## RPM Overview

The real-time performance monitoring (RPM) feature allows network operators and their customers to accurately measure the performance between two network endpoints. With the RPM tool, you configure and send probes to a specified target and monitor the analyzed results to determine packet loss, round-trip time, and jitter.

RPM allows you to perform service-level monitoring. When RPM is configured on a device, the device calculates network performance based on packet response time, jitter, and packet loss. These values are gathered by Hypertext Transfer Protocol (HTTP) GET requests, Internet Control Message Protocol (ICMP) requests, and TCP and UDP requests, depending on the configuration.

This section contains the following topics:

- [RPM Probes on page 1186](#)
- [RPM Tests on page 1186](#)
- [Probe and Test Intervals on page 1186](#)
- [Jitter Measurement with Hardware Timestamping on page 1187](#)
- [RPM Statistics on page 1187](#)
- [RPM Thresholds and Traps on page 1188](#)
- [RPM for BGP Monitoring on page 1189](#)

## RPM Probes

---

You gather RPM statistics by sending out probes to a specified probe target, identified by an IP address or URL. When the target receives the probe, it generates responses, which are received by the device. By analyzing the transit times to and from the remote server, the device can determine network performance statistics.

The device sends out the following probe types:

- HTTP GET request at a target URL
- HTTP GET request for metadata at a target URL
- ICMP echo request to a target address (the default)
- ICMP timestamp request to a target address
- UDP ping packets to a target device
- UDP timestamp requests to a target address
- TCP ping packets to a target device

UDP and TCP probe types require that the remote server be configured as an RPM receiver so that it generates responses to the probes.

The RPM probe results are also available in the form of MIB objects through the SNMP protocol.

## RPM Tests

---

Each probed target is monitored over the course of a test. A test represents a collection of probes, sent out at regular intervals, as defined in the configuration. Statistics are then returned for each test. Because a test is a collection of probes that have been monitored over some amount of time, test statistics such as standard deviation and jitter can be calculated and included with the average probe statistics.

## Probe and Test Intervals

---

Within a test, RPM probes are sent at regular intervals, configured in seconds. When the total number of probes has been sent and the corresponding responses received, the test is complete. You can manually set the probe interval for each test to control how the RPM test is conducted.

After all the probes for a particular test have been sent, the test begins again. The time between tests is the test interval. You can manually set the test interval to tune RPM performance.

**NOTE:** On SRX340 Low Memory devices and SRX340 High Memory devices, the RPM server operation does not work when the probe is configured with the option destination-interface.

---

### Jitter Measurement with Hardware Timestamping

Jitter is the difference in relative transit time between two consecutive probes.

You can timestamp the following RPM probes to improve the measurement of latency or jitter:

- ICMP ping
- ICMP ping timestamp
- UDP ping
- UDP ping timestamp

**NOTE:** The device supports hardware timestamping of UDP ping and UDP ping timestamp RPM probes only if the destination port is UDP-ECHO (port 7).

Timestamping takes place during the forwarding process of the device originating the probe (the RPM client), but not on the remote device that is the target of the probe (the RPM server).

The supported encapsulations on a device for timestamping are Ethernet including VLAN, synchronous PPP, and Frame Relay. The only logical interface supported is an *lt* services interface.

RPM probe generation with hardware timestamp can be retrieved through the SNMP protocol.

### RPM Statistics

At the end of each test, the device collects the statistics for packet round-trip time, packet inbound and outbound times (for ICMP timestamp probes only), and probe loss as shown in [Table 78](#).

**Table 78: RPM Statistics**

RPM Statistics	Description
<b>Round-Trip Times</b>	
Minimum round-trip time	Shortest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test
Maximum round-trip time	Longest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test
Average round-trip time	Average round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test
Standard deviation round-trip time	Standard deviation of the round-trip times from the Juniper Networks device to the remote server, as measured over the course of the test

Table 78: RPM Statistics (*continued*)

RPM Statistics	Description
Jitter	Difference between the maximum and minimum round-trip times, as measured over the course of the test
<b>Inbound and Outbound Times (ICMP Timestamp Probes Only)</b>	
Minimum egress time	Shortest one-way time from the Juniper Networks device to the remote server, as measured over the course of the test
Maximum ingress time	Shortest one-way time from the remote server to the Juniper Networks device, as measured over the course of the test
Average egress time	Average one-way time from the Juniper Networks device to the remote server, as measured over the course of the test
Average ingress time	Average one-way time from the remote server to the Juniper Networks device, as measured over the course of the test
Standard deviation egress time	Standard deviation of the one-way times from the Juniper Networks device to the remote server, as measured over the course of the test
Standard deviation ingress time	Standard deviation of the one-way times from the remote server to the Juniper Networks device, as measured over the course of the test
Egress jitter	Difference between the maximum and minimum outbound times, as measured over the course of the test
Ingress jitter	Difference between the maximum and minimum inbound times, as measured over the course of the test
<b>Probe Counts</b>	
Probes sent	Total number of probes sent over the course of the test
Probe responses received	Total number of probe responses received over the course of the test
Loss percentage	Percentage of probes sent for which a response was not received

### RPM Thresholds and Traps

You can configure RPM threshold values for the round-trip times, ingress (inbound) times, and egress (outbound) times that are measured for each probe, as well as for the standard deviation and jitter values that are measured for each test. Additionally, you can configure threshold values for the number of successive lost probes within a test and the total number of lost probes within a test.

If the result of a probe or test exceeds any threshold, the device generates a system log message and sends any Simple Network Management Protocol (SNMP) notifications (traps) that you have configured.

### RPM for BGP Monitoring

When managing peering networks that are connected using Border Gateway Protocol (BGP), you might need to find out if a path exists between the Juniper Networks device and its configured BGP neighbors. You can ping each BGP neighbor manually to determine the connection status, but this method is not practical when the device has a large number of BGP neighbors configured.

In the device, you can configure RPM probes to monitor the BGP neighbors and determine if they are active.

### IPv6 RPM Probes

Starting with Junos OS Release 15.1X49-D10, Route Engine-based RPM can send and receive IPv6 probe packets to monitor performance on IPv6 networks.

A probe request is a standard IPv6 packet with corresponding TCP, UDP, and ICMPv6 headers. A probe response is also a standard IPv6 packet with corresponding TCP, UDP, and ICMPv6 headers. No RPM header is appended to the standard packet for RE-based RPM. An IPv6-based RPM test occurs between an IPv6 RPM client and IPv6 RPM server.

**NOTE:** You can have both IPv4 tests and IPv6 tests in the same probe.

#### Related Documentation

- [Configuring IPv6 RPM Probes on page 1202](#)

### Guidelines for Configuring RPM Probes for IPv6

Keep the following guidelines in mind when you configure IPv6 addresses for RPM destinations or servers:

- IPv6 RPM uses ICMPv6 probe requests. You cannot configure ICMP or ICMP timestamp probe types.
- Only Routing Engine-based RPM is supported for IPv6 targets including VRF support, specification of the size of the data portion of ICMPv6 probes, data pattern, and traffic class.
- You can configure probes with a combination of IPv4 and IPv6 tests. However, an individual test must be either IPv4 or IPv6.

- Routing Engine-based RPM does not support hardware-based, or one-way hardware-based timestamping.
- We recommend that you include the **probe-limit** statement at the **[edit services rpm]** hierarchy level to set the limit on concurrent probes to 10. Higher concurrent probes can result in higher spikes.
- SNMP set operation is permitted only on ICMP probes and it is not supported for other probe types.
- The following table describes the IPv6 special address prefixes that you cannot configure in a probe.

IPv6 Address Type	IPv6 Address Prefix
Node-Scoped Unicast	::1/128 is the loopback address ::/128 is the unspecified address
IPv4-Mapped Addresses	::FFFF:0:0/96
IPv4-Compatible Addresses	:<ipv4-address>/96
Link-Scoped Unicast	fe80::/10
Unique-Local	fc00::/7
Documentation Prefix	2001:db8::/32
6to4	2002::/16
6bone	5f00::/8
ORCHID	2001:10::/28
Teredo	2001::/32
Default Route	::/0
Multicast	ff00::/8

- In Routing Engine-based RPM, route-trip time (RTT) spikes might occur because of queuing delays, even with a single test.
- Since RPM might open TCP and UDP ports to communicate between the RPM server and RPM client, we recommend that you use firewalls and distributed denial-of-service (DDoS) attack filters to protect against security threats.

- [Configuring IPv6 RPM Probes on page 1202](#)

## RPM Support for VPN Routing and Forwarding

Real-time performance monitoring (RPM) is supported on all Juniper Network devices.

VRF in a Layer 3 VPN implementation allows multiple instances of a routing table to coexist within the same device at the same time. Because the routing instances are independent, the same or overlapping IPv4 or IPv6 addresses can be used without conflicting each other.

RPM ICMP and UDP probe with VPN routing and forwarding (VRF) has been improved. In previous releases, the RPM probes specified to a VRF table were not handled by the real-time forwarding process (FWDD-RT). In Junos OS Release 10.0, RPM probes specified to a VRF table are handled by the FWDD-RT, thereby providing more accurate results.

This feature supports RPM ICMP and UDP probes configured with routing instances of type VRF.

## Example: Configuring Basic RPM Probes

This example shows how to configure basic RPM probes to measure performance between two network endpoints.

- [Requirements on page 1191](#)
- [Overview on page 1191](#)
- [Configuration on page 1192](#)
- [Verification on page 1194](#)

### Requirements

---

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

### Overview

---

In this example, you configure basic probes for two RPM owners, customerA and customerB. You configure the RPM test as icmp-test for customerA with a test interval of 15 seconds and specify a probe type as icmp-ping-timestamp, a probe timestamp, and a target address as 192.178.16.5. You then configure the RPM thresholds and corresponding SNMP traps to catch ingress (inbound) times greater than 3000 microseconds.

Then you configure the RPM test as http-test for customerB with a test interval of 30 seconds and specify a probe type as http-get and a target URL as http://customerB.net.

Finally, you configure RPM thresholds and corresponding SNMP traps as probe-failure and test-failure to catch three or more successive lost probes and total lost probes of 10.

### Configuration

---

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm probe customerA test icmp-test probe-interval 15
set services rpm probe customerA test icmp-test probe-type icmp-ping-timestamp
set services rpm probe customerA test icmp-test hardware-timestamp
set services rpm probe customerA test icmp-test target address 192.178.16.5
set services rpm probe customerA test icmp-test thresholds ingress-time 3000
set services rpm probe customerA test icmp-test traps ingress-time-exceeded
set services rpm probe customerB test http-test probe-interval 30
set services rpm probe customerB test http-test probe-type http-get
set services rpm probe customerB test http-test target url http://customerB.net
set services rpm probe customerB test http-test thresholds successive-loss 3
set services rpm probe customerB test http-test thresholds total-loss 10
set services rpm probe customerB test http-test traps probe-failure
set services rpm probe customerB test http-test traps test-failure
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure basic RPM probes:

1. Configure the RPM.

```
[edit]
user@host# edit services rpm
```

2. Configure the RPM owners.

```
[edit services rpm]
user@host# set probe customerA
user@host# set probe customerB
```

3. Configure the RPM test for customerA.

```
[edit services rpm]
user@host# edit probe customerA
user@host# set test icmp-test probe-interval 15
user@host# set test icmp-test probe-type icmp-ping-timestamp
```

4. Specify a probe timestamp and a target address.

```
[edit services rpm probe customerA]
user@host# set test icmp-test hardware-timestamp
user@host# set test icmp-test target address 192.178.16.5
```

5. Configure RPM thresholds and corresponding SNMP traps.

```
[edit services rpm probe customerA]
```

- ```

user@host# set test icmp-test thresholds ingress-time 3000
user@host# set test icmp-test traps ingress-time-exceeded

```
6. Configure the RPM test for customerB.
 

```

[edit]
user@host# edit services rpm probe customerB
user@host# set test http-test probe-interval 30

```
  7. Specify a probe type and a target URL.
 

```

[edit services rpm probe customerB]
user@host# set test http-test probe-type http-get
user@host# set test http-test target url http://customerB.net

```
  8. Configure RPM thresholds and corresponding SNMP traps.
 

```

[edit services rpm probe customerB]
user@host# set test http-test thresholds successive-loss 3
user@host# set test http-test thresholds total-loss 10
user@host# set test http-test traps probe-failure
user@host# set test http-test traps test-failure

```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show services rpm
probe customerA {
  test icmp-test {
    probe-type icmp-ping-timestamp;
    target address 192.178.16.5;
    probe-interval 15;
    thresholds {
      ingress-time 3000;
    }
    traps ingress-time-exceeded;
    hardware-timestamp;
  }
}
probe customerB {
  test http-test {
    probe-type http-get
    target url http://customerB.net;
    probe-interval 30;
    thresholds {
      successive-loss 3;
      total-loss 10;
    }
    traps [ probe-failure test-failure ];
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

---

Confirm that the configuration is working properly.

- [Verifying RPM Services on page 1194](#)
- [Verifying RPM Statistics on page 1194](#)

### *Verifying RPM Services*

**Purpose** Verify that the RPM configuration is within the expected values.

**Action** From configuration mode, enter the **show services rpm** command. The output shows the values that are configured for RPM on the device.

### *Verifying RPM Statistics*

**Purpose** Verify that the RPM probes are functioning and that the RPM statistics are within expected values.

**Action** From configuration mode, enter the **show services rpm probe-results** command.

```
user@host> show services rpm probe-results
```

```

## Example: Configuring RPM Using TCP and UDP Probes

This example shows how to configure RPM using TCP and UDP probes.

- [Requirements on page 1195](#)
- [Overview on page 1195](#)
- [Configuration on page 1195](#)
- [Verification on page 1197](#)

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Configure the probe owner, the test, and the specific parameters of the RPM probe. See [“Example: Configuring Basic RPM Probes” on page 1191](#).

### Overview

In this example, you configure both the host (device A) and the remote device (device B) to act as TCP and UDP servers. You configure a probe for customerC, which uses TCP packets. Device B is configured as an RPM server for both TCP and UDP packets, using an lt services interface as the destination interface, and ports 50000 and 50037, respectively.

**CAUTION:** Use probe classification with caution, because improper configuration can cause packets to be dropped.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
{device A}
set services rpm probe customerC test tcp-test probe-interval 5
set services rpm probe customerC test tcp-test probe-type tcp-ping
set services rpm probe customerC test tcp-test target address 192.162.45.6
```

```
set services rpm probe customerC test tcp-test destination-interface lt-0/0/0
set services rpm probe customerC test tcp-test destination-port 50000
```

```
{device B}
set services rpm probe-server tcp port 50000
set services rpm probe-server udp port 50037
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure RPM using TCP and UDP probes:

1. Configure the RPM owner on device A.

```
{device A}
[edit]
user@host# edit services rpm
user@host# set probe customerC
```
2. Configure the RPM test.

```
{device A}
[edit services rpm]
user@host# edit services rpm probe customerC
user@host# set test tcp-test probe-interval 5
```
3. Set the probe type.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test probe-type tcp-ping
```
4. Specify the target address.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test target address 192.162.45.6
```
5. Configure the destination interface.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test destination-interface lt-0/0/0
```
6. Configure port 50000 as the TCP port to which the RPM probes are sent.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test destination-port 50000
```
7. Configure device B to act as a TCP server using port 50000.

```
{device B}
[edit]
user@host# edit services rpm
user@host# set probe-server tcp port 50000
```
8. Configure device B to act as a UDP server using port 50037.

```
{device B}
[edit services rpm]
```

```
user@host# set probe-server udp port 50037
```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services rpm
  probe customerC {
    test tcp-test {
      probe-type tcp-ping;
      target address 192.162.45.6;
      probe-interval 5;
      destination-port 50000;
      destination-interface lt-0/0/0.0;
    }
  }
  probe-server {
    tcp {
      port 50000;
    }
    udp {
      port 50037;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying RPM Probe Servers

**Purpose** Confirm that the configuration is working properly.

Verify that the device is configured to receive and transmit TCP and UDP RPM probes on the correct ports.

**Action** From configuration mode, enter the **show services rpm active-servers** command. The output shows a list of the protocols and corresponding ports for which the device is configured as an RPM server.

```
user@host> show services rpm active-servers

Protocol: TCP, Port: 50000

Protocol: UDP, Port: 50037
```

- Related Documentation**

  - [Example: Configuring RPM Probes for BGP Monitoring on page 1198](#)
  - [Tuning RPM Probes on page 1202](#)

## Example: Configuring RPM Probes for BGP Monitoring

This example shows how to configure RPM probes to monitor BGP neighbors.

- [Requirements on page 1198](#)
- [Overview on page 1198](#)
- [Configuration on page 1198](#)
- [Verification on page 1200](#)

---

### Requirements

Before you begin:

- Configure the BGP parameters under RPM configuration to send RPM probes to BGP neighbors. See [“Example: Configuring Basic RPM Probes” on page 1191](#).
- Use TCP or UDP probes by configure both the probe server (Juniper Networks device) and the probe receiver (the remote device) to transmit and receive RPM probes on the same TCP or UDP port. See [“Example: Configuring RPM Using TCP and UDP Probes” on page 1195](#).

---

### Overview

In this example, you specify a hexadecimal value that you want to use for the data portion of the RPM probe as ABCD123. ( It ranges from 1 through 2048 characters.) You specify the data size of the RPM probe as 1024 bytes. ( The value ranges from 0 through 65,507.)

Then you configure destination port 50000 as the TCP port to which the RPM probes are sent. You specify the number of probe results to be saved in the probe history as 25. (It ranges from 0 through 255, and the default is 50.) You set the probe count to 5 and probe interval as 1. (The probe count ranges from 1 through 15, and the default is 1; and the probe interval ranges from 1 through 255, and the default is 3.) You then specify tcp-ping as the type of probe to be sent as part of the test.

Finally, you set the test interval as 60. The value ranges from 0 through 86,400 seconds for the interval between tests.

---

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm bgp data-fill ABCD123 data-size 1024
set services rpm bgp destination-port 50000 history-size 25
set services rpm bgp probe-count 5 probe-interval 1
set services rpm bgp probe-type tcp-ping test-interval 60
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure RPM probes to monitor BGP neighbors:

1. Configure the RPM and BGP.  

```
[edit]
user@host# edit services rpm bgp
```
2. Specify a hexadecimal value.  

```
[edit services rpm bgp]
user@host# set data-fill ABCD123
```
3. Specify the data size of the RPM probe.  

```
[edit services rpm bgp]
user@host# set data-size 1024
```
4. Configure the destination port.  

```
[edit services rpm bgp]
user@host# set destination-port 50000
```
5. Specify the number of probes.  

```
[edit services rpm bgp]
user@host# set history-size 25
```
6. Set the probe count and probe interval.  

```
[edit services rpm bgp]
user@host# set probe-count 5 probe-interval 1
```
7. Specify the type of probe.  

```
[edit services rpm bgp]
user@host# set probe-type tcp-ping
```

**NOTE:** If you do not specify the probe type the default ICMP probes are sent.

8. Set the test interval.  

```
[edit services rpm bgp]
user@host# set test-interval 60
```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services rpm
bgp {
  probe-type tcp-ping;
```

```
probe-count 5;
probe-interval 1;
test-interval 60;
destination-port 50000;
history-size 25;
data-size 1024;
data-fill ABCD123;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Verification

#### *Verifying RPM Probes for BGP Monitoring*

**Purpose** Confirm that the configuration is working properly.

Verify that the RPM probes for BGP monitoring is configured.

**Action** From configuration mode, enter the **show services rpm** command.

**Related Documentation**

- [RPM Overview on page 1185](#)

### Directing RPM Probes to Select BGP Devices

If a device has a large number of BGP neighbors configured, you can direct (filter) the RPM probes to a selected group of BGP neighbors rather than to all the neighbors. To identify the BGP devices to receive RPM probes, you can configure routing instances.

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To direct RPM probes to select BGP neighbors:

1. Configure routing instance **RI1** to send RPM probes to BGP neighbors within the routing instance.

```
[edit services rpm bgp]
user@host# set routing-instances RI1
```

2. If you are done configuring the device, enter **commit** from configuration mode.

## Configuring RPM Timestamping

To account for latency in the communication of probe messages, you can enable timestamping of the probe packets. You can timestamp the following RPM probe types: **icmp-ping**, **icmp-ping-timestamp**, **udp-ping**, and **udp-ping-timestamp**.

This example shows how to enable timestamping for customerA. The test for customerA is identified as customerA-test.

To configure timestamping:

1. Specify the RPM probe owner for which you want to enable timestamping.

```
[edit services rpm]
user@host# edit probe customerA
```

2. Specify a name for the test.

```
[edit services rpm probe customerA]
user@host# edit test customerA-test
```

3. Enable timestamping.

```
[edit services rpm probe customerA test customerA-test]
user@host# edit hardware-timestamp
```

4. (Optional) If preferred, indicate that you want timestamping to be only one-way.

```
[edit services rpm probe customerA test customerA-test]
user@host# edit one-way-hardware-timestamp
```

**NOTE:** You cannot include both the **source-address** and **hardware-timestamp** or **one-way-hardware-timestamp** statements at the **[edit services rpm probe probe-name test test-name]** hierarchy level simultaneously.

## Configuring IPv6 RPM Probes

You can configure IPv6 source and destination addresses for an IPv6-based RPM probe test.

To configure an IPv6 RPM test:

1. Specify the RPM probe owner for the probe you want to configure as an IPv6 test.

```
[edit services rpm]
user@host# edit probe customerA
```

2. Specify a name for the test.

```
[edit services rpm probe customerA]
user@host# edit test ipv6-test
```

3. Specify the probe type.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set probe-type icmp6-ping
```

4. Specify the source address for the test.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set source-address 2001:db8:1a:1112::20
```

5. Specify the target address for the test.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set target inet6-address 2001:db8:1a:1112::1
```

6. Configure the remaining RPM test parameters.

## Tuning RPM Probes

After configuring an RPM probe, you can set parameters to control probe functions, such as the interval between probes, the total number of concurrent probes that a system can handle, and the source address used for each probe packet. See [“Example: Configuring Basic RPM Probes” on page 1191](#).

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To tune RPM probes:

1. Set the maximum number of concurrent probes allowed on the system to 10.

```
[edit services rpm]
user@host# set probe-limit 10
```

2. Access the ICMP probe of customer A.

```
[edit]
user@host# edit services rpm probe customerA test icmp-test
```

- Set the time between probe transmissions to 15 seconds.

```
[edit services rpm probe customerA test icmp-test]
user@host# set probe-interval 15
```

- Set the number of probes within a test to 10.

```
[edit services rpm probe customerA test icmp-test]
user@host# set probe-count 10
```

- Set the source address for each probe packet to **192.168.2.9**. If you do not explicitly configure a source address, the address on the outgoing interface through which the probe is sent is used as the source address.

```
[edit services rpm probe customerA test icmp-test]
user@host# set source-address 192.168.2.9
```

- If you are done configuring the device, enter **commit** from configuration mode.

## RPM Configuration Options

You can configure real-time performance monitoring (RPM) parameters. See [Table 79](#) for a summary of the configuration options.

**Table 79: RPM Configuration Summary**

| Field                              | Function                                                                                                                                                                                                        | Your Action                                                                                                                                                                            |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Performance Probe Owners</b>    |                                                                                                                                                                                                                 |                                                                                                                                                                                        |
| Owner Name (required)              | Identifies an RPM owner for which one or more RPM tests are configured. In most implementations, the owner name identifies a network on which a set of tests is being run (a particular customer, for example). | Type the name of the RPM owner.                                                                                                                                                        |
| <b>Identification</b>              |                                                                                                                                                                                                                 |                                                                                                                                                                                        |
| Test name (required)               | Uniquely identifies the RPM test                                                                                                                                                                                | Type the name of the RPM test.                                                                                                                                                         |
| Target (Address or URL) (required) | IPv4 or IPv6 address or URL of probe target                                                                                                                                                                     | Type the IPv4 address, in dotted decimal notation, IPv6 address, or the URL of the probe target. If the target is a URL, type a fully formed URL that includes <b>http://</b> .        |
| Source Address                     | Explicitly configured IPv4 or IPv6 address to be used as the probe source address                                                                                                                               | Type the source address to be used for the probe. If the source address is not one of the device's assigned addresses, the packet uses the outgoing interface's address as its source. |

Table 79: RPM Configuration Summary (*continued*)

| Field                      | Function                                                                                                                                                                                                                                                                                                   | Your Action                                                                                                                                                                                                                                                                                               |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing Instance           | Particular routing instance over which the probe is sent                                                                                                                                                                                                                                                   | Type the routing instance name. The routing instance applies only to probes of type <b>icmp</b> , <b>icmp6-ping</b> , and <b>icmp-timestamp</b> . The default routing instance is <b>inet.0</b> .                                                                                                         |
| History Size               | Number of probe results saved in the probe history                                                                                                                                                                                                                                                         | Type a number between 0 and 255. The default history size is 50 probes.                                                                                                                                                                                                                                   |
| <b>Request Information</b> |                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                           |
| Probe Type (required)      | Specifies the type of probe to send as part of the test.                                                                                                                                                                                                                                                   | Select the desired probe type from the list: <ul style="list-style-type: none"> <li>• <b>http-get</b></li> <li>• <b>http-get-metadata</b></li> <li>• <b>icmp6-ping</b></li> <li>• <b>icmp-ping</b></li> <li>• <b>icmp-ping-timestamp</b></li> <li>• <b>tcp-ping</b></li> <li>• <b>udp-ping</b></li> </ul> |
| Interval                   | Sets the wait time (in seconds) between each probe transmission                                                                                                                                                                                                                                            | Type a number between 1 and 255 (seconds).                                                                                                                                                                                                                                                                |
| Test Interval (required)   | Sets the wait time (in seconds) between tests.                                                                                                                                                                                                                                                             | Type a number between 0 and 86400 (seconds).                                                                                                                                                                                                                                                              |
| Probe Count                | Sets the total number of probes to be sent for each test.                                                                                                                                                                                                                                                  | Type a number between 1 and 15.                                                                                                                                                                                                                                                                           |
| Destination Port           | Specifies the TCP or UDP port to which probes are sent.<br><br>To use TCP or UDP probes, you must configure the remote server as a probe receiver. Both the probe server and the remote server must be Juniper Networks devices configured to receive and transmit RPM probes on the same TCP or UDP port. | Type the number 7—a standard TCP or UDP port number—or a port number from 49152 through 65535.                                                                                                                                                                                                            |
| DSCP Bits                  | Specifies the Differentiated Services code point (DSCP) bits. This value must be a valid 6-bit pattern. The default is <b>000000</b> .                                                                                                                                                                     | Type a valid 6-bit pattern.                                                                                                                                                                                                                                                                               |
| Data Size                  | Specifies the size of the data portion of the ICMP probes.                                                                                                                                                                                                                                                 | Type a size (in bytes) between 0 and 65507.                                                                                                                                                                                                                                                               |
| Data Fill                  | Specifies the contents of the data portion of the ICMP probes.                                                                                                                                                                                                                                             | Type a hexadecimal value between 1 and 800h to use as the contents of the ICMP probe data.                                                                                                                                                                                                                |

Table 79: RPM Configuration Summary (*continued*)

| Field                           | Function                                                                                                                                                                                                                                                                                                                                                                      | Your Action                                            |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Hardware Timestamp              | <p>Enables timestamping of RPM probe messages. You can timestamp the following RPM probes to improve the measurement of latency or jitter:</p> <ul style="list-style-type: none"> <li>• ICMP ping</li> <li>• ICMP ping timestamp</li> <li>• UDP ping—destination port UDP-ECHO (port 7) only</li> <li>• UDP ping timestamp—destination port UDP-ECHO (port 7) only</li> </ul> | To enable timestamping, select the check box.          |
| <b>Maximum Probe Thresholds</b> |                                                                                                                                                                                                                                                                                                                                                                               |                                                        |
| Successive Lost Probes          | Sets the total number of probes that must be lost successively to trigger a probe failure and generate a system log message.                                                                                                                                                                                                                                                  | Type a number between 0 and 15.                        |
| Lost Probes                     | Sets the total number of probes that must be lost to trigger a probe failure and generate a system log message.                                                                                                                                                                                                                                                               | Type a number between 0 and 15.                        |
| Round Trip Time                 | Sets the total round-trip time (in microseconds), from the device to the remote server, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                     | Type a number between 0 and 60,000,000 (microseconds). |
| Jitter                          | Sets the total jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                                                        | Type a number between 0 and 60,000,000 (microseconds). |
| Standard Deviation              | Sets the maximum allowable standard deviation (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                                                                                  | Type a number between 0 and 60,000,000 (microseconds). |
| Egress Time                     | Sets the total one-way time (in microseconds), from the device to the remote server, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                        | Type a number between 0 and 60,000,000 (microseconds). |
| Ingress Time                    | Sets the total one-way time (in microseconds), from the remote server to the device, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                        | Type a number between 0 and 60,000,000 (microseconds)  |
| Jitter Egress Time              | Sets the total outbound-time jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                                          | Type a number between 0 and 60,000,000 (microseconds)  |
| Jitter Ingress Time             | Sets the total inbound-time jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                                           | Type a number between 0 and 60,000,000 (microseconds). |

Table 79: RPM Configuration Summary (*continued*)

| Field                               | Function                                                                                                                                                                       | Your Action                                                                                                                                                           |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress Standard Deviation           | Sets the maximum allowable standard deviation of outbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| Ingress Standard Deviation          | Sets the maximum allowable standard deviation of inbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message.  | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| <b>Traps</b>                        |                                                                                                                                                                                |                                                                                                                                                                       |
| Egress Jitter Exceeded              | Generates SNMP traps when the threshold for jitter in outbound time is exceeded.                                                                                               | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Egress Standard Deviation Exceeded  | Generates SNMP traps when the threshold for standard deviation in outbound times is exceeded.                                                                                  | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Egress Time Exceeded                | Generates SNMP traps when the threshold for maximum outbound time is exceeded.                                                                                                 | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Jitter Exceeded             | Generates SNMP traps when the threshold for jitter in inbound time is exceeded.                                                                                                | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Standard Deviation Exceeded | Generates SNMP traps when the threshold for standard deviation in inbound times is exceeded.                                                                                   | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Time Exceeded               | Generates traps when the threshold for maximum inbound time is exceeded.                                                                                                       | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Jitter Exceeded                     | Generates traps when the threshold for jitter in round-trip time is exceeded.                                                                                                  | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Probe Failure                       | Generates traps when the threshold for the number of successive lost probes is reached.                                                                                        | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| RTT Exceeded                        | Generates traps when the threshold for maximum round-trip time is exceeded.                                                                                                    | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Standard Deviation Exceeded         | Generates traps when the threshold for standard deviation in round-trip times is exceeded.                                                                                     | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |

Table 79: RPM Configuration Summary (*continued*)

| Field                           | Function                                                                           | Your Action                                                                                                                                                           |
|---------------------------------|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Test Completion                 | Generates traps when a test is completed.                                          | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Test Failure                    | Generates traps when the threshold for the total number of lost probes is reached. | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| <b>Performance Probe Server</b> |                                                                                    |                                                                                                                                                                       |
| TCP Probe Server                | Specifies the port on which the device is to receive and transmit TCP probes.      | Type the number 7—a standard TCP or UDP port number—or a port number from 49160 through 65535.                                                                        |
| UDP Probe Server                | Specifies the port on which the device is to receive and transmit UDP probes.      | Type the number 7—a standard TCP or UDP port number—or a port number from 49160 through 65535.                                                                        |

## Monitoring RPM Probes

The RPM information includes the round-trip time, jitter, and standard deviation values for each configured RPM test on the device. To view these RPM properties, select **Troubleshoot > RPM > View RPM** in the J-Web user interface, or in configuration mode enter the **show** command:

```
[edit]
user@host# run show services rpm probe-results
```

In addition to the RPM statistics for each RPM test, the J-Web user interface displays the round-trip times and cumulative jitter graphically. [Figure 28](#) shows sample graphs for an RPM test.

Figure 28: Sample RPM Graphs

Round Trip Time for Probe Owner 'customerA' Test 'icmp-test' (microsec

| Samples | Earliest Sample | Latest Sample | Mean Value | Standard Deviation |
|---------|-----------------|---------------|------------|--------------------|
| 50      | 06:31           | 06:37         | 1105.18    | 2646.66            |

Cumulative Jitter for Probe Owner 'customerA' Test 'icmp-test' (microsec

| Samples | Earliest Sample | Latest Sample | Mean Value | Standard Deviation |
|---------|-----------------|---------------|------------|--------------------|
| 50      | 06:31           | 06:37         | 1375.32    | 3381.55            |

In Figure 28, the round-trip time and jitter values are plotted as a function of the system time. Large spikes in round-trip time or jitter indicate a slower outbound (egress) or inbound (ingress) time for the probe sent at that particular time.

Table 80 summarizes key output fields in RPM displays.

Table 80: Summary of Key RPM Output Fields

| Field                          | Values                                 | Additional Information                                                                                                          |
|--------------------------------|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Currently Running Tests</b> |                                        |                                                                                                                                 |
| Graph                          |                                        | Click the <b>Graph</b> link to display the graph (if it is not already displayed) or to update the graph for a particular test. |
| Owner                          | Configured owner name of the RPM test. | —                                                                                                                               |
| Test Name                      | Configured name of the RPM test.       | —                                                                                                                               |

Table 80: Summary of Key RPM Output Fields (*continued*)

| Field                              | Values                                                                                                                                                                                                                                                                                                            | Additional Information                                                                                                                                                          |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Probe Type                         | Type of RPM probe configured for the specified test: <ul style="list-style-type: none"> <li>• <b>http-get</b></li> <li>• <b>http-get-metadata</b></li> <li>• <b>icmp-ping</b></li> <li>• <b>icmp6-ping</b></li> <li>• <b>icmp-ping-timestamp</b></li> <li>• <b>tcp-ping</b></li> <li>• <b>udp-ping</b></li> </ul> | —                                                                                                                                                                               |
| Target Address                     | IPv4 address, IPv6 address, or URL of the remote server that is being probed by the RPM test.                                                                                                                                                                                                                     | —                                                                                                                                                                               |
| Source Address                     | Explicitly configured IPv4 or IPv6 source address that is included in the probe packet headers.                                                                                                                                                                                                                   | If no source address is configured, the RPM probe packets use the outgoing interface as the source address, and the Source Address field is empty.                              |
| Minimum RTT                        | Shortest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test.                                                                                                                                                                                          | —                                                                                                                                                                               |
| Maximum RTT                        | Longest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test.                                                                                                                                                                                           | —                                                                                                                                                                               |
| Average RTT                        | Average round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test.                                                                                                                                                                                           | —                                                                                                                                                                               |
| Standard Deviation RTT             | Standard deviation of round-trip times from the Juniper Networks device to the remote server, as measured over the course of the test.                                                                                                                                                                            | —                                                                                                                                                                               |
| Probes Sent                        | Total number of probes sent over the course of the test.                                                                                                                                                                                                                                                          | —                                                                                                                                                                               |

- [Example: Configuring Chassis Cluster Redundancy Group IP Address Monitoring on page 1221](#)

### IP Monitoring Overview

This feature monitors IP on standalone SRX Series devices or a chassis cluster redundant Ethernet (reth) interface. Existing RPM probes are sent to an IP address to check for reachability. The user takes action based on the reachability result. Supported action currently is preferred static route injection to system route table.

The actions supported are:

- Adding or deleting a new static route that has a higher priority (lower preference) value than a route configured through the CLI command **set routing-options static route**
- Defining multiple probe names under the same IP monitoring policy. If any probe fails, the action is taken. If all probes are reachable, the action is reverted
- Configuring multiple tests in one RPM probe. All tests must fail for the RPM probe to be considered unreachable. If at least one test reaches its target, the RPM probe is considered reachable
- Configuring multiple failure thresholds in one RPM test. If one threshold is reached, the test fails. If no thresholds are reached, the test succeeds.
- Specifying the no-preempt option. If the no-preempt option is specified, the policy does not perform preemptive failback when it is in a failover state or when the RPM probe test recovers from a failure.
- Setting preferred metric values. If the preferred metric value is set, during failover, the route is injected with the set preferred metric value.
- Enabling and disabling interfaces.
  - **Interface-Enable**—On a physical or logical interface, when the interface-enable action is configured, the initial state of the interface is disable after startup, and it continues to remain in the disable state as long as the associated RPM probe is in

the pass state. When the associated RPM probe fails, the configured physical and logical interfaces are enabled.

- **Interface-Disable**—On a physical or logical interface, when the interface-disable action is configured, the interface state remains unchanged. When the associated RPM probe fails, the physical and logical interfaces are disabled.

**NOTE:** Multiple probe names and actions can be defined for the same IP monitoring policy.

## Understanding IP Monitoring Test Parameters

Each probed target is monitored over the course of a test, which represents a collection of probes during which statistics such as standard deviation and jitter are collected are calculated. During a test, probes are generated and responses collected at a rate defined by the probe interval, the number of seconds between probes.

**NOTE:** To avoid flap, an action is reverted only at the end of a test cycle. During the test cycle, if no threshold is reached, the action is reverted. Although action-failover takes place based on a predefined condition of a monitored IP, when the condition is reversed, the IP becomes reachable on the original route, and the newly added route is deleted. Recovery is performed only when all RPM probes report the IP as reachable.

Table 81 lists the test parameters and its default values:

**Table 81: Test Parameters and Default Values**

| Parameter      | Default Value |
|----------------|---------------|
| probe-count    | 1             |
| probe-interval | 3 seconds     |
| test-interval  | 1 second      |

Table 82 lists the supported threshold and its description:

**Table 82: Threshold Supported and Description**

| Threshold       | Description                     |
|-----------------|---------------------------------|
| Successive-Loss | Successive loss count of probes |
| Total-Loss      | Total probe lost count          |

## Example: Configuring IP Monitoring on Branch SRX Series Devices

This example shows how to monitor IP on branch SRX Series devices.

- [Requirements on page 1213](#)
- [Overview on page 1213](#)
- [Configuration on page 1213](#)
- [Verification on page 1215](#)

### Requirements

Before you begin:

Configure the following RPM options for RPM test:

- target-address
- probe-count
- probe-interval
- test-interval
- thresholds
- next-hop

### Overview

This example shows how to set up IP monitoring on an SRX Series for the branch device.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, past them into a text file, remove any line breaks, change any details to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm probe Probe-Payment-Server test paysvr target address 1.1.1.10
set services rpm probe Probe-Payment-Server test paysvr probe-count 10
set services rpm probe Probe-Payment-Server test paysvr probe-interval 5
set services rpm probe Probe-Payment-Server test paysvr test-interval 5
set services rpm probe Probe-Payment-Server test paysvr thresholds successive-loss 10
set services rpm probe Probe-Payment-Server test paysvr next-hop 2.2.2.1
set services ip-monitoring policy Payment-Server-Tracking match rpm-probe
Probe-Payment-Server
set services ip-monitoring policy Payment-Server-Tracking then preferred-route route
1.1.1.0/24 next-hop 1.1.1.99
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure IP monitoring on an SRX Series Services Gateway:

1. Configure the target address under the RPM probe.

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr target address
1.1.1.10
```

2. Configure the probe count under the RPM probe.

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr probe-count
10
```

3. Configure the probe interval (in seconds) under the RPM probe.

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr probe-interval
5
```

4. Configure the test interval (in seconds) under the RPM probe.

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr test-interval
5
```

5. Configure the threshold successive loss count under the RPM

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr thresholds
successive-loss 10
```

6. Configure the next-hop IP address under the RPM probe.

```
[edit ]
user@host# set services rpm probe Probe-Payment-Server test paysvr next-hop
2.2.2.1
```

7. Configure the IP monitoring policy under services.

```
[edit ]
user@host# set services ip-monitoring policy Payment-Server-Tracking match
rpm-probe Probe-Payment-Server
```

**NOTE:** The following steps are not mandatory. You can configure interface actions and route actions independently, or you can configure both the interface action and the route action together in one IP monitoring policy.

8. Configure the IP monitoring preferred route under services.

