp prunes
Group           Source prefix      Timeout Neighbor
224.0.1.1       128.112.0.0    /12    7077 192.168.1.1

show igmp group

List of Syntax
Syntax on page 4674
Syntax (EX Series Switch and the QFX Series) on page 4674

Syntax
show igmp group
<brief | detail>
<*group-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)
show igmp group
<brief | detail>
<*group-name*>

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description
Display Internet Group Management Protocol (IGMP) group membership information.

Options
none—Display standard information about membership for all IGMP groups.

brief | detail—(Optional) Display the specified level of output.

group-name—(Optional) Display group membership for the specified IP address only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

List of Sample Output
show igmp group (Include Mode) on page 4675
show igmp group (Exclude Mode) on page 4676
show igmp group brief on page 4676
show igmp group detail on page 4676

Output Fields
Table 396 describes the output fields for the **show igmp group** command. Output fields are listed in the approximate order in which they appear.

Table 396: show igmp group Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface that received the IGMP membership report. A name of **local** indicates that the local routing device joined the group itself.	All levels
Group	Group address.	All levels
Group Mode	Mode the SSM group is operating in: **Include** or **Exclude**.	All levels
Source	Source address.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 396: show igmp group Output Fields *(continued)*

Field Name	Field Description	Level of Output
Source timeout	Time remaining until the group traffic is no longer forwarded. The timer is refreshed when a listener in include mode sends a report. A group in exclude mode or configured as a static group displays a zero timer.	**detail**
Last reported by	Address of the host that last reported membership in this group.	All levels
Timeout	Time remaining until the group membership is removed.	**brief none**
Group timeout	Time remaining until a group in exclude mode moves to include mode. The timer is refreshed when a listener in exclude mode sends a report. A group in include mode or configured as a static group displays a zero timer.	**detail**
Type	Type of group membership: • **Dynamic**—Host reported the membership. • **Static**—Membership is configured.	All levels

Sample Output

show igmp group (Include Mode)

```
user@host> show igmp group
Interface: t1-0/1/0.0
    Group: 232.1.1.1
        Group mode: Include
        Source: 10.0.0.2

show igmp interface brief on page 4680
show igmp interface detail on page 4681

Output Fields
Table 397 describes the output fields for the **show igmp interface** command. Output fields are listed in the approximate order in which they appear.

Table 397: show igmp interface Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface.	All levels
Querier	Address of the routing device that has been elected to send membership queries.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 397: show igmp interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
State	State of the interface: **Up** or **Down**.	All levels
SSM Map Policy	Name of the source-specific multicast (SSM) map policy that has been applied to the IGMP interface.	All levels
Timeout	How long until the IGMP querier is declared to be unreachable, in seconds.	All levels
Version	IGMP version being used on the interface: **1** , **2** , or **3**.	All levels
Groups	Number of groups on the interface.	All levels
Immediate Leave	State of the immediate leave option: • **On**—Indicates that the router removes a host from the multicast group as soon as the router receives a leave group message from a host associated with the interface. • **Off**—Indicates that after receiving a leave group message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds.	All levels
Promiscuous Mode	State of the promiscuous mode option: • **On**—Indicates that the router can accept IGMP reports from subnetworks that are not associated with its interfaces. • **Off**—Indicates that the router can accept IGMP reports only from subnetworks that are associated with its interfaces.	All levels
Passive	State of the passive mode option: • **On**—Indicates that the router can run IGMP on the interface but not send or receive control traffic such as IGMP reports, queries, and leaves. • **Off**—Indicates that the router can run IGMP on the interface and send or receive control traffic such as IGMP reports, queries, and leaves. The **passive** statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the **on** state declaration: • **send-general-query**—The interface sends general queries. • **send-group-query**—The interface sends group-specific and group-source-specific queries. • **allow-receive**—The interface receives control traffic.	All levels
OIF map	Name of the OIF map (if configured) associated with the interface.	All levels
SSM map	Name of the source-specific multicast (SSM) map (if configured) used on the interface.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 397: show igmp interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
Configured Parameters	Information configured by the user: • **IGMP Query Interval**—Interval (in seconds) at which this router sends membership queries when it is the querier. • **IGMP Query Response Interval**—Time (in seconds) that the router waits for a report in response to a general query. • **IGMP Last Member Query Interval**—Time (in seconds) that the router waits for a report in response to a group-specific query. • **IGMP Robustness Count**—Number of times the router retries a query.	All levels
Derived Parameters	Derived information: • **IGMP Membership Timeout**—Timeout period (in seconds) for group membership. If no report is received for these groups before the timeout expires, the group membership is removed. • **IGMP Other Querier Present Timeout**—Time (in seconds) that the router waits for the IGMP querier to send a query.	All levels

Sample Output

show igmp interface

```
user@host> show igmp interface
Interface: at-0/3/1.0
    Querier: 10.111.30.1
    State:         Up Timeout:    None Version:  2 Groups:      4
    SSM Map Policy: ssm-policy-A
Interface: so-1/0/0.0
    Querier: 10.111.10.1
    State:         Up Timeout:    None Version:  2 Groups:      2
    SSM Map Policy: ssm-policy-B
Interface: so-1/0/1.0
    Querier: 10.111.20.1
    State:         Up Timeout:    None Version:  2 Groups:      4
    SSM Map Policy: ssm-policy-C
Immediate Leave: On
Promiscuous Mode: Off

Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2

Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0
```

Output Fields
Table 398 lists the output fields for the **show igmp snooping interface** command. Output fields are listed in the approximate order in which they appear.

Table 398: show igmp snooping interface Output Fields

Field Name	Field Description	Level of Output
Routing-instance	Routing instance for IGMP snooping.	All levels
Learning Domain	Learning domain for snooping.	All levels
IGMP Query Interval	Frequency (in seconds) with which this router sends membership queries when it is the querier.	**detail**
IGMP Query Response Interval	Time (in seconds) that the router waits for a response to a general query.	**detail**

Copyright © 2016, Juniper Networks, Inc.

Table 398: show igmp snooping interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
IGMP Last Member Query Interval	Time (in seconds) that the router waits for a report in response to a group-specific query.	**detail**
IGMP Robustness Count	Number of times the router retries a query.	**detail**
immediate-leave	State of immediate leave: **On** or **Off**.	All levels
router-interface	Router interfaces that are part of this learning domain.	All levels
Group limit	Maximum number of (source,group) pairs allowed per interface. When a group limit is not configured, this field is not shown.	All levels
interface	Interfaces that are being snooped in this learning domain.	All levels
Groups	Number of groups on the interface.	none
State	State of the interface: **Up** or **Down**.	none
Up Groups	Number of active multicast groups attached to the logical interface.	All levels
IGMP Membeship Timeout	Timeout for group membership. If no report is received for these groups before the timeout expires, the group membership is removed.	none
IGMP Other Querier Present Timeout	Time that the router waits for the IGMP querier to send a query.	none

Sample Output

show igmp snooping interface

```
user@host> show igmp snooping interface
Instance: bridge-domain bar

Learning-Domain: default
Interface: ge-0/1/0.200
    State:         Up Groups:      0
    Immediate leave: Off

Output Fields

Table 399 lists the output fields for the **show igmp snooping membership** command. Output fields are listed in the approximate order in which they appear.

Table 399: show igmp snooping membership Output Fields

Field Name	Field Description	Level of Output
Instance	Routing instance for IGMP snooping.	All levels
Learning Domain	Learning domain for snooping.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 399: show igmp snooping membership Output Fields *(continued)*

Field Name	Field Description	Level of Output
Interface	Interface on which this router is a proxy.	**detail**
Up Groups	Number of active multicast groups attached to the logical interface.	All levels
Group	Multicast group address in the membership database.	All levels
Group Mode	Mode the SSM group is operating in: **Include** or **Exclude**.	All levels
Source	Source address used on queries.	**detail**
Last reported by	Address of source last replying to the query.	**detail**
Group Timeout	Time remaining until a group in exclude mode moves to include mode. The timer is refreshed when a listener in exclude mode sends a report. A group in include mode or configured as a static group displays a zero timer.	All levels
Timeout	Length of time (in seconds) left until the entry is purged.	**detail**
Type	Way that the group membership information was learned: • **Dynamic**—Group membership was learned by the IGMP protocol. • **Static**—Group membership was learned by configuration.	**detail**
Include receiver	Source address of receiver included in membership with timeout (in seconds).	**detail**

Sample Output

show igmp snooping statistics

Syntax
show igmp snooping statistics
<brief | detail>
<bridge-domain *bridge-domain-name*>
<virtual-switch *virtual-switch-name*>
<vlan-id *vlan-identifier*>

Release Information
Command introduced in Junos OS Release 8.5.

Description
Display IGMP snooping statistics.

Options
none—(Optional) Display detailed information.

brief | detail—(Optional) Display the specified level of output.

bridge-domain *bridge-domain-name*—(Optional) Display information about a particular bridge domain.

virtual-switch *virtual-switch-name*—(Optional) Display information about a particular virtual switch.

vlan-id *vlan-identifier*—(Optional) Display information about a particular VLAN.

List of Sample Output
show igmp snooping statistics on page 4690

Output Fields
Table 400 lists the output fields for the **show igmp snooping statistics** command. Output fields are listed in the approximate order in which they appear.

Table 400: show igmp snooping statistics Output Fields

Field Name	Field Description	Level of Output
Routing-instance	Routing instance for IGMP snooping.	All levels
IGMP packet statistics	Heading for IGMP snooping statistics for all interfaces or for the specified interface.	All levels
learning-domain	Appears at end of "IGMP packets statistics" line.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 400: show igmp snooping statistics Output Fields *(continued)*

Field Name	Field Description	Level of Output
IGMP Message type	Summary of IGMP statistics: • **Membership Query**—Number of membership queries sent and received. • **V1 Membership Report**—Number of version 1 membership reports sent and received. • **DVMRP**—Number of DVMRP messages sent or received. • **PIM V1**—Number of PIM version 1 messages sent or received. • **Cisco Trace**—Number of Cisco trace messages sent or received. • **V2 Membership Report**—Number of version 2 membership reports sent or received. • **Group Leave**—Number of group leave messages sent or received. • **Domain Wide Report**—Number of domain-wide reports sent or received. • **V3 Membership Report**—Number of version 3 membership reports sent or received. • **Other Unknown types**—Number of unknown message types received. • **IGMP v3 unsupported type**—Number of messages received with unknown and unsupported IGMP version 3 message types. • **IGMP v3 source required for SSM**—Number of IGMP version 3 messages received that contained no source. • **IGMP v3 mode not applicable for SSM**—Number of IGMP version 3 messages received that did not contain a mode applicable for source-specific multicast (SSM).	All levels
Received	Number of messages received.	All levels
Sent	Number of messages sent.	All levels
Rx errors	Number of received packets that contained errors.	All levels
IGMP Global Statistics	Summary of IGMP snooping statistics for all interfaces. • **Bad Length**—Number of messages received with length errors so severe that further classification could not occur. • **Bad Checksum**—Number of messages received with a bad IP checksum. No further classification was performed. • **Rx non-local**—Number of messages received from senders that are not local.	All levels