```
[edit ]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
preferred-route route 1.1.1.0/24 preferred-metric 4
```

## 9. Configure the IP monitoring interface actions.

- Enable

```
[edit ]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
interface ge-0/0/1 enable
```

- Disable

```
[edit ]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
interface fe-0/0/[4-6] disable
```

## 10. Configure the no-preempt option.

```
[edit ]
user@host# set services ip-monitoring policy Payment-Server-Tracking no-preempt
```

### Verification

#### Verifying IP Monitoring

**Purpose** Verify the IP monitoring status of a policy.

**Action** To verify the configuration is working properly, enter the following command:

```
show services ip-monitoring status <policy-name>
```

- [Understanding IP Monitoring Test Parameters on page 1212](#)

## Understanding IP Monitoring Through Redundant Ethernet Interface Link Aggregation Groups

IP monitoring checks the reachability of an upstream device. It is designed to check the end-to-end connectivity of configured IP addresses and allows a redundancy group (RG) to automatically failover when the monitored IP address is not reachable through the redundant Ethernet. Both the primary and secondary devices in the chassis cluster monitor specific IP addresses to determine whether an upstream device in the network is reachable.

A redundant Ethernet interface contains physical interfaces from both the primary and secondary nodes in the SRX Series chassis cluster. In a redundant Ethernet interface, two physical interfaces are configured with each node contributing one physical interface. In a redundant Ethernet interface LAG, more than two physical interfaces are configured in the redundant Ethernet interface.

**Related Documentation**

- [IP Monitoring Overview on page 1211](#)

## Example: Configuring IP Monitoring on High-End SRX Series Devices

This example shows how to monitor IP on a high-end SRX Series device with chassis cluster enabled.

- [Requirements on page 1216](#)
- [Overview on page 1216](#)
- [Configuration on page 1217](#)
- [Verification on page 1219](#)

---

### Requirements

- You need two SRX5800 Services Gateways with identical hardware configurations, one SRX Series device and one EX8208 Ethernet Switch.
- Physically connect the two SRX5800 devices (back-to-back for the fabric and control ports) and ensure that they are the same models. Configure/add these two devices in a cluster.

---

### Overview

IP address monitoring checks end-to-end reachability of configured IP address and allows a redundancy group to automatically fail over when not reachable through the child link of redundant Ethernet interface (known as a reth) interface. Redundancy groups on both devices in a cluster can be configured to monitor specific IP addresses to determine whether an upstream device in the network is reachable.

This example shows how to set up IP monitoring on a high-end SRX Series device.

**NOTE:** IP monitoring is not supported on an NP-IOC card.

---

### Topology

[Figure 29](#) shows the topology used in this example.

**Figure 29: IP Monitoring on a High-End SRX Series Device Topology Example**

In this example, two SRX5800 devices in a chassis cluster are connected to an SRX650 device through an EX8208 Ethernet Switch. The example shows how the redundancy groups can be configured to monitor key upstream resources reachable through redundant Ethernet interfaces on either node in a cluster.

### Configuration

- [Configuring IP Monitoring on a High-End SRX Series Device on page 1218](#)

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis cluster reth-count 1
set chassis cluster redundancy-group 0 node 0 priority 254
set chassis cluster redundancy-group 0 node 1 priority 1
set chassis cluster redundancy-group 1 node 0 priority 200
set chassis cluster redundancy-group 1 node 1 priority 199
set chassis cluster redundancy-group 1 ip-monitoring global-weight 255
set chassis cluster redundancy-group 1 ip-monitoring global-threshold 80
set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
set chassis cluster redundancy-group 1 ip-monitoring family inet 111.111.111.111
weight 80
set chassis cluster redundancy-group 1 ip-monitoring family inet 111.111.111.111
interface reth0.0 secondary-ip-address 12.1.1.3
set interfaces ge-0/0/1 gigether-options redundant-parent reth0
```

```

set interfaces ge-4/0/1 gigether-options redundant-parent reth0
set interfaces reth0 redundant-ether-options redundancy-group 1
set interfaces reth0 unit 0 family inet address 12.1.1.1/24
set routing-options static route 111.111.111.111/32 next-hop 12.1.1.2

```

### Configuring IP Monitoring on a High-End SRX Series Device

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure IP monitoring on a high-end SRX Series device:

- Specify the number of redundant Ethernet interfaces.
 

```

{primary:node0}[edit]
user@host# set chassis cluster reth-count 1

```
- Specify a redundancy group's priority for primacy on each node of the cluster. The higher number takes precedence.
 

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 0 node 0 priority 254
user@host# set chassis cluster redundancy-group 0 node 1 priority 1
user@host# set chassis cluster redundancy-group 1 node 0 priority 200
user@host# set chassis cluster redundancy-group 1 node 1 priority 199

```
- Configure the redundant Ethernet interfaces to redundancy-group 1.
 

```

{primary:node0}[edit]
user@host# set interfaces reth0 redundant-ether-options redundancy-group 1
user@host# set interfaces reth0 unit 0 family inet address 12.1.1.1/24

```
- Assign child interfaces for the redundant Ethernet interfaces from node 0 and node 1.
 

```

{primary:node0}[edit]
user@host# set interfaces ge-0/0/1 gigether-options redundant-parent reth0
user@host# set interfaces ge-4/0/1 gigether-options redundant-parent reth0

```
- Configure the static route to the IP address that is to be monitored.
 

```

{primary:node0}[edit]
user@host# set routing-options static route 111.111.111.111/32 next-hop 12.1.1.2

```
- Configure IP monitoring under redundancy-group 1 with global weight and global threshold.
 

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-weight 255
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-threshold 80

```
- Specify the retry interval.
 

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3

```
- Specify the retry count.
 

```

{primary:node0}[edit]

```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
```

9. Assign a weight to the IP address to be monitored, and configure a secondary IP address that will be used to send ICMP packets from the secondary node to track the IP being monitored.

```
{primary:node0}[edit]
```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet  
111.111.111.111 weight 80
```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet  
111.111.111.111 interface reth0.0 secondary-ip-address 12.1.1.3
```

**NOTE:**

- The redundant Ethernet (reth0) IP address, 12.1.1.1/24, is used to send ICMP packets from node 0 to check the reachability of the monitored IP.
- The secondary IP address, 12.1.1.3, should belong to the same network as the reth0 IP address.
- The secondary IP address is used to send ICMP packets from node 1 to check the reachability of the monitored IP.

### Verification

Confirm the configuration is working properly.

- [Verifying Chassis Cluster Status—Before Failover on page 1219](#)
- [Verifying Chassis Cluster IP Monitoring Status—Before Failover on page 1220](#)
- [Verifying Chassis Cluster Status—After Failover on page 1220](#)
- [Verifying Chassis Cluster IP Monitoring Status—After Failover on page 1221](#)

#### *Verifying Chassis Cluster Status—Before Failover*

**Purpose** Verify the chassis cluster status, failover status, and redundancy group information before failover.

**Action** From operational mode, enter the **show chassis cluster status** command.

```
show chassis cluster status
```

Cluster ID: 11

| Node | Priority | Status | Preempt | Manual failover |
|------|----------|--------|---------|-----------------|
|------|----------|--------|---------|-----------------|

Redundancy group: 0 , Failover count: 0

|       |     |           |    |    |
|-------|-----|-----------|----|----|
| node0 | 254 | primary   | no | no |
| node1 | 1   | secondary | no | no |

Redundancy group: 1 , Failover count: 0

|       |     |           |    |    |
|-------|-----|-----------|----|----|
| node0 | 200 | primary   | no | no |
| node1 | 199 | secondary | no | no |

#### *Verifying Chassis Cluster IP Monitoring Status—Before Failover*

**Purpose** Verify the IP status being monitored from both nodes and the failover count for both nodes before failover.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status redundancy-group 1** command.

```
show chassis cluster ip-monitoring status redundancy-group 1
```

node0:

Redundancy group: 1

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

node1:

Redundancy group: 1

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

#### *Verifying Chassis Cluster Status—After Failover*

**Purpose** Verify the chassis cluster status, failover status, and redundancy group information after failover.

**NOTE:** If the IP address is not reachable, the following output will be displayed.

**Action** From operational mode, enter the **show chassis cluster status** command.

```
show chassis cluster status
```

```
Cluster ID: 11
Node          Priority      Status    Preempt  Manual failover

Redundancy group: 0 , Failover count: 0
  node0        254         primary   no        no
  node1         1         secondary no        no

Redundancy group: 1 , Failover count: 1
  node0         0         secondary no        no
  node1        199         primary  no        no
```

#### *Verifying Chassis Cluster IP Monitoring Status—After Failover*

**Purpose** Verify the IP status being monitored from both nodes and the failover count for both nodes after failover.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status redundancy-group 1** command.

```
show chassis cluster ip-monitoring status redundancy-group 1
```

```
node0:
```

```
Redundancy group: 1
```

| IP address      | Status      | Failure count | Reason  |
|-----------------|-------------|---------------|---------|
| 111.111.111.111 | unreachable | 1             | unknown |

```
node1:
```

```
Redundancy group: 1
```

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

**Related Documentation**

### Example: Configuring Chassis Cluster Redundancy Group IP Address Monitoring

This example shows how to configure redundancy group IP address monitoring for an SRX Series device in a chassis cluster.

- [Requirements on page 1222](#)
- [Overview on page 1222](#)
- [Configuration on page 1222](#)
- [Verification on page 1224](#)

## Requirements

---

Before you begin:

- Set the chassis cluster node ID and cluster ID. See *Example: Setting the Chassis Cluster Node ID and Cluster ID for Branch SRX Series Devices* or *Example: Setting the Chassis Cluster Node ID and Cluster ID for High-End SRX Series Devices*.
- Configure the chassis cluster management interface. See *Example: Configuring the Chassis Cluster Management Interface*.
- Configure the chassis cluster fabric. See *Example: Configuring the Chassis Cluster Fabric Interfaces*.

## Overview

---

You can configure redundancy groups to monitor upstream resources by pinging specific IP addresses that are reachable through redundant Ethernet interfaces on either node in a cluster. You can also configure global threshold, weight, retry interval, and retry count parameters for a redundancy group. When a monitored IP address becomes unreachable, the weight of that monitored IP address is deducted from the redundancy group IP address monitoring global threshold. When the global threshold reaches 0, the global weight is deducted from the redundancy group threshold. The retry interval determines the ping interval for each IP address monitored by the redundancy group. The pings are sent as soon as the configuration is committed. The retry count sets the number of allowed consecutive ping failures for each IP address monitored by the redundancy group.

In this example, you configure the following settings for redundancy group 1:

- IP address to monitor—10.1.1.10
- IP address monitoring global-weight—100
- IP address monitoring global-threshold—200

**NOTE:** The threshold applies cumulatively to all IP addresses monitored by the redundancy group.

- IP address retry-interval—3 seconds
- IP address retry-count—10
- Weight—150
- Redundant Ethernet interface—reth1.0
- Secondary IP address—10.1.1.101

## Configuration

---

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, and copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
{primary:node0}[edit]
user@host#
set chassis cluster redundancy-group 1 ip-monitoring global-weight 100
set chassis cluster redundancy-group 1 ip-monitoring global-threshold 200
set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
set chassis cluster redundancy-group 1 ip-monitoring family inet 10.1.1.10 weight 150
interface reth1.0 secondary-ip-address 10.1.1.101
```

#### Step-by-Step Procedure

To configure redundancy group IP address monitoring:

1. Specify a global monitoring weight.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-weight
100
```

2. Specify the global monitoring threshold.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-threshold
200
```

3. Specify the retry interval.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
```

4. Specify the retry count.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
```

5. Specify the IP address to be monitored, weight, redundant Ethernet interface, and secondary IP address.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet 10.1.1.10
weight 100 interface reth1.0 secondary-ip-address 10.1.1.101
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis cluster redundancy-group 1** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For brevity, this **show** command output includes only the configuration that is relevant to this example. Any other configuration on the system has been replaced with ellipses (...).

```
{primary:node0}[edit]
user@host# show chassis cluster redundancy-group 1
ip-monitoring {
  global-weight 100;
  global-threshold 200;
  family {
    inet {
```

```

    10.1.1.10 {
        weight 100;
        interface reth1.0 secondary-ip-address 10.1.1.101;
    }
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Status of Monitored IP Addresses for a Redundancy Group

**Purpose** Verify the status of monitored IP addresses for a redundancy group.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status** command. For information about a specific group, enter the **show chassis cluster ip-monitoring status redundancy-group** command.

```

{primary:node0}
user@host> show chassis cluster ip-monitoring status
node0:
-----

```

```

### Displaying Real-Time Information from Device to Host

---

- [Displaying Multicast Path Information on page 1225](#)
- [Displaying Real-Time Monitoring Information on page 1228](#)

### Displaying Multicast Path Information

To display information about a multicast path from a source to the device, enter the **mtrace from-source** command with the following syntax:

```
user@host> mtrace from-source source host <extra-hops number> <group address>
<interval seconds> <max-hops number> <max-queries number> <response host>
<routing-instance routing-instance-name> <tll number> <wait-time seconds> <loop>
<multicast-response | unicast-response> <no-resolve> <no-router-alert> <brief |
detail>
```

[Table 83](#) describes the **mtrace from-source** command options.

**Table 83: CLI mtrace from-source Command Options**

| Option                   | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>source host</b>       | Traces the path to the specified hostname or IP address.                                                          |
| <b>extra-hops number</b> | (Optional) Sets the number of extra hops to trace past nonresponsive devices. Specify a value from 0 through 255. |

Table 83: CLI mtrace from-source Command Options (*continued*)

| Option                                        | Description                                                                                                                                                                                                                                                                         |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>group address</b>                          | (Optional) Traces the path for the specified group address. The default value is <b>0.0.0.0</b> .                                                                                                                                                                                   |
| <b>interval seconds</b>                       | (Optional) Sets the interval between statistics gathering. The default value is <b>10</b> .                                                                                                                                                                                         |
| <b>max-hops number</b>                        | (Optional) Sets the maximum number of hops to trace toward the source. Specify a value from <b>0</b> through <b>255</b> . The default value is <b>32</b> .                                                                                                                          |
| <b>max-queries number</b>                     | (Optional) Sets the maximum number of query attempts for any hop. Specify a value from <b>1</b> through <b>32</b> . The default value is <b>3</b> .                                                                                                                                 |
| <b>response host</b>                          | (Optional) Sends the response packets to the specified hostname or IP address. By default, the response packets are sent to the device.                                                                                                                                             |
| <b>routing-instance routing-instance-name</b> | (Optional) Traces the routing instance you specify.                                                                                                                                                                                                                                 |
| <b>ttl number</b>                             | (Optional) Sets the time-to-live (TTL) value in the IP header of the query packets. Specify a hop count from <b>0</b> through <b>255</b> . The default value for local queries to the <b>all routers</b> multicast group is <b>1</b> . Otherwise, the default value is <b>127</b> . |
| <b>wait-time seconds</b>                      | (Optional) Sets the time to wait for a response packet. The default value is <b>3</b> seconds.                                                                                                                                                                                      |
| <b>loop</b>                                   | (Optional) Loops indefinitely, displaying rate and loss statistics. To quit the <b>mtrace</b> command, press Ctrl-C.                                                                                                                                                                |
| <b>multicast-response</b>                     | (Optional) Forces the responses to use multicast.                                                                                                                                                                                                                                   |
| <b>unicast-response</b>                       | (Optional) Forces the response packets to use unicast.                                                                                                                                                                                                                              |
| <b>no-resolve</b>                             | (Optional) Does not display hostnames.                                                                                                                                                                                                                                              |
| <b>no-router-alert</b>                        | (Optional) Does not use the device alert IP option in the IP header.                                                                                                                                                                                                                |
| <b>brief</b>                                  | (Optional) Does not display packet rates and losses.                                                                                                                                                                                                                                |
| <b>detail</b>                                 | (Optional) Displays packet rates and losses if a group address is specified.                                                                                                                                                                                                        |

The following is sample output from the **mtrace from-source** command:

```

user@host> mtrace from-source source 192.1.4.1 group 224.1.1.1

Mtrace from 192.1.4.1 to 192.1.30.2 via group 224.1.1.1 Querying full reverse

```

Each line of the trace display is usually in the following format (depending on the options selected and the responses from the devices along the path):

*hop-number host (ip-address) protocolttl*

Table 84 summarizes the output fields of the display.

**NOTE:** The packet statistics gathered from Juniper Networks devices and routing nodes always display as 0.

**Table 84: CLI mtrace from-source Command Output Summary**

| Field                                     | Description                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hop-number</i>                         | Number of the hop (device) along the path.                                                                                                      |
| <i>host</i>                               | Hostname, if available, or IP address of the device. If the <b>no-resolve</b> option was entered in the command, the hostname is not displayed. |
| <i>ip-address</i>                         | IP address of the device.                                                                                                                       |
| <i>protocol</i>                           | Protocol used.                                                                                                                                  |
| <i>ttl</i>                                | TTL threshold.                                                                                                                                  |
| <b>Round trip time milliseconds ms</b>    | Total time between the sending of the query packet and the receiving of the response packet.                                                    |
| <b>total ttl of number required</b>       | Total number of hops required to reach the source.                                                                                              |
| <b>Source</b>                             | Source IP address of the response packet.                                                                                                       |
| <b>Response Dest</b>                      | Response destination IP address.                                                                                                                |
| <b>Overall</b>                            | Average packet rate for all traffic at each hop.                                                                                                |
| <b>Packet Statistics For Traffic From</b> | Number of packets lost, number of packets sent, percentage of packets lost, and average packet rate at each hop.                                |
| <b>Receiver</b>                           | IP address receiving the multicast packets.                                                                                                     |
| <b>Query Source</b>                       | IP address of the host sending the query packets.                                                                                               |

## Displaying Real-Time Monitoring Information

To display real-time monitoring information about each device between the device and a specified destination host, enter the **traceroute monitor** command with the following syntax:

```
user@host> traceroute monitor host <count number> <inet | inet6> <interval seconds>
<no-resolve> <size bytes> <source source-address> <summary>
```

Table 85 describes the **traceroute monitor** command options.

**Table 85: CLI traceroute monitor Command Options**

| Option                  | Description                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>             | Sends traceroute packets to the hostname or IP address you specify.                                                                                                       |
| <i>count number</i>     | (Optional) Limits the number of ping requests, in packets, to send in summary mode. If you do not specify a count, ping requests are continuously sent until you press Q. |
| <i>inet</i>             | (Optional) Forces the traceroute packets to an IPv4 destination.                                                                                                          |
| <i>inet6</i>            | (Optional) Forces the traceroute packets to an IPv6 destination.                                                                                                          |
| <i>interval seconds</i> | (Optional) Sets the interval between ping requests, in seconds. The default value is 1 second.                                                                            |
| <i>no-resolve</i>       | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                                                            |
| <i>size bytes</i>       | (Optional) Sets the size of the ping request packet. The size can be from 0 through 65,468 bytes. The default packet size is 64 bytes.                                    |
| <i>source address</i>   | (Optional) Uses the source address that you specify, in the traceroute packet.                                                                                            |
| <i>summary</i>          | (Optional) Displays the summary traceroute information.                                                                                                                   |

To quit the **traceroute monitor** command, press Q.

The following is sample output from a **traceroute monitor** command:

```
user@host> traceroute monitor host2
My traceroute  [v0.69]
host (0.0.0.0)(tos=0x0 psize=64 bitpattern=0x00)
Wed Mar 14 23:14:11 2007

## Monitoring MGCP ALGs

This section contains the following topics:

- [Monitoring MGCP ALG Calls on page 1231](#)
- [Monitoring MGCP ALG Counters on page 1232](#)
- [Monitoring MGCP ALG Endpoints on page 1233](#)

### Monitoring MGCP ALG Calls

**Purpose** View information about MGCP ALG calls.

**Action** Select **Monitor>ALGs>MGCP>Calls** in the J-Web user interface. To view detailed information, select the endpoint on the MGCP calls page.

Alternatively, enter the **show security alg mgcp calls** command.

Table 88 summarizes key output fields in the MGCP calls display.

**Table 88: Summary of Key MGCP Calls Output Fields**

| Field                          | Values                                                                                                           | Additional Information |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>MGCP Calls Information</b>  |                                                                                                                  |                        |
| Endpoint@GW                    | Endpoint name.                                                                                                   | —                      |
| Zone                           | <ul style="list-style-type: none"> <li><b>trust</b>—Trust zone.</li> <li><b>untrust</b>—Untrust zone.</li> </ul> | —                      |
| Call ID                        | Call identifier for ALG MGCP.                                                                                    | —                      |
| RM Group                       | Resource manager group ID.                                                                                       | —                      |
| Call Duration                  | Duration for which connection is active.                                                                         | —                      |
| Connection Id                  | Connection identifier for MGCP ALG calls.                                                                        | —                      |
| <b>Calls Details: Endpoint</b> |                                                                                                                  |                        |
| Local SDP                      | IP address of the MGCP ALG local call owner, as per the Session Description Protocol (SDP).                      | —                      |
| Remote SDP                     | Remote IP address of the MGCP ALG remote call owner, as per the Session Description Protocol (SDP).              | —                      |

### Monitoring MGCP ALG Counters

**Purpose** View MGCP ALG counters information.

**Action** Select **Monitor>ALGs>MGCP>Counters** in the J-Web user interface, or enter the **show security alg mgcp counters** command.

Table 89 summarizes key output fields in the MGCP counters display.

**Table 89: Summary of Key MGCP Counters Output Fields**

| Field                            | Values                                | Additional Information |
|----------------------------------|---------------------------------------|------------------------|
| <b>MGCP Counters Information</b> |                                       |                        |
| Packets received                 | Number of MGCP ALG packets received.  | —                      |
| Packets dropped                  | Number of MGCP ALG packets dropped.   | —                      |
| Message received                 | Number of MGCP ALG messages received. | —                      |
| Number of connections            | Number of MGCP ALG connections.       | —                      |

Table 89: Summary of Key MGCP Counters Output Fields (*continued*)

| Field                         | Values                                             | Additional Information |
|-------------------------------|----------------------------------------------------|------------------------|
| Number of active connections  | Number of active MGCP ALG connections.             | —                      |
| Number of calls               | Number of MGCP ALG calls.                          | —                      |
| Number of active calls        | Number of MGCP ALG active calls.                   | —                      |
| Number of active transactions | Number of active transactions.                     | —                      |
| Number of re-transmission     | Number of MGCP ALG retransmissions.                | —                      |
| <b>Error Counters</b>         |                                                    |                        |
| Unknown-method                | MGCP ALG unknown method errors.                    | —                      |
| Decoding error                | MGCP ALG decoding errors.                          | —                      |
| Transaction error             | MGCP ALG transaction errors.                       | —                      |
| Call error                    | MGCP ALG counter errors.                           | —                      |
| Connection error              | MGCP ALG connection errors.                        | —                      |
| Connection flood drop         | MGCP ALG connection flood drop errors.             | —                      |
| Message flood drop            | MGCP ALG message flood drop errors.                | —                      |
| IP resolve error              | MGCP ALG IP address resolution errors.             | —                      |
| NAT error                     | MGCP ALG Network Address Translation (NAT) errors. | —                      |
| Resource manager error        | MGCP ALG resource manager errors.                  | —                      |

### Monitoring MGCP ALG Endpoints

**Purpose** View information about MGCP ALG endpoints.

**Action** Select **Monitor>ALGs>MGCP>Endpoints** in the J-Web user interface. To view detailed information, select the gateway on the MGCP endpoints page.

Alternatively, enter the **show security alg mgcp endpoints** command.

[Table 90](#) summarizes key output fields in the MGCP endpoints display.

Table 90: Summary of Key MGCP Endpoints Output Fields

| Field                          | Values                                                                                                           | Additional Information |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>MGCP Endpoints</b>          |                                                                                                                  |                        |
| Gateway                        | IP address of the gateway.                                                                                       | —                      |
| Zone                           | <ul style="list-style-type: none"> <li><b>trust</b>—Trust zone.</li> <li><b>untrust</b>—Untrust zone.</li> </ul> | —                      |
| IP                             | IP address.                                                                                                      | —                      |
| <b>Endpoints: Gateway name</b> |                                                                                                                  |                        |
| Endpoint                       | Endpoint name.                                                                                                   | —                      |
| Transaction #                  | Transaction identifier.                                                                                          | —                      |
| Call #                         | Call identifier.                                                                                                 | —                      |
| Notified Entity                | The certificate authority (CA) currently controlling the gateway.                                                | —                      |

## Monitoring SCCP ALGs

This section contains the following topics:

- [Monitoring SCCP ALG Calls on page 1234](#)
- [Monitoring SCCP ALG Counters on page 1235](#)

### Monitoring SCCP ALG Calls

**Purpose** View information about SCCP ALG calls.

**Action** Select **Monitor>ALGs>SCCP>Calls** in the J-Web user interface. To view detailed information, select the client IP address on the SCCP calls page.

Alternatively, enter the **show security alg sccp calls** command.

[Table 91](#) summarizes key output fields in the SCCP calls display.

Table 91: Summary of Key SCCP Calls Output Fields

| Field                         | Values | Additional Information |
|-------------------------------|--------|------------------------|
| <b>SCCP Calls Information</b> |        |                        |

Table 91: Summary of Key SCCP Calls Output Fields (*continued*)

| Field         | Values                             | Additional Information |
|---------------|------------------------------------|------------------------|
| Client IP     | IP address of the client.          | —                      |
| Zone          | Client zone identifier.            | —                      |
| Call Manager  | IP address of the call manager.    | —                      |
| Conference ID | Conference call identifier.        | —                      |
| RM Group      | Resource manager group identifier. | —                      |

### Monitoring SCCP ALG Counters

**Purpose** View SCCP ALG counters information.

**Action** Select **Monitor>ALGs>SCCP>Count** in the J-Web user interface, or enter the **show security alg sccp counters** command.

Table 92 summarizes key output fields in the SCCP counters display.

Table 92: Summary of Key SCCP Counters Output Fields

| Field                            | Values                                                   | Additional Information |
|----------------------------------|----------------------------------------------------------|------------------------|
| <b>SCCP Counters Information</b> |                                                          |                        |
| Clients currently registered     | Number of SCCP ALG clients currently registered.         | —                      |
| Active calls                     | Number of active SCCP ALG calls.                         | —                      |
| Total calls                      | Total number of SCCP ALG calls.                          | —                      |
| Packets received                 | Number of SCCP ALG packets received.                     | —                      |
| PDUs processed                   | Number of SCCP ALG protocol data units (PDUs) processed. | —                      |
| Current call rate                | Number of calls per second.                              | —                      |
| <b>Error counters</b>            |                                                          |                        |
| Packets dropped                  | Number of packets dropped by the SCCP ALG.               | —                      |

Table 92: Summary of Key SCCP Counters Output Fields (*continued*)

| Field                      | Values                                                                      | Additional Information |
|----------------------------|-----------------------------------------------------------------------------|------------------------|
| Decode errors              | SCCP ALG decoding errors.                                                   | —                      |
| Protocol errors            | Number of protocol errors.                                                  | —                      |
| Address translation errors | Number of Network Address Translation (NAT) errors encountered by SCCP ALG. | —                      |
| Policy lookup errors       | Number of packets dropped because of a failed policy lookup.                | —                      |
| Unknown PDUs               | Number of unknown protocol data units (PDUs).                               | —                      |
| Maximum calls exceed       | Number of times the maximum SCCP calls limit was exceeded.                  | —                      |
| Maximum call rate exceed   | Number of times the maximum SCCP call rate exceeded.                        | —                      |
| Initialization errors      | Number of initialization errors.                                            | —                      |
| Internal errors            | Number of internal errors.                                                  | —                      |
| Unsupported feature        | Number of unsupported feature errors.                                       | —                      |
| Non specific error         | Number of nonspecific errors.                                               | —                      |

### Monitoring SIP ALG Calls

**Purpose** View information about SIP ALG calls.

**Action** Select **Monitor>ALGs>SIP>Calls** in the J-Web user interface. To view detailed information, select the Call Leg on the SIP calls page.

Alternatively, enter the **show security alg sip calls detail** command.

[Table 93](#) summarizes key output fields in the SIP calls display.

**Table 93: Summary of Key SIP Calls Output Fields**

| Field                        | Values                                        | Additional Information |
|------------------------------|-----------------------------------------------|------------------------|
| <b>SIP Calls Information</b> |                                               |                        |
| Call Leg                     | Call length identifier.                       | —                      |
| Zone                         | Client zone identifier.                       | —                      |
| RM Group                     | Resource manager group identifier.            | —                      |
| Local Tag                    | Local tag for the SIP ALG User Agent server.  | —                      |
| Remote Tag                   | Remote tag for the SIP ALG User Agent server. | —                      |

### Monitoring SIP ALG Counters

**Purpose** View SIP ALG counters information.

**Action** Select **Monitor>ALGs>SIP>Count** in the J-Web user interface, or enter the **show security alg sip counters** command.

[Table 94](#) summarizes key output fields in the SIP counters display.

**Table 94: Summary of Key SIP Counters Output Fields**

| Field                           | Values                          | Additional Information                                                                                                                                                                                              |
|---------------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SIP Counters Information</b> |                                 |                                                                                                                                                                                                                     |
| INVITE                          | Number of INVITE requests sent. | An INVITE request is sent to invite another user to participate in a session.                                                                                                                                       |
| CANCEL                          | Number of CANCEL requests sent. | A user can send a CANCEL request to cancel a pending INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE had sent a final response for the INVITE before it received the CANCEL. |

Table 94: Summary of Key SIP Counters Output Fields (*continued*)

| Field                     | Values                             | Additional Information                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACK                       | Number of ACK requests sent.       | The user from whom the INVITE originated sends an ACK request to confirm reception of the final response to the INVITE request.                                                                                                                                                     |
| BYE                       | Number of BYE requests sent.       | A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.                                                                                                                                                               |
| REGISTER                  | Number of REGISTER requests sent.  | A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. A SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user. |
| OPTIONS                   | Number of OPTIONS requests sent.   | An OPTION message is used by the User Agent (UA) to obtain information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.                                             |
| INFO                      | Number of INFO requests sent.      | An INFO message is used to communicate mid-session signaling information along the signaling path for the call.                                                                                                                                                                     |
| MESSAGE                   | Number of MESSAGE requests sent.   | SIP messages consist of requests from a client to a server and responses to the requests from a server to a client with the purpose of establishing a session (or a call).                                                                                                          |
| NOTIFY                    | Number of NOTIFY requests sent.    | A NOTIFY message is sent to inform subscribers of changes in state to which the subscriber has a subscription.                                                                                                                                                                      |
| REFER                     | Number of REFER requests sent.     | A REFER request is used to refer the recipient (identified by the Request-URI) to a third party by the contact information provided in the request.                                                                                                                                 |
| SUBSCRIBE                 | Number of SUBSCRIBE requests sent. | A SUBSCRIBE request is used to request current state and state updates from a remote node.                                                                                                                                                                                          |
| UPDATE                    | Number of UPDATE requests sent.    | An UPDATE request is used to create a temporary opening in the firewall (pinhole) for new or updated Session Description Protocol (SDP) information. The following header fields are modified: Via, From, To, Call-ID, Contact, Route, and Record-Route.                            |
| <b>SIP Error Counters</b> |                                    |                                                                                                                                                                                                                                                                                     |
| Total Pkt-in              | SIP ALG total packets received.    | —                                                                                                                                                                                                                                                                                   |

Table 94: Summary of Key SIP Counters Output Fields (*continued*)

| Field                       | Values                                                                            | Additional Information |
|-----------------------------|-----------------------------------------------------------------------------------|------------------------|
| Total Pkt dropped on error  | Number of packets dropped by the SIP ALG.                                         | —                      |
| Transaction error           | SIP ALG transaction errors.                                                       | —                      |
| Call error                  | SIP ALG call errors.                                                              | —                      |
| IP resolve error            | SIP ALG IP address resolution errors.                                             | —                      |
| NAT error                   | SIP ALG NAT errors.                                                               | —                      |
| Resource manager error      | SIP ALG resource manager errors.                                                  | —                      |
| RR header exceeded max      | Number of times the SIP ALG RR (Record-Route) headers exceeded the maximum limit. | —                      |
| Contact header exceeded max | Number of times the SIP ALG contact header exceeded the maximum limit.            | —                      |
| Call dropped due to limit   | SIP ALG calls dropped because of call limits.                                     | —                      |
| SIP stack error             | SIP ALG stack errors.                                                             | —                      |

### Monitoring SIP ALG Rate Information

**Purpose** View SIP ALG rate information.

**Action** Select **Monitor>ALGs>SIP>Rate** in the J-Web user interface, or enter the **show security alg sip rate** command.

Table 95 summarizes key output fields in the SIP rate display.

Table 95: Summary of Key SIP Rate Output Fields

| Field                | Values | Additional Information |
|----------------------|--------|------------------------|
| SIP Rate Information |        |                        |

Table 95: Summary of Key SIP Rate Output Fields (*continued*)

| Field                                              | Values                                                                                                                                       | Additional Information |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| CPU ticks per microseconds is                      | SIP ALG CPU ticks per microsecond.                                                                                                           | —                      |
| Time taken for the last message in microseconds is | Time, in microseconds, that the last SIP ALG message needed to transit the network.                                                          | —                      |
| Number of messages in 10 minutes                   | Total number of SIP ALG messages transiting the network in 10 minutes.                                                                       | —                      |
| Time taken by the messages in 10 minutes           | Total time, in microseconds, during an interval of less than 10 minutes for the specified number of SIP ALG messages to transit the network. | —                      |
| Rate                                               | Number of SIP ALG messages per second transiting the network.                                                                                | —                      |

### Monitoring SIP ALG Transactions

**Purpose** View information about SIP ALG transactions.

**Action** Select **Monitor>ALGs>SIP>Transactions** in the J-Web user interface, or enter the **show security alg sip transactions** command.

Table 96 summarizes key output fields in the SIP transactions display.

Table 96: Summary of Key SIP Transactions Output Fields

| Field                        | Values                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information |

## Monitoring Voice ALG H.323

**Purpose** Use the monitoring functionality to view the ALG H.323 page.

**Action** To monitor ALG H.323 select **Monitor>Security>Voice ALGs>H.323** in the J-Web user interface.

**Meaning** [Table 97](#) summarizes key output fields in the ALG H.323 page.

**Table 97: ALG H.323 Monitoring Page**

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Display the list of virtual chassis member.      | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | —                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>clear</b> to clear the monitor summary.  |

### H.323 Counter Summary

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |   |

## Monitoring Voice ALG MGCP

**Purpose** Use the monitoring functionality to view the voice ALG MGCP page.

**Action** To monitor ALG MGCP, select **Monitor>Security>Voice ALGs>MGCP** in the J-Web user interface.

**Meaning** [Table 98](#) summarizes key output fields in the voice ALG MGCP page.

**Table 98: Voice ALG MGCP Monitoring Page**

| Field                        | Value                                            | Additional Information                            |
|------------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member       | Displays the list of virtual chassis member.     | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec)    | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                      | Displays the option to refresh the page.         | —                                                 |
| Clear                        | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |
| <b>Counters</b>              |                                                  |                                                   |

## Monitoring Voice ALG SCCP

**Purpose** Use the monitoring functionality to view the voice ALG SCCP page.

**Action** To monitor voice ALG SCCP, select **Monitor>Security>Voice ALGs>SCCP** in the J-Web user interface.

**Meaning** [Table 99](#) summarizes key output fields in the voice ALG SCCP page.

Table 99: Voice ALG SCCP Monitoring Page

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Displays the list of virtual chassis member.     | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | —                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |

## Monitoring Voice ALG SIP

**Purpose** Use the monitoring functionality to view the voice ALG SIP page.

**Action** To monitor voice ALG SIP select **Monitor>Security>Voice ALGs>SIP** in the J-Web user interface.

**Meaning** [Table 100](#) summarizes key output fields in the voice ALG SIP page.

**Table 100: Voice ALG SIP Monitoring Page**

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Displays the list of virtual chassis members.    | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | —                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |

| Field  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Additional Information |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Method | <p>Displays the SIP counter information. The available options are:</p> <ul style="list-style-type: none"> <li>• <b>BYE</b>— Number of BYE requests sent. A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.</li> <li>• <b>REGISTER</b>— Number of REGISTER requests sent. A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. The SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user.</li> <li>• <b>OPTIONS</b>— Number of OPTIONS requests sent. An OPTION message is used by the User Agent (UA) to obtain information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.</li> <li>• <b>INFO</b>— Number of INFO requests sent. An INFO message is used to communicate mid-session signaling information along the signaling path for the call.</li> <li>• <b>MESSAGE</b>— Number of MESSAGE requests sent. SIP messages consist of requests from a client to the server and responses to the requests from the server to a client for the purpose of establishing a session (or a call).</li> </ul> | —                      |

| Field        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Additional Information |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Method       | <ul style="list-style-type: none"> <li>• <b>NOTIFY</b>— Number of NOTIFY requests sent. A NOTIFY message is sent to inform subscribers about the change in state of the subscription.</li> <li>• <b>PRACK</b>— Number of PRACK requests sent. The PRACK request plays the same role as the ACK request, but for provisional responses.</li> <li>• <b>PUBLISH</b>— Number of PUBLISH requests sent. The PUBLISH request is used for publishing the event state. PUBLISH is similar to REGISTER that allows a user to create, modify, and remove state in another entity which manages this state on behalf of the user.</li> <li>• <b>REFER</b>— Number of REFER requests sent. A REFER request is used to refer the recipient (identified by the Request-URI) to a third party identified by the contact information provided in the request.</li> <li>• <b>SUBSCRIBE</b>— Number of SUBSCRIBE requests sent. A SUBSCRIBE request is used to request current state and state information updates from a remote node.</li> <li>• <b>UPDATE</b>— Number of UPDATE requests sent. An UPDATE request is used to create a temporary opening in the firewall (pinhole) for new or updated Session Description Protocol (SDP) information. The following header fields are modified: Via, From, To, Call-ID, Contact, Route, and Record-Route.</li> <li>• <b>BENOTIFY</b>— Number of BENOTIFY requests sent. A BENOTIFY request is used to reduce the unnecessary SIP signaling traffic on application servers. Applications that do not need a response for a NOTIFY request can enhance performance by enabling BENOTIFY.</li> <li>• <b>SERVICE</b>— Number of SERVICE requests sent. The SERVICE method is used by a SIP client to request a service from a SIP server. It is a standard SIP message and will be forwarded until it reaches the server or end user that is performing the service.</li> <li>• <b>OTHER</b>— Number of OTHER requests sent.</li> </ul> | —                      |
| T, RT        | Displays the transmit and retransmit method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                      |
| 1xx, RT      | Displays one transmit and retransmit method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                      |

## Monitoring Voice ALG Summary

**Purpose** Use the monitoring functionality to view the voice ALG summary page.

**Action** To monitor voice ALG summary, select **Monitor>Security>Voice ALGs>Summary** in the J-Web user interface.

**Meaning** [Table 101](#) summarizes key output fields in the voice ALG summary page.

**Table 101: Voice ALG Summary Monitoring Page**

| Field                      | Value                                            | Additional Information                            |
|----------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member     | Display the list of virtual chassis member.      | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec)  | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                    | Displays the option to refresh the page.         | –                                                 |
| Clear                      | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |
| Protocol Name              | Displays the protocols configured.               | –                                                 |
| Total Calls                | Displays the total number of calls.              | –                                                 |
| Number of Active Calls     | Displays the number of active calls.             | –                                                 |
| Number of Received Packets | Displays the number of packets received.         | –                                                 |
| Number of Errors           | Displays the number of errors.                   | –                                                 |
| H.323 Calls Chart          | Displays the H.323 calls chart.                  | –                                                 |
| MGCP Calls Chart           | Displays the MGCP calls chart.                   | –                                                 |
| SCCP Calls Chart           | Displays the SCCP calls chart.                   | –                                                 |
| SIP Calls Chart            | Displays the SIP calls chart.                    | –                                                 |

## Monitoring Class of Service

- [Monitoring Class-of-Service Performance on page 1255](#)
- [Monitoring CoS Classifiers on page 1262](#)

### Monitoring Class-of-Service Performance

The J-Web user interface provides information about the class-of-service (CoS) performance on a device. You can view information about the current status of CoS components—classifiers, CoS value aliases, red drop profiles, forwarding classes, rewrite rules and scheduler maps. You can also see the interfaces to which these components are assigned.

In addition, you can display the entire CoS configuration, including system-chosen defaults, by entering the **show class-of-service** command.

This section contains the following topics:

- [Monitoring CoS Interfaces on page 1255](#)
- [Monitoring CoS Classifiers on page 1256](#)
- [Monitoring CoS Value Aliases on page 1257](#)
- [Monitoring CoS RED Drop Profiles on page 1258](#)
- [Monitoring CoS Forwarding Classes on page 1258](#)
- [Monitoring CoS Rewrite Rules on page 1259](#)
- [Monitoring CoS Scheduler Maps on page 1260](#)

### Monitoring CoS Interfaces

- Purpose** Display details about the physical and logical interfaces and the CoS components assigned to them.
- Action** Select **Monitor>Class of Service>Interfaces** in the J-Web user interface, or enter the **show class-of-service interface *interface*** command.

[Table 102](#) summarizes key output fields for CoS interfaces.

**Table 102: Summary of Key CoS Interfaces Output Fields**

| Field     | Values                                                             | Additional Information                                                                                 |
|-----------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Interface | Name of a physical interface to which CoS components are assigned. | To display names of logical interfaces configured on this physical interface, click the plus sign (+). |

Table 102: Summary of Key CoS Interfaces Output Fields (*continued*)

| Field             | Values                                                                                            | Additional Information |
|-------------------|---------------------------------------------------------------------------------------------------|------------------------|
| Scheduler Map     | Name of the scheduler map associated with this interface.                                         | –                      |
| Queues Supported  | Number of queues you can configure on the interface.                                              | –                      |
| Queues in Use     | Number of queues currently configured.                                                            | –                      |
| Logical Interface | Name of a logical interface on the physical interface, to which CoS components are assigned.      | –                      |
| Object            | Category of an object—for example, <b>classifier</b> , <b>scheduler-map</b> , or <b>rewrite</b> . | –                      |
| Name              | Name that you have given to an object—for example, <b>ba-classifier</b> .                         | –                      |
| Type              | Type of an object—for example, <b>dscp</b> , or <b>exp</b> for a classifier.                      | –                      |
| Index             | Index of this interface or the internal index of a specific object.                               | –                      |

### Monitoring CoS Classifiers

**Purpose** Display the mapping of incoming CoS value to forwarding class and loss priority.

**Action** For each classifier, select **Monitor>Class of Service>Classifiers** in the J-Web user interface, or enter the **show class-of-service classifier** command.

Table 103 summarizes key output fields for CoS classifiers.

Table 103: Summary of Key CoS Classifier Output Fields

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Classifier Name | Name of a classifier.                                                                                                                                                                                                                                                                                                                                                                                                     | To display classifier assignments, click the plus sign (+). |
| CoS Value Type  | The classifiers are displayed by type: <ul style="list-style-type: none"> <li>• <b>dscp</b>—All classifiers of the DSCP type.</li> <li>• <b>dscp ipv6</b>—All classifiers of the DSCP IPv6 type.</li> <li>• <b>exp</b>—All classifiers of the MPLS EXP type.</li> <li>• <b>ieee-802.1</b>—All classifiers of the IEEE 802.1 type.</li> <li>• <b>inet-precedence</b>—All classifiers of the IP precedence type.</li> </ul> |                                                             |

Table 103: Summary of Key CoS Classifier Output Fields (*continued*)

|                            |                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index                      | Internal index of the classifier.                                                                                                                                                       |
| Incoming CoS Value         | CoS value of the incoming packets, in bits. These values are used for classification.                                                                                                   |
| Assign to Forwarding Class | Forwarding class that the classifier assigns to an incoming packet. This class affects the forwarding and scheduling policies that are applied to the packet as it transits the device. |
| Assign to Loss Priority    | Loss priority value that the classifier assigns to the incoming packet based on its CoS value.                                                                                          |

### Monitoring CoS Value Aliases

**Purpose** Display information about the CoS value aliases that the system is currently using to represent DSCP, DSCP IPv6, MPLS EXP, and IPv4 precedence bits.

**Action** Select **Monitor>Class of Service>CoS Value Aliases** in the J-Web user interface, or enter the **show class-of-service code-point-aliases** command.

Table 104 summarizes key output fields for CoS value aliases.

Table 104: Summary of Key CoS Value Alias Output Fields

| Field           | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Additional Information                                        |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| CoS Value Type  | Type of the CoS value: <ul style="list-style-type: none"> <li><b>dscp</b>—Examines Layer 3 packet headers for IP packet classification.</li> <li><b>dscp ipv6</b>—Examines Layer 3 packet headers for IPv6 packet classification.</li> <li><b>exp</b>—Examines Layer 2 packet headers for MPLS packet classification.</li> <li><b>ieee-802.1</b>—Examines Layer 2 packet header for packet classification.</li> <li><b>inet-precedence</b>—Examines Layer 3 packet headers for IP packet classification.</li> </ul> | To display aliases and bit patterns, click the plus sign (+). |
| CoS Value Alias | Name given to a set of bits—for example, <b>af11</b> is a name for <b>001010</b> bits.                                                                                                                                                                                                                                                                                                                                                                                                                              | —                                                             |
| Bit Pattern     | Set of bits associated with an alias.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | —                                                             |

### Monitoring CoS RED Drop Profiles

**Purpose** Display data point information for each CoS random early detection (RED) drop profile currently on a system.

**Action** Select **Monitor>Class of Service>RED Drop Profiles** in the J-Web user interface, or enter the **show class-of-service drop-profile** command.

Table 105 summarizes key output fields for CoS RED drop profiles.

**Table 105: Summary of Key CoS RED Drop Profile Output Fields**

| Field                 | Values                                                                                                                                                                                                                                                                                                                                 | Additional Information                                                                             |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| RED Drop Profile Name | Name of the RED drop profile.<br><br>A drop profile consists of pairs of values between 0 and 100, one for queue buffer fill level and one for drop probability, that determine the relationship between a buffer's fullness and the likelihood it will drop packets.                                                                  | To display profile values, click the plus sign (+).                                                |
| Graph RED Profile     | Link to a graph of a RED curve that the system uses to determine the drop probability based on queue buffer fullness.                                                                                                                                                                                                                  | The x axis represents the queue buffer fill level, and the y axis represents the drop probability. |
| Type                  | Type of a specific drop profile: <ul style="list-style-type: none"> <li><b>interpolated</b>—The two coordinates (x and y) of the graph are interpolated to produce a smooth profile.</li> <li><b>segmented</b>—The two coordinates (x and y) of the graph are represented by line fragments to produce a segmented profile.</li> </ul> | —                                                                                                  |
| Index                 | Internal index of this drop profile.                                                                                                                                                                                                                                                                                                   | —                                                                                                  |
| Fill Level            | Percentage fullness of a buffer queue. This value is the x coordinate of the RED drop profile graph.                                                                                                                                                                                                                                   | —                                                                                                  |
| Drop Probability      | Drop probability of a packet corresponding to a specific queue buffer fill level. This value is the y coordinate of the RED drop profile graph.                                                                                                                                                                                        | —                                                                                                  |

### Monitoring CoS Forwarding Classes

**Purpose** View the current assignment of CoS forwarding classes to queue numbers on the system.

**Action** Select **Monitor>Class of Service>Forwarding Classes** in the J-Web user interface, or enter the **show class-of-service forwarding-class** command.

Table 106 summarizes key output fields for CoS forwarding classes.

**Table 106: Summary of Key CoS Forwarding Class Output Fields**

| Field            | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Additional Information                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Forwarding Class | Names of forwarding classes assigned to queue numbers. By default, the following forwarding classes are assigned to queues 0 through 3: <ul style="list-style-type: none"> <li>• <b>best-effort</b>—Provides no special CoS handling of packets. Loss priority is typically not carried in a CoS value, and RED drop profiles are more aggressive.</li> <li>• <b>expedited-forwarding</b>—Provides low loss, low delay, low jitter, assured bandwidth, and end-to-end service.</li> <li>• <b>assured-forwarding</b>—Provides high assurance for packets within specified service profile. Excess packets are dropped.</li> <li>• <b>network-control</b>—Packets can be delayed but not dropped.</li> </ul> | —                                                                         |
| Queue            | Queue number corresponding to the forwarding class name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | By default, four queues, 0 through 3, are assigned to forwarding classes. |

### Monitoring CoS Rewrite Rules

**Purpose** Display information about CoS value rewrite rules, which are based on the forwarding class and loss priority.

**Action** Select **Monitor>Class of Service>Rewrite Rules** in the J-Web user interface, or enter the **show class-of-service rewrite-rules** command.

Table 107 summarizes key output fields for CoS rewrite rules.

**Table 107: Summary of Key CoS Rewrite Rules Output Fields**

| Field             | Values                  | Additional Information |
|-------------------|-------------------------|------------------------|
| Rewrite Rule Name | Names of rewrite rules. | —                      |

Table 107: Summary of Key CoS Rewrite Rules Output Fields (*continued*)

| Field                | Values                                                                                                                                                                                                                                                                                                             | Additional Information                                                                                           |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| CoS Value Type       | Rewrite rule type: <ul style="list-style-type: none"> <li>• <b>dscp</b>—For IPv4 DiffServ traffic.</li> <li>• <b>dscp-ipv6</b>—For IPv6 DiffServ traffic.</li> <li>• <b>exp</b>—For MPLS traffic.</li> <li>• <b>ieee-802.1</b>—For Layer 2 traffic.</li> <li>• <b>inet-precedence</b>—For IPv4 traffic.</li> </ul> | To display forwarding classes, loss priorities, and rewritten CoS values, click the plus sign (+).               |
| Index                | Internal index for this particular rewrite rule.                                                                                                                                                                                                                                                                   | —                                                                                                                |
| Forwarding Class     | Forwarding class that in combination with loss priority is used to determine CoS values for rewriting.                                                                                                                                                                                                             | Rewrite rules are applied to CoS values in outgoing packets based on forwarding class and loss priority setting. |
| Loss Priority        | Loss priority that in combination with forwarding class is used to determine CoS values for rewriting.                                                                                                                                                                                                             | —                                                                                                                |
| Rewrite CoS Value To | Value that the CoS value is rewritten to.                                                                                                                                                                                                                                                                          | —                                                                                                                |

### Monitoring CoS Scheduler Maps

**Purpose** Display assignments of CoS forwarding classes to schedulers.

**Action** Select **Monitor>Class of Service>Scheduler Maps** in the J-Web user interface, or enter the **show class-of-service scheduler-map** command.

Table 108 summarizes key output fields for CoS scheduler maps.

Table 108: Summary of Key CoS Scheduler Maps Output Fields

| Field            | Values                                                                   | Additional Information                |
|------------------|--------------------------------------------------------------------------|---------------------------------------|
| Scheduler Map    | Name of a scheduler map.                                                 | For details, click the plus sign (+). |
| Index            | Index of a specific object—scheduler maps, schedulers, or drop profiles. | —                                     |
| Scheduler Name   | Name of a scheduler.                                                     | —                                     |
| Forwarding Class | Forwarding classes this scheduler is assigned to.                        | —                                     |

Table 108: Summary of Key CoS Scheduler Maps Output Fields (*continued*)

| Field         | Values                                                                                                                                                                                                                                                                                                                                                                                                         | Additional Information |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Transmit Rate | <p>Configured transmit rate of the scheduler in bits per second (bps). The rate value can be either of the following:</p> <ul style="list-style-type: none"> <li>A percentage—The scheduler receives the specified percentage of the total interface bandwidth.</li> <li><b>remainder</b>—The scheduler receives the remaining bandwidth of the interface after allocation to other schedulers.</li> </ul>     | —                      |
| Rate Limit    | <p>Rate limiting configuration of the queue:</p> <ul style="list-style-type: none"> <li><b>none</b>—No rate limiting.</li> <li><b>exact</b>—The queue transmits at only the configured rate.</li> </ul>                                                                                                                                                                                                        | —                      |
| Buffer Size   | <p>Delay buffer size in the queue or the amount of transmit delay (in milliseconds). The buffer size can be either of the following:</p> <ul style="list-style-type: none"> <li>A percentage—The buffer is a percentage of the total buffer allocation.</li> <li><b>remainder</b>—The buffer is sized according to what remains after other scheduler buffer allocations.</li> </ul>                           | —                      |
| Priority      | <p>Scheduling priority of a queue:</p> <ul style="list-style-type: none"> <li><b>high</b>—Packets in this queue are transmitted first.</li> <li><b>low</b>—Packets in this queue are transmitted last.</li> <li><b>medium-high</b>—Packets in this queue are transmitted after high-priority packets.</li> <li><b>medium-low</b>—Packets in this queue are transmitted before low-priority packets.</li> </ul> | —                      |
| Drop Profiles | <p>Name and index of a drop profile that is assigned to a specific loss priority and protocol pair.</p>                                                                                                                                                                                                                                                                                                        | —                      |
| Loss Priority | <p>Packet loss priority corresponding to a drop profile:</p> <ul style="list-style-type: none"> <li><b>low</b>—Packet has a low loss priority.</li> <li><b>high</b>—Packet has a high loss priority.</li> <li><b>medium-low</b>—Packet has a medium-low loss priority.</li> <li><b>medium-high</b>—Packet has a medium-high loss priority.</li> </ul>                                                          | —                      |

Table 108: Summary of Key CoS Scheduler Maps Output Fields (*continued*)

| Field             | Values                                              | Additional Information |
|-------------------|-----------------------------------------------------|------------------------|
| Protocol          | Transport protocol corresponding to a drop profile. | –                      |
| Drop Profile Name | Name of the drop profile.                           | –                      |

## Monitoring CoS Classifiers

**Purpose** Display the mapping of incoming CoS value to forwarding class and loss priority.

**Action** For each classifier, select **Monitor>Class of Service>Classifiers** in the J-Web user interface, or enter the **show class-of-service classifier** command.

[Table 103](#) summarizes key output fields for CoS classifiers.

Table 109: Summary of Key CoS Classifier Output Fields

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Classifier Name            | Name of a classifier.                                                                                                                                                                                                                                                                                                                                                                                                     | To display classifier assignments, click the plus sign (+). |
| CoS Value Type             | The classifiers are displayed by type: <ul style="list-style-type: none"> <li>• <b>dscp</b>—All classifiers of the DSCP type.</li> <li>• <b>dscp ipv6</b>—All classifiers of the DSCP IPv6 type.</li> <li>• <b>exp</b>—All classifiers of the MPLS EXP type.</li> <li>• <b>ieee-802.1</b>—All classifiers of the IEEE 802.1 type.</li> <li>• <b>inet-precedence</b>—All classifiers of the IP precedence type.</li> </ul> |                                                             |
| Index                      | Internal index of the classifier.                                                                                                                                                                                                                                                                                                                                                                                         |                                                             |
| Incoming CoS Value         | CoS value of the incoming packets, in bits. These values are used for classification.                                                                                                                                                                                                                                                                                                                                     |                                                             |
| Assign to Forwarding Class | Forwarding class that the classifier assigns to an incoming packet. This class affects the forwarding and scheduling policies that are applied to the packet as it transits the device.                                                                                                                                                                                                                                   |                                                             |
| Assign to Loss Priority    | Loss priority value that the classifier assigns to the incoming packet based on its CoS value.                                                                                                                                                                                                                                                                                                                            |                                                             |

### Displaying Real-Time Interface Information

Enter the **monitor interface** command to display real-time traffic, error, alarm, and filter statistics about a physical or logical interface:

```
user@host> monitor interface (interface-name | traffic)
```

Replace ***interface-name*** with the name of a physical or logical interface. If you specify the **traffic** option, statistics for all active interfaces display.

The real-time statistics update every second. The **Current delta** and **Delta** columns display the amount the statistics counters have changed since the **monitor interface** command was entered or since you cleared the delta counters. [Table 110](#) and [Table 111](#) list the keys you use to control the display using the ***interface-name*** and **traffic** options. (The keys are not case sensitive.)

**Table 110: CLI monitor interface Output Control Keys**

| Key | Action                                                                                                                |
|-----|-----------------------------------------------------------------------------------------------------------------------|
| c   | Clears (returns to 0) the delta counters in the <b>Current delta</b> column. The statistics counters are not cleared. |
| f   | Freezes the display, halting the update of the statistics and delta counters.                                         |
| i   | Displays information about a different interface. You are prompted for the name of a specific interface.              |

Table 110: CLI monitor interface Output Control Keys (*continued*)

| Key      | Action                                                                                                                                                                                                   |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n        | Displays information about the next interface. The device scrolls through the physical and logical interfaces in the same order in which they are displayed by the <b>show interfaces terse</b> command. |
| q or ESC | Quits the command and returns to the command prompt.                                                                                                                                                     |
| t        | Thaws the display, resuming the update of the statistics and delta counters.                                                                                                                             |

Table 111: CLI monitor interface traffic Output Control Keys

| Key      | Action                                                                                                        |
|----------|---------------------------------------------------------------------------------------------------------------|
| b        | Displays the statistics in units of bytes and bytes per second (bps).                                         |
| c        | Clears (returns to 0) the delta counters in the <b>Delta</b> column. The statistics counters are not cleared. |
| d        | Displays the <b>Delta</b> column instead of the rate column—in bps or packets per second (pps).               |
| p        | Displays the statistics in units of packets and packets per second (pps).                                     |
| q or ESC | Quits the command and returns to the command prompt.                                                          |
| r        | Displays the rate column—in bps and pps—instead of the <b>Delta</b> column.                                   |

The following are sample displays from the **monitor interface** command:

```
user@host> monitor interface fe-0/0/0
```

```

host1                               Seconds: 5                               Time: 04:38:40
                                      Delay: 3/0/10

Interface: fe-0/0/0, Enabled, Link is Up
Encapsulation: Ethernet, Speed: 1000mbps
Traffic statistics:
  Input bytes:           885405423 (3248 bps)           [2631]
  Output bytes:          137411893 (3344 bps)           [10243]
  Input packets:         7155064 (2 pps)                [28]
  Output packets:        636071 (1 pps)                 [23]
Error statistics:
  Input errors:          0                               [0]
  Input drops:           0                               [0]
  Input framing errors:  0                               [0]
  Policed discards:      0                               [0]
  L3 incompletes:        0                               [0]
  L2 channel errors:     0                               [0]
  L2 mismatch timeouts:  0                               [0]
  Carrier transitions:    1                               [0]
  Output errors:         0                               [0]
  Output drops:          0                               [0]
  Aged packets:          0                               [0]
```

```

Active alarms : None
Active defects: None
Input MAC/Filter statistics:
  Unicast packets          73083          [16]
  Broadcast packets        3629058        [5]
  Multicast packets        3511364        [3]
  Oversized frames         0            [0]
  Packet reject count      0            [0]
  DA rejects               0            [0]
  SA rejects               0            [0]
Output MAC/Filter Statistics:
  Unicast packets          629555          [28]
  Broadcast packets        6494      Multicast packet [0]

```

**NOTE:** The output fields that display when you enter the `monitor interface` *interface-name* command are determined by the interface you specify.

```
user@host> monitor interface traffic
```

| Interface | Link | Input packets | (pps)   | Output packets | (pps)   |
|-----------|------|---------------|---------|----------------|---------|
| fe-0/0/0  | Up   | 42334         | (5)     | 23306          | (3)     |
| fe-0/0/1  | Up   | 587525876     | (12252) | 589621478      | (12891) |

## Monitoring Address Pools

**Purpose** Use the monitoring functionality to view the Address Pools page.

**Action** To monitor Address Pools, select **Monitor>Access>Address Pools** in the J-Web user interface.

**Meaning** [Table 112](#) summarizes key output fields in the Address Pools page.

**Table 112: Address Pools Monitoring Page**

| Field                          | Values                                                                        | Additional Information |
|--------------------------------|-------------------------------------------------------------------------------|------------------------|
| <b>Address Pool Properties</b> |                                                                               |                        |
| Address Pool Name              | Displays the name of the address pool.                                        | -                      |
| Network Address                | Displays the IP network address of the address pool.                          | -                      |
| Address Ranges                 | Displays the name, the lower limit, and the upper limit of the address range. | -                      |
| Primary DNS                    | Displays the primary-dns IP address.                                          | -                      |
| Secondary DNS                  | Displays the secondary-dns IP address.                                        | -                      |

Table 112: Address Pools Monitoring Page (*continued*)

| Field                                  | Values                                                    | Additional Information                                                                 |
|----------------------------------------|-----------------------------------------------------------|----------------------------------------------------------------------------------------|
| Primary WINS                           | Displays the primary-wins IP address.                     | -                                                                                      |
| Secondary WINS                         | Displays the secondary-wins IP address.                   | -                                                                                      |
| <b>Address Pool Address Assignment</b> |                                                           |                                                                                        |
| IP Address                             | Displays the IP address of the address pool.              | -                                                                                      |
| Hardware Address                       | Displays the hardware MAC address of the address pool.    | -                                                                                      |
| Host/User                              | Displays the user name using the address pool.            | -                                                                                      |
| Type                                   | Displays the authentication type used by the address pool | The authentication types can be extended authentication (XAuth) or IKE Authentication. |

## Monitoring Ethernet Switching

**Purpose** View information about the Ethernet Switching interface details.

**Action** Select **Monitor>Switching>Ethernet Switching** in the J-Web user interface, or enter the following CLI commands:

- **show ethernet-switching table**
- **show ethernet-switching mac-learning-log**

[Table 113](#) summarizes the Ethernet Switching output fields.

Table 113: Summary of Ethernet Switching Output Fields

| Field       | Values                                                                                                                                                                                           | Additional Information |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| VLAN        | The VLAN for which Ethernet Switching is enabled.                                                                                                                                                | -                      |
| MAC Address | The MAC address associated with the VLAN. If a VLAN range has been configured for a VLAN, the output displays the MAC addresses for the entire series of VLANs that were created with that name. | -                      |

Table 113: Summary of Ethernet Switching Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                                                                             | Additional Information |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Type        | The type of MAC address. Values are: <ul style="list-style-type: none"> <li>static—The MAC address is manually created.</li> <li>learn—The MAC address is learned dynamically from a packet's source MAC address.</li> <li>flood—The MAC address is unknown and flooded to all members.</li> </ul> | -                      |
| Age         | The time remaining before the entry ages out and is removed from the Ethernet switching table.                                                                                                                                                                                                     | -                      |
| Interfaces  | Interface associated with learned MAC addresses or All-members (flood entry).                                                                                                                                                                                                                      | -                      |
| VLAN-ID     | The VLAN ID.                                                                                                                                                                                                                                                                                       | -                      |
| MAC Address | The learned MAC address.                                                                                                                                                                                                                                                                           | -                      |
| Time        | Timestamp when the MAC address was added or deleted from the log.                                                                                                                                                                                                                                  | -                      |
| State       | Indicates the MAC address learned on the interface.                                                                                                                                                                                                                                                | -                      |

## Monitoring GVRP

**Purpose** Use the monitoring functionality to view the GVRP page.

**Action** To monitor GVRP select **Monitor>Switching>GVRP** in the J-Web user interface.

**Meaning** [Table 114](#) summarizes key output fields in the GVRP page.

Table 114: GVRP Monitoring Page

| Field                            | Value                                         | Additional Information |
|----------------------------------|-----------------------------------------------|------------------------|
| <b>Global GVRP Configuration</b> |                                               |                        |
| GVRP Status                      | Displays whether GVRP is enabled or disabled. | —                      |
| GVRP Timer                       | Displays the GVRP timer in millisecond.       | —                      |

Table 114: GVRP Monitoring Page (*continued*)

| Field                         | Value                                                                                                                                                                 | Additional Information |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Join                          | The number of milliseconds the interfaces must wait before sending VLAN advertisements.                                                                               | —                      |
| Leave                         | The number of milliseconds an interface must wait after receiving a Leave message to remove the interface from the VLAN specified in the message.                     | —                      |
| Leave All                     | The interval in milliseconds at which Leave All messages are sent on interfaces. Leave All messages maintain current GVRP VLAN membership information in the network. | —                      |
| <b>GVRP Interface Details</b> |                                                                                                                                                                       |                        |
| Interface Name                | The interface on which GVRP is configured.                                                                                                                            | —                      |
| Protocol Status               | Displays whether GVRP is enabled or disabled.                                                                                                                         | —                      |

## Monitoring Interfaces

**Purpose** View general information about all physical and logical interfaces for a device.

**Action** Select **Monitor>Interfaces** in the J-Web user interface. The J-Web Interfaces page displays the following details about each device interface:

- Port—Indicates the interface name.
- Admin Status—Indicates whether the interface is enabled (Up) or disabled (Down).
- Link Status—Indicates whether the interface is linked (Up) or not linked (Down).
- Address—Indicates the IP address of the interface.
- Zone—Indicates whether the zone is an untrust zone or a trust zone.
- Services—Indicates services that are enabled on the device, such as HTTP and SSH.
- Protocols—Indicates protocols that are enabled on the device, such as BGP and IGMP.
- Input Rate graph—Displays interface bandwidth utilization. Input rates are shown in bytes per second.
- Output Rate graph—Displays interface bandwidth utilization. Output rates are shown in bytes per second.

- Error Counters chart—Displays input and output error counters in the form of a bar chart.
- Packet Counters chart—Displays the number of broadcast, unicast, and multicast packet counters in the form of a pie chart. (Packet counter charts are supported only for interfaces that support MAC statistics.)

To change the interface display, use the following options:

- Port for FPC—Controls the member for which information is displayed.
- Start/Stop button—Starts or stops monitoring the selected interfaces.
- Show Graph—Displays input and output packet counters and error counters in the form of charts.
- Pop-up button—Displays the interface graphs in a separate pop-up window.
- Details—Displays extensive statistics about the selected interface, including its general status, traffic information, IP address, I/O errors, class-of-service data, and statistics.
- Refresh Interval—Indicates the duration of time after which you want the data on the page to be refreshed.
- Clear Statistics—Clears the statistics for the selected interface.

Alternatively, you can enter the following **show** commands in the CLI to view interface status and traffic statistics:

- **show interfaces terse**

**NOTE:** On SRX Series devices, on configuring identical IPs on a single interface, you will not see a warning message; instead, you will see a syslog message.

- **show interfaces detail**
- **show interfaces extensive**
- **show interfaces *interface-name***

### Monitoring MPLS Interfaces

**Purpose** View the interfaces on which MPLS is configured, including operational state and any administrative groups applied to an interface.

**Action** Select **Monitor>MPLS>Interfaces** in the J-Web user interface, or enter the **show mpls interface** command.

[Table 115](#) summarizes key output fields in the MPLS interface information display.

**Table 115: Summary of Key MPLS Interface Information Output Fields**

| Field                 | Values                                                                         | Additional Information |
|-----------------------|--------------------------------------------------------------------------------|------------------------|
| Interface             | Name of the interface on which MPLS is configured.                             | –                      |
| State                 | State of the specified interface: <b>Up</b> or <b>Dn</b> (down).               | –                      |
| Administrative groups | Administratively assigned colors of the MPLS link configured on the interface. | –                      |

### Monitoring MPLS LSP Information

**Purpose** View all label-switched paths (LSPs) configured on the services router, including all inbound (ingress), outbound (egress), and transit LSP information.

**Action** Select **Monitor>MPLS>LSP Information** in the J-Web user interface, or enter the **show mpls lsp** command.

[Table 116](#) summarizes key output fields in the MPLS LSP information display.

**Table 116: Summary of Key MPLS LSP Information Output Fields**

| Field       | Values                                                                                  | Additional Information                                                                                       |
|-------------|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Ingress LSP | Information about LSPs on the inbound device. Each session has one line of output.      | –                                                                                                            |
| Egress LSP  | Information about the LSPs on the outbound device. Each session has one line of output. | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| Transit LSP | Number of LSPs on the transit routers and the state of these paths.                     | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| To          | Destination (outbound device) of the session.                                           | –                                                                                                            |

Table 116: Summary of Key MPLS LSP Information Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                             | Additional Information                                                                                                                                                                           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| From        | Source (inbound device) of the session.                                                                                                                                                                                                            | –                                                                                                                                                                                                |
| State       | State of the path. It can be <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                                                                                                                         | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                                            |
| Rt          | Number of active routes (prefixes) installed in the routing table.                                                                                                                                                                                 | For inbound RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and outbound RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ). |
| Active Path | Name of the active path: <b>Primary</b> or <b>Secondary</b> .                                                                                                                                                                                      | This field is used for inbound LSPs only.                                                                                                                                                        |
| P           | An asterisk (*) in this column indicates that the LSP is a primary path.                                                                                                                                                                           | This field is used for inbound LSPs only.                                                                                                                                                        |
| LSPname     | Configured name of the LSP.                                                                                                                                                                                                                        | –                                                                                                                                                                                                |
| Style       | RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | This field is used for outbound and transit LSPs only.                                                                                                                                           |
| Labelin     | Incoming label for this LSP.                                                                                                                                                                                                                       | –                                                                                                                                                                                                |
| Labelout    | Outgoing label for this LSP.                                                                                                                                                                                                                       | –                                                                                                                                                                                                |
| Total       | Total number of LSPs displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> .                                                                                                                    | –                                                                                                                                                                                                |

### Monitoring MPLS LSP Statistics

**Purpose** Display statistics for LSP sessions currently active on the device, including the total number of packets and bytes forwarded through an LSP.

**Action** Select **Monitor>MPLS>LSP Statistics** in the J-Web user interface, or enter the **show mpls lsp statistics** command.

**NOTE:** Statistics are not available for LSPs on the outbound device, because the penultimate device in the LSP sets the label to 0. Also, as the packet arrives at the outbound device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

Table 117 summarizes key output fields in the MPLS LSP statistics display.

**Table 117: Summary of Key MPLS LSP Statistics Output Fields**

| Field       | Values                                                                                                                          | Additional Information                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Ingress LSP | Information about LSPs on the inbound device. Each session has one line of output.                                              | —                                                                                                            |
| Egress LSP  | Information about the LSPs on the outbound device. Each session has one line of output.                                         | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| Transit LSP | Number of LSPs on the transit routers and the state of these paths.                                                             | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| To          | Destination (outbound device) of the session.                                                                                   | —                                                                                                            |
| From        | Source (inbound device) of the session.                                                                                         | —                                                                                                            |
| State       | State of the path: <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                        |
| Packets     | Total number of packets received on the LSP from the upstream neighbor.                                                         | —                                                                                                            |
| Bytes       | Total number of bytes received on the LSP from the upstream neighbor.                                                           | —                                                                                                            |
| LSPname     | Configured name of the LSP.                                                                                                     | —                                                                                                            |
| Total       | Total number of LSPs displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> . | —                                                                                                            |

### Monitoring RSVP Session Information

**Purpose** View information about RSVP-signaled LSP sessions currently active on the device, including inbound (ingress) and outbound (egress) addresses, LSP state, and LSP name.

**Action** Select **Monitor>MPLS>RSVP Sessions** in the J-Web user interface, or enter the **show rsvp session** command.

Table 118 summarizes key output fields in the RSVP session information display.

**Table 118: Summary of Key RSVP Session Information Output Fields**

| Field       | Values                                                                        | Additional Information |
|-------------|-------------------------------------------------------------------------------|------------------------|
| Ingress LSP | Information about inbound RSVP sessions. Each session has one line of output. | —                      |

Table 118: Summary of Key RSVP Session Information Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                             | Additional Information                                                                                                                                                                           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress LSP  | Information about outbound RSVP sessions. Each session has one line of output.                                                                                                                                                                     | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information.                                                                                     |
| Transit LSP | Information about transit RSVP sessions.                                                                                                                                                                                                           | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information.                                                                                     |
| To          | Destination (outbound device) of the session.                                                                                                                                                                                                      | —                                                                                                                                                                                                |
| From        | Source (inbound device) of the session.                                                                                                                                                                                                            | —                                                                                                                                                                                                |
| State       | State of the path: <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                                                                                                                                   | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                                            |
| Rt          | Number of active routes (prefixes) installed in the routing table.                                                                                                                                                                                 | For inbound RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and outbound RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ). |
| Style       | RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | This field is used for outbound and transit LSPs only.                                                                                                                                           |
| Labelin     | Incoming label for this RSVP session.                                                                                                                                                                                                              | —                                                                                                                                                                                                |
| Labelout    | Outgoing label for this RSVP session.                                                                                                                                                                                                              | —                                                                                                                                                                                                |
| LSPname     | Configured name of the LSP.                                                                                                                                                                                                                        | —                                                                                                                                                                                                |
| Total       | Total number of RSVP sessions displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> .                                                                                                           | —                                                                                                                                                                                                |

### Monitoring MPLS RSVP Interfaces Information

**Purpose** View information about the interfaces on which RSVP is enabled, including the interface name, total bandwidth through the interface, and total current reserved and reservable (available) bandwidth on the interface.

**Action** Select **Monitor>MPLS>RSVP Interfaces** in the J-Web user interface, or enter the **show rsvp interface** command.

Table 119 summarizes key output fields in the RSVP interfaces information display.

Table 119: Summary of Key RSVP Interfaces Information Output Fields

| Field          | Values                                                                                                                                                                                                                                                                                                                       | Additional Information |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| RSVP Interface | Number of interfaces on which RSVP is active. Each interface has one line of output.                                                                                                                                                                                                                                         | —                      |
| Interface      | Name of the interface.                                                                                                                                                                                                                                                                                                       | —                      |
| State          | State of the interface: <ul style="list-style-type: none"> <li>• <b>Disabled</b>—No traffic engineering information is displayed.</li> <li>• <b>Down</b>—The interface is not operational.</li> <li>• <b>Enabled</b>—Displays traffic engineering information.</li> <li>• <b>Up</b>—The interface is operational.</li> </ul> | —                      |
| Active resv    | Number of reservations that are actively reserving bandwidth on the interface.                                                                                                                                                                                                                                               | —                      |
| Subscription   | User-configured subscription factor.                                                                                                                                                                                                                                                                                         | —                      |
| Static BW      | Total interface bandwidth, in bits per second (bps).                                                                                                                                                                                                                                                                         | —                      |
| Available BW   | Amount of bandwidth that RSVP is allowed to reserve, in bits per second (bps). It is equal to <b>(static bandwidth X subscription factor)</b> .                                                                                                                                                                              | —                      |
| Reserved BW    | Currently reserved bandwidth, in bits per second (bps).                                                                                                                                                                                                                                                                      | —                      |
| Highwater mark | Highest bandwidth that has ever been reserved on this interface, in bits per second (bps).                                                                                                                                                                                                                                   | —                      |

## Monitoring PPP

- Purpose** Display PPP monitoring information, including PPP address pool information, session status for PPP interfaces, cumulative statistics for all PPP interfaces, and a summary of PPP sessions.

**NOTE:** PPP monitoring information is available only in the CLI. The J-Web user interface does not include pages for displaying PPP monitoring information.

**Action** Enter the following CLI commands:

- `show ppp address-pool pool-name`
- `show ppp interface interface-name`
- `show ppp statistics`
- `show ppp summary`

## Monitoring Spanning Tree

**Purpose** Use the monitoring functionality to view the Spanning Tree page.

**Action** To monitor spanning tree, select **Monitor>Switching>Spanning Tree** in the J-Web user interface.

**Meaning** [Table 120](#) summarizes key output fields in the spanning tree page.

**Table 120: Spanning Tree Monitoring Page**

| Field                    | Value                                                       | Additional Information                                                                      |
|--------------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Bridge parameters</b> |                                                             |                                                                                             |
| Context ID               | An internally generated identifier.                         | —                                                                                           |
| Enabled Protocol         | Spanning tree protocol type enabled.                        | —                                                                                           |
| Root ID                  | Bridge ID of the elected spanning tree root bridge.         | The bridge ID consists of a configurable bridge priority and the MAC address of the bridge. |
| Bridge ID                | Locally configured bridge ID.                               | —                                                                                           |
| Inter instance ID        | An internally generated instance identifier.                | —                                                                                           |
| Extended system ID       | Extended system generated instance identifier.              | —                                                                                           |
| Maximum age              | Maximum age of received bridge protocol data units (BPDUs). | —                                                                                           |

Table 120: Spanning Tree Monitoring Page (*continued*)

| Field                      | Value                                                                                  | Additional Information |
|----------------------------|----------------------------------------------------------------------------------------|------------------------|
| Number of topology changes | Total number of STP topology changes detected since the switch last booted.            | –                      |
| Forward delay              | Spanning tree forward delay.                                                           | –                      |
| <b>Interface List</b>      |                                                                                        |                        |
| Interface Name             | Interface configured to participate in the STP instance.                               | –                      |
| Port ID                    | Logical interface identifier configured to participate in the STP instance.            | –                      |
| Designated Port ID         | Port ID of the designated port for the LAN segment to which the interface is attached. | –                      |
| Port Cost                  | Configured cost for the interface.                                                     | –                      |
| State                      | STP port state. Forwarding (FWD), blocking (BLK), listening, learning, or disabled.    | –                      |
| Role                       | MSTP or RSTP port role. Designated (DESG), backup (BKUP), alternate (ALT), or root.    | –                      |

## Monitoring the WAN Acceleration Interface

**Purpose** View status information and traffic statistics for the WAN acceleration interface.

**Action** Select **Monitor>WAN Acceleration** in the J-Web user interface, or select **Monitor>Interfaces** and select the interface name (**wx-slot/0/0**). Alternatively, enter the following CLI command:

```
[edit]
user@host# show interfaces wx-slot/0/0 detail
```

### Monitoring Source NAT Information

**Purpose** Display configured information about source Network Address Translation (NAT) rules, pools, persistent NAT, and paired addresses.

**Action** Select **Monitor>NAT>Source NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat source summary**
- **show security nat source pool *pool-name***
- **show security nat source persistent-nat-table**
- **show security nat source paired-address**

[Table 121](#) describes the available options for monitoring source NAT.