Sample Output

show igmp snooping statistics

```
user@host> show igmp snooping statistics
Routing-instance foo

 IGMP packet statistics for all interfaces in learning-domain vlan-100

 IGMP Message type      Received       Sent  Rx errors
 Membership Query             89         51          0
 V1 Membership Report          0          0          0

Syntax (EX Series Switch and the QFX Series)
show igmp statistics
<brief | detail>
<interface *interface-name*>

Release Information
Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description
Display Internet Group Management Protocol (IGMP) statistics.

Options
none—Display IGMP statistics for all interfaces.

brief | detail—(Optional) Display the specified level of output.

interface *interface-name*—(Optional) Display IGMP statistics about the specified interface only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields
Table 401 describes the output fields for the **show igmp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 401: show igmp statistics Output Fields

Field Name	Field Description
IGMP packet statistics	Heading for IGMP packet statistics for all interfaces or for the specified interface name.

Copyright © 2016, Juniper Networks, Inc.

Table 401: show igmp statistics Output Fields *(continued)*

Field Name	Field Description
IGMP Message type	Summary of IGMP statistics: • **Membership Query**—Number of membership queries sent and received. • **V1 Membership Report**—Number of version 1 membership reports sent and received. • **DVMRP**—Number of DVMRP messages sent or received. • **PIM V1**—Number of PIM version 1 messages sent or received. • **Cisco Trace**—Number of Cisco trace messages sent or received. • **V2 Membership Report**—Number of version 2 membership reports sent or received. • **Group Leave**—Number of group leave messages sent or received. • **Mtrace Response**—Number of Mtrace response messages sent or received. • **Mtrace Request**—Number of Mtrace request messages sent or received. • **Domain Wide Report**—Number of domain-wide reports sent or received. • **V3 Membership Report**—Number of version 3 membership reports sent or received. • **Other Unknown types**—Number of unknown message types received. • **IGMP v3 unsupported type**—Number of messages received with unknown and unsupported IGMP version 3 message types. • **IGMP v3 source required for SSM**—Number of IGMP version 3 messages received that contained no source. • **IGMP v3 mode not applicable for SSM**—Number of IGMP version 3 messages received that did not contain a mode applicable for source-specific multicast (SSM).
Received	Number of messages received.
Sent	Number of messages sent.
Rx errors	Number of received packets that contained errors.
IGMP Global Statistics	Summary of IGMP statistics for all interfaces. • **Bad Length**—Number of messages received with length errors so severe that further classification could not occur. • **Bad Checksum**—Number of messages received with a bad IP checksum. No further classification was performed. • **Bad Receive If**—Number of messages received on an interface not enabled for IGMP. • **Rx non-local**—Number of messages received from senders that are not local. • **Timed out**—Number of groups that timed out as a result of not receiving an explicit leave message. • **Rejected Report**—Number of reports dropped because of the IGMP group policy. • **Total Interfaces**—Number of interfaces configured to support IGMP.

Sample Output

show igmp statistics

```
user@host> show igmp statistics
IGMP packet statistics for all interfaces

Output Fields
Table 402 describes the output fields for the **show mld group** command. Output fields are listed in the approximate order in which they appear.

Table 402: show mld group Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface that received the MLD membership report; **local** means that the local router joined the group itself.	All levels
Group	Group address.	All levels
Source	Source address.	All levels
Group Mode	Mode the SSM group is operating in: **Include** or **Exclude**.	All levels
Last reported by	Address of the host that last reported membership in this group.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 402: show mld group Output Fields *(continued)*

Field Name	Field Description	Level of Output
Source timeout	Time remaining until the group traffic is no longer forwarded. The timer is refreshed when a listener in include mode sends a report. A group in exclude mode or configured as a static group displays a zero timer.	**detail**
Timeout	Time remaining until the group membership is removed.	**brief none**
Group timeout	Time remaining until a group in exclude mode moves to include mode. The timer is refreshed when a listener in exclude mode sends a report. A group in include mode or configured as a static group displays a zero timer.	**detail**
Type	Type of group membership: • **Dynamic**—Host reported the membership. • **Static**—Membership is configured.	All levels

Sample Output

show mld group (Include Mode)

```
user@host> show mld group

show mld interface

Syntax
show mld interface
<brief | detail>
<*interface-name*>
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced before Junos OS Release 7.4.

Description
Display information about Multicast Listener Discovery (MLD)-enabled interfaces.

Options
none—Display standard information about all MLD-enabled interfaces.

brief | detail—(Optional) Display the specified level of output.

interface-name—(Optional) Display information about the specified interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

Related Documentation

List of Sample Output
show mld interface on page 4701
show mld interface brief on page 4701
show mld interface detail on page 4701

Output Fields
Table 403 describes the output fields for the **show mld interface** command. Output fields are listed in the approximate order in which they appear.

Table 403: show mld interface Output Fields

Field Name	Field Description	Level of Output
Interface	Name of the interface.	All levels
Querier	Address of the router that has been elected to send membership queries.	All levels
State	State of the interface: **Up** or **Down**.	All levels
SSM Map Policy	Name of the source-specific multicast (SSM) map policy that has been applied to the interface.	All levels
SSM Map Policy	Name of the source-specific multicast (SSM) map policy at the MLD interface.	All levels
Timeout	How long until the MLD querier is declared to be unreachable, in seconds.	All levels
Version	MLD version being used on the interface: **1** or **2**.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 403: show mld interface Output Fields *(continued)*

Field Name	Field Description	Level of Output
Groups	Number of groups on the interface.	All levels
Passive	State of the passive mode option: • **On**—Indicates that the router can run IGMP or MLD on the interface but not send or receive control traffic such as IGMP or MLD reports, queries, and leaves. • **Off**—Indicates that the router can run IGMP or MLD on the interface and send or receive control traffic such as IGMP or MLD reports, queries, and leaves. The **passive** statement enables you to selectively activate up to two out of a possible three available query or control traffic options. When enabled, the following options appear after the **on** state declaration: • **send-general-query**—The interface sends general queries. • **send-group-query**—The interface sends group-specific and group-source-specific queries. • **allow-receive**—The interface receives control traffic	All levels
OIF map	Name of the OIF map associated to the interface.	All levels
SSM map	Name of the source-specific multicast (SSM) map used on the interface, if configured.	All levels
Immediate Leave	State of the immediate leave option: • **On**—Indicates that the router removes a host from the multicast group as soon as the router receives a multicast listener done message from a host associated with the interface. • **Off**—Indicates that after receiving a multicast listener done message, instead of removing a host from the multicast group immediately, the router sends a group query to determine if another receiver responds.	All levels
Configured Parameters	Information configured by the user. • **MLD Query Interval (.1 secs)**—Interval at which this router sends membership queries when it is the querier. • **MLD Query Response Interval (.1 secs)**—Time that the router waits for a report in response to a general query. • **MLD Last Member Query Interval (.1 secs)**—Time that the router waits for a report in response to a group-specific query. • **MLD Robustness Count**—Number of times the router retries a query.	All levels
Derived Parameters	Derived information. • **MLD Membership Timeout (.1 secs)**—Timeout period for group membership. If no report is received for these groups before the timeout expires, the group membership will be removed. • **MLD Other Querier Present Timeout (.1 secs)**—Time that the router waits for the IGMP querier to send a query.	All levels

Sample Output

show mld interface