**Table 121: Source NAT Monitoring Page**

| Field                | Description                                                              | Action                                                                |
|----------------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Rules</b>         |                                                                          |                                                                       |
| Rule-set Name        | Name of the rule set.                                                    | Select all rule sets or a specific rule set to display from the list. |
| Total rules          | Number of rules configured.                                              | —                                                                     |
| ID                   | Rule ID number.                                                          | —                                                                     |
| Name                 | Name of the rule .                                                       | —                                                                     |
| From                 | Name of the routing instance/zone/interface from which the packet flows. | —                                                                     |
| To                   | Name of the routing instance/zone/interface to which the packet flows.   | —                                                                     |
| Source address range | Source IP address range in the source pool.                              | —                                                                     |

Table 121: Source NAT Monitoring Page (*continued*)

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                         | Action                                                        |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| Destination address range              | Destination IP address range in the source pool.                                                                                                                                                                                                                                                                                                    | —                                                             |
| Source ports                           | Source port numbers.                                                                                                                                                                                                                                                                                                                                | —                                                             |
| Ip protocol                            | IP protocol.                                                                                                                                                                                                                                                                                                                                        | —                                                             |
| Action                                 | Action taken for a packet that matches a rule.                                                                                                                                                                                                                                                                                                      | —                                                             |
| Persistent NAT type                    | Persistent NAT type.                                                                                                                                                                                                                                                                                                                                | —                                                             |
| Inactivity timeout                     | Inactivity timeout interval for the persistent NAT binding.                                                                                                                                                                                                                                                                                         | —                                                             |
| Alarm threshold                        | Utilization alarm threshold.                                                                                                                                                                                                                                                                                                                        | —                                                             |
| Max session number                     | The maximum number of sessions.                                                                                                                                                                                                                                                                                                                     | —                                                             |
| Sessions (Succ/<br>Failed/<br>Current) | Successful, failed, and current sessions. <ul style="list-style-type: none"> <li>• Succ—Number of successful session installations after the NAT rule is matched.</li> <li>• Failed—Number of unsuccessful session installations after the NAT rule is matched.</li> <li>• Current—Number of sessions that reference the specified rule.</li> </ul> | —                                                             |
| Translation Hits                       | Number of times a translation in the translation table is used for a source NAT rule.                                                                                                                                                                                                                                                               | —                                                             |

| Name                                   | Name of the source pool.                                                                                                                                                                                                                                                                                                                            | —                                                             |
| Address range                          | IP address range in the source pool.                                                                                                                                                                                                                                                                                                                | —                                                             |

Table 121: Source NAT Monitoring Page (*continued*)

| Field                                  | Description                                                                    | Action                                                        |
|----------------------------------------|--------------------------------------------------------------------------------|---------------------------------------------------------------|
| Single/Twin ports                      | Number of allocated single and twin ports.                                     | —                                                             |
| Port                                   | Source port number in the pool.                                                | —                                                             |
| Address assignment                     | Displays the type of address assignment.                                       | —                                                             |
| Alarm threshold                        | Utilization alarm threshold.                                                   | —                                                             |
| Port overloading factor                | Port overloading capacity.                                                     | —                                                             |
| Routing instance                       | Name of the routing instance.                                                  | —                                                             |
| Total addresses                        | Total IP address, IP address set, or address book entry.                       | —                                                             |
| Host address base                      | Host base address of the original source IP address range.                     | —                                                             |
| Translation hits                       | Number of times a translation in the translation table is used for source NAT. | —                                                             |
| <b>Top 10 Translation Hits</b>         |                                                                                |                                                               |
| Graph                                  | Displays the graph of top 10 translation hits.                                 | —                                                             |
| <b>Persistent NAT</b>                  |                                                                                |                                                               |
| <b>Persistent NAT table statistics</b> |                                                                                |                                                               |
| binding total                          | Displays the total number of persistent NAT bindings for the FPC.              | —                                                             |
| binding in use                         | Number of persistent NAT bindings that are in use for the FPC.                 | —                                                             |
| enode total                            | Total number of persistent NAT enodes for the FPC.                             | —                                                             |
| enode in use                           | Number of persistent NAT enodes that are in use for the FPC.                   | —                                                             |
| <b>Persistent NAT table</b>            |                                                                                |                                                               |
| Source NAT pool                        | Name of the pool.                                                              | Select all pools or a specific pool to display from the list. |

Table 121: Source NAT Monitoring Page (*continued*)

| Field                               | Description                                                                                               | Action                                                                     |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Internal IP                         | Internal IP address.                                                                                      | Select all IP addresses or a specific IP address to display from the list. |
| Internal port                       | Displays the internal ports configured in the system.                                                     | Select the port to display from the list.                                  |
| Internal protocol                   | Internal protocols .                                                                                      | Select all protocols or a specific protocol to display from the list.      |
| Internal IP                         | Internal transport IP address of the outgoing session from internal to external.                          | —                                                                          |
| Internal port                       | Internal transport port number of the outgoing session from internal to external.                         | —                                                                          |
| Internal protocol                   | Internal protocol of the outgoing session from internal to external.                                      | —                                                                          |
| Reflective IP                       | Translated IP address of the source IP address.                                                           | —                                                                          |
| Reflective port                     | Displays the translated number of the port.                                                               | —                                                                          |
| Reflective protocol                 | Translated protocol.                                                                                      | —                                                                          |
| Source NAT pool                     | Name of the source NAT pool where persistent NAT is used.                                                 | —                                                                          |
| Type                                | Persistent NAT type.                                                                                      | —                                                                          |
| Left time/Conf time                 | Inactivity timeout period that remains and the configured timeout value.                                  | —                                                                          |
| Current session num/Max session num | Number of current sessions associated with the persistent NAT binding and the maximum number of sessions. | —                                                                          |
| Source NAT rule                     | Name of the source NAT rule to which this persistent NAT binding applies.                                 | —                                                                          |
| <b>External node table</b>          |                                                                                                           |                                                                            |
| Internal IP                         | Internal transport IP address of the outgoing session from internal to external.                          | —                                                                          |

### Monitoring Destination NAT Information

**Purpose** View the destination Network Address Translation (NAT) summary table and the details of the specified NAT destination address pool information.

**Action** Select **Monitor>NAT> Destination NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat destination summary**
- **show security nat destination pool *pool-name***

Table 122 summarizes key output fields in the destination NAT display.

**Table 122: Summary of Key Destination NAT Output Fields**

| Field                     | Values                                                                   | Action                                                                |
|---------------------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Rules</b>              |                                                                          |                                                                       |
| Rule-set Name             | Name of the rule set.                                                    | Select all rule sets or a specific rule set to display from the list. |
| Total rules               | Number of rules configured.                                              | —                                                                     |
| ID                        | Rule ID number.                                                          | —                                                                     |
| Name                      | Name of the rule .                                                       | —                                                                     |
| Ruleset Name              | Name of the rule set.                                                    | —                                                                     |
| From                      | Name of the routing instance/zone/interface from which the packet flows. | —                                                                     |
| Source address range      | Source IP address range in the source pool.                              | —                                                                     |
| Destination address range | Destination IP address range in the source pool.                         | —                                                                     |

### Monitoring Static NAT Information

**Purpose** View static NAT rule information.

**Action** Select **Monitor>NAT>Static NAT** in the J-Web user interface, or enter the following CLI command:

**show security nat static rule**

Table 123 summarizes key output fields in the static NAT display.

**Table 123: Summary of Key Static NAT Output Fields**

| Field                                  | Values                                                                                                                                                                                                                                                                                                                                              | Action                                                                |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| Rule-set Name                          | Name of the rule set.                                                                                                                                                                                                                                                                                                                               | Select all rule sets or a specific rule set to display from the list. |
| Total rules                            | Number of rules configured.                                                                                                                                                                                                                                                                                                                         | —                                                                     |
| ID                                     | Rule ID number.                                                                                                                                                                                                                                                                                                                                     | —                                                                     |
| Position                               | Position of the rule that indicates the order in which it applies to traffic.                                                                                                                                                                                                                                                                       | —                                                                     |
| Name                                   | Name of the rule.                                                                                                                                                                                                                                                                                                                                   | —                                                                     |
| Ruleset Name                           | Name of the rule set.                                                                                                                                                                                                                                                                                                                               | —                                                                     |
| From                                   | Name of the routing instance/interface/zone from which the packet comes                                                                                                                                                                                                                                                                             | —                                                                     |
| Source addresses                       | Source IP addresses.                                                                                                                                                                                                                                                                                                                                | —                                                                     |
| Source ports                           | Source port numbers.                                                                                                                                                                                                                                                                                                                                | —                                                                     |
| Destination addresses                  | Destination IP address and subnet mask.                                                                                                                                                                                                                                                                                                             | —                                                                     |

| Host routing instance                  | Name of the routing instance from which the packet comes.                                                                                                                                                                                                                                                                                           | —                                                                     |
| Alarm threshold                        | Utilization alarm threshold.                                                                                                                                                                                                                                                                                                                        | —                                                                     |
| Sessions (Succ/<br>Failed/<br>Current) | Successful, failed, and current sessions. <ul style="list-style-type: none"> <li>• Succ—Number of successful session installations after the NAT rule is matched.</li> <li>• Failed—Number of unsuccessful session installations after the NAT rule is matched.</li> <li>• Current—Number of sessions that reference the specified rule.</li> </ul> | —                                                                     |

Table 123: Summary of Key Static NAT Output Fields (*continued*)

| Field                          | Values                                                                                | Action |
|--------------------------------|---------------------------------------------------------------------------------------|--------|
| Translation hits               | Number of times a translation in the translation table is used for a static NAT rule. | –      |
| <b>Top 10 Translation Hits</b> |                                                                                       |        |
| Graph                          | Displays the graph of top 10 translation hits.                                        | –      |

### Monitoring Incoming Table Information

**Purpose** View NAT table information.

**Action** Select **Monitor>NAT>Incoming Table** in the J-Web user interface, or enter the following CLI command:

**show security nat incoming-table**

Table 124 summarizes key output fields in the incoming table display.

Table 124: Summary of Key Incoming Table Output Fields

| Field                   | Values                                                                        |
|-------------------------|-------------------------------------------------------------------------------|
| <b>Statistics</b>       |                                                                               |
| In use                  | Number of entries in the NAT table.                                           |
| Maximum                 | Maximum number of entries possible in the NAT table.                          |
| Entry allocation failed | Number of entries failed for allocation.                                      |
| <b>Incoming Table</b>   |                                                                               |
| <b>Clear</b>            |                                                                               |
| Destination             | Destination IP address and port number.                                       |
| Host                    | Host IP address and port number that the destination IP address is mapped to. |
| References              | Number of sessions referencing the entry.                                     |
| Timeout                 | Timeout, in seconds, of the entry in the NAT table.                           |
| Source-pool             | Name of source pool where translation is allocated.                           |

### Monitoring Interface NAT Port Information

**Purpose** View port usage for an interface source pool information.

**Action** Select **Monitor>Firewall/NAT>Interface NAT** in the J-Web user interface, or enter the following CLI command:

- **show security nat interface-nat-ports**

Table 125 summarizes key output fields in the interface NAT display.

**Table 125: Summary of Key Interface NAT Output Fields**

| Field                              | Values                                                         | Additional Information |
|------------------------------------|----------------------------------------------------------------|------------------------|
| <b>Interface NAT Summary Table</b> |                                                                |                        |
| Pool Index                         | Port pool index.                                               | —                      |
| Total Ports                        | Total number of ports in a port pool.                          | —                      |
| Single Ports Allocated             | Number of ports allocated one at a time that are in use.       | —                      |
| Single Ports Available             | Number of ports allocated one at a time that are free for use. | —                      |
| Twin Ports Allocated               | Number of ports allocated two at a time that are in use.       | —                      |
| Twin Ports Available               | Number of ports allocated two at a time that are free for use. | —                      |

### Monitoring Policy Statistics

**Purpose** Monitor and record traffic that Junos OS permits or denies based on previously configured policies.

**Action** To monitor traffic, enable the count and log options.

**Count**—Configurable in an individual policy. If count is enabled, statistics are collected for sessions that enter the device for a given policy, and for the number of packets and

bytes that pass through the device in both directions for a given policy. For counts (only for packets and bytes), you can specify that alarms be generated whenever the traffic exceeds specified thresholds. See *count* (*Security Policies*).

**Log**—Logging capability can be enabled with security policies during session initialization (**session-init**) or session close (**session-close**) stage. See *log* (*Security Policies*).

- To view logs from denied connections, enable log on **session-init**.
- To log sessions after their conclusion/tear-down, enable log on **session-close**.

**NOTE:** Session log is enabled at real time in the flow code which impacts the user performance. If both **session-close** and **session-init** are enabled, performance is further degraded as compared to enabling **session-init** only.

---

For details about information collected for session logs, see *Information Provided in Session Log Entries for SRX Series Services Gateways*.

### Monitoring Route Information

---

- |                |                                                                                                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | View information about the routes in a routing table, including destination, protocol, state, and parameter information.                                                                                                             |
| <b>Action</b>  | Select <b>Monitor&gt;Routing&gt;Route Information</b> in the J-Web user interface, or enter the following CLI commands: <ul style="list-style-type: none"><li>• <b>show route terse</b></li><li>• <b>show route detail</b></li></ul> |

**NOTE:** When you use an HTTPS connection in the Microsoft Internet Explorer browser to save a report from this page in the J-Web interface, the error message "Internet Explorer was not able to open the Internet site" is displayed. This problem occurs because the Cache-Control: no cache HTTP header is added on the server side and Internet Explorer does not allow you to download the encrypted file with the Cache-Control: no cache HTTP header set in the response from the server.

As a workaround, refer to Microsoft Knowledge Base article 323308, which is available at this URL: <http://support.microsoft.com/kb/323308>. Also, you can alternatively use HTTP in the Internet Explorer browser or use HTTPS in the Mozilla Firefox browser to save a file from this page.

Table 126 describes the different filters, their functions, and the associated actions.

Table 127 summarizes key output fields in the routing information display.

**Table 126: Filtering Route Messages**

| Field               | Function                                                                                                                             | Your Action                                                     |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Destination Address | Specifies the destination address of the route.                                                                                      | Enter the destination address.                                  |
| Protocol            | Specifies the protocol from which the route was learned.                                                                             | Enter the protocol name.                                        |
| Next hop address    | Specifies the network layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it. | Enter the next hop address.                                     |
| Receive protocol    | Specifies the dynamic routing protocol using which the routing information was received through a particular neighbor.               | Enter the routing protocol.                                     |
| Best route          | Specifies only the best route available.                                                                                             | Select the view details of the best route.                      |
| Inactive routes     | Specifies the inactive routes.                                                                                                       | Select the view details of inactive routes.                     |
| Exact route         | Specifies the exact route.                                                                                                           | Select the view details of the exact route.                     |
| Hidden routes       | Specifies the hidden routes.                                                                                                         | Select the view details of hidden routes.                       |
| Search              | Applies the specified filter and displays the matching messages.                                                                     | To apply the filter and display messages, click <b>Search</b> . |
| Reset               | Resets selected options to default                                                                                                   | To reset the filter, click <b>Reset</b> .                       |

Table 127: Summary of Key Routing Information Output Fields

| Field                  | Values                                                                                                                                                                                                                                                                     | Additional Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Static Route Addresses | The list of static route addresses.                                                                                                                                                                                                                                        | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Protocol               | Protocol from which the route was learned: <b>Static</b> , <b>Direct</b> , <b>Local</b> , or the name of a particular protocol.                                                                                                                                            | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Preference             | The preference is the individual preference value for the route.                                                                                                                                                                                                           | The route preference is used as one of the route selection criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Next-Hop               | Network Layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it.                                                                                                                                                     | <p>If a next hop is listed as <b>Discard</b>, all traffic with that destination address is discarded rather than routed. This value generally means that the route is a static route for which the <b>discard</b> attribute has been set.</p> <p>If a next hop is listed as <b>Reject</b>, all traffic with that destination address is rejected. This value generally means that the address is unreachable. For example, if the address is a configured interface address and the interface is unavailable, traffic bound for that address is rejected.</p> <p>If a next hop is listed as <b>Local</b>, the destination is an address on the host (either the loopback address or Ethernet management port 0 address, for example).</p> |
| Age                    | How long the route has been active.                                                                                                                                                                                                                                        | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| State                  | Flags for this route.                                                                                                                                                                                                                                                      | There are many possible flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| AS Path                | <p>AS path through which the route was learned. The letters of the AS path indicate the path origin:</p> <ul style="list-style-type: none"> <li>• <b>I</b>—IGP.</li> <li>• <b>E</b>—EGP.</li> <li>• <b>?</b>—Incomplete. Typically, the AS path was aggregated.</li> </ul> | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Monitoring RIP Routing Information

**Purpose** View RIP routing information, including a summary of RIP neighbors and statistics.

**Action** Select **Monitor>Routing>RIP Information** in the J-Web user interface, or enter the following CLI commands:

- **show rip statistics**
- **show rip neighbors**

[Table 128](#) summarizes key output fields in the RIP routing display in the J-Web user interface.

Table 128: Summary of Key RIP Routing Output Fields

| Field                    | Values                                                                                 | Additional Information                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>RIP Statistics</b>    |                                                                                        |                                                                                                                       |
| Protocol Name            | The RIP protocol name.                                                                 | —                                                                                                                     |
| Port number              | The port on which RIP is enabled.                                                      | —                                                                                                                     |
| Hold down time           | The interval during which routes are neither advertised nor updated.                   | —                                                                                                                     |
| Global routes learned    | Number of RIP routes learned on the logical interface.                                 | —                                                                                                                     |
| Global routes held down  | Number of RIP routes that are not advertised or updated during the hold-down interval. | —                                                                                                                     |
| Global request dropped   | Number of requests dropped.                                                            | —                                                                                                                     |
| Global responses dropped | Number of responses dropped.                                                           | —                                                                                                                     |
| <b>RIP Neighbors</b>     |                                                                                        |                                                                                                                       |
| Details                  | Tab used to view the details of the interface on which RIP is enabled.                 | —                                                                                                                     |
| Neighbor                 | Name of the RIP neighbor.                                                              | This value is the name of the interface on which RIP is enabled. Click the name to see the details for this neighbor. |
| State                    | State of the RIP connection: <b>Up</b> or <b>Dn</b> (Down).                            | —                                                                                                                     |
| Source Address           | Local source address.                                                                  | This value is the configured address of the interface on which RIP is enabled.                                        |
| Destination Address      | Destination address.                                                                   | This value is the configured address of the immediate RIP adjacency.                                                  |
| Send Mode                | The mode of sending RIP messages.                                                      | —                                                                                                                     |
| Receive Mode             | The mode in which messages are received.                                               | —                                                                                                                     |
| In Metric                | Value of the incoming metric configured for the RIP neighbor.                          | —                                                                                                                     |

### Monitoring OSPF Routing Information

**Purpose** View OSPF routing information, including a summary of OSPF neighbors, interfaces, and statistics.

**Action** Select **Monitor>Routing>OSPF Information** in the J-Web user interface, or enter the following CLI commands:

- **show ospf neighbors**
- **show ospf interfaces**
- **show ospf statistics**

[Table 129](#) summarizes key output fields in the OSPF routing display in the J-Web user interface.

**Table 129: Summary of Key OSPF Routing Output Fields**

| Field                    | Values                                                                                                                            | Additional Information                                                                                                                                                                          |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OSPF Interfaces</b>   |                                                                                                                                   |                                                                                                                                                                                                 |
| Details                  | Tab used to view the details of the selected OSPF.                                                                                | —                                                                                                                                                                                               |
| Interface                | Name of the interface running OSPF.                                                                                               | —                                                                                                                                                                                               |
| State                    | State of the interface: <b>BDR</b> , <b>Down</b> , <b>DR</b> , <b>DRother</b> , <b>Loop</b> , <b>PtToPt</b> , or <b>Waiting</b> . | The <b>Down</b> state, indicating that the interface is not functioning, and <b>PtToPt</b> state, indicating that a point-to-point connection has been established, are the most common states. |
| Area                     | Number of the area that the interface is in.                                                                                      | —                                                                                                                                                                                               |
| DR ID                    | ID of the area's designated device.                                                                                               | —                                                                                                                                                                                               |
| BDR ID                   | ID of the area's backup designated device.                                                                                        | —                                                                                                                                                                                               |
| Neighbors                | Number of neighbors on this interface.                                                                                            | —                                                                                                                                                                                               |
| <b>OSPF Statistics</b>   |                                                                                                                                   |                                                                                                                                                                                                 |
| <b>Packets tab</b>       |                                                                                                                                   |                                                                                                                                                                                                 |
| Sent                     | Displays the total number of packets sent.                                                                                        | —                                                                                                                                                                                               |
| Received                 | Displays the total number of packets received.                                                                                    | —                                                                                                                                                                                               |

| Flood Queue Depth        | Number of entries in the extended queue.                                                                                          | —                                                                                                                                                                                               |
| Total Retransmits        | Number of retransmission entries enqueued.                                                                                        | —                                                                                                                                                                                               |
| Total Database Summaries | Total number of database description packets.                                                                                     | —                                                                                                                                                                                               |
| <b>OSPF Neighbors</b>    |                                                                                                                                   |                                                                                                                                                                                                 |
| Address                  | Address of the neighbor.                                                                                                          | —                                                                                                                                                                                               |

Table 129: Summary of Key OSPF Routing Output Fields (*continued*)

| Field         | Values                                                                                                                                                 | Additional Information                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface     | Interface through which the neighbor is reachable.                                                                                                     | –                                                                                                                                                                                                                                                                                                              |
| State         | State of the neighbor: <b>Attempt</b> , <b>Down</b> , <b>Exchange</b> , <b>ExStart</b> , <b>Full</b> , <b>Init</b> , <b>Loading</b> , or <b>2way</b> . | Generally, only the <b>Down</b> state, indicating a failed OSPF adjacency, and the <b>Full</b> state, indicating a functional adjacency, are maintained for more than a few seconds. The other states are transitional states that a neighbor is in only briefly while an OSPF adjacency is being established. |
| ID            | ID of the neighbor.                                                                                                                                    | –                                                                                                                                                                                                                                                                                                              |
| Priority      | Priority of the neighbor to become the designated router.                                                                                              | –                                                                                                                                                                                                                                                                                                              |
| Activity Time | The activity time.                                                                                                                                     | –                                                                                                                                                                                                                                                                                                              |
| Area          | Area that the neighbor is in.                                                                                                                          | –                                                                                                                                                                                                                                                                                                              |
| Options       | Option bits received in the hello packets from the neighbor.                                                                                           | –                                                                                                                                                                                                                                                                                                              |
| DR Address    | Address of the designated router.                                                                                                                      | –                                                                                                                                                                                                                                                                                                              |
| BDR Address   | Address of the backup designated router.                                                                                                               | –                                                                                                                                                                                                                                                                                                              |
| Uptime        | Length of time since the neighbor came up.                                                                                                             | –                                                                                                                                                                                                                                                                                                              |
| Adjacency     | Length of time since the adjacency with the neighbor was established.                                                                                  | –                                                                                                                                                                                                                                                                                                              |

### Monitoring BGP Routing Information

**Purpose** Monitor BGP routing information on the routing device, including a summary of BGP routing and neighbor information.

**Action** Select **Monitor>Routing>BGP Information** in the J-Web user interface, or enter the following CLI commands:

- **show bgp summary**
- **show bgp neighbor**

[Table 130](#) summarizes key output fields in the BGP routing display in the J-Web user interface.

Table 130: Summary of Key BGP Routing Output Fields

| Field                   | Values                                                                                                                                                                 | Additional Information |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>BGP Peer Summary</b> |                                                                                                                                                                        |                        |
| Total Groups            | Number of BGP groups.                                                                                                                                                  | —                      |
| Total Peers             | Number of BGP peers.                                                                                                                                                   | —                      |
| Down Peers              | Number of unavailable BGP peers.                                                                                                                                       | —                      |
| Unconfigured Peers      | Address of each BGP peer.                                                                                                                                              | —                      |
| <b>RIB Summary tab</b>  |                                                                                                                                                                        |                        |
| RIB Name                | Name of the RIB group.                                                                                                                                                 | —                      |
| Total Prefixes          | Total number of prefixes from the peer, both active and inactive, that are in the routing table.                                                                       | —                      |
| Active Prefixes         | Number of prefixes received from the EBGp peers that are active in the routing table.                                                                                  | —                      |
| Suppressed Prefixes     | Number of routes received from EBGp peers currently inactive because of damping or other reasons.                                                                      | —                      |
| History Prefixes        | History of the routes received or suppressed.                                                                                                                          | —                      |
| Dumped Prefixes         | Number of routes currently inactive because of damping or other reasons. These routes do not appear in the forwarding table and are not exported by routing protocols. | —                      |
| Pending Prefixes        | Number of pending routes.                                                                                                                                              | —                      |
| State                   | Status of the graceful restart process for this routing table: BGP restart is complete, BGP restart in progress, VPN restart in progress, or VPN restart is complete.  | —                      |
| <b>BGP Neighbors</b>    |                                                                                                                                                                        |                        |
| Details                 | Click this button to view the selected BGP neighbor details.                                                                                                           | —                      |
| Peer Address            | Address of the BGP neighbor.                                                                                                                                           | —                      |
| Autonomous System       | AS number of the peer.                                                                                                                                                 | —                      |

Table 130: Summary of Key BGP Routing Output Fields (*continued*)

| Field        | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Additional Information                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer State   | <p>Current state of the BGP session:</p> <ul style="list-style-type: none"> <li>• <b>Active</b>—BGP is initiating a TCP connection in an attempt to connect to a peer. If the connection is successful, BGP sends an open message.</li> <li>• <b>Connect</b>—BGP is waiting for the TCP connection to become complete.</li> <li>• <b>Established</b>—The BGP session has been established, and the peers are exchanging BGP update messages.</li> <li>• <b>Idle</b>—This is the first stage of a connection. BGP is waiting for a Start event.</li> <li>• <b>OpenConfirm</b>—BGP has acknowledged receipt of an open message from the peer and is waiting to receive a keepalive or notification message.</li> <li>• <b>OpenSent</b>—BGP has sent an open message and is waiting to receive an open message from the peer.</li> </ul> | Generally, the most common states are <b>Active</b> , which indicates a problem establishing the BGP connection, and <b>Established</b> , which indicates a successful session setup. The other states are transition states, and BGP sessions normally do not stay in those states for extended periods of time. |
| Elapsed Time | Elapsed time since the peering session was last reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | —                                                                                                                                                                                                                                                                                                                 |
| Description  | Description of the BGP session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | —                                                                                                                                                                                                                                                                                                                 |

## Monitoring Security Events by Policy

**Purpose** Monitor security events by policy and display logged event details with the J-Web user interface.

**Action** 1. Select **Monitor>Events and Alarms>Security Events** in the J-Web user interface. The View Policy Log pane appears. [Table 131](#) describes the content of this pane.

Table 131: View Policy Log Fields

| Field               | Value                                                        |
|---------------------|--------------------------------------------------------------|
| Log file name       | Name of the event log files to search.                       |
| Policy name         | Name of the policy of the events to be retrieved.            |
| Source address      | Source address of the traffic that triggered the event.      |
| Destination address | Destination address of the traffic that triggered the event. |

Table 131: View Policy Log Fields (*continued*)

| Field                | Value                                                         |
|----------------------|---------------------------------------------------------------|
| Event type           | Type of event that was triggered by the traffic.              |
| Application          | Application of the traffic that triggered the event.          |
| Source port          | Source port of the traffic that triggered the event.          |
| Destination port     | Destination port of the traffic that triggered the event.     |
| Source zone          | Source zone of the traffic that triggered the event.          |
| Destination zone     | Destination zone of the traffic that triggered the event.     |
| Source NAT rule      | Source NAT rule of the traffic that triggered the event.      |
| Destination NAT rule | Destination NAT rule of the traffic that triggered the event. |
| Is global policy     | Specifies that the policy is a global policy.                 |

If your device is not configured to store session log files locally, the Create log configuration button is displayed in the lower-right portion of the View Policy Log pane.

- To store session log files locally, click **Create log configuration**.

If session logs are being sent to an external log collector (stream mode has been configured for log files), a message appears indicating that event mode must be configured to view policy logs.

**NOTE:** Reverting to event mode will discontinue event logging to the external log collector.

- To reset the **mode** option to **event**, enter the **set security log** command.

2. Enter one or more search fields in the View Policy Log pane and click **Search** to display events matching your criteria.

For example, enter the event type **Session Close** and the policy **pol1** to display event details from all Session Close logs that contain the specified policy. To reduce search results further, add more criteria about the particular event or group of events that you want displayed.

The Policy Events Detail pane displays information from each matching session log. [Table 132](#) describes the contents of this pane.

Table 132: Policy Events Detail Fields

| Field                   | Value                                                                   |
|-------------------------|-------------------------------------------------------------------------|
| Timestamp               | Time when the event occurred.                                           |
| Policy name             | Policy that triggered the event.                                        |
| Record type             | Type of event log providing the data.                                   |
| Source IP/Port          | Source address (and port, if applicable) of the event traffic.          |
| Destination IP/Port     | Destination address (and port, if applicable) of the event traffic.     |
| Service name            | Service name of the event traffic.                                      |
| NAT source IP/Port      | NAT source address (and port, if applicable) of the event traffic.      |
| NAT destination IP/Port | NAT destination address (and port, if applicable) of the event traffic. |

### Monitoring Policies

- Purpose** Display, sort, and review policy activity for every activated policy configured on the device. Policies are grouped by Zone Context (the from and to zones of the traffic) to control the volume of data displayed at one time. From the policy list, select a policy to display statistics and current network activity.

**Action** To review policy activity:

1. Select **Monitor>Security>Policy>Activities** in the J-Web user interface. The Security Policies Monitoring page appears and lists the policies from the first Zone Context. See [Table 133](#) for field descriptions.
2. Select the **Zone Context** of the policy you want to monitor, and click **Filter**. All policies within the zone context appear in match sequence.
3. Select a policy, and click **Clear Statistics** to set all counters to zero for the selected policy.

**Table 133: Security Policies Monitoring Output Fields**

| Field                  | Value                                                                                                                                                                                                                                                                               | Additional Information                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Zone Context (Total #) | Displays a list of all from and to zone combinations for the configured policies. The total number of active policies for each context is specified in the Total # field. By default, the policies from the first Zone Context are displayed.                                       | To display policies for a different context, select a zone context and click <b>Filter</b> . Both inactive and active policies appear for each context. However, the Total # field for a context specifies the number of active policies only. |
| Default Policy action  | Specifies the action to take for traffic that does not match any of the policies in the context: <ul style="list-style-type: none"> <li>• permit-all—Permit all traffic that does not match a policy.</li> <li>• deny-all—Deny all traffic that does not match a policy.</li> </ul> | —                                                                                                                                                                                                                                              |
| From Zone              | Displays the source zone to be used as match criteria for the policy.                                                                                                                                                                                                               | —                                                                                                                                                                                                                                              |
| To Zone                | Displays the destination zone to be used as match criteria for the policy.                                                                                                                                                                                                          | —                                                                                                                                                                                                                                              |
| Name                   | Displays the name of the policy.                                                                                                                                                                                                                                                    | —                                                                                                                                                                                                                                              |
| Source Address         | Displays the source addresses to be used as match criteria for the policy. Address sets are resolved to their individual names. (In this case, only the names are given, not the IP addresses).                                                                                     | —                                                                                                                                                                                                                                              |
| Destination Address    | Displays the destination addresses (or address sets) to be used as match criteria for the policy. Addresses are entered as specified in the destination zone's address book.                                                                                                        | —                                                                                                                                                                                                                                              |
| Source Identity        | Displays the name of the source identities set for the policy.                                                                                                                                                                                                                      | To display the value of the source identities, hover the mouse on this field. Unknown source identities are also displayed.                                                                                                                    |
| Application            | Displays the name of a predefined or custom application signature to be used as match criteria for the policy.                                                                                                                                                                      | —                                                                                                                                                                                                                                              |

Table 133: Security Policies Monitoring Output Fields (*continued*)

| Field                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Additional Information                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic App               | <p>Displays the dynamic application signatures to be used as match criteria if an application firewall rule set is configured for the policy.</p> <p>For a network firewall, a dynamic application is not defined.</p>                                                                                                                                                                                                                                                                                                   | <p>The rule set appears in two lines. The first line displays the configured dynamic application signatures in the rule set. The second line displays the default dynamic application signature.</p> <p>If more than two dynamic application signatures are specified for the rule set, hover over the output field to display the full list in a tooltip.</p> |
| Action                    | <p>Displays the action portion of the rule set if an application firewall rule set is configured for the policy.</p> <ul style="list-style-type: none"> <li>• permit—Permits access to the network services controlled by the policy. A green background signifies permission.</li> <li>• deny—Denies access to the network services controlled by the policy. A red background signifies denial.</li> </ul>                                                                                                             | <p>The action portion of the rule set appears in two lines. The first line identifies the action to be taken when the traffic matches a dynamic application signature. The second line displays the default action when traffic does not match a dynamic application signature.</p>                                                                            |
| NW Services               | <p>Displays the network services permitted or denied by the policy if an application firewall rule set is configured. Network services include:</p> <ul style="list-style-type: none"> <li>• gprs-gtp-profile—Specify a GPRS Tunneling Protocol profile name.</li> <li>• idp—Perform intrusion detection and prevention.</li> <li>• redirect-wx—Set WX redirection.</li> <li>• reverse-redirect-wx—Set WX reverse redirection.</li> <li>• uac-policy—Enable unified access control enforcement of the policy.</li> </ul> | —                                                                                                                                                                                                                                                                                                                                                              |
| Policy Hit Counters Graph | <p>Provides a representation of the value over time for a specified counter. The graph is blank if Policy Counters indicates no data. As a selected counter accumulates data, the graph is updated at each refresh interval.</p>                                                                                                                                                                                                                                                                                         | <p>To toggle a graph on and off, click the counter name below the graph.</p>                                                                                                                                                                                                                                                                                   |

Table 133: Security Policies Monitoring Output Fields (*continued*)

| Field           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Additional Information                                                                                                                             |

| Policy Counters | <p>Lists statistical counters for the selected policy if Count is enabled. The following counters are available for each policy:</p> <ul style="list-style-type: none"> <li>• input-bytes</li> <li>• input-byte-rate</li> <li>• output-bytes</li> <li>• output-byte-rate</li> <li>• input-packets</li> <li>• input-packet-rate</li> <li>• output-packets</li> <li>• output-packet-rate</li> <li>• session-creations</li> <li>• session-creation-rate</li> <li>• active-sessions</li> </ul> | To graph or to remove a counter from the Policy Hit Counters Graph, toggle the counter name. The names of enabled counters appear below the graph. |

### Checking Policies

- Purpose** Enter match criteria and conduct a policy search. The search results include all policies that match the traffic criteria in the sequence in which they will be encountered.
- Because policy matches are listed in the sequence in which they would be encountered, you can determine whether a specific policy is being applied correctly or not. The first policy in the list is applied to all matching traffic. Policies listed after this one remain in the “shadow” of the first policy and are never encountered by this traffic.
- By manipulating the traffic criteria and policy sequence, you can tune policy application to suit your needs. During policy development, you can use this feature to establish the appropriate sequence of policies for optimum traffic matches. When troubleshooting, use this feature to determine if specific traffic is encountering the appropriate policy.
- Action**
1. Select **Monitor>Security>Policy>Shadow Policies** in the J-Web user interface. The Check Policies page appears. [Table 134](#) explains the content of this page.
  2. In the top pane, enter the From Zone and To Zone to supply the context for the search.
  3. Enter match criteria for the traffic, including the source address and port, the destination address and port, and the protocol of the traffic.
  4. Enter the number of matching policies to display.
  5. Click **Search** to find policies matching your criteria. The lower pane displays all policies matching the criteria up to the number of policies you specified.
    - The first policy will be applied to all traffic with this match criteria.

- Remaining policies will not be encountered by any traffic with this match criteria.
6. To manipulate the position and activation of a policy, select the policy and click the appropriate button:
- **Move**—Moves the selected policy up or down to position it at a more appropriate point in the search sequence.
  - **Move to**—Moves the selected policy by allowing you to drag and drop it to a different location on the same page.

Table 134: Check Policies Output

| Field                                   | Function                                                                                                            |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Check Policies Search Input Pane</b> |                                                                                                                     |
| From Zone                               | Name or ID of the source zone. If a From Zone is specified by name, the name is translated to its ID internally.    |
| To Zone                                 | Name or ID of the destination zone. If a To Zone is specified by name, the name is translated to its ID internally. |
| Source Address                          | Address of the source in IP notation.                                                                               |
| Source Port                             | Port number of the source.                                                                                          |
| Destination Address                     | Address of the destination in IP notation.                                                                          |
| Destination Port                        | Port number of the destination.                                                                                     |
| Source Identity                         | Name of the source identity.                                                                                        |

Table 134: Check Policies Output (*continued*)

| Field                      | Function                                                                                                                                                                                                                                              |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Result Count               | (Optional) Number of policies to display. Default value is 1. Maximum value is 16.                                                                                                                                                                    |
| <b>Check Policies List</b> |                                                                                                                                                                                                                                                       |
| From Zone                  | Name of the source zone.                                                                                                                                                                                                                              |
| To Zone                    | Name of the destination zone.                                                                                                                                                                                                                         |
| Total Policies             | Number of policies retrieved.                                                                                                                                                                                                                         |
| Default Policy action      | The action to be taken if no match occurs.                                                                                                                                                                                                            |
| Name                       | Policy name                                                                                                                                                                                                                                           |
| Source Address             | Name of the source address (not the IP address) of a policy. Address sets are resolved to their individual names.                                                                                                                                     |

Table 134: Check Policies Output (*continued*)

| Field               | Function                                                                                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Destination Address | Name of the destination address or address set. A packet's destination address must match this value for the policy to apply to it. |
| Source Identity     | Name of the source identity for the policy.                                                                                         |
| Application         | Name of a preconfigured or custom application of the policy match.                                                                  |
| Action              | Action taken when a match occurs as specified in the policy.                                                                        |
| Hit Counts          | Number of matches for this policy. This value is the same as the Policy Lookups in a policy statistics report.                      |
| Active Sessions     | Number of active sessions matching this policy.                                                                                     |

Alternatively, to list matching policies using the CLI, enter the **show security match-policies** command and include your match criteria and the number of matching policies to display.

### Monitoring Screen Counters

**Purpose** View screen statistics for a specified security zone.

**Action** Select **Monitor>Security>Screen Counters** in the J-Web user interface, or enter the following CLI command:

**show security screen statistics zone *zone-name***

Table 135 summarizes key output fields in the screen counters display.

Table 135: Summary of Key Screen Counters Output Fields

| Field        | Values                                                      | Additional Information                                                                                                                                                               |
|--------------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Zones</b> |                                                             |                                                                                                                                                                                      |
| ICMP Flood   | Internet Control Message Protocol (ICMP) flood counter.     | An ICMP flood typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.                                  |
| UDP Flood    | User Datagram Protocol (UDP) flood counter.                 | UDP flooding occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the resources, such that valid connections can no longer be handled. |
| TCP Winnuke  | Number of Transport Control Protocol (TCP) WinNuke attacks. | WinNuke is a denial-of-service (DoS) attack targeting any computer on the Internet running Windows.                                                                                  |

Table 135: Summary of Key Screen Counters Output Fields (*continued*)

| Field                  | Values                                                     | Additional Information                                                                                                                                     |
|------------------------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCP Port Scan          | Number of TCP port scans.                                  | The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.       |
| ICMP Address Sweep     | Number of ICMP address sweeps.                             | An IP address sweep can occur with the intent of triggering responses from active hosts.                                                                   |
| IP Tear Drop           | Number of teardrop attacks.                                | Teardrop attacks exploit the reassembly of fragmented IP packets.                                                                                          |
| TCP SYN Attack         | Number of TCP SYN attacks.                                 | —                                                                                                                                                          |
| IP Spoofing            | Number of IP spoofs.                                       | IP spoofing occurs when an invalid source address is inserted in the packet header to make the packet appear to come from a trusted source.                |
| ICMP Ping of Death     | ICMP ping of death counter.                                | Ping of death occurs when IP packets are sent that exceed the maximum legal length (65,535 bytes).                                                         |
| IP Source Route        | Number of IP source route attacks.                         | —                                                                                                                                                          |
| TCP Land Attack        | Number of land attacks.                                    | Land attacks occur when attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and source IP address.          |
| TCP SYN Fragment       | Number of TCP SYN fragments.                               | —                                                                                                                                                          |
| TCP No Flag            | Number of TCP headers without flags set.                   | A normal TCP segment header has at least one control flag set.                                                                                             |
| IP Unknown Protocol    | Number of unknown Internet protocols.                      | —                                                                                                                                                          |
| IP Bad Options         | Number of invalid options.                                 | —                                                                                                                                                          |
| IP Record Route Option | Number of packets with the IP record route option enabled. | This option records the IP addresses of the network devices along the path that the IP packet travels.                                                     |
| IP Timestamp Option    | Number of IP timestamp option attacks.                     | This option records the time (in Universal Time) when each network device receives the packet during its trip from the point of origin to its destination. |
| IP Security Option     | Number of IP security option attacks.                      | —                                                                                                                                                          |

Table 135: Summary of Key Screen Counters Output Fields (*continued*)

| Field                         | Values                                                      | Additional Information                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Loose route Option         | Number of IP loose route option attacks.                    | This option specifies a partial route list for a packet to take on its journey from source to destination.                                                                                                                                                                         |
| IP Strict Source Route Option | Number of IP strict source route option attacks.            | This option specifies the complete route list for a packet to take on its journey from source to destination.                                                                                                                                                                      |
| IP Stream Option              | Number of stream option attacks.                            | This option provides a way for the 16-bit SATNET stream identifier to be carried through networks that do not support streams.                                                                                                                                                     |
| ICMP Fragment                 | Number of ICMP fragments.                                   | Because ICMP packets contain very short messages, there is no legitimate reason for ICMP packets to be fragmented. If an ICMP packet is so large that it must be fragmented, something is amiss.                                                                                   |
| ICMP Large Packet             | Number of large ICMP packets.                               | —                                                                                                                                                                                                                                                                                  |
| TCP SYN FIN Packet            | Number of TCP SYN FIN packets.                              | —                                                                                                                                                                                                                                                                                  |
| TCP FIN without ACK           | Number of TCP FIN flags without the acknowledge (ACK) flag. | —                                                                                                                                                                                                                                                                                  |
| TCP SYN-ACK-ACK Proxy         | Number of TCP flags enabled with SYN-ACK-ACK.               | To prevent flooding with SYN-ACK-ACK sessions, you can enable the SYN-ACK-ACK proxy protection screen option. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold, Junos OS rejects further connection requests from that IP address. |
| IP Block Fragment             | Number of IP block fragments.                               | —                                                                                                                                                                                                                                                                                  |

### Monitoring IDP Status

**Purpose** View detailed information about the IDP Status, Memory, Counters, Policy Rulebase Statistics, and Attack table statistics.