```
user@host> show mld interface
Interface: fe-0/0/0
    Querier: None
    State: Up         Timeout:       0    Version:  1    Groups:      0
    SSM Map Policy: ssm-policy-A
Interface: at-0/3/1.0
    Querier:  8038::c0a8:c345
    State: Up         Timeout:    None    Version:  1    Groups:      0
    SSM Map Policy: ssm-policy-B
Interface: fe-1/0/1.0
    Querier:  ::192.168.195.73
    State: Up         Timeout:    None    Version:  1    Groups:      3
    SSM Map Policy: ssm-policy-C
    SSM map: ipv6map1
Immediate Leave: On

Configured Parameters:
MLD Query Interval (.1 secs): 1250
MLD Query Response Interval (.1 secs): 100
MLD Last Member Query Interval (.1 secs): 10
MLD Robustness Count: 2

Derived Parameters:
MLD Membership Timeout (.1secs): 2600
MLD Other Querier Present Timeout (.1 secs): 2550
```

show mld interface brief

The output for the **show mld interface brief** command is identical to that for the **show mld interface** command. For sample output, see show mld interface on page 4701.

show mld interface detail

The output for the **show mld interface detail** command is identical to that for the **show mld interface** command. For sample output, see show mld interface on page 4701.

show mld statistics interface on page 4704

Output Fields

Table 404 describes the output fields for the **show mld statistics** command. Output fields are listed in the approximate order in which they appear.

Table 404: show mld statistics Output Fields

Field Name	Field Description
Received	Number of received packets.
Sent	Number of transmitted packets.
Rx errors	Number of received packets that contained errors.

Copyright © 2016, Juniper Networks, Inc.

Table 404: show mld statistics Output Fields *(continued)*

Field Name	Field Description
MLD Message type	Summary of MLD statistics. • **Listener Query (v1/v2)**—Number of membership queries sent and received. • **Listener Report (v1)**—Number of version 1 membership reports sent and received. • **Listener Done (v1/v2)**—Number of Listener Done messages sent and received. • **Listener Report (v2)**—Number of version 2 membership reports sent and received. • **Other Unknown types**—Number of unknown message types received. • **MLD v2 source required for SSM**—Number of MLD version 2 messages received that contained no source. • **MLD v2 mode not applicable for SSM**—Number of MLD version 2 messages received that did not contain a mode applicable for source-specific multicast (SSM).
MLD Global Statistics	Summary of MLD statistics for all interfaces. • **Bad Length**—Number of messages received with length errors so severe that further classification could not occur. • **Bad Checksum**—Number of messages received with an invalid IP checksum. No further classification was performed. • **Bad Receive If**—Number of messages received on an interface not enabled for MLD. • **Rx non-local**—Number of messages received from nonlocal senders. • **Timed out**—Number of groups that timed out as a result of not receiving an explicit leave message. • **Rejected Report**—Number of reports dropped because of the MLD group policy. • **Total Interfaces**—Number of interfaces configured to support IGMP.

Sample Output

show mld statistics

```
user@host> show mld statistics
MLD packet statistics for all interfaces
MLD Message type            Received       Sent  Rx errors
Listener Query (v1/v2)             0          2          0
Listener Report (v1)               0          0          0
Listener Done (v1/v2)              0          0          0
Listener Report (v2)               0          0          0
Other Unknown types                                      0
MLD v2 source required for SSM     2
MLD v2 mode not applicable for SSM 0

MLD Global Statistics
Bad Length                         0
Bad Checksum                       0
Bad Receive If                     0

show msdp

Syntax

show msdp
<brief | detail>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<peer *peer-address*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 12.1 for the QFX Series.

Description

Display Multicast Source Discovery Protocol (MSDP) information.

Options

none—Display standard MSDP information for all routing instances.

brief | detail—(Optional) Display the specified level of output.

instance *instance-name*—(Optional) Display information for the specified instance only.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

peer *peer-address*—(Optional) Display information about the specified peer only,

Output Fields

Table 405 describes the output fields for the **show msdp** command. Output fields are listed in the approximate order in which they appear.

Table 405: show msdp Output Fields

Field Name	Field Description	Level of Output
Peer address	IP address of the peer.	All levels
Local address	Local address of the peer.	All levels
State	Status of the MSDP connection: **Listen**, **Established**, or **Inactive**.	All levels
Last up/down	Time at which the most recent peer-state change occurred.	All levels

Copyright © 2016, Juniper Networks, Inc.