**Action** To view Intrusion Detection and Prevention (IDP) table information, select **Monitor>Security>IDP>Status** in the J-Web user interface, or enter the following CLI commands:

- **show security idp status**
- **show security idp memory**

Table 136 summarizes key output fields in the IDP display.

Table 136: Summary of IDP Status Output Fields

| Field                            | Values                                                                                                | Additional Information |
|----------------------------------|-------------------------------------------------------------------------------------------------------|------------------------|
| <b>IDP Status</b>                |                                                                                                       |                        |
| Status of IDP                    | Displays the status of the current IDP policy.                                                        | —                      |
| Up Since                         | Displays the time from when the IDP policy first began running on the system.                         | —                      |
| Packets/Second                   | Displays the number of packets received and returned per second.                                      | —                      |
| Peak                             | Displays the maximum number of packets received per second and the time when the maximum was reached. | —                      |
| Kbits/Second                     | Displays the aggregated throughput (kilobits per second) for the system.                              | —                      |
| Peak Kbits                       | Displays the maximum kilobits per second and the time when the maximum was reached.                   | —                      |
| Latency (Microseconds)           | Displays the delay, in microseconds, for a packet to receive and return by a node .                   | —                      |
| Current Policy                   | Displays the name of the current installed IDP policy.                                                | —                      |
| <b>IDP Memory Status</b>         |                                                                                                       |                        |
| IDP Memory Statistics            | Displays the status of all IDP data plane memory.                                                     | —                      |
| PIC Name                         | Displays the name of the PIC.                                                                         | —                      |
| Total IDP Data Plane Memory (MB) | Displays the total memory space, in megabytes, allocated for the IDP data plane.                      | —                      |
| Used (MB)                        | Displays the used memory space, in megabytes, for the data plane.                                     | —                      |
| Available (MB)                   | Displays the available memory space, in megabytes, for the data plane.                                | —                      |

### Monitoring Flow Gate Information

|                |                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | View information about temporary openings known as pinholes or gates in the security firewall.                                   |
| <b>Action</b>  | Select <b>Monitor&gt;Security&gt;Flow Gate</b> in the J-Web user interface, or enter the <b>show security flow gate</b> command. |

Table 137 summarizes key output fields in the flow gate display.

**Table 137: Summary of Key Flow Gate Output Fields**

| Field                        | Values                                                                                                                                                                           | Additional Information |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>Flow Gate Information</b> |                                                                                                                                                                                  |                        |
| Hole                         | Range of flows permitted by the pinhole.                                                                                                                                         | —                      |
| Translated                   | Tuples used to create the session if it matches the pinhole: <ul style="list-style-type: none"> <li>• Source address and port</li> <li>• Destination address and port</li> </ul> | —                      |
| Protocol                     | Application protocol, such as UDP or TCP.                                                                                                                                        | —                      |
| Application                  | Name of the application.                                                                                                                                                         | —                      |
| Age                          | Idle timeout for the pinhole.                                                                                                                                                    | —                      |
| Flags                        | Internal debug flags for pinhole.                                                                                                                                                | —                      |
| Zone                         | Incoming zone.                                                                                                                                                                   | —                      |
| Reference count              | Number of resource manager references to the pinhole.                                                                                                                            | —                      |
| Resource                     | Resource manager information about the pinhole.                                                                                                                                  | —                      |

### Monitoring Firewall Authentication Table

**Purpose** View information about the authentication table, which divides firewall authentication user information into multiple parts.

**Action** Select **Monitor>Security>Firewall Authentication>Authentication Table** in the J-Web user interface. To view detailed information about the user with a particular identifier, select the ID on the Authentication Table page. To view detailed information about the user at a particular source IP address, select the Source IP on the Authentication Table page.

Alternatively, enter the following CLI **show** commands:

- **show security firewall-authentication users**
- **show security firewall-authentication users address *ip-address***
- **show security firewall-authentication users identifier *identifier***

Table 138 summarizes key output fields in firewall authentication table display.

Table 138: Summary of Key Firewall Authentication Table Output Fields

| Field                                             | Values                                                         | Additional Information |
|---------------------------------------------------|----------------------------------------------------------------|------------------------|
| <b>Firewall authentication users</b>              |                                                                |                        |
| Total users in table                              | Number of users in the authentication table.                   | —                      |
| <b>Authentication table</b>                       |                                                                |                        |
| ID                                                | Authentication identification number.                          | —                      |
| Source Ip                                         | IP address of the authentication source.                       | —                      |
| Age                                               | Idle timeout for the user.                                     | —                      |
| Status                                            | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| user                                              | Name of the user.                                              | —                      |
| <b>Detailed report per ID selected: <i>ID</i></b> |                                                                |                        |
| Source Zone                                       | Name of the source zone.                                       | —                      |
| Destination Zone                                  | Name of the destination zone.                                  | —                      |
| profile                                           | Name of the profile.                                           | Users information.     |
| Authentication method                             | Path chosen for authentication.                                | —                      |
| Policy Id                                         | Policy Identifier.                                             | —                      |
| Interface name                                    | Name of the interface.                                         | —                      |
| Bytes sent by this user                           | Number of packets in bytes sent by this user.                  | —                      |
| Bytes received by this user                       | Number of packets in bytes received by this user.              | —                      |
| Client-groups                                     | Name of the client group.                                      | —                      |
| <b>Detailed report per Source Ip selected</b>     |                                                                |                        |
| Entries from Source IP                            | IP address of the authentication source.                       | —                      |
| Source Zone                                       | Name of the source zone.                                       | —                      |
| Destination Zone                                  | Name of the destination zone.                                  | —                      |

| Age                                               | Idle timeout for the user.                                     | —                      |
| Status                                            | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |

Table 138: Summary of Key Firewall Authentication Table Output Fields (*continued*)

| Field                       | Values                                            | Additional Information |
|-----------------------------|---------------------------------------------------|------------------------|
| user                        | Name of the user.                                 | —                      |
| Authentication method       | Path chosen for authentication.                   | —                      |
| Policy Id                   | Policy Identifier.                                | —                      |
| Interface name              | Name of the interface.                            | —                      |
| Bytes sent by this user     | Number of packets in bytes sent by this user.     | —                      |
| Bytes received by this user | Number of packets in bytes received by this user. | —                      |
| Client-groups               | Name of the client group.                         | —                      |

### Monitoring Firewall Authentication History

**Purpose** View information about the authentication history, which is divided into multiple parts.

**Action** Select **Monitor>Security>Firewall Authentication>Authentication History** in the J-Web user interface. To view the detailed history of the authentication with this identifier, select the ID on the Firewall Authentication History page. To view a detailed authentication history of this source IP address, select the Source IP on the Firewall Authentication History page.

Alternatively, enter the following CLI **show** commands:

- **show security firewall-authentication history**
- **show security firewall-authentication history address *ip-address***
- **show security firewall-authentication history identifier *identifier***

Table 139 summarizes key output fields in firewall authentication history display.

Table 139: Summary of Key Firewall Authentication History Output Fields

| Field                                          | Values                                   | Additional Information |
|------------------------------------------------|------------------------------------------|------------------------|
| <b>History of Firewall Authentication Data</b> |                                          |                        |
| Total authentications                          | Number of authentication.                | —                      |
| <b>History Table</b>                           |                                          |                        |
| ID                                             | Identification number.                   | —                      |
| Source Ip                                      | IP address of the authentication source. | —                      |

Table 139: Summary of Key Firewall Authentication History Output Fields (*continued*)

| Field                                                 | Values                                                         | Additional Information |
|-------------------------------------------------------|----------------------------------------------------------------|------------------------|
| Start Date                                            | Authentication date.                                           | —                      |
| Start Time                                            | Authentication time.                                           | —                      |
| Duration                                              | Authentication duration.                                       | —                      |
| Status                                                | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| User                                                  | Name of the user.                                              | —                      |
| <b>Detail history of selected Id: ID</b>              |                                                                |                        |
| Authentication method                                 | Path chosen for authentication.                                | —                      |
| Policy Id                                             | Security policy identifier.                                    | —                      |
| Source zone                                           | Name of the source zone.                                       | —                      |
| Destination Zone                                      | Name of the destination zone.                                  | —                      |
| Interface name                                        | Name of the interface.                                         | —                      |
| Bytes sent by this user                               | Number of packets in bytes sent by this user.                  | —                      |
| Bytes received by this user                           | Number of packets in bytes received by this user.              | —                      |
| Client-groups                                         | Name of the client group.                                      | —                      |
| <b>Detail history of selected Source Ip:Source Ip</b> |                                                                |                        |
| User                                                  | Name of the user.                                              | —                      |
| Start Date                                            | Authentication date.                                           | —                      |
| Start Time                                            | Authentication time.                                           | —                      |

| Status                                                | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| Profile                                               | Name of the profile.                                           | —                      |
| Authentication method                                 | Path chosen for authentication.                                | —                      |
| Policy Id                                             | Security policy identifier.                                    | —                      |
| Source zone                                           | Name of the source zone.                                       | —                      |

Table 139: Summary of Key Firewall Authentication History Output Fields (*continued*)

| Field                       | Values                                            | Additional Information |
|-----------------------------|---------------------------------------------------|------------------------|
| Destination Zone            | Name of the destination zone.                     | —                      |
| Interface name              | Name of the interface.                            | —                      |
| Bytes sent by this user     | Number of packets in bytes sent by this user.     | —                      |
| Bytes received by this user | Number of packets in bytes received by this user. | —                      |
| Client-groups               | Name of the client group.                         | —                      |

### Monitoring 802.1x

**Purpose** View information about 802.1X properties.

**Action** Select **Monitor>Security>802.1x** in the J-Web user interface, or enter the following CLI commands:

- **show dot1x interfaces *interface-name***
- **show dot1x authentication-failed-users**

Table 140 summarizes the Dot1X output fields.

Table 140: Summary of Dot1X Output Fields

| Field                                      | Values                                                                  | Additional Information |
|--------------------------------------------|-------------------------------------------------------------------------|------------------------|
| Select Port                                | List of ports for selection.                                            | —                      |
| Number of connected hosts                  | Total number of hosts connected to the port.                            | —                      |
| Number of authentication bypassed hosts    | Total number of authentication-bypassed hosts with respect to the port. | —                      |
| <b>Authenticated Users Summary</b>         |                                                                         |                        |
| MAC Address                                | MAC address of the connected host.                                      | —                      |
| User Name                                  | Name of the user.                                                       | —                      |
| Status                                     | Information about the host connection status.                           | —                      |
| Authentication Due                         | Information about host authentication.                                  | —                      |
| <b>Authentication Failed Users Summary</b> |                                                                         |                        |

Table 140: Summary of Dot1X Output Fields (*continued*)

| Field       | Values                                         | Additional Information |
|-------------|------------------------------------------------|------------------------|
| MAC Address | MAC address of the authentication-failed host. | –                      |
| User Name   | Name of the authentication-failed user.        | –                      |

## Monitoring Events, Services and System

- [Monitoring DHCP Client Bindings on page 1312](#)
- [Monitoring Events on page 1312](#)
- [Monitoring the System on page 1315](#)

### Monitoring DHCP Client Bindings

**Purpose** View information about DHCP client bindings.

**Action** Select **Monitor>Services>DHCP>Binding** in the J-Web user interface, or enter the **show system services dhcp binding** command.

[Table 141](#) summarizes the key output fields in the DHCP client binding displays.

Table 141: Summary of Key DHCP Client Binding Output Fields

| Field            | Values                                                                          | Additional Information |
|------------------|---------------------------------------------------------------------------------|------------------------|
| IP Address       | List of IP addresses the DHCP server has assigned to clients.                   | –                      |
| Hardware Address | Corresponding media access control (MAC) address of the client.                 | –                      |
| Type             | Type of binding assigned to the client: dynamic or static.                      | –                      |
| Lease Expires at | Date and time the lease expires, or <b>never</b> for leases that do not expire. | –                      |

### Monitoring Events

**Purpose** Use the monitoring functionality to view the events page.

**Action** To monitor events select **Monitor>Events and Alarms>View Events** in the J-Web user interface.

**NOTE:** When you use an HTTPS connection in the Microsoft Internet Explorer browser to save a report from this page in the J-Web interface, the error message "Internet Explorer was not able to open the Internet site" is displayed. This problem occurs because the Cache-Control: no cache HTTP header is added on the server side and Internet Explorer does not allow you to download the encrypted file with the Cache-Control: no cache HTTP header set in the response from the server.

As a workaround, refer to Microsoft Knowledge Base article 323308, which is available at this URL: <http://support.microsoft.com/kb/323308>. Also, you can alternatively use HTTP in the Internet Explorer browser or use HTTPS in the Mozilla Firefox browser to save a file from this page.

**Meaning** Table 142 summarizes key output fields in the events page.

**Table 142: Events Monitoring Page**

| Field                  | Value                                                                                      | Additional Information |
|------------------------|--------------------------------------------------------------------------------------------|------------------------|
| <b>Events Filter</b>   |                                                                                            |                        |
| System Log File        | Specifies the name of the system log file that records errors and events.                  | -                      |
| Process                | Specifies the system processes that generate the events to display.                        | -                      |
| Include archived files | Specifies to enable the option to include archived files.                                  | Select to enable.      |
| Date From              | Specifies the beginning date range to monitor. Set the date using the calendar pick tool.  | -                      |
| To                     | Specifies the end of the date range to monitor. Set the date using the calendar pick tool. | -                      |
| Event ID               | Specifies the specific ID of the error or event to monitor.                                | -                      |
| Description            | Enter a description for the errors or events.                                              | -                      |
| Search                 | Fetches the errors and events specified in the search criteria.                            | -                      |
| Reset                  | Clears the cache of errors and events that were previously selected.                       | -                      |

Table 142: Events Monitoring Page (*continued*)

| Field                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Additional Information |

| Generate Report      | Creates an HTML report based on the specified parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | -                      |
| <b>Events Detail</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |
| Process              | Displays the system process that generated the error or event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | -                      |
| Severity             | <p>Displays the severity level that indicates how seriously the triggering event affects routing platform functions. Only messages from the facility that are rated at that level or higher are logged. Possible severities and their corresponding color code are:</p> <ul style="list-style-type: none"> <li>• <b>Debug/Info/Notice (Green)</b>—Indicates conditions that are not errors but are of interest or might warrant special handling.</li> <li>• <b>Warning (Yellow)</b> — Indicates conditions that warrant monitoring.</li> <li>• <b>Error (Blue)</b> — Indicates standard error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels.</li> <li>• <b>Critical (Pink)</b> — Indicates critical conditions, such as hard drive errors.</li> <li>• <b>Alert (Orange)</b> — Indicates conditions that require immediate correction, such as a corrupted system database.</li> <li>• <b>Emergency (Red)</b> — Indicates system panic or other conditions that cause the routing platform to stop functioning.</li> </ul> | -                      |
| Event ID             | Displays the unique ID of the error or event. The prefix on each code identifies the generating software process. The rest of the code indicates the specific event or error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | -                      |
| Event Description    | Displays a more detailed explanation of the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | -                      |
| Time                 | Time that the error or event occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | -                      |

## Monitoring the System

The J-Web user interface lets you monitor a device's physical characteristics, current processing status and alarms, and ongoing resource utilization to quickly assess the condition of a device at any time.

On SRX Series devices, the **Dashboard** lets you customize your view by selecting which informational panes to include on the Dashboard.

This section contains the following topics:

- [Monitoring System Properties for SRX Series Devices on page 1315](#)
- [Monitoring Chassis Information on page 1317](#)
- [System Health Management for Branch SRX Series Devices on page 1319](#)

### Monitoring System Properties for SRX Series Devices

**Purpose** View system properties and customize the Dashboard.

When you start the J-Web user interface on an SRX Series device, the interface opens to the Dashboard. At the top and bottom of the page, the Dashboard displays an interactive representation of your device and a current log messages pane. By default, the center panes of the Dashboard display System Information, Resource Utilization, Security Resources, and System Alarms. However, you can customize the Dashboard panes to provide the best overview of your system.

**Action** To control the content and appearance of the Dashboard:

1. Click the **Preferences** icon at the top-right corner of the page. The Dashboard Preference dialog box appears.
2. Select the types of information you want to display.
3. (Optional) Specify the Automatically Refresh Data option to specify how often you want the data on the Dashboard to be refreshed.
4. Click **OK** to save the configuration or **Cancel** to clear it.
5. On the Dashboard, minimize, maximize, or drag the individual information panes to customize the display as needed.

**Chassis View**—Displays an image of the device chassis, including line cards, link states, errors, individual PICs, FPCs, fans, and power supplies.

You can use the Chassis View to link to corresponding configuration and monitoring pages for the device. To link to interface configuration pages for a selected port from the Chassis View, right-click the port in the device image and choose one of the following options:

- **Chassis Information**—Links to the Chassis page.
- **Configure Port: *Port-name***—Links to the interfaces configuration page for the selected port.

- Monitor Port: *Port-name*—Links to the monitor interfaces page for the selected port.

System Identification—Displays the device's serial number, hostname, current software version, the BIOS version, the amount of time since the device was last booted, and the system's time.

---

**NOTE:**

- To view the BIOS version under system identification, delete your browser cookies.
- The hostname that appears in this pane is defined using the **set system hostname** command.

On SRX Series devices, security logs were always timestamped using the UTC time zone by running **set system time-zone utc** and **set security log utc-timestamp** CLI commands. Now, time zone can be defined using the local time zone by running the **set system time-zone time-zone** command to specify the local time zone that the system should use when timestamping the security logs.

---

Resource Utilization—Provides a graphic representation of resource use. Each bar represents the percentage of CPU, memory, or storage utilization for the data plane or the control plane.

Security Resources—Provides the maximum, configured, and active sessions; firewall and VPN policies; and IPsec VPNs. Click **Sessions**, **FW/VPN Policies**, or **IPsec VPNs** for detailed statistics about each category.

System Alarms—Indicates a missing rescue configuration or software license, where valid. System alarms are preset and cannot be modified.

File Usage—Displays the usage statistics for log files, temporary files, crash (core) files, and database files.

Login Sessions—Provides a list of all currently logged in sessions. The display includes user credentials, login time, and idle time for each session.

Chassis Status—Provides a snapshot of the current physical condition of the device, including temperature and fan status.

Storage Usage—Displays the storage usage report in detail.

Threat Activity—Provides information about the most current threats received on the device.

Message Logs—Displays log messages and errors. You can clear old logs from the Message Logs pane by clicking the Clear button.

To control the information that is displayed in the Chassis View, use the following options:

- To view an image of the front of the device, right-click the image and choose **View Front**.
- To view an image of the back of the device, right-click the image and choose **View Rear**.
- To enlarge or shrink the device view, use the **Zoom** bar.
- To return the device image to its original position and size, click **Reset**.

**NOTE:** To use the Chassis View, a recent version of Adobe Flash that supports ActionScript and AJAX (Version 9) must be installed. Also note that the Chassis View appears by default on the Dashboard page. You can enable or disable it using options in the Dashboard Preference dialog box. Clearing cookies in Internet Explorer also causes the Chassis View appear on the Dashboard page.

To return to the Dashboard at any time, select **Dashboard** in the J-Web user interface.

Alternatively, you can view system properties by entering the following **show** commands in the CLI:

- **show system uptime**
- **show system users**
- **show system storage**
- **show version**
- **show chassis hardware**

### Monitoring Chassis Information

**Purpose** View chassis properties, which include the status of hardware components on the device.

**Action** To view these chassis properties, select **Monitor>System View>Chassis Information** in the J-Web user interface.

**CAUTION:** Do not install a combination of Physical Interface Modules (PIMs) in a single chassis that exceeds the maximum power and heat capacity of the chassis. If power management is enabled, PIMs that exceed the maximum power and heat limits remain offline when the chassis is powered on. To check PIM power and heat status, use the **show chassis fpc** and **show chassis power-ratings** commands.

The Chassis Information page displays the following types of information:

- **Routing Engine Details**—This section of the page includes the following tabs:
  - **Master**—Master tab displays information about the routing engine, including the routing engine module, model number, version, part number, serial number, memory utilization, temperature, and start time. Additionally, this tab displays the CPU load averages for the last 1, 5, and 15 minutes.
  - **Backup**—If a backup routing engine is available, the Backup tab displays the routing engine module, model number, version, part number, serial number, memory utilization, temperature, and start time. Additionally, this tab displays the CPU load averages for the last 1, 5, and 15 minutes.

**NOTE:** If you need to contact customer support about the device chassis, supply them with the version and serial number displayed in the Routing Engine Details section of the page.

- **Power and Fan Tray Details**—This Details section of the page includes the following tabs:
  - **Power**—Power tab displays the names of the device's power supply units and their statuses.
  - **Fan**—Fan tab displays the names of the device's fans and their speeds (normal or high). (The fan speeds are adjusted automatically according to the current temperature.)
- **Chassis Component Details**—This section of the page includes the following tabs:
  - **General**—General tab displays the version number, part number, serial number, and description of the selected device component.
  - **Temperature**—Temperature tab displays the temperature of the selected device component (if applicable).
  - **Resource**—Resource tab displays the state, total CPU DRAM, and start time of the selected device component (if applicable).

**NOTE:** On some devices, you can have an FPC state as “offline.” You might want to put an FPC offline because of an error or if the FPC is not responding. You can put the FPC offline by using the CLI command `request chassis fpc slot number offline`.

- **Sub-Component**—Sub-Component tab displays information about the device's sub-components (if applicable). Details include the sub-component's version, part number, serial number, and description.

To control which component details appear, select a hardware component from the **Select component** list.

Alternatively, you can view chassis details by entering the following **show** commands in the CLI configuration editor:

- **show chassis hardware**
- **show chassis routing-engine**
- **show chassis environment**
- **show chassis redundant-power-supply**
- **show redundant-power-supply status**

---

### System Health Management for Branch SRX Series Devices

---

**Purpose** Tracking the utilization of critical resources in the system ensures that all parameters are within normal limits and the system remains functional.

In the event of a malfunction caused by abnormal resource usage, the system health management feature provides the right diagnostic information to identify the source of the problem.

When the system health management action is configured by the user, the system takes appropriate monitoring, preventive, and recovery actions to ensure that the system is accessible. The system configuration might be updated based on the information collected by system health management feature to ensure that the system stays in the normal operating environment. For example, when a system runs out of memory, then the configuration associated with applications identified to be consuming memory resources can be updated to bring down the memory resource consumption.

**Action** The system health management feature periodically monitors critical system resources against configurable thresholds. The resources that can be monitored include CPU usage, memory, storage, open-file-descriptor, process-count, and temperature. The system health management feature collects usage information for each resource at the configured interval and compares it against the three levels of thresholds: moderate, high, and critical. Based on the configurations, appropriate action is taken.

The intervals, thresholds, and action are associated with system health management and can be configured at both the resource level and the global level. Configurable and default levels are as follows:

- **Default configuration level**— Default configuration is applied when system health monitoring is enabled, and neither a global nor a resource-specific configuration is present.
- **Global configuration level**—Configuration that is applied to resources when no resource-specific configuration is available.
- **Resource-specific configuration level**—Configuration that, if available, overrides both the global and the default configurations.

Per-resource configurations take precedence over the global configuration, and a global configuration takes precedence over the defaults.

When resource usage exceeds the configured thresholds, the system collects information that can be used to find the source of the increased usage and saves it in history for analysis and action.

When resource utilization exceeds the high threshold, a minor system alarm is generated, and the alarm LED lights yellow. When resource utilization exceeds the critical threshold, a major alarm is generated, and the alarm LED lights red.

An SNMP trap is also sent to the remote monitoring server (NMS) for all events that exceed the threshold.

To enable the system health monitor, use the **set snmp health-monitor routing engine** command. You can view system properties by using CLI show commands.

## Monitoring Unified Threat Management Features

- [Monitoring Antivirus Scan Engine Status on page 1320](#)
- [Monitoring Antivirus Scan Results on page 1321](#)
- [Monitoring Antivirus Session Status on page 1323](#)
- [Monitoring Content Filtering Configurations on page 1324](#)
- [Monitoring Reports on page 1324](#)
- [Monitoring Web Filtering Configurations on page 1331](#)

### Monitoring Antivirus Scan Engine Status

**Purpose** Using the CLI, you can view the following scan engine status items:

Antivirus license key status

- View license expiration dates.

Scan engine status and settings

- View last action result.
- View default file extension list.

Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

Antivirus pattern database status

- View auto update status.
- View last result of database loading.

- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

**Action** In the CLI, enter the `user@host> show security utm anti-virus status` command.

Example status result:

```
AV Key Expire Date: 03/01/2010 00:00:00
Update Server: http://update.juniper-updates.net/AV/device-name
interval: 60 minutes
auto update status: next update in 12 minutes
last result: new database loaded
AV signature version: 12/21/2008 00:35 GMT, virus records: 154018
Scan Engine Info: last action result: No error(0x00000000)
```

  - [Monitoring Antivirus Scan Results on page 1321](#)

## Monitoring Antivirus Scan Results

**Purpose** View statistics for antivirus requests, scan results, and fallback counters.

Scan requests provide

- The total number of scan request forwarded to the engine.
- The number of scan request being pre-windowed.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.
- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
- Maximum content size reached.

- Too many requests.
- Password protected file found.
- Decompress layer too large.
- Corrupt file found.
- Timeout occurred.
- Out of resources.
- Other.

**Action** To view antivirus scan results using the CLI editor, enter the **user@host> show security utm anti-virus statistics status** command.

To view antivirus scan results using J-Web:

1. Select **Monitor>Security>UTM>Anti-Virus**.

The following information becomes viewable in the right pane.

Antivirus license key status

- View license expiration dates.

Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

Antivirus pattern database status

- View auto update status.
- View last result of database loading.
- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

Antivirus statistics provide

- The number of scan request being pre-windowed.
- The total number of scan request forwarded to the engine.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.

- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
- Password protected file found.
- Decompress layer too large.
- Corrupt file found.
- Out of resources.
- Timeout occurred.
- Maximum content size reached.
- Too many requests.
- Other.

2. You can click the **Clear Anti-Virus Statistics** button to clear all current viewable statistics and begin collecting new statistics.

**Related Documentation** • [Monitoring Antivirus Session Status on page 1323](#)

## Monitoring Antivirus Session Status

**Purpose** Using the CLI, you can view the following session status items:

Antivirus session status displays a snapshot of current antivirus sessions. It includes

- Maximum supported antivirus session numbers.
- Total allocated antivirus session numbers.
- Total freed antivirus session numbers.
- Current active antivirus session numbers.

**Action** In the CLI, enter the `user@host> show security utm session status` command.

**Related Documentation** • [Full Antivirus Configuration Overview](#)  
• [Monitoring Antivirus Scan Engine Status on page 1320](#)  
• [Monitoring Antivirus Scan Results on page 1321](#)

## Monitoring Content Filtering Configurations

**Purpose** View content filtering statistics.

**Action** To view content filtering statistics in the CLI, enter the **user@host > show security utm content-filtering statistics** command.

The content filtering **show statistics** command displays the following information:

```
Base on command list: # Blocked
Base on mime list: # Blocked
Base on extension list: # Blocked
ActiveX plugin: # Blocked
Java applet: # Blocked
EXE files: # Blocked
ZIP files: # Blocked
HTTP cookie: # Blocked
```

To view content filtering statistics using J-Web:

1. Select **Clear Content filtering statisticsMonitor>Security>UTM>Content FilteringMonitor>Security>UTM>Content Filtering**.

The following statistics become viewable in the right pane.

```
Base on command list: # Passed # Blocked
Base on mime list: # Passed # Blocked
Base on extension list: # Passed # Blocked
ActiveX plugin: # Passed # Blocked
Java applet: # Passed # Blocked
EXE files: # Passed # Blocked
ZIP files: # Passed # Blocked
HTTP cookie: # Passed # Blocked
```

2. You can click **Clear Content filtering statistics** to clear all current viewable statistics and begin collecting new statistics.

## Monitoring Reports

On-box reporting offers a comprehensive reporting facility where your security management team can spot a security event when it occurs, immediately access and review pertinent details about the event, and quickly decide appropriate remedial action. The J-Web reporting feature provides one- or two-page reports that are equivalent to a compilation of numerous log entries.

This section contains the following topics:

- [Threats Monitoring Report on page 1325](#)
- [Traffic Monitoring Report on page 1329](#)

### Threats Monitoring Report

**Purpose** Use the Threats Report to monitor general statistics and activity reports of current threats to the network. You can analyze logging data for threat type, source and destination details, and threat frequency information. The report calculates, displays, and refreshes the statistics, providing graphic presentations of the current state of the network.

**Action** To view the Threats Report:

1. Click **Threats Report** in the bottom right of the Dashboard, or select **Monitor>Reports>Threats** in the J-Web user interface. The Threats Report appears.
2. Select one of the following tabs:
  - **Statistics** tab. See [Table 143](#) for a description of the page content.
  - **Activities** tab. See [Table 144](#) for a description of the page content.

**Table 143: Statistics Tab Output in the Threats Report**

| Field                          | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Statistics Pane</b> |                                                                                                                                                                                                                                                                                                                                                                                                       |
| Threat Category                | One of the following categories of threats: <ul style="list-style-type: none"> <li>• Traffic</li> <li>• IDP</li> <li>• Content Security               <ul style="list-style-type: none"> <li>• Antivirus</li> <li>• Antispam</li> <li>• Web Filter—Click the Web filter category to display counters for 39 subcategories.</li> <li>• Content Filter</li> </ul> </li> <li>• Firewall Event</li> </ul> |
| Severity                       | Severity level of the threat: <ul style="list-style-type: none"> <li>• emerg</li> <li>• alert</li> <li>• crit</li> <li>• err</li> <li>• warning</li> <li>• notice</li> <li>• info</li> <li>• debug</li> </ul>                                                                                                                                                                                         |
| Hits in past 24 hours          | Number of threats encountered per category in the past 24 hours.                                                                                                                                                                                                                                                                                                                                      |

Table 143: Statistics Tab Output in the Threats Report (*continued*)

| Field                                     | Description                                                                                                                                                                                                                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hits in current hour                      | Number of threats encountered per category in the last hour.                                                                                                                                                                                                                 |
| <b>Threat Counts in the Past 24 Hours</b> |                                                                                                                                                                                                                                                                              |
| By Severity                               | Graph representing the number of threats received each hour for the past 24 hours sorted by severity level.                                                                                                                                                                  |
| By Category                               | Graph representing the number of threats received each hour for the past 24 hours sorted by category.                                                                                                                                                                        |
| X Axis                                    | Twenty-four hour span with the current hour occupying the right-most column of the display. The graph shifts to the left every hour.                                                                                                                                         |
| Y Axis                                    | Number of threats encountered. The axis automatically scales based on the number of threats encountered.                                                                                                                                                                     |
| <b>Most Recent Threats</b>                |                                                                                                                                                                                                                                                                              |
| Threat Name                               | Names of the most recent threats. Depending on the threat category, you can click the threat name to go to a scan engine site for a threat description.                                                                                                                      |
| Category                                  | Category of each threat: <ul style="list-style-type: none"> <li>Traffic</li> <li>IDP</li> <li>Content Security <ul style="list-style-type: none"> <li>Antivirus</li> <li>Antispam</li> <li>Web Filter</li> <li>Content Filter</li> </ul> </li> <li>Firewall Event</li> </ul> |
| Source IP/Port                            | Source IP address (and port number, if applicable) of the threat.                                                                                                                                                                                                            |
| Destination IP/Port                       | Destination IP address (and port number, if applicable) of the threat.                                                                                                                                                                                                       |
| Protocol                                  | Protocol name of the threat.                                                                                                                                                                                                                                                 |
| Description                               | Threat identification based on the category type: <ul style="list-style-type: none"> <li>Antivirus—URL</li> <li>Web filter—category</li> <li>Content filter—reason</li> <li>Antispam—sender e-mail</li> </ul>                                                                |
| Action                                    | Action taken in response to the threat.                                                                                                                                                                                                                                      |
| Hit Time                                  | Time the threat occurred.                                                                                                                                                                                                                                                    |

| Hits in current hour                   | Number of threats encountered in the last hour.                                                                                                                                                                       |
| <b>Most Recent IDP Attacks</b>         |                                                                                                                                                                                                                       |
| Attack                                 |                                                                                                                                                                                                                       |

Table 144: Activities Tab Output in the Threats Report (*continued*)

| Field               | Function                                                                                                                                                                                                 |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Severity            | Severity of each threat: <ul style="list-style-type: none"> <li>• emerg</li> <li>• alert</li> <li>• crit</li> <li>• err</li> <li>• warning</li> <li>• notice</li> <li>• info</li> <li>• debug</li> </ul> |
| Source IP/Port      | IP address (and port number, if applicable) of the source.                                                                                                                                               |
| Destination IP/Port | IP address (and port number, if applicable) of the destination.                                                                                                                                          |
| Protocol            | Protocol name of the threat.                                                                                                                                                                             |
| Action              | Action taken in response to the threat.                                                                                                                                                                  |
| Last Send Time      | Last time the IDP threat was sent.                                                                                                                                                                       |

### Traffic Monitoring Report

**Purpose** Monitor network traffic by reviewing reports of flow sessions over the past 24 hours. You can analyze logging data for connection statistics and session usage by a transport protocol.

**Action** To view network traffic in the past 24 hours, select **Monitor>Reports>Traffic** in the J-Web user interface. See [Table 145](#) for a description of the report.

Table 145: Traffic Report Output

| Field                                         | Description                                                                                                                                                                                                                            |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sessions in Past 24 Hours per Protocol</b> |                                                                                                                                                                                                                                        |
| Protocol Name                                 | Name of the protocol. To see hourly activity by protocol, click the protocol name and review the “Protocol activities chart” in the lower pane. <ul style="list-style-type: none"> <li>• TCP</li> <li>• UDP</li> <li>• ICMP</li> </ul> |
| Total Session                                 | Total number of sessions for the protocol in the past 24 hours.                                                                                                                                                                        |
| Bytes In (KB)                                 | Total number of incoming bytes in KB.                                                                                                                                                                                                  |
| Bytes Out (KB)                                | Total number of outgoing bytes in KB.                                                                                                                                                                                                  |

## Monitoring Web Filtering Configurations

**Purpose** View Web-filtering statistics.

**Action** To view Web-filtering statistics using the CLI, enter the following commands:

```
user@host> show security utm web-filtering status
user@host> show security utm web-filtering statistics
```

To view Web-filtering statistics using J-Web:

1. Select **Clear Web Filtering Statistics**.

The following information is displayed in the right pane.

```
Total Requests: #
White List Hit: #
Black List Hit: #
Queries to Server: #
Server Reply Permit: #
Server Reply Block: #
Custom Category Permit: #
Custom Category Block: #
Cache Hit Permit: #
Cache Hit Block: #
Web Filtering Session Total: #
Web Filtering Session Inuse: #
Fall Back: Log-and-Permit Block
Default # #
Timeout # #
Server-Connectivity # #
Too-Many-Requests # #
```

2. You can click the **Clear Web Filtering Statistics** button to clear all current viewable statistics and begin collecting new statistics.

### Monitoring IKE Gateway Information

**Purpose** View information about IKE security associations (SAs).

**Action** Select **Monitor>IPSec VPN>IKE Gateway** in the J-Web user interface. To view detailed information for a particular SA, select the IKE SA index on the IKE gateway page.

Alternatively, enter the following CLI commands:

- **show security ike security-associations**
- **show security ike security-associations index *index-id* detail**

[Table 146](#) summarizes key output fields in the IKE gateway display.

**Table 146: Summary of Key IKE SA Information Output Fields**

| Field                            | Values                                                                                                                                                                                                       | Additional Information                                                                                                                               |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IKE Security Associations</b> |                                                                                                                                                                                                              |                                                                                                                                                      |
| IKE SA Index                     | Index number of an SA.                                                                                                                                                                                       | This number is an internally generated number you can use to display information about a single SA.                                                  |
| Remote Address                   | IP address of the destination peer with which the local peer communicates.                                                                                                                                   | —                                                                                                                                                    |
| State                            | State of the IKE security associations: <ul style="list-style-type: none"> <li>• <b>DOWN</b>—SA has not been negotiated with the peer.</li> <li>• <b>UP</b>—SA has been negotiated with the peer.</li> </ul> | —                                                                                                                                                    |
| Initiator cookie                 | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                                      | —                                                                                                                                                    |
| Responder cookie                 | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                                  | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |

Table 146: Summary of Key IKE SA Information Output Fields (*continued*)

| Field                                      | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Additional Information                                                                                                                               |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mode                                       | <p>Negotiation method agreed on by the two IPsec endpoints, or peers, used to exchange information between themselves. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are:</p> <ul style="list-style-type: none"> <li>• <b>Main</b>—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>• <b>Aggressive</b>—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul> | –                                                                                                                                                    |
| <b>IKE Security Association (SA) Index</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                      |
| IKE Peer                                   | IP address of the destination peer with which the local peer communicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | –                                                                                                                                                    |
| IKE SA Index                               | Index number of an SA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | This number is an internally generated number you can use to display information about a single SA.                                                  |
| Role                                       | Part played in the IKE session. The device triggering the IKE negotiation is the initiator, and the device accepting the first IKE exchange packets is the responder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | –                                                                                                                                                    |

| Initiator cookie                           | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | –                                                                                                                                                    |
| Responder cookie                           | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |

Table 146: Summary of Key IKE SA Information Output Fields (*continued*)

| Field                 | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Additional Information |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Exchange Type         | <p>Negotiation method agreed on by the two IPsec endpoints, or peers, used to exchange information between themselves. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are:</p> <ul style="list-style-type: none"> <li>• <b>Main</b>—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>• <b>Aggressive</b>—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul>                                                                                                                                                                                                                                                                | —                      |
| Authentication Method | Path chosen for authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | —                      |
| Local                 | Address of the local peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                      |
| Remote                | Address of the remote peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | —                      |

| Role                        | Part played in the IKE session. The device triggering the IKE negotiation is the initiator, and the device accepting the first IKE exchange packets is the responder.                                                                                                                                                                                                                                                                                           | —                      |
| Message ID                  | Message identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                             | —                      |
| Local identity              | Specifies the identity of the local peer so that its partner destination gateway can communicate with it. The value is specified as any of the following: IPv4 address, fully qualified domain name, e-mail address, or distinguished name.                                                                                                                                                                                                                     | —                      |
| Remote identity             | IPv4 address of the destination peer gateway.                                                                                                                                                                                                                                                                                                                                                                                                                   | —                      |

### Monitoring IPsec VPN—Phase I

**Purpose** View IPsec VPN Phase I information.

**Action** Select **Monitor>IPSec VPN>Phase I** in the J-Web user interface.

Table 147 describes the available options for monitoring IPsec VPN-Phase I.