Table 405: show msdp Output Fields *(continued)*

Field Name	Field Description	Level of Output
Peer-Group	Peer group name.	All levels
SA Count	Number of source-active cache entries advertised by each peer that were accepted, compared to the number that were received, in the format *number-accepted/number-received*.	All levels
Peer Connect Retries	Number of peer connection retries.	**detail**
State timer expires	Number of seconds before another message is sent to a peer.	**detail**
Peer Times out	Number of seconds to wait for a response from the peer before the peer is declared unavailable.	**detail**
SA accepted	Number of entries in the source-active cache accepted from the peer.	**detail**
SA received	Number of entries in the source-active cache received by the peer.	**detail**

Sample Output

show msdp

```
user@host> show msdp
Peer address     Local address   State       Last up/down Peer-Group SA Count
198.32.8.193     198.32.8.195    Established  5d 19:25:44 North23    120/150

Output Fields Table 406 describes the output fields for the **show msdp source** command. Output fields are listed in the approximate order in which they appear.

Table 406: show msdp source Output Fields

Field Name	Field Description
Source address	IP address of the source.
/Len	Length of the prefix for this IP address.
Type	Discovery method for this multicast source: • **Configured**—Source-active limit explicitly configured for this source. • **Dynamic**—Source-active limit established when this source was discovered.
Maximum	Source-active limit applied to this source.
Threshold	Source-active threshold applied to this source.
Exceeded	Number of source-active messages received from this source exceeding the established maximum.

Sample Output

show msdp source

```
user@host> show msdp source
Source address /Len   Type       Maximum   Threshold    Exceeded
0.0.0.0        /0     Configured        5       none           0
10.1.0.0       /16    Configured      500       none           0
10.1.1.1       /32    Configured    10000       none           0

Output Fields

Table 408 describes the output fields for the **show msdp statistics** command. Output fields are listed in the approximate order in which they appear.

Table 408: show msdp statistics Output Fields

Field Name	Field Description
Global active source limit exceeded	Number of times all peers have exceeded configured active source limits.
Global active source limit maximum	Configured number of active source messages accepted by the device.
Global active source limit threshold	Configured threshold for applying random early discard (RED) to drop some but not all MSDP active source messages.
Global active source limit log-warning	Threshold at which a warning message is logged (percentage of the number of active source messages accepted by the device).
Global active source limit log interval	Time (in seconds) between consecutive log messages.

Copyright © 2016, Juniper Networks, Inc.

Table 408: show msdp statistics Output Fields *(continued)*

Field Name	Field Description
Peer	Address of peer.
Last State Change	How long ago the peer state changed.
Last message received from the peer	How long ago the last message was received from the peer.
RPF Failures	Number of reverse path forwarding (RPF) failures.
Remote Closes	Number of times the remote peer closed.
Peer Timeouts	Number of peer timeouts.
SA messages sent	Number of source-active messages sent.
SA messages received	Number of source-active messages received.
SA request messages sent	Number of source-active request messages sent.
SA request messages received	Number of source-active request messages received.
SA response messages sent	Number of source-active response messages sent.
SA response messages received	Number of source-active response messages received.
SA response messages received	Entry Count is a field within SA message that defines how many source/group tuples are present in the SA message. The counter is incremented each time an SA with an Entry Count of zero is received.
Active source exceeded	Number of times this peer has exceeded configured source-active limits.
Active source Maximum	Configured number of active source messages accepted by this peer.
Active source threshold	Configured threshold on this peer for applying random early discard (RED) to drop some but not all MSDP active source messages.
Active source log-warning	Configured threshold on this peer at which a warning message is logged (percentage of the number of active source messages accepted by the device).
Active source log-interval	Time (in seconds) between consecutive log messages on this peer.
Keepalive messages sent	Number of keepalive messages sent.

Copyright © 2016, Juniper Networks, Inc.

Table 408: show msdp statistics Output Fields *(continued)*

Field Name	Field Description
Keepalive messages received	Number of keepalive messages received.
Unknown messages received	Number of unknown messages received.
Error messages received	Number of error messages received.

Sample Output

show msdp statistics

```
user@host> show msdp statistics
Global active source limit exceeded: 0
Global active source limit maximum: 10
Global active source limit threshold: 8
Global active source limit log-warning: 60

show multicast backup-pe-groups

Syntax

show multicast backup-pe-groups
<address *pe-address*>
<group *group-name*>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Release Information

Command introduced in Junos OS Release 9.0.

Description

Display backup PE router group information when ingress PE redundancy is configured. Ingress PE redundancy provides a backup resource when point-to-multipoint LSPs are configured for multicast distribution.

Options

none—Display standard information about all backup PE groups.

address *pe-address*—(Optional) Display the groups that a PE address is associated with.

group *group*—(Optional) Display the backup PE group information for a particular group.

instance *instance-name*—(Optional) Display backup PE group information for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

view

List of Sample Output

show multicast backup-pe-groups on page 4716

Output Fields

Table 409 describes the output fields for the **show multicast backup-pe-groups** command. Output fields are listed in the approximate order in which they appear.

Table 409: show multicast backup-pe-groups Output Fields

Field Name	Field Description
Backup PE Group	Group name.
Designated PE	Primary PE router. Address of the PE router that is currently forwarding traffic on the static route.
Transitions	Number of times that the designated PE router has transitioned from the most eligible PE router to a backup PE router and back again to the most eligible PE router.
Last Transition	Time of the most recent transition.
Local Address	Address of the local PE router.
Backup PE List	List of PE routers that are configured to be backups for the group.

Copyright © 2016, Juniper Networks, Inc.

Sample Output

show multicast backup-pe-groups

```
user@host> show multicast backup-pe-groups
Instance: master

Backup PE group: b1
    Designated PE:   10.255.165.7
    Transitions:     1
    Last Transition: 03:15:01
    Local Address:   10.255.165.7
    Backup PE List:
                     10.255.165.8