Table 147: IPsec VPN—Phase I Monitoring Page

| Field                     | Values                                                                     | Additional Information |
|---------------------------|----------------------------------------------------------------------------|------------------------|
| IKE SA Tab Options        |                                                                            |                        |
| IKE Security Associations |                                                                            |                        |
| SA Index                  | Index number of an SA.                                                     | —                      |
| Remote Address            | IP address of the destination peer with which the local peer communicates. | —                      |

| State            | State of the IKE security associations: <ul style="list-style-type: none"> <li>DOWN—SA has not been negotiated with the peer.</li> <li>UP—SA has been negotiated with the peer.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | –                                                                                                                                                    |
| Initiator Cookie | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | –                                                                                                                                                    |
| Responder Cookie | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |
| Mode             | Negotiation method agreed upon by the two IPsec endpoints, or peers, used to exchange information. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are: <ul style="list-style-type: none"> <li>Main—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>Aggressive—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul> | –                                                                                                                                                    |

### Monitoring IPsec VPN—Phase II

**Purpose** View IPsec VPN Phase II information.

**Action** Select **Monitor>IPSec VPN>Phase II** in the J-Web user interface.

Table 148 describes the available options for monitoring IPsec VPN-Phase II.

| ID                                 | Index number of the SA.                                                                                                                                                                                                                                                                                                                                           | —                      |
| Gateway/Port                       | IP address of the remote gateway/port.                                                                                                                                                                                                                                                                                                                            | —                      |
| Algorithm                          | <p>Cryptography scheme used to secure exchanges between peers during the IKE Phase II negotiations:</p> <ul style="list-style-type: none"> <li>An authentication algorithm used to authenticate exchanges between the peers. Options are hmac-md5-95 or hmac-sha1-96.</li> </ul>                                                                                  | —                      |
| SPI                                | Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase I and Phase II. | —                      |
| Life                               | The lifetime of the SA, after which it expires, expressed either in seconds or kilobytes.                                                                                                                                                                                                                                                                         | —                      |
| Monitoring                         | Specifies if VPN-Liveliness Monitoring has been enabled/disabled. Enabled - 'U', Disabled- '—'                                                                                                                                                                                                                                                                    | —                      |
| Vsys                               | Specifies the root system.                                                                                                                                                                                                                                                                                                                                        | —                      |

### Monitoring IPsec VPN Information

**Purpose** View information about IPsec security (SAs).

**Action** Select **Monitor>IPsec VPN>IPsec VPN** in the J-Web user interface. To view the IPsec statistics information for a particular SA, select the IPsec SA ID value on the IPsec VPN page.

Alternatively, enter the following CLI commands:

- **show security ipsec security-associations**
- **show security ipsec statistics**

Table 149 summarizes key output fields in the IPsec VPN display.

**Table 149: Summary of Key IPsec VPN Information Output Fields**

| Field                              | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Additional Information                                                            |

| AH Statistics                | <p>Authentication Header (AH) statistics include the following:</p> <ul style="list-style-type: none"> <li>• <b>Input bytes</b>—The number of bytes presented for processing by the device.</li> <li>• <b>Output bytes</b>—The number of bytes actually processed by the device.</li> <li>• <b>Input packets</b>—The number of packets presented for processing by the device.</li> <li>• <b>Output packets</b>—The number of packets actually processed by the device.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                | —                      |
| Errors                       | <p>Errors include the following</p> <ul style="list-style-type: none"> <li>• <b>AH authentication failures</b>—Total number of authentication header (AH) failures. An AH failure occurs when there is a mismatch of the authentication header in a packet transmitted across an IPsec tunnel.</li> <li>• <b>Replay errors</b>—Total number of replay errors. A replay error is generated when a duplicate packet is received within the replay window.</li> <li>• <b>ESP authentication failures</b>—Total number of Encapsulation Security Payload (ESP) failures. An ESP failure occurs when there is an authentication mismatch in ESP packets.</li> <li>• <b>ESP decryption failures</b>—Total number of ESP decryption errors.</li> <li>• <b>Bad headers</b>—Total number of invalid headers detected.</li> <li>• <b>Bad trailers</b>—Total number of invalid trailers detected.</li> </ul> | —                      |

Table 149: Summary of Key IPsec VPN Information Output Fields (*continued*)

| Field                                        | Values                                                                                                                                                                                                                                                                                                                                                                                        | Additional Information |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>Details for IPsec SA Index: <i>ID</i></b> |                                                                                                                                                                                                                                                                                                                                                                                               |                        |
| Virtual System                               | The root system.                                                                                                                                                                                                                                                                                                                                                                              | —                      |
| Local Gateway                                | Gateway address of the local system.                                                                                                                                                                                                                                                                                                                                                          | —                      |
| Remote Gateway                               | Gateway address of the remote system.                                                                                                                                                                                                                                                                                                                                                         | —                      |
| Local identity                               | Specifies the identity of the local peer so that its partner destination gateway can communicate with it. The value is specified as any of the following: IPv4 address, fully qualified domain name, e-mail address, or distinguished name.                                                                                                                                                   | —                      |
| Remote identity                              | IPv4 address of the destination peer gateway.                                                                                                                                                                                                                                                                                                                                                 | —                      |
| Df bit                                       | State of the don't fragment bit— <b>set</b> or <b>cleared</b> .                                                                                                                                                                                                                                                                                                                               | —                      |
| Policy name                                  | Name of the applicable policy.                                                                                                                                                                                                                                                                                                                                                                | —                      |
| Direction                                    | Direction of the security association— <b>inbound</b> , or <b>outbound</b> .                                                                                                                                                                                                                                                                                                                  | —                      |
| SPI                                          | Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase 1 and Phase 2.                              | —                      |
| Mode                                         | Mode of the security association. Mode can be transport or tunnel. <ul style="list-style-type: none"> <li>• <b>transport</b>—Protects host-to-host connections.</li> <li>• <b>tunnel</b>—Protects connections between security gateways.</li> </ul>                                                                                                                                           | —                      |
| Type                                         | Type of the security association, either <b>manual</b> or <b>dynamic</b> . <ul style="list-style-type: none"> <li>• <b>manual</b>—Security parameters require no negotiation. They are static and are configured by the user.</li> <li>• <b>dynamic</b>—Security parameters are negotiated by the IKE protocol. Dynamic security associations are not supported in transport mode.</li> </ul> | —                      |

Table 149: Summary of Key IPsec VPN Information Output Fields (*continued*)

| Field                     | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information                                                                                                                                                                                                                                        |

## Understanding Data Path Debugging for SRX Series Devices

Data path debugging, or end-to-end debugging, support provides tracing and debugging at multiple processing units along the packet-processing path. The packet filter can be executed with minimal impact to the production system.

On a high-end SRX Series device, a packet goes through series of events involving different components from ingress to egress processing.

With the data path debugging feature, you can trace and debug (capture packets) at different data points along the processing path. The events available in the

packet-processing path are: NP ingress, load-balancing thread (LBT), jexec, packet-ordering thread (POT), and NP egress. You can also enable flow module trace if the security flow trace flag for a certain module is set.

At each event, you can specify any of the four actions (count, packet dump, packet summary, and trace). Data path debugging provides filters to define what packets to capture, and only the matched packets are traced. The packet filter can filter out packets based on logical interface, protocol, source IP address prefix, source port, destination IP address prefix, and destination port.

To enable end-to-end debugging, you must perform the following steps:

1. Define the capture file and specify the maximum capture size.
2. Define the packet filter to trace only a certain type of traffic based on the requirement.
3. Define the action profile specifying the location on the processing path from where to capture the packets (for example, LBT or NP ingress).
4. Enable the data path debugging.
5. Capture traffic.
6. Disable data path debugging.
7. View or analyze the report.

**NOTE:**

The packet-filtering behavior for the port and interface options is as follows:

- The packet filter traces both IPv4 and IPv6 traffic if only **port** is specified.
  - The packet filter traces IPv4, IPV6, and non-IP traffic if only **interface** is specified.
-

## Debugging the Data Path (CLI Procedure)

To configure the device for data path debugging:

1. Specify the following request command to set the data path debugging for the multiple processing units along the packet-processing path:

```
[edit]  
user@host# set security datapath-debug
```

- Specify the trace options for data path-debug using the following command:

```
[edit]
user@host# set security datapath-debug traceoptions
```

- Using the request security packet-filter command, you can set the packet filter to specify the related packets to perform data path-debug action. A maximum of four filters are supported at the same time. For example, the following command sets the first packet-filter:

```
[edit]
user@host# set security datapath-debug packet-filter name
```

- Using the request security action-profile command, you can set the action for the packet match for a specified filter. Only the default action profile is supported, which is the trace option for network processor ezchip ingress, ezchip egress, spu.lbt, and spu.pot:

```
[edit]
user@host# set security datapath-debug packet-filter name action-profile
```

### Example: Configuring End-to-End Debugging on a High-End SRX Series Device

This example shows how to configure end-to-end debugging on an SRX Series device with an SRX5K-MPC.

- [Requirements on page 1345](#)
- [Overview on page 1346](#)
- [Configuration on page 1346](#)
- [Enabling Data Path Debugging on page 1348](#)
- [Verification on page 1348](#)

#### Requirements

This example uses the following hardware and software components:

- SRX5600 device with an SRX5K-MPC installed with 100-Gigabit Ethernet CFP installed
- Junos OS Release 12.1X47-D15 or later for SRX Series devices

Before you begin:

- See *Understanding Data Path Debugging for SRX Series Devices*.

No special configuration beyond device initialization is required before configuring this feature.

## Overview

Data path debugging enhances troubleshooting capabilities by providing tracing and debugging at multiple processing units along the packet-processing path. With the data path debugging feature, you can trace and debug (capture packets) at different data points along the processing path. At each event, you can specify an action (count, packet dump, packet summary, and trace) and you can set filters to define what packets to capture.

In this example, you define a traffic filter, then you apply an action profile. The action profile specifies a variety of actions on the processing unit. The NP ingress and NP egress are specified as location on the processing path to capture the data for incoming and outgoing traffic.

Next, you enable data path debugging in operational mode, and finally you view the data capture report.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security datapath-debug traceoptions file e2e.trace size 10m
set security datapath-debug capture-file datapcap format pcap
set security datapath-debug maximum-capture-size 1500
set security datapath-debug action-profile profile-1 preserve-trace-order
set security datapath-debug action-profile profile-1 record-pic-history
set security datapath-debug action-profile profile-1 event np-ingress trace
set security datapath-debug action-profile profile-1 event np-ingress count
set security datapath-debug action-profile profile-1 event np-ingress packet-summary
set security datapath-debug action-profile profile-1 event np-ingress packet-count
set security datapath-debug action-profile profile-1 event np-egress trace
set security datapath-debug action-profile profile-1 event np-egress count
set security datapath-debug action-profile profile-1 event np-egress packet-summary
set security datapath-debug action-profile profile-1 event np-egress packet-count
set security datapath-debug packet-filter filter-1
set security datapath-debug packet-filter filter-1 action-profile profile-1
set security datapath-debug packet-filter filter-1 protocol tcp
set security datapath-debug packet-filter filter-1 source-prefix 200.7.6.0/24
set security datapath-debug packet-filter filter-1 destination-prefix 200.8.6.0/24
set security datapath-debug packet-filter filter-1 source-port 1000
set security datapath-debug packet-filter filter-1 destination-port 80
set security datapath-debug packet-filter filter-1 interface xe-2/2/0.0
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure data path debugging:

1. Edit the security datapath-debug option for the multiple processing units along the packet-processing path:

```
[edit]
user@host# edit security datapath-debug
```

2. Enable the capture file, file format, file size, and the number of files.

```
[edit security datapath-debug]
user@host# set traceoptions file e2e.trace size 10m
user@host# set capture-file datapcap format pcap;
user@host# set maximum-capture-size 1500
```

3. Configure action profile, event type, and actions for the action profile.

```
[edit security datapath-debug]
user@host# set action-profile profile-1 preserve-trace-order
user@host# set action-profile profile-1 record-pic-history
user@host# set action-profile profile-1 event np-ingress trace
user@host# set action-profile profile-1 event np-ingress count
user@host# set action-profile profile-1 event np-ingress packet-summary
user@host# set action-profile profile-1 event np-ingress packet-count
user@host# set action-profile profile-1 event np-egress trace
user@host# set action-profile profile-1 event np-egress count
user@host# set action-profile profile-1 event np-egress packet-summary
user@host# set action-profile profile-1 event np-egress packet-count
```

4. Configure packet filter, action, and filter options.

```
[edit security datapath-debug]
user@host# set packet-filter filter-1
user@host# set packet-filter filter-1 action-profile profile-1
user@host# set packet-filter filter-1 protocol tcp
user@host# set packet-filter filter-1 source-prefix 200.7.6.0/24
user@host# set packet-filter filter-1 destination-prefix 200.8.6.0/24
user@host# set packet-filter filter-1 source-port 1000
user@host# set packet-filter filter-1 destination-port 80
user@host# set packet-filter filter-1 interface xe-2/2/0.0
```

**Results** From configuration mode, confirm your configuration by entering the **show security datapath-debug** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
traceoptions {
  file e2e.trace size 10m;
}
capture-file datapcap format pcap;
maximum-capture-size 1500;
action-profile {
  profile-1 {
    preserve-trace-order;
```

```
record-pic-history;
event np-ingress {
    trace;

    packet-summary;
    packet-dump;
}
event np-egress {
    trace;
    count;
    packet-summary;
    packet-dump;
}
}
}
packet-filter filter-1 {
    action-profile profile-1;
    protocol tcp;
    source-prefix 200.7.6.0/24;
    destination-prefix 200.8.6.0/24;
    source-port 1000;
    destination-port 80;
    interface xe-2/2/0.0;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Enabling Data Path Debugging

#### Step-by-Step Procedure

After configuring data path debugging, you must start the process on the device from operational mode.

1. Enable data path debugging.  

```
user@host> request security datapath-debug capture start
```

  
datapath-debug capture started on file datapcap
2. Once you are done, you must disable data path debugging before you verify the configuration and view the reports.  

```
user@host> request security datapath-debug capture stop
```

  
datapath-debug capture successfully stopped, use show security datapath-debug capture to view

---

### Verification

Confirm that the configuration is working properly.

#### Verifying Data Path Debug Packet Capture Details

**Purpose** Verify the data captured by enabling the data path debugging configuration.

**Action** From operational mode, enter the **show security datapath-debug capture** command.

```
Packet 8, len 152: (C2/F2/P0/SEQ:57935:np-ingress)
00 10 db ff 10 02 00 30 48 83 8d 4f 08 00 45 00
```

26 27 28 29 2a 2b 2c 2d 2e 2f 30 31 32 33 34 35
36 37....

```

For brevity, the **show** command output is truncated to display only a few samples. Additional samples have been replaced with ellipses (...).

To view the results, from CLI operational mode, access the local UNIX shell and navigate to the directory `/var/log/<file-name>`. The result can be read by using the **tcpdump** utility.

## Understanding Security Debugging Using Trace Options

The Junos OS trace function allows applications to write security debugging information to a file. The information that appears in this file is based on criteria you set. You can use this information to analyze security application issues.

The trace function operates in a distributed manner, with each thread writing to its own trace buffer. These trace buffers are then collected at one point, sorted, and written to trace files. Trace messages are delivered using the InterProcess Communications (IPC) protocol. A trace message has a lower priority than that of control protocol packets such as BGP, OSPF, and IKE, and therefore delivery is not considered to be as reliable.

## Setting Security Trace Options (CLI Procedure)

Use the following configuration statements to configure security trace options in the CLI configuration editor.

- To disable remote tracing, enter the following statement:

```

[edit]
user@host# set security traceoptions no-remote-trace

```

- To write trace messages to a local file, enter the following statement. The system saves the trace file in the `/var/log/` directory.

```
[edit]
user@host# set security traceoptions use-local-files
```

- To specify a name for the trace file, enter the following statement. Valid values range from 1 and 1024 characters. The name cannot include spaces, `/`, or `%` characters. The default filename is `security`.

```
[edit]
user@host# set security traceoptions file filename
```

- To specify the maximum number of trace files that can accumulate, enter the following statement. Valid values range from 2 to 1000. The default value is 3.

```
[edit]
user@host# set security traceoptions file files 3
```

- To specify the match criteria that you want the system to use when logging information to the file, enter the following statement. Enter a regular expression. Wildcard (`*`) characters are accepted.

```
[edit]
user@host# set security traceoptions file match *thread
```

- To allow any user to read the trace file, enter the **world-readable** statement. Otherwise, enter the **no-world-readable** statement.

```
[edit]
user@host# set security traceoptions file world-readable
user@host# set security traceoptions file no-world-readable
```

- To specify the maximum size to which the trace file can grow, enter the following statement. Once the file reaches the specified size, it is compressed and renamed *filename0.gz*, the next file is named *filename1.gz*, and so on. Valid values range from 10240 to 1,073,741,824.

```
[edit]
user@host# set security traceoptions file size 10240
```

- To turn on trace options and to perform more than one tracing operation, set the following flags.

```
[edit]
user@host# set security traceoptions flag all
user@host# set security traceoptions flag compilation
user@host# set security traceoptions flag configuration
user@host# set security traceoptions flag routing-socket
```

- To specify the groups that these trace option settings do or do not apply to, enter the following statements:

```
[edit]
user@host# set security traceoptions apply-groups value
user@host# set security traceoptions apply-groups-except value
```

## Displaying Log and Trace Files

Enter the **monitor start** command to display real-time additions to system logs and trace files:

```
user@host> monitor start filename
```

When the device adds a record to the file specified by **filename**, the record displays on the screen. For example, if you have configured a system log file named **system-log** (by including the **syslog** statement at the [edit system] hierarchy level), you can enter the **monitor start system-log** command to display the records added to the system log.

To display a list of files that are being monitored, enter the **monitor list** command. To stop the display of records for a specified file, enter the **monitor stop filename** command.

## Displaying Output for Security Trace Options

**Purpose** Display output for security trace options.

**Action** Use the **show security traceoptions** command to display the output of your trace files. For example:

```
[edit]
user@host # show security traceoptions file usp_trace
user@host # show security traceoptions flag all
user@host # show security traceoptions rate-limit 888
```

The output for this example is as follows:

```
Apr 11 16:06:42 21:13:15.750395:CID-906489336:FPC-01:PIC-01:THREAD_ID-01:PFE:now

## Displaying Multicast Trace Operations

To monitor and display multicast trace operations, enter the **mtrace monitor** command:

```
user@host> mtrace monitor
```

```
Mtrace query at Apr 21 16:00:54 by 192.1.30.2, resp to 224.0.1.32, qid 2a83aa
packet from 192.1.30.2 to 224.0.0.2 from 192.1.30.2 to 192.1.4.1 via group
224.1.1.1 (mxhop=60) Mtrace query at Apr 21 16:00:57 by 192.1.30.2, resp to
224.0.1.32, qid 25dc17 packet from 192.1.30.2 to 224.0.0.2 from 192.1.30.2 to
192.1.4.1 via group 224.1.1.1 (mxhop=60) Mtrace query at Apr 21 16:01:00 by
192.1.30.2, resp to same, qid 20e046 packet from 192.1.30.2 to 224.0.0.2 from
192.1.30.2 to 192.1.4.1 via group 224.1.1.1 (mxhop=60) Mtrace query at Apr 21
16:01:10 by 192.1.30.2, resp to same, qid 1d25ad packet from 192.1.30.2 to
224.0.0.2 from 192.1.30.2 to 192.1.4.1 via group 224.1.1.1 (mxhop=60)
```

This example displays only **mtrace** queries. However, when the device captures an **mtrace** response, the display is similar, but the complete **mtrace** response also appears (exactly as it is appears in the **mtrace from-source** command output).

Table 150 summarizes the output fields of the display.

Table 150: CLI mtrace monitor Command Output Summary

| Field                                       | Description                                                                                                                                                                                                                               |

- Related Documentation**
- [Using the J-Web Traceroute Tool on page 1352](#)
  - [J-Web Traceroute Results and Output Summary on page 1354](#)

## Using the J-Web Traceroute Tool

You can use the traceroute diagnostic tool to display a list of devices between the device and a specified destination host. The output is useful for diagnosing a point of failure in

the path from the device to the destination host, and addressing network traffic latency and throughput problems.

The device generates the list of devices by sending a series of ICMP traceroute packets in which the time-to-live (TTL) value in the messages sent to each successive device is incremented by 1. (The TTL value of the first traceroute packet is set to 1.) In this manner, each device along the path to the destination host replies with a Time Exceeded packet from which the source IP address can be obtained.

To use the traceroute tool:

1. Select **Troubleshoot>Traceroute**.
2. Next to Advanced options, click the expand icon.
3. Enter information into the Traceroute page (see [Table 151](#)).

**Table 151: Traceroute Field Summary**

| Field                   | Function                                                                                                                                                                                                                                                                                            | Your Action                                                                                                                                                                                                                                                                        |

| <b>Advanced Options</b> |                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                    |
| Don't Resolve Addresses | Determines whether hostnames of the hops along the path are displayed, in addition to IP addresses.                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>• Suppress the display of the hop hostnames by selecting the check box.</li> <li>• Display the hop hostnames by clearing the check box.</li> </ul>                                                                                          |
| Gateway                 | Specifies the IP address of the gateway to route through.                                                                                                                                                                                                                                           | Type the gateway IP address.                                                                                                                                                                                                                                                       |
| Source Address          | Specifies the source address of the outgoing traceroute packets.                                                                                                                                                                                                                                    | Type the source IP address.                                                                                                                                                                                                                                                        |
| Bypass Routing          | <p>Determines whether traceroute packets are routed by means of the routing table.</p> <p>If the routing table is not used, traceroute packets are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, traceroute responses are not sent.</p> | <ul style="list-style-type: none"> <li>• Bypass the routing table and send the traceroute packets to hosts on the specified interface only by selecting the check box.</li> <li>• Route the traceroute packets by means of the routing table by clearing the check box.</li> </ul> |
| Interface               | Specifies the interface on which the traceroute packets are sent.                                                                                                                                                                                                                                   | Select the interface on which traceroute packets are sent from the list. If you select <b>any</b> , the traceroute requests are sent on all interfaces.                                                                                                                            |
| Time-to-Live            | Specifies the maximum time-to-live (TTL) hop count for the traceroute request packet.                                                                                                                                                                                                               | Select the TTL from the list.                                                                                                                                                                                                                                                      |
| Type-of-Service         | Specifies the type-of-service (TOS) value to include in the IP header of the traceroute request packet.                                                                                                                                                                                             | Select the decimal value of the TOS field from the list.                                                                                                                                                                                                                           |

Table 151: Traceroute Field Summary (*continued*)

| Field              | Function                                                                                                                                | Your Action                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resolve AS Numbers | Determines whether the autonomous system (AS) number of each intermediate hop between the device and the destination host is displayed. | <ul style="list-style-type: none"> <li>Display the AS numbers by selecting the check box.</li> <li>Suppress the display of the AS numbers by clearing the check box.</li> </ul> |

4. Click **Start**.

The results of the traceroute operation are displayed in the main pane. If no options are specified, each line of the traceroute display is in the following format:

*hop-number host (ip-address) [as-number]time1 time2 time3*

The device sends a total of three traceroute packets to each router along the path and the round-trip time for each traceroute operation appears. If the device times out before receiving a **Time Exceeded** message, an asterisk (\*) appears for that round-trip time.

5. You can stop the traceroute operation before it is complete by clicking **OK** while the results of the traceroute operation appear.

## J-Web Traceroute Results and Output Summary

Table 152 summarizes the output in the traceroute display.

Table 152: J-Web Traceroute Results and Output Summary

| Field             | Description                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hop-number</i> | Number of the hop (device) along the path.                                                                                                                  |
| <i>host</i>       | Hostname, if available, or IP address of the device. If the Don't Resolve Addresses check box is selected, the hostname does not appear.                    |
| <i>ip-address</i> | IP address of the device.                                                                                                                                   |
| <i>as-number</i>  | AS number of the device.                                                                                                                                    |
| <i>time1</i>      | Round-trip time between the sending of the first traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device. |

Table 152: J-Web Traceroute Results and Output Summary (*continued*)

| Field        | Description                                                                                                                                                  |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time2</i> | Round-trip time between the sending of the second traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device. |
| <i>time3</i> | Round-trip time between the sending of the third traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device.  |

If the device does not display the complete path to the destination host, one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host, or a router along the path, might be configured to ignore ICMP traceroute messages.
- The host, or a device along the path, might be configured with a firewall filter that blocks ICMP traceroute requests or ICMP time exceeded responses.
- The value you selected in the Time Exceeded box was less than the number of hops in the path to the host. In this case, the host might reply with an ICMP error message.

## Understanding Flow Debugging Using Trace Options

For flow trace options, you can define a packet filter using combinations of **destination-port**, **destination-prefix**, **interface**, **protocol**, **source-port**, and **source-prefix**. If the security flow trace flag for a certain module is set, the packet matching the specific packet filter triggers flow tracing and writes debugging information to the trace file.

## Setting Flow Debugging Trace Options (CLI Procedure)

The following examples display the options you can set by using **security flow traceoptions**.

- To match the imap destination port for the filter1 packet filter, use the following statement:

[edit]

```
user@host# set security flow traceoptions packet-filter filter1 destination-port imap
```

- To set the 1.2.3.4 destination IPv4 prefix address for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 destination-prefix 1.2.3.4
```

- To set the fxp0 logical interface for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 interface fxp0
```

- To match the TCP IP protocol for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 protocol tcp
```

- To match the HTTP source port for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 source-port http
```

- To set the 5.6.7.8 IPv4 prefix address for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 source-prefix 5.6.7.8
```

## Displaying a List of Devices

To display a list of devices between the device and a specified destination host, enter the **traceroute** command with the following syntax:

```
user@host> traceroute host <interface interface-name> <as-number-lookup>
<bypass-routing> <gateway address> <inet | inet6> <no-resolve>
<routing-instance routing-instance-name> <source source-address> <tos number>
<tll number> <wait seconds>
```

[Table 153](#) describes the **traceroute** command options.

**Table 153: CLI traceroute Command Options**

| Option                          | Description                                                                                                                                             |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>                     | Sends traceroute packets to the hostname or IP address you specify.                                                                                     |
| <i>interface interface-name</i> | (Optional) Sends the traceroute packets on the interface you specify. If you do not include this option, traceroute packets are sent on all interfaces. |
| <i>as-number-lookup</i>         | (Optional) Displays the autonomous system (AS) number of each intermediate hop between the device and the destination host.                             |

Table 153: CLI traceroute Command Options (*continued*)

| Option                                                  | Description                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bypass-routing</b>                                   | (Optional) Bypasses the routing tables and sends the traceroute packets only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.<br><br>Use this option to display a route to a local system through an interface that has no route through it. |
| <b>gateway address</b>                                  | (Optional) Uses the gateway you specify to route through.                                                                                                                                                                                                                                                                |
| <b>inet</b>                                             | (Optional) Forces the traceroute packets to an IPv4 destination.                                                                                                                                                                                                                                                         |
| <b>inet6</b>                                            | (Optional) Forces the traceroute packets to an IPv6 destination.                                                                                                                                                                                                                                                         |
| <b>no-resolve</b>                                       | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                                                                                                                                                                                                           |
| <b>routing-instance</b><br><i>routing-instance-name</i> | (Optional) Uses the routing instance you specify for the traceroute.                                                                                                                                                                                                                                                     |
| <b>source address</b>                                   | (Optional) Uses the source address that you specify, in the traceroute packet.                                                                                                                                                                                                                                           |
| <b>tos number</b>                                       | (Optional) Sets the type-of-service (TOS) value in the IP header of the traceroute packet. Specify a value from 0 through 255.                                                                                                                                                                                           |
| <b>ttl number</b>                                       | (Optional) Sets the time-to-live (TTL) value for the traceroute packet. Specify a hop count from 0 through 128.                                                                                                                                                                                                          |
| <b>wait seconds</b>                                     | (Optional) Sets the maximum time to wait for a response.                                                                                                                                                                                                                                                                 |

To quit the **traceroute** command, press Ctrl-C.

The following is sample output from a **traceroute** command:

```
user@host> traceroute host2

traceroute to 173.24.232.66 (172.24.230.41), 30 hops max, 40 byte packets 1
173.18.42.253 (173.18.42.253) 0.482 ms 0.346 ms 0.318 ms 2 host4.site1.net
(173.18.253.5) 0.401 ms 0.435 ms 0.359 ms 3 host5.site1.net (173.18.253.5)
0.401 ms 0.360 ms 0.357 ms 4 173.24.232.65 (173.24.232.65) 0.420 ms 0.456
ms 0.378 ms 5 173.24.232.66 (173.24.232.66) 0.830 ms 0.779 ms 0.834 ms
```

The fields in the display are the same as those displayed by the J-Web traceroute diagnostic tool.

## MPLS Connection Checking Overview

Use either the J-Web ping MPLS diagnostic tool or the CLI commands **ping mpls**, **ping mpls l2circuit**, **ping mpls l2vpn**, and **ping mpls l3vpn** to diagnose the state of label-switched paths (LSPs), Layer 2 and Layer 3 virtual private networks (VPNs), and Layer 2 circuits.

Based on how the LSP or VPN outbound (egress) node at the remote endpoint of the connection replies to the probes, you can determine the connectivity of the LSP or VPN.

Each probe is an echo request sent to the LSP or VPN exit point as an MPLS packet with a UDP payload. If the outbound node receives the echo request, it checks the contents of the probe and returns a value in the UDP payload of the response packet. If the device receives the response packet, it reports a successful ping response.

Responses that take longer than 2 seconds are identified as failed probes.

[Table 154](#) summarizes the options for using either the J-Web ping MPLS diagnostic tool or the CLI **ping mpls** command to display information about MPLS connections in VPNs and LSPs.

**Table 154: Options for Checking MPLS Connections**

| J-Web Ping MPLS Tool   | ping mpls Command     | Purpose                                                                                                                                                                                           | Additional Information                                                                                                                                                                            |
|------------------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ping RSVP-signaled LSP | <b>ping mpls rsvp</b> | Checks the operability of an LSP that has been set up by the Resource Reservation Protocol (RSVP). The device pings a particular LSP using the configured LSP name.                               | When an RSVP-signaled LSP has several paths, the device sends the ping requests on the path that is currently active.                                                                             |
| Ping LDP-signaled LSP  | <b>ping mpls ldp</b>  | Checks the operability of an LSP that has been set up by the Label Distribution Protocol (LDP). The device pings a particular LSP using the forwarding equivalence class (FEC) prefix and length. | When an LDP-signaled LSP has several gateways, the device sends the ping requests through the first gateway.<br><br>Ping requests sent to LDP-signaled LSPs use only the master routing instance. |

Table 154: Options for Checking MPLS Connections (*continued*)

| J-Web Ping MPLS Tool                        | ping mpls Command                   | Purpose                                                                                                                                                                                                                                                                                                                                 | Additional Information                                                                       |
|---------------------------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Ping LSP to Layer 3 VPN prefix              | ping mpls l3vpn                     | Checks the operability of the connections related to a Layer 3 VPN. The device tests whether a prefix is present in a provider edge (PE) device's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix.                                                                                                 | The device does not test the connection between a PE device and a customer edge (CE) router. |
| Locate LSP using interface name             | ping mpls l2vpn interface           | Checks the operability of the connections related to a Layer 2 VPN. The device directs outgoing request probes out the specified interface.                                                                                                                                                                                             | —                                                                                            |
| Instance to which this connection belongs   | ping mpls l2vpn instance            | Checks the operability of the connections related to a Layer 2 VPN. The device pings on a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, to test the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the inbound and outbound PE routers. | —                                                                                            |
| Locate LSP from interface name              | ping mpls l2circuit interface       | Checks the operability of the Layer 2 circuit connections. The device directs outgoing request probes out the specified interface.                                                                                                                                                                                                      | —                                                                                            |
| Locate LSP from virtual circuit information | ping mpls l2circuit virtual-circuit | Checks the operability of the Layer 2 circuit connections. The device pings on a combination of the IPv4 prefix and the virtual circuit identifier on the outbound PE router, testing the integrity of the Layer 2 circuit between the inbound and outbound PE routers.                                                                 | —                                                                                            |
| Ping end point of LSP                       | ping mpls lsp-end-point             | Checks the operability of an LSP endpoint. The device pings an LSP endpoint using either an LDP FEC prefix or an RSVP LSP endpoint address.                                                                                                                                                                                             | —                                                                                            |

## Configuring Ping MPLS

Before using the ping MPLS feature, make sure that the receiving interface on the VPN or LSP remote endpoint has MPLS enabled, and that the loopback interface on the outbound node is configured as **127.0.0.1**. The source address for MPLS probes must be a valid address on the device.

- **MPLS Enabled**—To process ping MPLS requests, the remote endpoint of the VPN or LSP must be configured appropriately. You must enable MPLS on the receiving interface of the outbound node for the VPN or LSP. If MPLS is not enabled, the remote endpoint drops the incoming request packets and returns an “ICMP host unreachable” message to the device.
- **Loopback Address**—The loopback address (**lo0**) on the outbound node must be configured as **127.0.0.1**. If this interface address is not configured correctly, the outbound node does not have this forwarding entry. It drops the incoming request packets and returns a “host unreachable” message to the device.
- **Source Address for Probes**—The source IP address you specify for a set of probes must be an address configured on one of the device interfaces. If it is not a valid device address, the ping request fails with the error message “Can't assign requested address.”

## Using the ping Command

You can perform certain tasks only through the CLI. Use the CLI **ping** command to verify that a host can be reached over the network. This command is useful for diagnosing host and network connectivity problems. The device sends a series of ICMP echo (ping) requests to a specified host and receives ICMP echo responses.

Enter the **ping** command with the following syntax:

```
user@host> ping host <interface source-interface> <bypass-routing> <count number>
<do-not-fragment> <inet | inet6> <interval seconds> <loose-source [hosts]>
<no-resolve> <pattern string> <rapid> <record-route>
<routing-instance routing-instance-name> <size bytes> <source source-address> <strict>
<strict-source [hosts]> <tos number> <ttl number> <wait seconds> <detail> <verbose>
```

[Table 155](#) describes the **ping** command options.

To quit the **ping** command, press Ctrl-C.

Table 155: CLI ping Command Options

| Option                                            | Description                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>                                       | Pings the hostname or IP address you specify.                                                                                                                                                                                                                                                         |
| <i>interface source-interface</i>                 | (Optional) Sends the ping requests on the interface you specify. If you do not include this option, ping requests are sent on all interfaces.                                                                                                                                                         |
| <i>bypass-routing</i>                             | (Optional) Bypasses the routing tables and sends the ping requests only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.<br><br>Use this option to ping a local system through an interface that has no route through it. |
| <i>countnumber</i>                                | (Optional) Limits the number of ping requests to send. Specify a count from 1 through 2,000,000,000. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.                                                                                                       |
| <i>do-not-fragment</i>                            | (Optional) Sets the Don't Fragment (DF) bit in the IP header of the ping request packet.                                                                                                                                                                                                              |
| <i>inet</i>                                       | (Optional) Forces the ping requests to an IPv4 destination.                                                                                                                                                                                                                                           |
| <i>inet6</i>                                      | (Optional) Forces the ping requests to an IPv6 destination.                                                                                                                                                                                                                                           |
| <i>interval seconds</i>                           | (Optional) Sets the interval between ping requests, in seconds. Specify an interval from 0.1 through 10,000. The default value is 1 second.                                                                                                                                                           |
| <i>loose-source [hosts]</i>                       | (Optional) For IPv4, sets the loose source routing option in the IP header of the ping request packet.                                                                                                                                                                                                |
| <i>no-resolve</i>                                 | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                                                                                                                                                                                        |
| <i>pattern string</i>                             | (Optional) Includes the hexadecimal string you specify, in the ping request packet.                                                                                                                                                                                                                   |
| <i>rapid</i>                                      | (Optional) Sends ping requests rapidly. The results are reported in a single message, not in individual messages for each ping request. By default, five ping requests are sent before the results are reported. To change the number of requests, include the <b>count</b> option.                   |
| <i>record-route</i>                               | (Optional) For IPv4, sets the record route option in the IP header of the ping request packet. The path of the ping request packet is recorded within the packet and displayed on the screen.                                                                                                         |
| <i>routing-instance<br/>routing-instance-name</i> | (Optional) Uses the routing instance you specify for the ping request.                                                                                                                                                                                                                                |
| <i>size bytes</i>                                 | (Optional) Sets the size of the ping request packet. Specify a size from 0 through 65,468. The default value is 56 bytes, which is effectively 64 bytes because 8 bytes of ICMP header data are added to the packet.                                                                                  |
| <i>source source-address</i>                      | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                                                                                                      |
| <i>strict</i>                                     | (Optional) For IPv4, sets the strict source routing option in the IP header of the ping request packet.                                                                                                                                                                                               |

Table 155: CLI ping Command Options (*continued*)

| Option                              | Description                                                                                                                                                                                                                                                                  |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>strict-source</b> <i>[hosts]</i> | (Optional) For IPv4, sets the strict source routing option in the IP header of the ping request packet, and uses the list of hosts you specify for routing the packet.                                                                                                       |
| <b>tos</b> <i>number</i>            | (Optional) Sets the type-of-service (TOS) value in the IP header of the ping request packet. Specify a value from <b>0</b> through <b>255</b> .                                                                                                                              |
| <b>ttl</b> <i>number</i>            | (Optional) Sets the time-to-live (TTL) value for the ping request packet. Specify a value from <b>0</b> through <b>255</b> .                                                                                                                                                 |
| <b>wait</b> <i>seconds</i>          | (Optional) Sets the maximum time to wait after sending the last ping request packet. If you do not specify this option, the default delay is <b>10</b> seconds. If you use this option without the <b>count</b> option, the device uses a default count of <b>5</b> packets. |
| <b>detail</b>                       | (Optional) Displays the interface on which the ping response was received.                                                                                                                                                                                                   |
| <b>verbose</b>                      | (Optional) Displays detailed output.                                                                                                                                                                                                                                         |

The following is sample output from a **ping** command:

```

user@host> ping host3 count 4

PING host3.site.net (176.26.232.111): 56 data bytes 64 bytes from 176.26.232.111:
icmp_seq=0 ttl=122 time=0.661 ms 64 bytes from 176.26.232.111: icmp_seq=1 ttl=122
time=0.619 ms 64 bytes from 176.26.232.111: icmp_seq=2 ttl=122 time=0.621 ms 64
bytes from 176.26.232.111: icmp_seq=3 ttl=122 time=0.634 ms --- host3.site.net
ping statistics --- 4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.619/0.634/0.661/0.017 ms

```

The fields in the display are the same as those displayed by the J-Web ping host diagnostic tool.

## Using the J-Web Ping Host Tool

You can ping a host to verify that the host can be reached over the network. The output is useful for diagnosing host and network connectivity problems. The device sends a series of ICMP echo (ping) requests to a specified host and receives ICMP echo responses.

Alternatively, you can use the CLI **ping** command. (See [“Using the ping Command” on page 1360.](#))

To use the ping host tool:

1. Select **Troubleshoot>Ping Host** from the task bar.
2. Next to Advanced options, click the expand icon.
3. Enter information into the Ping Host page (see [Table 156](#)).

**Table 156: J-Web Ping Host Field Summary**

| Field                   | Function                                                                                                                                                                    | Your Action                                                                                                                                                                                                                  |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote Host             | Identifies the host to ping.<br><br>This is the only required field.                                                                                                        | Type the hostname or IP address of the host to ping.                                                                                                                                                                         |
| <b>Advanced Options</b> |                                                                                                                                                                             |                                                                                                                                                                                                                              |
| Don't Resolve Addresses | Determines whether to display hostnames of the hops along the path.                                                                                                         | <ul style="list-style-type: none"> <li>• Suppress the display of the hop hostnames by selecting the check box.</li> <li>• Display the hop hostnames by clearing the check box.</li> </ul>                                    |
| Interface               | Specifies the interface on which the ping requests are sent.                                                                                                                | Select the interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces.                                                                                 |
| Count                   | Specifies the number of ping requests to send.                                                                                                                              | Select the number of ping requests to send from the list.                                                                                                                                                                    |
| Don't Fragment          | Specifies the Don't Fragment (DF) bit in the IP header of the ping request packet.                                                                                          | <ul style="list-style-type: none"> <li>• Set the DF bit by selecting the check box.</li> <li>• Clear the DF bit by clearing the check box.</li> </ul>                                                                        |
| Record Route            | Sets the record route option in the IP header of the ping request packet. The path of the ping request packet is recorded within the packet and displayed in the main pane. | <ul style="list-style-type: none"> <li>• Record and display the path of the packet by selecting the check box.</li> <li>• Suppress the recording and display of the path of the packet by clearing the check box.</li> </ul> |
| Type-of-Service         | Specifies the type-of-service (TOS) value in the IP header of the ping request packet.                                                                                      | Select the decimal value of the TOS field from the list.                                                                                                                                                                     |
| Routing Instance        | Names the routing instance for the ping attempt.                                                                                                                            | Select the routing instance name from the list.                                                                                                                                                                              |
| Interval                | Specifies the interval, in seconds, between the transmission of each ping request.                                                                                          | Select the interval from the list.                                                                                                                                                                                           |
| Packet Size             | Specifies the size of the ping request packet.                                                                                                                              | Type the size, in bytes, of the packet. The size can be from 0 through 65,468. The device adds 8 bytes of ICMP header to the size.                                                                                           |
| Source Address          | Specifies the source address of the ping request packet.                                                                                                                    | Type the source IP address.                                                                                                                                                                                                  |

Table 156: J-Web Ping Host Field Summary (*continued*)

| Field          | Function                                                                                                                                                                                                                                                                            | Your Action                                                                                                                                                                                                                                                    |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Time-to-Live   | Specifies the time-to-live (TTL) hop count for the ping request packet.                                                                                                                                                                                                             | Select the TTL from the list.                                                                                                                                                                                                                                  |
| Bypass Routing | <p>Determines whether ping requests are routed by means of the routing table.</p> <p>If the routing table is not used, ping requests are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, ping responses are not sent.</p> | <ul style="list-style-type: none"> <li>Bypass the routing table and send the ping requests to hosts on the specified interface only by selecting the check box.</li> <li>Route the ping requests using the routing table by clearing the check box.</li> </ul> |

4. Click **Start**.

The results of the ping operation appear in the main pane. If no options are specified, each ping response is in the following format:

*bytes bytes from ip-address: icmp\_seq=number ttl=number time=time*

5. You can stop the ping operation before it is complete by clicking **OK**.**Related Documentation**

**J-Web Ping Host Results and Output Summary**

Table 157 summarizes the output in the ping host display.

Table 157: Ping Host Results and Output

| Ping Host Result                            | Description                                                                                                                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bytes bytes from ip-address</i>          | <ul style="list-style-type: none"> <li><b>bytes</b>—Size of ping response packet, which is equal to the value you entered in the Packet Size box, plus 8.</li> <li><b>ip-address</b>—IP address of destination host that sent the ping response packet.</li> </ul> |
| <i>icmp_seq=0</i><br><i>icmp_seq=number</i> | <b>number</b> —Sequence Number field of the ping response packet. You can use this value to match the ping response to the corresponding ping request.                                                                                                             |
| <i>ttl=number</i>                           | <b>number</b> —Time-to-live hop-count value of the ping response packet.                                                                                                                                                                                           |
| <i>number packets transmitted</i>           | <b>number</b> —Number of ping requests (probes) sent to host.                                                                                                                                                                                                      |

Table 157: Ping Host Results and Output (*continued*)

| Ping Host Result                                                                | Description                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percentage</i> packet loss                                                   | <i>percentage</i> —Number of ping responses divided by the number of ping requests, specified as a percentage.                                                                                                                                                                                                |
| round-trip min/avg/max/stddev =<br><i>min-time/avg-time/max-time/std-dev</i> ms | <ul style="list-style-type: none"> <li><i>min-time</i>—Minimum round-trip time (see <i>time=time</i> field in this table).</li> <li><i>avg-time</i>—Average round-trip time.</li> <li><i>max-time</i>—Maximum round-trip time.</li> <li><i>std-dev</i>—Standard deviation of the round-trip times.</li> </ul> |

If the device does not receive ping responses from the destination host (the output shows a packet loss of 100 percent), one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host might be configured to ignore ICMP echo requests.
- The host might be configured with a firewall filter that blocks ICMP echo requests or ICMP echo responses.
- The size of the ICMP echo request packet exceeds the MTU of a host along the path.
- The value you selected in the Time-to-Live box was less than the number of hops in the path to the host, in which case the host might reply with an ICMP error message.

## Using the J-Web Ping MPLS Tool

Before using the ping MPLS feature, make sure that the receiving interface on the VPN or LSP remote endpoint has MPLS enabled, and that the loopback interface on the outbound node is configured as **127.0.0.1**. The source address for MPLS probes must be a valid address on the device.

To use the ping MPLS tool:

1. Select **Troubleshoot>Ping MPLS** from the task bar.
2. Next to the ping MPLS option you want to use, click the expand icon.
3. Enter information into the Ping MPLS page (see [Table 158](#)).

Table 158: J-Web Ping MPLS Field Summary

| Field                                  | Function                                                                | Your Action                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ping RSVP-signaled LSP</b>          |                                                                         |                                                                                                                                                     |
| LSP Name                               | Identifies the LSP to ping.                                             | Type the name of the LSP to ping.                                                                                                                   |
| Source Address                         | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Count                                  | Specifies the number of ping requests to send.                          | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                        | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| <b>Ping LDP-signaled LSP</b>           |                                                                         |                                                                                                                                                     |
| FEC Prefix                             | Identifies the LSP to ping.                                             | Type the forwarding equivalence class (FEC) prefix and length of the LSP to ping.                                                                   |
| Source Address                         | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Count                                  | Specifies the number of ping requests to send.                          | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                        | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| <b>Ping LSP to Layer 3 VPN prefix</b>  |                                                                         |                                                                                                                                                     |
| Layer 3 VPN Name                       | Identifies the Layer 3 VPN to ping.                                     | Type the name of the VPN to ping.                                                                                                                   |
| Count                                  | Specifies the number of ping requests to send.                          | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                        | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| VPN Prefix                             | Identifies the IP address prefix and length of the Layer 3 VPN to ping. | Type the IP address prefix and length of the VPN to ping.                                                                                           |
| Source Address                         | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| <b>Locate LSP using interface name</b> |                                                                         |                                                                                                                                                     |
| Interface                              | Specifies the interface on which the ping requests are sent.            | Select the device interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces. |
| Source Address                         | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |

Table 158: J-Web Ping MPLS Field Summary (*continued*)

| Field                                              | Function                                                                       | Your Action                                                                                                                                         |
|----------------------------------------------------|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                                                                    |
| <b>Instance to which this connection belongs</b>   |                                                                                |                                                                                                                                                     |
| Layer 2VPN Name                                    | Identifies the Layer 2 VPN to ping.                                            | Type the name of the VPN to ping.                                                                                                                   |
| Remote Site Identifier                             | Specifies the remote site identifier of the Layer 2 VPN to ping.               | Type the remote site identifier for the VPN.                                                                                                        |
| Source Address                                     | Specifies the source address of the ping request packet.                       | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Local Site Identifier                              | Specifies the local site identifier of the Layer 2 VPN to ping.                | Type the local site identifier for the VPN.                                                                                                         |
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                                                                    |
| <b>Locate LSP from interface name</b>              |                                                                                |                                                                                                                                                     |
| Interface                                          | Specifies the interface on which the ping requests are sent.                   | Select the device interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces. |
| Source Address                                     | Specifies the source address of the ping request packet.                       | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                                                                    |
| <b>Locate LSP from virtual circuit information</b> |                                                                                |                                                                                                                                                     |
| Remote Neighbor                                    | Identifies the remote neighbor (PE device) within the virtual circuit to ping. | Type the IP address of the remote neighbor within the virtual circuit.                                                                              |
| Circuit Identifier                                 | Specifies the virtual circuit identifier for the Layer 2 circuit to ping.      | Type the virtual circuit identifier for the Layer 2 circuit.                                                                                        |
| Source Address                                     | Specifies the source address of the ping request packet.                       | Type the source IP address—a valid address configured on a device interface.                                                                        |

Table 158: J-Web Ping MPLS Field Summary (*continued*)

| Field                        | Function                                                         | Your Action                                                                                     |
|------------------------------|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Count                        | Specifies the number of ping requests to send.                   | Select the number of ping requests to send from the list.                                       |
| Detailed Output              | Requests the display of extensive rather than brief ping output. | Select the check box to display detailed output.                                                |
| <b>Ping end point of LSP</b> |                                                                  |                                                                                                 |
| VPN Prefix                   | Identifies the LSP endpoint to ping.                             | Type either the LDP FEC prefix and length or the RSVP LSP endpoint address for the LSP to ping. |
| Source Address               | Specifies the source address of the ping request packet.         | Type the source IP address—a valid address configured on a device interface.                    |
| Count                        | Specifies the number of ping requests to send.                   | Select the number of ping requests to send from the list.                                       |
| Detailed Output              | Requests the display of extensive rather than brief ping output. | Select the check box to display detailed output.                                                |

4. Click **Start**.

5. You can stop the ping operation before it is complete by clicking **OK**.

## J-Web Ping MPLS Results and Output Summary

Table 159 summarizes the output in the ping MPLS display.

Table 159: J-Web Ping MPLS Results and Output Summary

| Field                 | Description                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Exclamation point (!) | Echo reply was received.                                                                                                                    |
| Period (.)            | Echo reply was not received within the timeout period.                                                                                      |
| x                     | Echo reply was received with an error code. Errored packets are not counted in the received packets count and are accounted for separately. |

Table 159: J-Web Ping MPLS Results and Output Summary (*continued*)

| Field                             | Description                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>number</i> packets transmitted | <i>number</i> —Number of ping requests (probes) sent to a host.                                                                                                                             |
| <i>number</i> packets received    | <i>number</i> —Number of ping responses received from a host.                                                                                                                               |
| <i>percentage</i> packet loss     | <i>percentage</i> —Number of ping responses divided by the number of ping requests, specified as a percentage.                                                                              |
| time                              | For Layer 2 circuits only, the number of milliseconds required for the ping packet to reach the destination. This value is approximate, because the packet has to reach the Routing Engine. |

If the device does not receive ping responses from the destination host (the output shows a packet loss of 100 percent), one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host might be configured to ignore echo requests.
- The host might be configured with a firewall filter that blocks echo requests or echo responses.
- The size of the echo request packet exceeds the MTU of a host along the path.
- The outbound node at the remote endpoint is not configured to handle MPLS packets.
- The remote endpoint's loopback address is not configured to 127.0.0.1.

## Pinging Layer 2 Circuits

Enter the **ping mpls l2circuit** command with the following syntax:

```
user@host> ping mpls l2circuit (interface interface-name | virtual-circuit neighbor
    prefix-name virtual-circuit-id) <exp forwarding-class> <count number>
    <source source-address> <detail>
```

Table 160 describes the **ping mpls l2circuit** command options.

Table 160: CLI ping mpls l2circuit Command Options

| Option                                                                                    | Description                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l2circuit interface</b><br><i>interface-name</i>                                       | Sends ping requests out the specified interface configured for the Layer 2 circuit on the outbound PE device.                                                                                                       |
| <b>l2circuit virtual-circuit neighbor</b> <i>prefix-name</i><br><i>virtual-circuit-id</i> | Pings on a combination of the IPv4 prefix and the virtual circuit identifier on the outbound PE device, testing the integrity of the Layer 2 circuit between the inbound and outbound PE devices.                   |
| <b>exp forwarding-class</b>                                                               | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                         |
| <b>count</b> <i>number</i>                                                                | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C. |
| <b>source</b> <i>source-address</i>                                                       | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                    |
| <b>detail</b>                                                                             | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                |

To quit the **ping mpls l2circuit** command, press Ctrl-C.

The following is sample output from a **ping mpls l2circuit** command:

```
user@host> ping mpls l2circuit interface fe-1/0/0.0
Request for seq 1, to interface 69, labels <100000, 100208>
Reply for seq 1, return code: Egress-ok, time: 0.439 ms
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

## Pinging Layer 2 VPNs

Enter the **ping mpls l2vpn** command with the following syntax:

```
user@host> ping mpls l2vpn interface interface-name | instance l2vpn-instance-name
local-site-id local-site-id-number remote-site-id remote-site-id-number
<bottom-label-ttl> <exp forwarding-class> <count number> <source source-address>
<detail>
```

[Table 161](#) describes the **ping mpls l2vpn** command options.

Table 161: CLI ping mpls l2vpn Command Options

| Option                                                                                                                                                              | Description                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l2vpn interface</b><br><i>interface-name</i>                                                                                                                     | Sends ping requests out the specified interface configured for the Layer 2 VPN on the outbound (egress) PE device.                                                                                                                                                 |
| <b>l2vpn instance</b><br><i>l2vpn-instance-name</i><br><i>local-site-id</i><br><i>local-site-id-number</i><br><i>remote-site-id</i><br><i>remote-site-id-number</i> | Pings on a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the inbound (ingress) and outbound PE devices. |
| <b>bottom-label-ttl</b>                                                                                                                                             | (Optional) Displays the time-to-live (TTL) value for the bottom label in the MPLS label stack.                                                                                                                                                                     |
| <b>exp forwarding-class</b>                                                                                                                                         | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                                                                        |
| <b>countnumber</b>                                                                                                                                                  | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.                                                |
| <b>source source-address</b>                                                                                                                                        | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                                                                   |
| <b>detail</b>                                                                                                                                                       | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                                                               |

To quit the **ping mpls l2vpn** command, press Ctrl-C.

The following is sample output from a **ping mpls l2vpn** command:

```

user@host> ping mpls l2vpn instance vpn1 remote-site-id 1 local-site-id 2 detail
Request for seq 1, to interface 68, labels <800001, 100176>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <800001, 100176>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <800001, 100176>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <800001, 100176>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <800001, 100176>
Reply for seq 5, return code: Egress-ok

--- 1sping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

## Pinging Layer 3 VPNs

Enter the **ping mpls l3vpn** command with the following syntax:

```
user@host> ping mpls l3vpn prefix prefix-name <l3vpn-name> <bottom-label-ttl>
<exp forwarding-class> <count number> <source source-address> <detail>
```

[Table 162](#) describes the **ping mpls l3vpn** command options.

**Table 162: CLI ping mpls l3vpn Command Options**

| Option                                 | Description                                                                                                                                                                                                                   |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l3vpn prefix <i>prefix-name</i></b> | Pings the remote host specified by the prefix to verify that the prefix is present in the PE device's VPN routing and forwarding (VRF) table. This option does not test the connectivity between a PE device and a CE device. |
| <b><i>l3vpn-name</i></b>               | (Optional) Layer 3 VPN name.                                                                                                                                                                                                  |
| <b>bottom-label-ttl</b>                | (Optional) Displays the time-to-live (TTL) value for the bottom label in the MPLS label stack.                                                                                                                                |
| <b>exp forwarding-class</b>            | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                                   |
| <b>countnumber</b>                     | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.           |
| <b>source source-address</b>           | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                              |
| <b>detail</b>                          | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                          |

To quit the **ping mpls l3vpn** command, press Ctrl-C.

The following is sample output from a **ping mpls l3vpn** command:

```
user@host> ping mpls l3vpn vpn1 prefix 10.255.245.122/32
!!!!
--- 1ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

Pinging RSVP-Signaled LSPs and LDP-Signaled LSPs

Enter the **ping mpls** command with the following syntax:

```
user@host> ping mpls (ldp fec | lsp-end-point prefix-name | rsvp lsp-name)
<exp forwarding-class> <count number> <source source-address> <detail>
```

Table 163 describes the **ping mpls** command options.

Table 163: CLI ping mpls ldp and ping mpls lsp-end-point Command Options

| Option                    | Description                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldp fec                   | Pings an LDP-signaled LSP identified by the forwarding equivalence class (FEC) prefix and length.                                                                                                                   |
| lsp-end-point prefix-name | Pings an LSP endpoint using either an LDP FEC or a RSVP LSP endpoint address.                                                                                                                                       |
| rsvp lsp-name             | Pings an RSVP-signaled LSP identified by the specified LSP name.                                                                                                                                                    |
| exp forwarding-class      | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                         |
| countnumber               | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C. |
| source source-address     | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                    |
| detail                    | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                |

To quit the **ping mpls** command, press Ctrl-C.

The following is sample output from a **ping mpls** command:

```
user@host> ping mpls rsvp count 5
!!xxx
--- lsping statistics ---
5 packets transmitted, 2 packets received, 60% packet loss
3 packets received with error status, not counted as received.
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

### Packet Capture Overview

Packet capture is a tool that helps you to analyze network traffic and troubleshoot network problems. The packet capture tool captures real-time data packets traveling over the network for monitoring and logging.

**NOTE:** Packet capture is supported on physical interfaces, reth interfaces, and tunnel interfaces, such as gr, ip, st0, and lsq-/ls.

Packets are captured as binary data, without modification. You can read the packet information offline with a packet analyzer such as Ethereal or tcpdump. If you need to quickly capture packets destined for, or originating from, the Routing Engine and analyze them online, you can use the J-Web packet capture diagnostic tool.

**NOTE:** The packet capture tool does not support IPv6 packet capture.

You can use either the J-Web configuration editor or CLI configuration editor to configure packet capture.

Network administrators and security engineers use packet capture to perform the following tasks:

- Monitor network traffic and analyze traffic patterns.
- Identify and troubleshoot network problems.

- Detect security breaches in the network, such as unauthorized intrusions, spyware activity, or ping scans.

Packet capture operates like traffic sampling on the device, except that it captures entire packets including the Layer 2 header and saves the contents to a file in libpcap format. Packet capture also captures IP fragments. You cannot enable packet capture and traffic sampling on the device at the same time. Unlike traffic sampling, there are no tracing operations for packet capture.

**NOTE:** You can enable packet capture and port mirroring simultaneously on a device.

This section contains the following topics:

- [Packet Capture on Device Interfaces on page 1375](#)
- [Firewall Filters for Packet Capture on page 1376](#)

### Packet Capture on Device Interfaces

Packet capture is supported on the T1, T3, E1, E3, serial, Fast Ethernet, ADSL, G.SHDSL, PPPoE, and ISDN interfaces.

To capture packets on an ISDN interface, configure packet capture on the dialer interface. To capture packets on a PPPoE interface, configure packet capture on the PPPoE logical interface.

Packet capture supports PPP, Cisco HDLC, Frame Relay, and other ATM encapsulations. Packet capture also supports Multilink PPP (MLPPP), Multilink Frame Relay end-to-end (MLFR), and Multilink Frame Relay UNI/NNI (MFR) encapsulations.

You can capture all IPv4 packets flowing on an interface in the inbound or outbound direction. However, on traffic that bypasses the flow software module (protocol packets such as ARP, OSPF, and PIM), packets generated by the Routing Engine are not captured unless you have configured and applied a firewall filter on the interface in the outbound direction.

Tunnel interfaces can support packet capture in the outbound direction only.

Use the J-Web configuration editor or CLI configuration editor to specify the maximum packet size, the filename to be used for storing the captured packets, the maximum file size, the maximum number of packet capture files, and the file permissions.

**NOTE:** For packets captured on T1, T3, E1, E3, serial, and ISDN interfaces in the outbound (egress) direction, the size of the packet captured might be 1 byte less than the maximum packet size configured because of the packet loss priority (PLP) bit.

To modify encapsulation on an interface that has packet capture configured, you must first disable packet capture.

### Firewall Filters for Packet Capture

---

When you enable packet capture on a device, all packets flowing in the direction specified in packet capture configuration (inbound, outbound, or both) are captured and stored. Configuring an interface to capture all packets might degrade the performance of the device. You can control the number of packets captured on an interface with firewall filters and specify various criteria to capture packets for specific traffic flows.

You must also configure and apply appropriate firewall filters on the interface if you need to capture packets generated by the host device, because interface sampling does not capture packets originating from the host device.

### Packet Capture Files

---

When packet capture is enabled on an interface, the entire packet including the Layer 2 header is captured and stored in a file. You can specify the maximum size of the packet to be captured, up to 1500 bytes. Packet capture creates one file for each physical interface. You can specify the target filename, the maximum size of the file, and the maximum number of files.

File creation and storage take place in the following way. Suppose you name the packet capture file **pcap-file**. Packet capture creates multiple files (one per physical interface), suffixing each file with the name of the physical interface; for example, **pcap-file.fe-0.0.1** for the Fast Ethernet interface **fe-0.0.1**. When the file named **pcap-file.fe-0.0.1** reaches the maximum size, the file is renamed **pcap-file.fe-0.0.1.0**. When the file named **pcap-file.fe-0.0.1** reaches the maximum size again, the file named **pcap-file.fe-0.0.1.0** is renamed **pcap-file.fe-0.0.1.1** and **pcap-file.fe-0.0.1** is renamed **pcap-file.fe-0.0.1.0**. This process continues until the maximum number of files is exceeded and the oldest file is overwritten. The **pcap-file.fe-0.0.1** file is always the latest file.

Packet capture files are not removed even after you disable packet capture on an interface.

### Analysis of Packet Capture Files

---

Packet capture files are stored in libpcap format in the **/var/tmp** directory. You can specify user or administrator privileges for the files.

Packet capture files can be opened and analyzed offline with tcpdump or any packet analyzer that recognizes the libpcap format. You can also use FTP or the Session Control Protocol (SCP) to transfer the packet capture files to an external device.

**NOTE:** Disable packet capture before opening the file for analysis or transferring the file to an external device with FTP or SCP. Disabling packet capture ensures that the internal file buffer is flushed and all the captured packets are written to the file.

---

- Related Documentation**
- [Example: Enabling Packet Capture on a Device on page 1377](#)
  - [Example: Configuring Packet Capture on an Interface on page 1380](#)

  - [Using the J-Web Packet Capture Tool on page 1393](#)

## Example: Enabling Packet Capture on a Device

This example shows how to enable packet capture on a device, allowing you to analyze network traffic and troubleshoot network problems

- [Requirements on page 1377](#)
- [Overview on page 1377](#)
- [Configuration on page 1377](#)
- [Verification on page 1378](#)

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

### Overview

In this example, you set the maximum packet capture size in each file as 500 bytes. The range is from 68 through 1500, and the default is 68 bytes. You specify the target filename for the packet capture file as pcap-file. You then specify the maximum number of files to capture as 100. The range is from 2 through 10,000, and the default is 10 files. You set the maximum size of each file to 1024 bytes. The range is from 1,024 through 104,857,600, and the default is 512,000 bytes. Finally, you specify that all users have permission to read the packet capture files.

### Configuration

- CLI Quick Configuration**
- To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set forwarding-options packet-capture maximum-capture-size 500
set forwarding-options packet-capture file filename pcap-file files 100 size 1024
world-readable
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To enable packet capture on a device:

1. Set the maximum packet capture size.

```
[edit]
user@host# edit forwarding-options
user@host# set packet-capture maximum-capture-size 500
```

2. Specify the target filename.

```
[edit forwarding-options]
user@host# set packet-capture file filename pcap-file
```

3. Specify the maximum number of files to capture.

```
[edit forwarding-options]
user@host# set packet-capture file files 100
```

4. Specify the maximum size of each file.

```
[edit forwarding-options]
user@host# set packet-capture file size 1024
```

5. Specify that all users have permission to read the file.

```
[edit forwarding-options]
user@host# set packet-capture file world-readable
```

**Results** From configuration mode, confirm your configuration by entering the **show forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show forwarding-options
packet-capture {
  file filename pcap-file files 100 size 1k world-readable;
  maximum-capture-size 500;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Verification

Confirm that the configuration is working properly.

- [Verifying the Packet Capture Configuration on page 1378](#)
- [Verifying Captured Packets on page 1379](#)

#### *Verifying the Packet Capture Configuration*

**Purpose** Verify that the packet capture is configured on the device.

**Action** From configuration mode, enter the **show forwarding-options** command. Verify that the output shows the intended file configuration for capturing packets.

### *Verifying Captured Packets*

**Purpose** Verify that the packet capture file is stored under the **/var/tmp** directory and the packets can be analyzed offline.

**Action** 1. Disable packet capture.

Using FTP, transfer a packet capture file (for example, **126b.fe-0.0.1**), to a server where you have installed packet analyzer tools (for example, **tools-server**).

a. From configuration mode, connect to **tools-server** using FTP.

```
[edit]
user@host# run ftp tools-server
Connected to tools-server.mydomain.net
220 tools-server.mydomain.net FTP server (Version 6.00LS) ready
Name (tools-server:user):remoteuser
331 Password required for remoteuser.
Password:
230 User remoteuser logged in.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp>
```

b. Navigate to the directory where packet capture files are stored on the device.

```
ftp> lcd /var/tmp
Local directory now /cf/var/tmp
```

c. Copy the packet capture file that you want to analyze to the server, for example **126b.fe-0.0.1**.

```
ftp> put 126b.fe-0.0.1
local: 126b.fe-0.0.1 remote: 126b.fe-0.0.1
200 PORT command successful.
150 Opening BINARY mode data connection for '126b.fe-0.0.1'.
100% 1476 00:00 ETA
226 Transfer complete.
1476 bytes sent in 0.01 seconds (142.42 KB/s)
```

d. Return to configuration mode.

```
ftp> bye
221 Goodbye.
[edit]
user@host#
```

2. Open the packet capture file on the server with **tcpdump** or any packet analyzer that supports libpcap format and review the output.

```
root@server% tcpdump -r 126b.fe-0.0.1 -xevvvv
01:12:36.279769 Out 0:5:85:c4:e3:d1 > 0:5:85:c8:f6:d1, ethertype IPv4 (0x0800),
length 98: (tos 0x0, ttl 64, id 33133, offset 0, flags [none], proto: ICMP (1),
```

```

length: 84) 14.1.1.1 > 15.1.1.1: ICMP echo request seq 0, length 64

## Example: Configuring Packet Capture on an Interface

This example shows how to configure packet capture on an interface to analyze traffic.

- [Requirements on page 1380](#)
- [Overview on page 1380](#)
- [Configuration on page 1381](#)
- [Verification on page 1381](#)

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

### Overview

In this example, you create an interface called fe-0/0/1. You then configure the direction of the traffic for which you are enabling packet capture on the logical interface as inbound and outbound.

**NOTE:** On traffic that bypasses the flow software module (protocol packets such as ARP, OSPF, and PIM), packets generated by the Routing Engine are not captured unless you have configured and applied a firewall filter on the interface in the output direction.

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
edit interfaces fe-0/0/1
set unit 0 family inet sampling input output
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure packet capture on an interface:

1. Create an interface.  

```
[edit]
user@host# edit interfaces fe-0/0/1
```
2. Configure the direction of the traffic.  

```
[edit interfaces fe-0/0/1]
user@host# set unit 0 family inet sampling input output
```
3. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

### Verification

#### Verifying the Packet Capture Configuration

**Purpose** Confirm that the configuration is working properly.

Verify that packet capture is configured on the interface.

**Action** From configuration mode, enter the **show interfaces fe-0/0/1** command.

**Related Documentation**

- [Packet Capture Overview on page 1374](#)
- [Changing Encapsulation on Interfaces with Packet Capture Configured on page 1388](#)
- [Example: Configuring a Firewall Filter for Packet Capture on page 1382](#)

- [Deleting Packet Capture Files on page 1387](#)
- [Disabling Packet Capture on page 1387](#)

## Example: Configuring a Firewall Filter for Packet Capture

This example shows how to configure a firewall filter for packet capture and apply it to a logical interface.

- [Requirements on page 1382](#)
- [Overview on page 1382](#)
- [Configuration on page 1382](#)
- [Verification on page 1383](#)

---

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

---

### Overview

In this example, you set a firewall filter called `dest-all` and a term name called `dest-term` to capture packets from a specific destination address, which is `192.168.1.1/32`. You define the match condition to accept the sampled packets. Finally, you apply the `dest-all` filter to all of the outgoing packets on interface `fe-0/0/1`.

**NOTE:** If you apply a firewall filter on the loopback interface, it affects all traffic to and from the Routing Engine. If the firewall filter has a `sample` action, packets to and from the Routing Engine are sampled. If packet capture is enabled, then packets to and from the Routing Engine are captured in the files created for the input and output interfaces.

---

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter **commit** from configuration mode.

```
set firewall filter dest-all term dest-term from destination-address 192.168.1.1/32
set firewall filter dest-all term dest-term then sample accept
edit interfaces
set interfaces fe-0/0/1 unit 0 family inet filter output dest-all
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a firewall filter for packet capture and apply it to a logical interface:

1. Specify the firewall filter and its destination address.

```
[edit]
user@host# edit firewall
user@host# set filter dest-all term dest-term from destination-address 192.168.1.1/32
```

2. Define the match condition and its action.

```
[edit firewall]
user@host# set filter dest-all term dest-term then sample accept
```

3. Apply the filter to all the outgoing packets.

```
[edit interfaces]
user@host# set interfaces fe-0/0/1 unit 0 family inet filter output dest-all
```

**Results** From configuration mode, confirm your configuration by entering the **show firewall filter dest-all** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show firewall filter dest-all
term dest-term {
  from {
    destination-address 192.168.1.1/32;
  }
  then {
    sample;
    accept;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Firewall Filter for Packet Capture Configuration

**Purpose** Confirm that the configuration is working properly.

Verify that the firewall filter for packet capture is configured.

**Action** From configuration mode, enter the **show firewall filter dest-all** command. Verify that the output shows the intended configuration of the firewall filter for capturing packets sent to the destination address.

**Related Documentation**

- [Packet Capture Overview on page 1374](#)
- [Example: Configuring Packet Capture on an Interface on page 1380](#)

- [Example: Enabling Packet Capture on a Device on page 1377](#)
- [Deleting Packet Capture Files on page 1387](#)
- [Disabling Packet Capture on page 1387](#)

## Example: Configuring Packet Capture for Datapath Debugging

This example shows how to configure packet capture to monitor traffic that passes through the device. Packet capture then dumps the packets into a PCAP file format that can be later examined by the tcpdump utility.

- [Requirements on page 1384](#)
- [Overview on page 1384](#)
- [Configuration on page 1384](#)
- [Verification on page 1386](#)

---

### Requirements

Before you begin, see “Debugging the Data Path (CLI Procedure)” on page 1344.

---

### Overview

A filter is defined to filter traffic; then an action profile is applied to the filtered traffic. The action profile specifies a variety of actions on the processing unit. One of the supported actions is packet dump, which sends the packet to the Routing Engine and stores it in proprietary form to be read using the **show security datapath-debug capture** command.

---

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security datapath-debug capture-file my-capture
set security datapath-debug capture-file format pcap
set security datapath-debug capture-file size 1m
set security datapath-debug capture-file files 5
set security datapath-debug maximum-capture-size 400
set security datapath-debug action-profile do-capture event np-ingress packet-dump
set security datapath-debug packet-filter my-filter action-profile do-capture
set security datapath-debug packet-filter my-filter source-prefix 1.2.3.4/32
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure packet capture:

1. Edit the security datapath-debug option for the multiple processing units along the packet-processing path:

```
[edit]
user@host# edit security datapath-debug
```

2. Enable the capture file, the file format, the file size, and the number of files. Size number limits the size of the capture file. After the limit size is reached, if the file number is specified, then the capture file will be rotated to filename x, where x is auto-incremented until it reaches the specified index and then returns to zero. If no files index is specified, the packets will be discarded after the size limit is reached. The default size is 512 kilobytes.

```
[edit security datapath-debug]
user@host# set capture-file my-capture format pcap size 1m files 5
[edit security datapath-debug]
user@host# set maximum-capture-size 400
```

3. Enable action profile and set the event. Set the action profile as do-capture and the event type as np-ingress:

```
[edit security datapath-debug]
user@host# edit action-profile do-capture
[edit security datapath-debug action-profile do-capture]
user@host# edit event np-ingress
```

4. Enable packet dump for the action profile:

```
[edit security datapath-debug action-profile do-capture event np-ingress]
user@host# set packet-dump
```

5. Enable packet filter, action, and filter options. The packet filter is set to my-filter, the action profile is set to do-capture, and filter option is set to source-prefix 1.2.3.4/32.

```
[edit security datapath-debug]
user@host# set security datapath-debug packet-filter my-filter action-profile
do-capture

[edit security datapath-debug]
user@host# set security datapath-debug packet-filter my-filter source-prefix
1.2.3.4/32
```

**Results** From configuration mode, confirm your configuration by entering the **show security datapath-debug** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it. The following is **show security datapath-debug** output from the **show security datapath-debug** command:

```
security {
  datapath-debug {
    capture-file {
      my-capture
      format pcap
      size 1m
      files 5;
    }
  }
  maximum-capture-size 100;
  action-profile do-capture {
    event np-ingress {
```

```
        packet-dump
    }
}
packet-filter my-filter {
    source-prefix 1.2.3.4/32
    action-profile do-capture
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Verification

Confirm that the configuration is working properly.

- [Verifying Packet Capture on page 1386](#)
- [Verifying Data Path Debugging Capture on page 1386](#)
- [Verifying Data Path Debugging Counter on page 1386](#)

#### *Verifying Packet Capture*

**Purpose** Verify if the packet capture is working.

**Action** From operational mode, enter the **request security datapath-debug capture start** command to start packet capture and enter the **request security datapath-debug capture stop** command to stop packet capture.

To view the results, from CLI operational mode, access the local UNIX shell and navigate to the directory `/var/log/my-capture`. The result can be read by using the `tcpdump` utility.

#### *Verifying Data Path Debugging Capture*

**Purpose** Verify the details of data path debugging capture file.

**Action** From operational mode, enter the **show security datapath-debug capture** command.

```
user@host>show security datapath-debug capture
```

**WARNING:** When you are done troubleshooting, make sure to remove or deactivate all the traceoptions configurations (not limited to flow traceoptions) and the complete security datapath-debug configuration stanza. If any debugging configurations remain active, they will continue to use the device's CPU and memory resources.

---

#### *Verifying Data Path Debugging Counter*

**Purpose** Verify the details of the data path debugging counter.

**Action** From operational mode, enter the **show security datapath-debug counter** command.

- Related Documentation**
- [Packet Capture Overview on page 1374](#)
  - [Understanding Data Path Debugging for SRX Series Devices on page 1343](#)
  - [Debugging the Data Path \(CLI Procedure\) on page 1344](#)

## Disabling Packet Capture

You must disable packet capture before opening the packet capture file for analysis or transferring the file to an external device. Disabling packet capture ensures that the internal file buffer is flushed and all the captured packets are written to the file.

To disable packet capture, enter from configuration mode:

```
[edit forwarding-options]
user@host# set packet-capture disable
```

If you are done configuring the device, enter **commit** from configuration mode.

- Related Documentation**
- [Packet Capture Overview on page 1374](#)
  - [Example: Configuring Packet Capture on an Interface on page 1380](#)
  - [Example: Configuring a Firewall Filter for Packet Capture on page 1382](#)
  - [Example: Enabling Packet Capture on a Device on page 1377](#)
  - [Deleting Packet Capture Files on page 1387](#)

## Deleting Packet Capture Files

Deleting packet capture files from the `/var/tmp` directory only temporarily removes the packet capture files. Packet capture files for the interface are automatically created again the next time a packet capture configuration change is committed or as part of a packet capture file rotation.

To delete a packet capture file:

1. Disable packet capture (see [“Disabling Packet Capture” on page 1387](#)).
2. Delete the packet capture file for the interface.
  - a. From operational mode, access the local UNIX shell.
 

```
user@host> start shell
%
```
  - b. Navigate to the directory where packet capture files are stored.
 

```
% cd /var/tmp
%
```
  - c. Delete the packet capture file for the interface; for example `pcap-file.fe.0.0.0`.
 

```
% rm pcap-file.fe.0.0.0
%
```

- d. Return to operational mode.

```
% exit
user@host>
```

3. Reenable packet capture (see [“Example: Enabling Packet Capture on a Device” on page 1377](#)).
4. If you are done configuring the device, enter **commit** from configuration mode.

#### Related Documentation

- [Packet Capture Overview on page 1374](#)
- [Example: Configuring Packet Capture on an Interface on page 1380](#)
- [Example: Configuring a Firewall Filter for Packet Capture on page 1382](#)

- [Changing Encapsulation on Interfaces with Packet Capture Configured on page 1388](#)
- [Disabling Packet Capture on page 1387](#)

## Changing Encapsulation on Interfaces with Packet Capture Configured

Before modifying the encapsulation on a device interface that is configured for packet capture, you must disable packet capture and rename the latest packet capture file. Otherwise, packet capture saves the packets with different encapsulations in the same packet capture file. Packet files containing packets with different encapsulations are not useful, because packet analyzer tools like tcpdump cannot analyze such files.

After modifying the encapsulation, you can safely reenable packet capture on the device.

To change the encapsulation on interfaces with packet capture configured:

1. Disable packet capture (see [“Disabling Packet Capture” on page 1387](#)).
2. Enter **commit** from configuration mode.
3. Rename the latest packet capture file on which you are changing the encapsulation with the **.chdsl** extension.

- a. From operational mode, access the local UNIX shell.

```
user@host> start shell
%
```

- b. Navigate to the directory where packet capture files are stored.

```
% cd /var/tmp
%
```

- c. Rename the latest packet capture file for the interface on which you are changing the encapsulation; for example **fe.0.0.0**.

```
% mv pcap-file.fe.0.0.0 pcap-file.fe.0.0.0.chdsl
%
```

- d. Return to operational mode.

```
% exit
user@host>
```

4. Change the encapsulation on the interface using the J-Web user interface or CLI configuration editor.
5. If you are done configuring the device, enter **commit** from configuration mode.
6. Reenable packet capture (see [“Example: Enabling Packet Capture on a Device” on page 1377](#)).
7. If you are done configuring the device, enter **commit** from configuration mode.

## Displaying Packet Headers

Enter the **monitor traffic** command to display packet headers transmitted through network interfaces with the following syntax:

**NOTE:** Using the **monitor traffic** command can degrade system performance. We recommend that you use filtering options—such as **count** and **matching**—to minimize the impact to packet throughput on the system.

```
user@host> monitor traffic <absolute-sequence> <count number>
<interface interface-name> <layer2-headers> <matching "expression">
<no-domain-names> <no-promiscuous> <no-resolve> <no-timestamp> <print-ascii>
<print-hex> <size bytes> <brief | detail | extensive>
```

[Table 164](#) describes the **monitor traffic** command options.