Backup PE group: b2
    Designated PE:   10.255.165.7
    Transitions:     2
    Last Transition: 02:58:20
    Local Address:   10.255.165.7
    Backup PE List:
                     10.255.165.9
                     10.255.165.8
```

show multicast flow-map

List of Syntax
Syntax on page 4717
Syntax (EX Series Switch and the QFX Series) on page 4717

Syntax
show multicast flow-map
<brief | detail>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)
show multicast flow-map
<brief | detail>

Release Information
Command introduced in Junos OS Release 8.2.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description
Display configuration information about IP multicast flow maps.

Options
none—Display configuration information about IP multicast flow maps on all systems.

brief | detail—(Optional) Display the specified level of output.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields
Table 410 describes the output fields for the **show multicast flow-map** command. Output fields are listed in the approximate order in which they appear.

Table 410: show multicast flow-map Output Fields

Field Name	Field Description	Levels of Output
Name	Name of the flow map.	All levels
Policy	Name of the policy associated with the flow map.	All levels
Cache-timeout	Cache timeout value assigned to the flow map.	All levels
Bandwidth	Bandwidth setting associated with the flow map.	All levels
Adaptive	Whether or not adaptive mode is enabled for the flow map.	none
Flow-map	Name of the flow map.	**detail**

Copyright © 2016, Juniper Networks, Inc.

Table 410: show multicast flow-map Output Fields *(continued)*

Field Name	Field Description	Levels of Output
Adaptive Bandwidth	Whether or not adaptive mode is enabled for the flow map.	**detail**
Redundant Sources	Redundant sources defined for the same destination group.	**detail**

Sample Output

show multicast flow-map

```
user@host> show multicast flow-map
Instance: master
Name            Policy                  Cache timeout        Bandwidth Adaptive
map2            policy2                         never          2000000 no
map1            policy1                    60 seconds          2000000 no
```

Sample Output

show multicast flow-map detail

```
user@host> show multicast flow-map detail
Instance: master
Flow-map: map1
    Policy:             policy1
    Cache Timeout:      600 seconds
    Bandwidth:          2000000
    Adaptive Bandwidth: yes
    Redundant Sources:  11.11.11.11
    Redundant Sources:  11.11.11.12
    Redundant Sources:  11.11.11.13

show multicast interface

List of Syntax
Syntax on page 4719
Syntax (EX Series Switch and the QFX Series) on page 4719

Syntax
show multicast interface
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)
show multicast interface

Release Information
Command introduced in Junos OS Release 8.3.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description
Display bandwidth information about IP multicast interfaces.

Options
none—Display all interfaces that have multicast configured.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level
view

List of Sample Output
show multicast interface on page 4720

Output Fields
Table 411 describes the output fields for the **show multicast interface** command. Output fields are listed in the approximate order in which they appear.

Table 411: show multicast interface Output Fields

Field Name	Field Description
Interface	Name of the multicast interface.
Maximum bandwidth (bps)	Maximum bandwidth setting, in bits per second, for this interface.
Remaining bandwidth (bps)	Amount of bandwidth, in bits per second, remaining on the interface.
Mapped bandwidth deduction (bps)	Amount of bandwidth, in bits per second, used by any flows that are mapped to the interface. NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface. This field does not appear in the output when the no QoS adjustment feature is disabled.

Copyright © 2016, Juniper Networks, Inc.

Table 411: show multicast interface Output Fields *(continued)*

Field Name	Field Description
Local bandwidth deduction (bps)	Amount of bandwidth, in bits per second, used by any mapped flows that are traversing the interface. NOTE: Adding the mapped bandwidth deduction value to the local bandwidth deduction value results in the total deduction value for the interface. This field does not appear in the output when the no QoS adjustment feature is disabled.
Reverse OIF mapping	State of the reverse OIF mapping feature (**on** or **off**). NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
Reverse OIF mapping no QoS adjustment	State of the no QoS adjustment feature (**on** or **off**) for interfaces that are using reverse OIF mapping. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
Leave timer	Amount of time a mapped interface remains active after the last mapping ends. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.
No QoS adjustment	State (**on**) of the no QoS adjustment feature when this feature is enabled. NOTE: This field does not appear in the output when the no QoS adjustment feature is disabled.

Sample Output

show multicast interface

```
user@host> show multicast interface
Interface               Maximum bandwidth (bps) Remaining bandwidth (bps)
fe-0/0/3                              10000000                          0
fe-0/0/3.210                          10000000                   -2000000
fe-0/0/3.220                         100000000                  100000000
fe-0/0/3.230                          20000000                   18000000
fe-0/0/2.200                         100000000                  100000000
```

show multicast pim-to-igmp-proxy

List of Syntax
Syntax on page 4721
Syntax (EX Series Switch and the QFX Series) on page 4721

Syntax

show multicast pim-to-igmp-proxy
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>

Syntax (EX Series Switch and the QFX Series)

show multicast pim-to-igmp-proxy
<instance *instance-name*>

Release Information

Command introduced in Junos OS Release 9.6.
Command introduced in Junos OS Release 9.6 for EX Series switches.
instance option introduced in Junos OS Release 10.0.
instance option introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display configuration information about PIM-to-IGMP message translation, also known as PIM-to-IGMP proxy.

Options

none—Display configuration information about PIM-to-IGMP message translation for all routing instances.

instance *instance-name*—(Optional) Display configuration information about PIM-to-IGMP message translation for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Required Privilege Level

show multicast route

List of Syntax
Syntax on page 4725
Syntax (EX Series Switch and the QFX Series) on page 4725

Syntax

show multicast route
<brief | detail | extensive | summary>
<active | all | inactive>
<group *group*>
<inet | inet6>
<instance *instance name*>
<logical-system (all | *logical-system-name*)>
<*regular-expression*>
<source-prefix *source-prefix*>

Syntax (EX Series Switch and the QFX Series)

show multicast route
<brief | detail | extensive | summary>
<active | all | inactive>
<group *group*>
<inet | inet6>
<instance *instance name*>
<*regular-expression*>
<source-prefix *source-prefix*>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.
Support for bidirectional PIM added in Junos OS Release 12.1.
Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

Display the entries in the IP multicast forwarding table. You can display similar information with the **show route table inet.1** command.

Options

none—Display standard information about all entries in the multicast forwarding table for all routing instances.

brief | detail | extensive | summary—(Optional) Display the specified level of output.

active | all | inactive—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast forwarding table.

group *group*—(Optional) Display the cache entries for a particular group.

inet | inet6—(Optional) Display multicast forwarding table entries for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display entries in the multicast forwarding table for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Copyright © 2016, Juniper Networks, Inc.

regular-expression—(Optional) Display information about the multicast forwarding table entries that match a UNIX OS-style regular expression.

source-prefix *source-prefix*—(Optional) Display the cache entries for a particular source prefix.

Output Fields Table 414 describes the output fields for the **show multicast route** command. Output fields are listed in the approximate order in which they appear.

Table 414: show multicast route Output Fields

Field Name	Field Description	Level of Output
family	IPv4 address family (**INET**) or IPv6 address family (**INET6**).	All levels
Group	Group address. For any-source multicast routes, for example for bidirectional PIM, the group address includes the prefix length.	All levels
Source	Prefix and length of the source as it is in the multicast forwarding table.	All levels
Incoming interface list	List of interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.	All levels
Upstream interface	Name of the interface on which the packet with this source prefix is expected to arrive.	All levels
Upstream rpf interface list	When multicast-only fast reroute (MoFRR) is enabled, a PIM router propagates join messages on two upstream RPF interfaces to receive multicast traffic on both links for the same join request.	All levels
Downstream interface list	List of interface names to which the packet with this source prefix is forwarded.	All levels
Number of outgoing interfaces	Total number of outgoing interfaces for each (S,G) entry.	**extensive**
Session description	Name of the multicast session.	**detail extensive**

Copyright © 2016, Juniper Networks, Inc.

Table 414: show multicast route Output Fields *(continued)*

Field Name	Field Description	Level of Output
Statistics	Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix. If one or more of the kilobits per second packet forwarding statistic queries fails or times out, the statistics field displays **Forwarding statistics are not available**. NOTE: On QFX Series switches and OCX Series switches, this field does not report valid statistics.	**detail extensive**
Next-hop ID	Next-hop identifier of the prefix. The identifier is returned by the routing device's Packet Forwarding Engine and is also displayed in the output of the **show multicast nexthops** command.	**detail extensive**
Incoming interface list ID	For bidirectional PIM, incoming interface list identifier. Identifiers for interfaces that accept incoming traffic. Only shown for routes that do not use strict RPF-based forwarding, for example for bidirectional PIM.	**detail extensive**
Upstream protocol	The protocol that maintains the active multicast forwarding route for this group or source. When the **show multicast route extensive** command is used with the **display-origin-protocol** option, the field name is only **Protocol** and not **Upstream Protocol**. However, this field also displays the protocol that installed the active route.	**detail extensive**
Route type	Type of multicast route. Values can be (S,G) or (*,G).	**summary**
Route state	Whether the group is **Active** or **Inactive**.	**summary extensive**
Route count	Number of multicast routes.	**summary**
Forwarding state	Whether the prefix is pruned or forwarding.	**extensive**
Cache lifetime/timeout	Number of seconds until the prefix is removed from the multicast forwarding table. A value of **never** indicates a permanent forwarding entry. A value of **forever** indicates routes that do not have keepalive times.	**extensive**
Wrong incoming interface notifications	Number of times that the upstream interface was not available.	**extensive**
Uptime	Time since the creation of a multicast route.	**extensive**

show multicast rpf

List of Syntax
Syntax on page 4731
Syntax (EX Series Switch and the QFX Series) on page 4731

Syntax

show multicast rpf
<inet | inet6>
<instance *instance-name*>
<logical-system (all | *logical-system-name*)>
<*prefix*>
<summary>

Syntax (EX Series Switch and the QFX Series)

show multicast rpf
<inet | inet6>
<instance *instance-name*>
<*prefix*>
<summary>

Release Information

Command introduced before Junos OS Release 7.4.
Command introduced in Junos OS Release 9.0 for EX Series switches.
inet6 and **instance** options introduced in Junos OS Release 10.0 for EX Series switches.
Command introduced in Junos OS Release 11.3 for the QFX Series.

Description

Display information about multicast reverse-path-forwarding (RPF) calculations.

Options

none—Display RPF calculation information for all supported address families.

inet | inet6—(Optional) Display the RPF calculation information for IPv4 or IPv6 family addresses, respectively.

instance *instance-name*—(Optional) Display information about multicast RPF calculations for a specific multicast instance.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

prefix—(Optional) Display the RPF calculation information for the specified prefix.

summary—(Optional) Display a summary of all multicast RPF information.

Output Fields Table 415 describes the output fields for the **show multicast rpf** command. Output fields are listed in the approximate order in which they appear.

Table 415: show multicast rpf Output Fields

Field Name	Field Description
Instance	Name of the routing instance. (Displayed when multicast is configured within a routing instance.)
Source prefix	Prefix and length of the source as it exists in the multicast forwarding table.
Protocol	How the route was learned.
Interface	Upstream RPF interface. NOTE: The displayed interface information does not apply to bidirectional PIM RP addresses. This is because the **show multicast rpf** command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF interface information, always use the **show pim join extensive** command when bidirectional PIM is configured.
Neighbor	Upstream RPF neighbor. NOTE: The displayed neighbor information does not apply to bidirectional PIM. This is because the **show multicast rpf** command does not take into account equal-cost paths or the designated forwarder. For accurate upstream RPF neighbor information, always use the **show pim join extensive** command when bidirectional PIM is configured.

Sample Output

show multicast rpf

show multicast snooping route

Syntax

show multicast snooping route
<brief | detail | extensive>
<active | all | inactive>
<bridge-domain *bridge-domain-name*>
<group *group*>
<instance *instance-name*>
<mesh-group *mesh-group-name*>
<*regular-expression*>
<source-prefix *source-prefix*>

Release Information

Command introduced in Junos OS Release 8.5.

Description

Display the entries in the IP multicast snooping forwarding table. You can display some of this information with the **show route table inet.1** command.

Options

none—Display standard information about all entries in the multicast snooping table for all virtual switches and all bridge domains.

brief | detail | extensive—(Optional) Display the specified level of output.

active | all | inactive—(Optional) Display all active entries, all entries, or all inactive entries, respectively, in the multicast snooping table.

bridge-domain *bridge-domain*—(Optional) Display the entries for a particular bridge domain.

group *group*—(Optional) Display the entries for a particular group.

instance *instance-name*—(Optional) Display the entries for a multicast instance.

mesh-group *mesh-group-name*—(Optional) Display the entries for a particular mesh group.

regular-expression—(Optional) Display information about the multicast forwarding table entries that match a UNIX-style regular expression.

source-prefix *source-prefix*—(Optional) Display the entries for a particular source prefix.

Required Privilege Level

show multicast snooping route bridge-domain on page 4741
show multicast snooping route instance vs on page 4741

Output Fields

Table 418 describes the output fields for the **show multicast snooping route** command. Output fields are listed in the approximate order in which they appear.

Copyright © 2016, Juniper Networks, Inc.

Table 418: show multicast snooping route Output Fields

Field Name	Field Description	Level of Output
Nexthop Bulking	Displays whether next-hop bulk updating is **ON** or **OFF** (only for routing-instance type of **virtual switch** or **vpls**).	All levels
Family	IPv4 address family (**INET**) or IPv6 address family (**INET6**).	All levels
Group	Group address.	All levels
Source	Prefix and length of the source as it is in the multicast forwarding table.	All levels
Routing-instance	Name of the routing instance to which this routing information applies. (Displayed when multicast is configured within a routing instance.)	All levels
Learning Domain	Name of the learning domain to which this routing information applies.	**detail extensive**
Statistics	Rate at which packets are being forwarded for this source and group entry (in Kbps and pps), and number of packets that have been forwarded to this prefix.	**detail extensive**
Next-hop ID	Next-hop identifier of the prefix. The identifier is returned by the router's Packet Forwarding Engine and is also displayed in the output of the **show multicast nexthops** command.	**detail extensive**
Route state	Whether the group is **Active** or **Inactive**.	**extensive**
Forwarding state	Whether the prefix is **Pruned** or **Forwarding**.	**extensive**
Cache lifetime/timeout	Number of seconds until the prefix is removed from the multicast forwarding table. A value of **never** indicates a permanent forwarding entry.	**extensive**

Sample Output

show multicast snooping route bridge-domain

```
user@host> show multicast snooping route bridge-domain br-dom-1 extensive

show multicast snooping statistics

Syntax
show multicast snooping statistics
<instance *instance-name*>
<interface *interface-name*>
<logical-system (all | *logical-system-name*)>

Release Information
Command introduced in Junos OS Release 8.5.

Description
Display IP multicast snooping statistics.

Options
none—Display multicast snooping statistics for all supported address families for all routing instances.

instance *instance-name*—(Optional) Display statistics for a specific routing instance.

interface *interface-name*—(Optional) Display statistics for a specific interface.

logical-system (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

Additional Information
The input and output interface multicast snooping statistics are consistent, but not timely. They are constructed from the forwarding statistics, which are gathered at 30-second intervals. Therefore, the output from this command always lags the true count by up to 30 seconds.

Output Fields
Table 419 describes the output fields for the **show multicast snooping statistics** command. Output fields are listed in the approximate order in which they appear.

Table 419: show multicast snooping statistics Output Fields

Field Name	Field Description
Routing-instance	Name of the routing instance. (Displayed when multicast is configured within a routing instance.)
Family	Protocol family for which multicast statistics are displayed: **INET** or **INET6**.
Interface	Name of the interface for which statistics are being reported.
Routing Protocol	Primary multicast protocol on the interface: **PIM**, **DVMRP for INET**, or **PIM for INET6**.
Mismatch	Number of multicast packets that did not arrive on the correct upstream interface.

Copyright © 2016, Juniper Networks, Inc.

Table 419: show multicast snooping statistics Output Fields *(continued)*

Field Name	Field Description
Kernel Resolve	Number of resolve requests processed by the primary multicast protocol on the interface.
Resolve No Route	Number of resolve requests that were ignored because there was no route to the source.
In Kbytes	Total accumulated incoming packets (in KB) since the last time the **clear multicast snooping statistics** command was issued.
Out Kbytes	Total accumulated outgoing packets (in KB) since the last time the **clear multicast snooping statistics** command was issued.
Mismatch error	Number of mismatches that were ignored because of internal errors.
Mismatch No Route	Number of mismatches that were ignored because there was no route to the source.
Routing Notify	Number of times that the multicast routing system has been notified of a new multicast source by a multicast routing protocol.
Resolve Error	Number of resolve requests that were ignored because of internal errors.
In packets	Total number of incoming packets since the last time the **clear multicast snooping statistics** command was issued.
Out packets	Total number of outgoing packets since the last time the **clear multicast snooping statistics** command was issued.