**Table 164: CLI monitor traffic Command Options**

| Option                          | Description                                                                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>absolute-sequence</b>        | (Optional) Displays the absolute TCP sequence numbers.                                                                                                                              |
| <b>count number</b>             | (Optional) Displays the specified number of packet headers. Specify a value from 0 through 100,000. The command quits and exits to the command prompt after this number is reached. |
| <b>interface interface-name</b> | (Optional) Displays packet headers for traffic on the specified interface. If an interface is not specified, the lowest numbered interface is monitored.                            |
| <b>layer2-headers</b>           | (Optional) Displays the link-layer packet header on each line.                                                                                                                      |

Table 164: CLI monitor traffic Command Options (*continued*)

| Option                       | Description                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>matching "expression"</b> | (Optional) Displays packet headers that match an expression enclosed in quotation marks (" "). <a href="#">Table 165</a> through <a href="#">Table 167</a> list match conditions, logical operators, and arithmetic, binary, and relational operators you can use in the expression. |
| <b>no-domain-names</b>       | (Optional) Suppresses the display of the domain name portion of the hostname.                                                                                                                                                                                                        |
| <b>no-promiscuous</b>        | (Optional) Specifies <i>not</i> to place the monitored interface in promiscuous mode.<br><br>In promiscuous mode, the interface reads every packet that reaches it. In nonpromiscuous mode, the interface reads only the packets addressed to it.                                    |
| <b>no-resolve</b>            | (Optional) Suppresses the display of hostnames.                                                                                                                                                                                                                                      |
| <b>no-timestamp</b>          | (Optional) Suppresses the display of packet header timestamps.                                                                                                                                                                                                                       |
| <b>print-ascii</b>           | (Optional) Displays each packet header in ASCII format.                                                                                                                                                                                                                              |
| <b>print-hex</b>             | (Optional) Displays each packet header, except link-layer headers, in hexadecimal format.                                                                                                                                                                                            |
| <b>size bytes</b>            | (Optional) Displays the number of bytes for each packet that you specify. If a packet header exceeds this size, the displayed packet header is truncated. The default value is <b>96</b> .                                                                                           |
| <b>brief</b>                 | (Optional) Displays minimum packet header information. This is the default.                                                                                                                                                                                                          |
| <b>detail</b>                | (Optional) Displays packet header information in moderate detail. For some protocols, you must also use the <b>size</b> option to see detailed information.                                                                                                                          |
| <b>extensive</b>             | (Optional) Displays the most extensive level of packet header information. For some protocols, you must also use the <b>size</b> option to see extensive information.                                                                                                                |

To quit the **monitor traffic** command and return to the command prompt, press Ctrl-C.

To limit the packet header information displayed by the **monitor traffic** command, include the **matching "expression"** option. An expression consists of one or more match conditions listed in [Table 165](#), enclosed in quotation marks (" "). You can combine match conditions by using the logical operators listed in [Table 166](#) (shown in order of highest to lowest precedence).

For example, to display TCP or UDP packet headers, enter:

```
user@host> monitor traffic matching "tcp || udp"
```

To compare the following types of expressions, use the relational operators listed in [Table 167](#) (listed from highest to lowest precedence):

- Arithmetic—Expressions that use the arithmetic operators listed in [Table 167](#).
- Binary—Expressions that use the binary operators listed in [Table 167](#).
- Packet data accessor—Expressions that use the following syntax:

*protocol* [*byte-offset* <*size*>]

Replace *protocol* with any protocol in [Table 165](#). Replace *byte-offset* with the byte offset, from the beginning of the packet header, to use for the comparison. The optional *size* parameter represents the number of bytes examined in the packet header—1, 2, or 4 bytes.

For example, the following command displays all multicast traffic:

```
user@host> monitor traffic matching "ether[0] & 1 != 0"
```

Table 165: CLI monitor traffic Match Conditions

| Match Condition                                       | Description                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Entity Type</b>                                    |                                                                                                                                                                                                                                                                 |
| <b>host</b> [ <i>address</i>   <i>hostname</i> ]      | Matches packet headers that contain the specified address or hostname. You can prepend any of the following protocol match conditions, followed by a space, to <b>host</b> : <b>arp</b> , <b>ip</b> , <b>rarp</b> , or any of the Directional match conditions. |
| <b>network address</b>                                | Matches packet headers with source or destination addresses containing the specified network address.                                                                                                                                                           |
| <b>network address mask mask</b>                      | Matches packet headers containing the specified network address and subnet mask.                                                                                                                                                                                |
| <b>port</b> [ <i>port-number</i>   <i>port-name</i> ] | Matches packet headers containing the specified source or destination TCP or UDP port number or port name.                                                                                                                                                      |
| <b>Directional</b>                                    |                                                                                                                                                                                                                                                                 |
| <b>destination</b>                                    | Matches packet headers containing the specified destination. Directional match conditions can be prepended to any Entity Type match conditions, followed by a space.                                                                                            |
| <b>source</b>                                         | Matches packet headers containing the specified source.                                                                                                                                                                                                         |
| <b>source and destination</b>                         | Matches packet headers containing the specified source <i>and</i> destination.                                                                                                                                                                                  |
| <b>source or destination</b>                          | Matches packet headers containing the specified source <i>or</i> destination.                                                                                                                                                                                   |
| <b>Packet Length</b>                                  |                                                                                                                                                                                                                                                                 |
| <b>less bytes</b>                                     | Matches packets with lengths less than or equal to the specified value, in bytes.                                                                                                                                                                               |
| <b>greater bytes</b>                                  | Matches packets with lengths greater than or equal to the specified value, in bytes.                                                                                                                                                                            |
| <b>Protocol</b>                                       |                                                                                                                                                                                                                                                                 |

Table 165: CLI monitor traffic Match Conditions (*continued*)

| Match Condition                                             | Description                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>arp</b>                                                  | Matches all ARP packets.                                                                                                                                                                                                                                                 |
| <b>ether</b>                                                | Matches all Ethernet frames.                                                                                                                                                                                                                                             |
| <b>ether [broadcast   multicast]</b>                        | Matches broadcast or multicast Ethernet frames. This match condition can be prepended with <b>source</b> or <b>destination</b> .                                                                                                                                         |
| <b>ether protocol [address   (\arp   \ip   \rarp)]</b>      | Matches Ethernet frames with the specified address or protocol type. The arguments <b>arp</b> , <b>ip</b> , and <b>rarp</b> are also independent match conditions, so they must be preceded with a backslash (\) when used in the <b>ether protocol</b> match condition. |
| <b>icmp</b>                                                 | Matches all ICMP packets.                                                                                                                                                                                                                                                |
| <b>ip</b>                                                   | Matches all IP packets.                                                                                                                                                                                                                                                  |
| <b>ip [broadcast   multicast]</b>                           | Matches broadcast or multicast IP packets.                                                                                                                                                                                                                               |
| <b>ip protocol [address   (\icmp   igmp   \tcp   \udp)]</b> | Matches IP packets with the specified address or protocol type. The arguments <b>icmp</b> , <b>tcp</b> , and <b>udp</b> are also independent match conditions, so they must be preceded with a backslash (\) when used in the <b>ip protocol</b> match condition.        |
| <b>isis</b>                                                 | Matches all IS-IS routing messages.                                                                                                                                                                                                                                      |
| <b>rarp</b>                                                 | Matches all RARP packets.                                                                                                                                                                                                                                                |
| <b>tcp</b>                                                  | Matches all TCP packets.                                                                                                                                                                                                                                                 |
| <b>udp</b>                                                  | Matches all UDP packets.                                                                                                                                                                                                                                                 |

Table 166: CLI monitor traffic Logical Operators

| Logical Operator  | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>!</b>          | Logical NOT. If the first condition does not match, the next condition is evaluated.                                                                |
| <b>&amp;&amp;</b> | Logical AND. If the first condition matches, the next condition is evaluated. If the first condition does not match, the next condition is skipped. |
| <b>  </b>         | Logical OR. If the first condition matches, the next condition is skipped. If the first condition does not match, the next condition is evaluated.  |
| <b>()</b>         | Group operators to override default precedence order. Parentheses are special characters, each of which must be preceded by a backslash (\).        |

Table 167: CLI monitor traffic Arithmetic, Binary, and Relational Operators

| Operator                   | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| <b>Arithmetic Operator</b> |                                                                                |
| +                          | Addition operator.                                                             |
| –                          | Subtraction operator.                                                          |
| /                          | Division operator.                                                             |
| <b>Binary Operator</b>     |                                                                                |
| &                          | Bitwise AND.                                                                   |
| *                          | Bitwise exclusive OR.                                                          |
|                            | Bitwise inclusive OR.                                                          |
| <b>Relational Operator</b> |                                                                                |
| <=                         | A match occurs if the first expression is less than or equal to the second.    |
| >=                         | A match occurs if the first expression is greater than or equal to the second. |
| <                          | A match occurs if the first expression is less than the second.                |
| >                          | A match occurs if the first expression is greater than the second.             |
| =                          | A match occurs if the first expression is equal to the second.                 |
| !=                         | A match occurs if the first expression is not equal to the second.             |

The following is sample output from the **monitor traffic** command:

```
user@host> monitor traffic count 4 matching "arp" detail
```

```
Listening on fe-0/0/0, capture size 96 bytes 15:04:16.276780 In arp who-has
193.1.1.1 tell host1.site2.net 15:04:16.376848 In arp who-has host2.site2.net
tell host1.site2.net 15:04:16.376887 In arp who-has 193.1.1.2 tell host1.site2.net
15:04:16.601923 In arp who-has 193.1.1.3 tell host1.site2.net
```

## Using the J-Web Packet Capture Tool

You can use the J-Web packet capture diagnostic tool when you need to quickly capture and analyze router control traffic on a device. Packet capture on the J-Web user interface

allows you to capture traffic destined for, or originating from, the Routing Engine. You can use the J-Web packet capture tool to compose expressions with various matching criteria to specify the packets that you want to capture. You can either choose to decode and view the captured packets in the J-Web user interface as they are captured, or save the captured packets to a file and analyze them offline using packet analyzers such as Ethereal. The J-Web packet capture tool does not capture transient traffic.

To capture transient traffic and entire IPv4 data packets for offline analysis, you must configure packet capture with the J-Web user interface or CLI configuration editor.

To use J-Web packet capture:

1. Select **Troubleshoot>Packet Capture**.
2. Enter information into the Packet Capture page (see [Table 168](#)). The sample configuration captures the next 10 TCP packets originating from the IP address **10.1.40.48** on port 23 and passing through the Gigabit Ethernet interface **ge-0/0/0**.
3. Save the captured packets to a file, or specify other advanced options by clicking the expand icon next to Advanced options.
4. Click **Start**.

The captured packet headers are decoded and appear in the Packet Capture display.

5. Do one of the following:
  - To stop capturing the packets and stay on the same page while the decoded packet headers are being displayed, click **Stop Capturing**.
  - To stop capturing packets and return to the Packet Capture page, click **OK**.

**Table 168: Packet Capture Field Summary**

| Field        | Function                                                                                                                                                                                                                                                                                                                                                    | Your Action                                                                        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Interface    | Specifies the interface on which the packets are captured.<br><br>If you select <b>default</b> , packets on the Ethernet management port 0 are captured.                                                                                                                                                                                                    | Select an interface from the list—for example, <b>ge-0/0/0</b> .                   |
| Detail level | Specifies the extent of details to be displayed for the packet headers.<br><br><ul style="list-style-type: none"> <li>• Brief—Displays the minimum packet header information. This is the default.</li> <li>• Detail—Displays packet header information in moderate detail.</li> <li>• Extensive—Displays the maximum packet header information.</li> </ul> | Select <b>Detail</b> from the list.                                                |
| Packets      | Specifies the number of packets to be captured. Values range from 1 to <b>1000</b> . Default is <b>10</b> . Packet capture stops capturing packets after this number is reached.                                                                                                                                                                            | Select the number of packets to be captured from the list—for example, <b>10</b> . |

Table 168: Packet Capture Field Summary (*continued*)

| Field                   | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Your Action                                                                                                                                                                                                                                                                                         |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addresses               | <p>Specifies the addresses to be matched for capturing the packets using a combination of the following parameters:</p> <ul style="list-style-type: none"> <li>• Direction—Matches the packet headers for IP address, hostname, or network address of the source, destination or both.</li> <li>• Type—Specifies if packet headers are matched for host address or network address.</li> </ul> <p>You can add multiple entries to refine the match criteria for addresses.</p> | <p>Select address-matching criteria. For example:</p> <ol style="list-style-type: none"> <li>1. From the Direction list, select <b>source</b>.</li> <li>2. From the Type list, select <b>host</b>.</li> <li>3. In the Address box, type <b>10.1.40.48</b>.</li> <li>4. Click <b>Add</b>.</li> </ol> |
| Protocols               | <p>Matches the protocol for which packets are captured. You can choose to capture TCP, UDP, or ICMP packets or a combination of TCP, UDP, and ICMP packets.</p>                                                                                                                                                                                                                                                                                                                | <p>Select a protocol from the list—for example, <b>tcp</b>.</p>                                                                                                                                                                                                                                     |
| Ports                   | <p>Matches packet headers containing the specified source or destination TCP or UDP port number or port name.</p>                                                                                                                                                                                                                                                                                                                                                              | <p>Select a direction and a port. For example:</p> <ol style="list-style-type: none"> <li>1. From the Type list, select <b>src</b>.</li> <li>2. In the Port box, type <b>23</b>.</li> </ol>                                                                                                         |
| <b>Advanced Options</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                     |
| Absolute TCP Sequence   | <p>Specifies that absolute TCP sequence numbers are to be displayed for the packet headers.</p>                                                                                                                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>• Display absolute TCP sequence numbers in the packet headers by selecting this check box.</li> <li>• Stop displaying absolute TCP sequence numbers in the packet headers by clearing this check box.</li> </ul>                                             |
| Layer 2 Headers         | <p>Specifies that link-layer packet headers to display.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• Include link-layer packet headers while capturing packets, by selecting this check box.</li> <li>• Exclude link-layer packet headers while capturing packets by clearing this check box.</li> </ul>                                                        |
| Non-Promiscuous         | <p>Specifies not to place the interface in promiscuous mode, so that the interface reads only packets addressed to it.</p> <p>In promiscuous mode, the interface reads every packet that reaches it.</p>                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>• Read all packets that reach the interface by selecting this check box.</li> <li>• Read only packets addressed to the interface by clearing this check box.</li> </ul>                                                                                      |
| Display Hex             | <p>Specifies that packet headers, except link-layer headers, are to be displayed in hexadecimal format.</p>                                                                                                                                                                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• Display the packet headers in hexadecimal format by selecting this check box.</li> <li>• Stop displaying the packet headers in hexadecimal format by clearing this check box.</li> </ul>                                                                   |
| Display ASCII and Hex   | <p>Specifies that packet headers are to be displayed in hexadecimal and ASCII format.</p>                                                                                                                                                                                                                                                                                                                                                                                      | <ul style="list-style-type: none"> <li>• Display the packet headers in ASCII and hexadecimal formats by selecting this check box.</li> <li>• Stop displaying the packet headers in ASCII and hexadecimal formats by clearing this check box.</li> </ul>                                             |

Table 168: Packet Capture Field Summary (*continued*)

| Field                     | Function                                                                                                                                                                                                                                                                                 | Your Action                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Header Expression         | Specifies the match condition for the packets to capture.<br><br>The match conditions you specify for Addresses, Protocols, and Ports appear in expression format in this field.                                                                                                         | Enter match conditions in expression format or modify the expression composed from the match conditions you specified for Addresses, Protocols, and Ports. If you change the match conditions specified for Addresses, Protocols, and Ports again, packet capture overwrites your changes with the new match conditions. |
| Packet Size               | Specifies the number of bytes to be displayed for each packet. If a packet header exceeds this size, the display is truncated for the packet header. The default value is 96 bytes.                                                                                                      | Type the number of bytes you want to capture for each packet header—for example, <b>256</b> .                                                                                                                                                                                                                            |
| Don't Resolve Addresses   | Specifies that IP addresses are not to be resolved into hostnames in the packet headers displayed.                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>Prevent packet capture from resolving IP addresses to hostnames by selecting this check box.</li> <li>Resolve IP addresses into hostnames by clearing this check box.</li> </ul>                                                                                                  |
| No Timestamp              | Suppresses the display of packet header timestamps.                                                                                                                                                                                                                                      | <ul style="list-style-type: none"> <li>Stop displaying timestamps in the captured packet headers by selecting this check box.</li> <li>Display the timestamp in the captured packet headers by clearing this check box.</li> </ul>                                                                                       |
| Write Packet Capture File | Writes the captured packets to a file in PCAP format in <code>/var/tmp</code> . The files are named with the prefix <code>jweb-pcap</code> and the extension <code>.pcap</code> .<br><br>If you select this option, the decoded packet headers do not appear on the packet capture page. | <ul style="list-style-type: none"> <li>Save the captured packet headers to a file by selecting this check box.</li> <li>Decode and display the packet headers on the J-Web page by clearing this check box.</li> </ul>                                                                                                   |

## J-Web Packet Capture Results and Output Summary

Table 169 summarizes the output in the packet capture display.

Table 169: J-Web Packet Capture Results and Output Summary

| Field                      | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>timestamp</i>           | Time when the packet was captured. The timestamp <b>00:45:40.823971</b> means 00 hours (12.00 a.m.), 45 minutes, and 40.823971 seconds.<br><br><b>NOTE:</b> The time displayed is local time.                                                                                                                                                  |
| <i>direction</i>           | Direction of the packet. Specifies whether the packet originated from the Routing Engine ( <b>Out</b> ), or was destined for the Routing Engine ( <b>In</b> ).                                                                                                                                                                                 |
| <i>protocol</i>            | Protocol for the packet.<br><br>In the sample output, <b>IP</b> indicates the Layer 3 protocol.                                                                                                                                                                                                                                                |
| <i>source address</i>      | Hostname, if available, or IP address and the port number of the packet's origin. If the Don't Resolve Addresses check box is selected, only the IP address of the source displays.<br><br><b>NOTE:</b> When a string is defined for the port, the packet capture output displays the string instead of the port number.                       |
| <i>destination address</i> | Hostname, if available, or IP address of the packet's destination with the port number. If the Don't Resolve Addresses check box is selected, only the IP address of the destination and the port appear.<br><br><b>NOTE:</b> When a string is defined for the port, the packet capture output displays the string instead of the port number. |
| <i>protocol</i>            | Protocol for the packet.<br><br>In the sample output, <b>TCP</b> indicates the Layer 4 protocol.                                                                                                                                                                                                                                               |
| <i>data size</i>           | Size of the packet (in bytes).                                                                                                                                                                                                                                                                                                                 |

## Recovering the Root Password for SRX Series Devices

If you forget the root password for an SRX Series device, you can use the password recovery procedure to reset the root password. This procedure also involves disabling the watchdog functionality to allow the system to properly boot into single-user mode (KB article 17565).

**NOTE:** You need console access to recover the root password

To recover the root password for an SRX Series device:

1. Power on the device by pressing the power button on the front panel. Verify that the **POWER** LED on the front panel turns green.

The device's boot sequence on your management device appears on the terminal emulation screen.

2. When the autoboot completes, press the Spacebar a few times to access the bootstrap loader prompt.
3. In operational mode, disable the watchdog functionality and enter **boot -s** to start up the system in single-user mode.

```
loader>boot -s
```

The SRX Series device will start up in single-user mode.

4. Enter **recovery** to start the root password recovery procedure.

```
System watchdog timer disabled.
```

```
Enter full pathname of shell or 'recovery' for root password recovery or RETURN for /bin/sh: recovery
```

5. Enter configuration mode in the CLI.
6. Set the root password.

```
[edit]
```

```
user@host# set system root-authentication plain-text-password
```

7. Enter the new root password.

```
New password: juniper1
```

```
Retype new password:
```

8. At the second prompt, reenter the new root password.
9. If you are finished configuring the network, commit the configuration.

```
root@host# commit
```

```
commit complete
```

10. Exit from configuration mode.
11. Exit from operational mode.
12. Enter **y** to reboot the device.

```
Reboot the system? [y/n] y
```

The start up messages display on the screen.

13. Once again, press the Spacebar a few times to access the bootstrap loader prompt.

14. In operational mode, enable the watchdog functionality and enter **boot** to start up the system.

```
loader>watchdog enable
loader>boot
```

15. The SRX Series device starts up again and prompts you to enter a user name and password. Enter the newly configured password:

```
Wed Jul 12 14:20:21 UTC 2011
Deviceabc (ttyu0)
login: root
Password: juniper1
```

## Troubleshooting DNS Name Resolution in Logical System Security Policies (Master Administrators Only)

**Problem** **Description:** The address of a hostname in an address book entry that is used in a security policy might fail to resolve correctly.

**Cause** Normally, address book entries that contain dynamic hostnames refresh automatically for SRX Series devices. The TTL field associated with a DNS entry indicates the time after which the entry should be refreshed in the policy cache. Once the TTL value expires, the SRX Series device automatically refreshes the DNS entry for an address book entry.

However, if the SRX Series device is unable to obtain a response from the DNS server (for example, the DNS request or response packet is lost in the network or the DNS server cannot send a response), the address of a hostname in an address book entry might fail to resolve correctly. This can cause traffic to drop as no security policy or session match is found.

**Solution** The master administrator can use the **show security dns-cache** command to display DNS cache information on the SRX Series device. If the DNS cache information needs to be refreshed, the master administrator can use the **clear security dns-cache** command.

**NOTE:** These commands are only available to the master administrator on devices that are configured for logical systems. This command is not available in user logical systems or on devices that are not configured for logical systems.

## Troubleshooting the Link Services Interface

To solve configuration problems on a link services interface:

- [Determine Which CoS Components Are Applied to the Constituent Links on page 1400](#)
- [Determine What Causes Jitter and Latency on the Multilink Bundle on page 1401](#)
- [Determine If LFI and Load Balancing Are Working Correctly on page 1402](#)
- [Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device on page 1408](#)

### Determine Which CoS Components Are Applied to the Constituent Links

**Problem** **Description:** You are configuring a multilink bundle, but you also have traffic without MLPPP encapsulation passing through constituent links of the multilink bundle. Do you apply all CoS components to the constituent links, or is applying them to the multilink bundle enough?

**Solution** You can apply a scheduler map to the multilink bundle and its constituent links. Although you can apply several CoS components with the scheduler map, configure only the ones that are required. We recommend that you keep the configuration on the constituent links simple to avoid unnecessary delay in transmission.

[Table 170](#) shows the CoS components to be applied on a multilink bundle and its constituent links.

**Table 170: CoS Components Applied on Multilink Bundles and Constituent Links**

| Cos Component    | Multilink Bundle | Constituent Links | Explanation                                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Classifier       | Yes              | No                | CoS classification takes place on the incoming side of the interface, not on the transmitting side, so no classifiers are needed on constituent links.                                                                                                                                                                                             |
| Forwarding class | Yes              | No                | Forwarding class is associated with a queue, and the queue is applied to the interface by a scheduler map. The queue assignment is predetermined on the constituent links. All packets from Q2 of the multilink bundle are assigned to Q2 of the constituent link, and packets from all the other queues are queued to Q0 of the constituent link. |

Table 170: CoS Components Applied on Multilink Bundles and Constituent Links (*continued*)

| Cos Component                                                         | Multilink Bundle | Constituent Links | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------|------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scheduler map                                                         | Yes              | Yes               | <p>Apply scheduler maps on the multilink bundle and the constituent link as follows:</p> <ul style="list-style-type: none"> <li>• Transmit rate—Make sure that the relative order of the transmit rate configured on Q0 and Q2 is the same on the constituent links as on the multilink bundle.</li> <li>• Scheduler priority—Make sure that the relative order of the scheduler priority configured on Q0 and Q2 is the same on the constituent links as on the multilink bundle.</li> <li>• Buffer size—Because all non-LFI packets from the multilink bundle transit on Q0 of the constituent links, make sure that the buffer size on Q0 of the constituent links is large enough.</li> <li>• RED drop profile—Configure a RED drop profile on the multilink bundle only. Configuring the RED drop profile on the constituent links applies a back pressure mechanism that changes the buffer size and introduces variation. Because this behavior might cause fragment drops on the constituent links, make sure to leave the RED drop profile at the default settings on the constituent links.</li> </ul> |
| Shaping rate for a per-unit scheduler or an interface-level scheduler | No               | Yes               | Because per-unit scheduling is applied only at the end point, apply this shaping rate to the constituent links only. Any configuration applied earlier is overwritten by the constituent link configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Transmit-rate exact or queue-level shaping                            | Yes              | No                | The interface-level shaping applied on the constituent links overrides any shaping on the queue. Thus apply transmit-rate exact shaping on the multilink bundle only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Rewrite rules                                                         | Yes              | No                | Rewrite bits are copied from the packet into the fragments automatically during fragmentation. Thus what you configure on the multilink bundle is carried on the fragments to the constituent links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Virtual channel group                                                 | Yes              | No                | Virtual channel groups are identified through firewall filter rules that are applied on packets only before the multilink bundle. Thus you do not need to apply the virtual channel group configuration to the constituent links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Determine What Causes Jitter and Latency on the Multilink Bundle

**Problem**    **Description:** To test jitter and latency, you send three streams of IP packets. All packets have the same IP precedence settings. After configuring LFI and CRTP, the latency increased even over a noncongested link. How can you reduce jitter and latency?

**Solution**    To reduce jitter and latency, do the following:

1. Make sure that you have configured a shaping rate on each constituent link.
2. Make sure that you have not configured a shaping rate on the link services interface.
3. Make sure that the configured shaping rate value is equal to the physical interface bandwidth. See *Example: Configuring Interface Shaping Rates*.
4. If shaping rates are configured correctly, and jitter still persists, contact the Juniper Networks Technical Assistance Center (JTAC).

---

### Determine If LFI and Load Balancing Are Working Correctly

---

**Problem** **Description:** In this case, you have a single network that supports multiple services. The network transmits data and delay-sensitive voice traffic. After configuring MLPPP and LFI, make sure that voice packets are transmitted across the network with very little delay and jitter. How can you find out if voice packets are being treated as LFI packets and load balancing is performed correctly?

**Solution** When LFI is enabled, data (non-LFI) packets are encapsulated with an MLPPP header and fragmented to packets of a specified size. The delay-sensitive, voice (LFI) packets are PPP-encapsulated and interleaved between data packet fragments. Queuing and load balancing are performed differently for LFI and non-LFI packets.

To verify that LFI is performed correctly, determine that packets are fragmented and encapsulated as configured. After you know whether a packet is treated as an LFI packet or a non-LFI packet, you can confirm whether the load balancing is performed correctly.

**Solution Scenario**—Suppose two Juniper Networks devices, R0 and R1, are connected by a multilink bundle `lsq-0/0/0.0` that aggregates two serial links, `se-1/0/0` and `se-1/0/1`. On R0 and R1, MLPPP and LFI are enabled on the link services interface and the fragmentation threshold is set to 128 bytes.

In this example, we used a packet generator to generate voice and data streams. You can use the packet capture feature to capture and analyze the packets on the incoming interface.

The following two data streams were sent on the multilink bundle:

- 100 data packets of 200 bytes (larger than the fragmentation threshold)
- 500 data packets of 60 bytes (smaller than the fragmentation threshold)

The following two voice streams were sent on the multilink bundle:

- 100 voice packets of 200 bytes from source port 100
- 300 voice packets of 200 bytes from source port 200

To confirm that LFI and load balancing are performed correctly:

**NOTE:** Only the significant portions of command output are displayed and described in this example. For more information, see *Verifying the Link Services Interface*.

1. Verify packet fragmentation. From operational mode, enter the **show interfaces lsq-0/0/0** command to check that large packets are fragmented correctly.

```
user@R0#> show interfaces lsq-0/0/0
Physical interface: lsq-0/0/0, Enabled, Physical link is Up
  Interface index: 136, SNMP ifIndex: 29
  Link-level type: LinkService, MTU: 1504
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
  Last flapped   : 2006-08-01 10:45:13 PDT (2w0d 06:06 ago)
  Input rate      : 0 bps (0 pps)
  Output rate     : 0 bps (0 pps)

Logical interface lsq-0/0/0.0 (Index 69) (SNMP ifIndex 42)
  Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: Multilink-PPP
  Bandwidth: 16mbps
  Statistics
  Bundle:
    Fragments:
      Input :           0           0           0           0
      Output:        1100           0       118800           0
    Packets:
      Input :           0           0           0           0
      Output:        1000           0       112000           0
  ...
  Protocol inet, MTU: 1500
  Flags: None
  Addresses, Flags: Is-Preferred Is-Primary
    Destination: 9.9.9/24, Local: 9.9.9.10
```

**Meaning**—The output shows a summary of packets transiting the device on the multilink bundle. Verify the following information on the multilink bundle:

- The total number of transiting packets = 1000
- The total number of transiting fragments=1100
- The number of data packets that were fragmented =100

The total number of packets sent (600 + 400) on the multilink bundle match the number of transiting packets (1000), indicating that no packets were dropped.

The number of transiting fragments exceeds the number of transiting packets by 100, indicating that 100 large data packets were correctly fragmented.

**Corrective Action**—If the packets are not fragmented correctly, check your fragmentation threshold configuration. Packets smaller than the specified fragmentation threshold are not fragmented. See *Example: Configuring Link Fragmentation and Interleaving*.

2. Verify packet encapsulation. To find out whether a packet is treated as an LFI or non-LFI packet, determine its encapsulation type. LFI packets are PPP encapsulated, and non-LFI packets are encapsulated with both PPP and MLPPP. PPP and MLPPP encapsulations have different overheads resulting in different-sized packets. You can compare packet sizes to determine the encapsulation type.

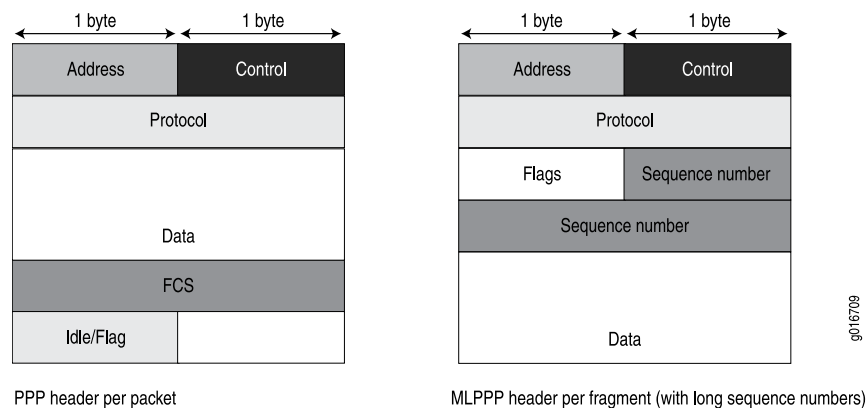

A small unfragmented data packet contains a PPP header and a single MLPPP header. In a large fragmented data packet, the first fragment contains a PPP header and an MLPPP header, but the consecutive fragments contain only an MLPPP header.

PPP and MLPPP encapsulations add the following number of bytes to a packet:

- PPP encapsulation adds 7 bytes:  
4 bytes of header+2 bytes of frame check sequence (FCS)+1 byte that is idle or contains a flag
- MLPPP encapsulation adds between 6 and 8 bytes:  
4 bytes of PPP header+2 to 4 bytes of multilink header

Figure 30 shows the overhead added to PPP and MLPPP headers.

**Figure 30: PPP and MLPPP Headers**

For CRTP packets, the encapsulation overhead and packet size are even smaller than for an LFI packet. For more information, see *Example: Configuring the Compressed Real-Time Transport Protocol*.

Table 171 shows the encapsulation overhead for a data packet and a voice packet of 70 bytes each. After encapsulation, the size of the data packet is larger than the size of the voice packet.

**Table 171: PPP and MLPPP Encapsulation Overhead**

| Packet Type                                 | Encapsulation | Initial Packet Size | Encapsulation Overhead       | Packet Size after Encapsulation |
|---------------------------------------------|---------------|---------------------|------------------------------|---------------------------------|
| Voice packet (LFI)                          | PPP           | 70 bytes            | 4 + 2 + 1 = 7 bytes          | 77 bytes                        |
| Data fragment (non-LFI) with short sequence | MLPPP         | 70 bytes            | 4 + 2 + 1 + 4 + 2 = 13 bytes | 83 bytes                        |

Table 171: PPP and MLPPP Encapsulation Overhead (*continued*)

| Packet Type                                | Encapsulation | Initial Packet Size | Encapsulation Overhead       | Packet Size after Encapsulation |
|--------------------------------------------|---------------|---------------------|------------------------------|---------------------------------|
| Data fragment (non-LFI) with long sequence | MLPPP         | 70 bytes            | 4 + 2 + 1 + 4 + 4 = 15 bytes | 85 bytes                        |

From operational mode, enter the **show interfaces queue** command to display the size of transmitted packet on each queue. Divide the number of bytes transmitted by the number of packets to obtain the size of the packets and determine the encapsulation type.

3. Verify load balancing. From operational mode, enter the **show interfaces queue** command on the multilink bundle and its constituent links to confirm whether load balancing is performed accordingly on the packets.

```

user@R0> show interfaces queue lsq-0/0/0

```

**Meaning**—The output from these commands shows the packets transmitted and queued on each queue of the link services interface and its constituent links. [Table 172](#) shows a summary of these values. (Because the number of transmitted packets equaled the number of queued packets on all the links, this table shows only the queued packets.)

**Table 172: Number of Packets Transmitted on a Queue**

| Packets Queued | Bundle<br>lsq-0/0/0.0 | Constituent Link<br>se-1/0/0 | Constituent Link<br>se-1/0/1 | Explanation                                                                                                                                                          |
|----------------|-----------------------|------------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Packets on Q0  | 600                   | 350                          | 350                          | The total number of packets transiting the constituent links (350+350 = 700) exceeded the number of packets queued (600) on the multilink bundle.                    |
| Packets on Q2  | 400                   | 100                          | 300                          | The total number of packets transiting the constituent links equaled the number of packets on the bundle.                                                            |
| Packets on Q3  | 0                     | 19                           | 18                           | The packets transiting Q3 of the constituent links are for keepalive messages exchanged between constituent links. Thus no packets were counted on Q3 of the bundle. |

On the multilink bundle, verify the following:

- The number of packets queued matches the number transmitted. If the numbers match, no packets were dropped. If more packets were queued than were transmitted, packets were dropped because the buffer was too small. The buffer size on the constituent links controls congestion at the output stage. To correct this problem, increase the buffer size on the constituent links. For more information, see *Example: Configuring Scheduler Maps*.
- The number of packets transiting Q0 (600) matches the number of large and small data packets received (100+500) on the multilink bundle. If the numbers match, all data packets correctly transited Q0.
- The number of packets transiting Q2 on the multilink bundle (400) matches the number of voice packets received on the multilink bundle. If the numbers match, all voice LFI packets correctly transited Q2.

On the constituent links, verify the following:

- The total number of packets transiting Q0 (350+350) matches the number of data packets and data fragments (500+200). If the numbers match, all the data packets after fragmentation correctly transited Q0 of the constituent links.

Packets transited both constituent links, indicating that load balancing was correctly performed on non-LFI packets.

- The total number of packets transiting Q2 (300+100) on constituent links matches the number of voice packets received (400) on the multilink bundle. If the numbers match, all voice LFI packets correctly transited Q2.

LFI packets from source port **100** transited **se-1/0/0**, and LFI packets from source port **200** transited **se-1/0/1**. Thus all LFI (Q2) packets were hashed based on the source port and correctly transited both constituent links.

**Corrective Action**—If the packets transited only one link, take the following steps to resolve the problem:

- a. Determine whether the physical link is **up** (operational) or **down** (unavailable). An unavailable link indicates a problem with the PIM, interface port, or physical connection (link-layer errors). If the link is operational, move to the next step.
  - b. Verify that the classifiers are correctly defined for non-LFI packets. Make sure that non-LFI packets are not configured to be queued to Q2. All packets queued to Q2 are treated as LFI packets.
  - c. Verify that at least one of the following values is different in the LFI packets: source address, destination address, IP protocol, source port, or destination port. If the same values are configured for all LFI packets, the packets are all hashed to the same flow and transit the same link.
4. Use the results to verify load balancing.

---

#### Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device

---

**Problem**    **Description:** You are configuring a permanent virtual circuit (PVC) between T1, E1, T3, or E3 interfaces on a Juniper Networks device and a third-party device, and packets are being dropped and ping fails.

**Solution**    If the third-party device does not have the same FRF.12 support as the Juniper Networks device or supports FRF.12 in a different way, the Juniper Networks device interface on the PVC might discard a fragmented packet containing FRF.12 headers and count it as a "Policed Discard."

As a workaround, configure multilink bundles on both peers, and configure fragmentation thresholds on the multilink bundles.

#### Checking a Security Policy Commit Failure

---

**Problem**    **Description:** Most policy configuration failures occur during a commit or runtime. Commit failures are reported directly on the CLI when you execute the CLI command **commit-check** in configuration mode. These errors are configuration errors, and you cannot commit the configuration without fixing these errors.

**Solution** To fix these errors, do the following:

1. Review your configuration data.
2. Open the file `/var/log/nsd_chk_only`. This file is overwritten each time you perform a commit check and contains detailed failure information.

### Verifying a Security Policy Commit

**Problem** **Description:** Upon performing a policy configuration commit, if you notice that the system behavior is incorrect, use the following steps to troubleshoot this problem:

- Solution**
1. Operational **show** Commands—Execute the operational commands for security policies and verify that the information shown in the output is consistent with what you expected. If not, the configuration needs to be changed appropriately.
  2. Traceoptions—Set the **traceoptions** command in your policy configuration. The flags under this hierarchy can be selected as per user analysis of the **show** command output. If you cannot determine what flag to use, the flag option **all** can be used to capture all trace logs.

```
user@host# set security policies traceoptions <flag all>
```

You can also configure an optional filename to capture the logs.

```
user@host# set security policies traceoptions <filename>
```

If you specified a filename in the trace options, you can look in the `/var/log/<filename>` for the log file to ascertain if any errors were reported in the file. (If you did not specify a filename, the default filename is `eventd`.) The error messages indicate the place of failure and the appropriate reason.

After configuring the trace options, you must recommit the configuration change that caused the incorrect system behavior.

### Debugging Policy Lookup

**Problem** **Description:** When you have the correct configuration, but some traffic was incorrectly dropped or permitted, you can enable the **lookup** flag in the security policies traceoptions. The **lookup** flag logs the lookup related traces in the trace file.

**Solution** `user@host# set security policies traceoptions <flag lookup>`

## Understanding Log Error Messages for Troubleshooting ISSU-Related Problems

The following problems might occur during an ISSU upgrade. You can identify the errors by using the details in the logs. You can also see the details of the error messages in the *Junos OS System Log Reference*.

- [Chassisd Process Errors on page 1410](#)
- [Kernel State Synchronization on page 1410](#)
- [Installation Related Errors on page 1410](#)
- [ISSU Support Related Errors on page 1411](#)
- [Redundancy Group Failover Errors on page 1411](#)
- [Initial Validation Checks Fail on page 1411](#)

---

### Chassisd Process Errors

**Problem**    **Description:** Errors related to chassisd.

**Solution**    Use the error messages to understand the issues related to chassisd.

When ISSU starts, a request is sent to chassisd to check whether there are any problems related to ISSU from a chassis perspective. If there is a problem, a log message is created.

---

### Kernel State Synchronization

**Problem**    **Description:** Errors related to ksyncd.

**Solution**    Use the following error messages to understand the issues related to ksyncd:

Failed to get kernel-replication error information from Standby Routing Engine.  
mgd\_slave\_peer\_has\_errors() returns error at line 4414 in mgd\_package\_issu.

ISSU checks whether there are any ksyncd errors on the secondary node (node 1) and displays the error message if there are any problems and aborts the ISSU.

---

### Installation Related Errors

**Problem**    **Description:** The install image file does not exist or the remote site is inaccessible.

**Solution**    Use the following error messages to understand the installation related problems:

error: File does not exist: /var/tmp/junos-srx5000-11.4X3.2-domest  
error: Couldn't retrieve package /var/tmp/junos-srx5000-11.4X3.2-domest

ISSU downloads the install image as specified in the ISSU command as an argument. The image file can be a local file or located at a remote site. If the file does not exist or the remote site is inaccessible, an error is reported.

### ISSU Support Related Errors

**Problem** **Description:** Installation failure because of unsupported software and unsupported feature configuration.

**Solution** Use the following error messages to understand the compatibility-related problems:

```
WARNING: Current configuration not compatible with
/var/tmp/junos-srx5000-11.4X3.2-domestic.tgz
Exiting in-service-upgrade window
Exiting in-service-upgrade window
```

### Redundancy Group Failover Errors

**Problem** **Description:** Problem with automatic redundancy group (RG) failure.

**Solution** Use the following error messages to understand the problem:

```
failover all RG 1+ groups to node 0
error: Command failed. None of the redundancy-groupss has been failed over.
Some redundancy-groups on node1 are already in manual failover mode.
Please execute 'failover reset all' first..
```

### Initial Validation Checks Fail

**Problem** **Description:** The initial validation checks fail.

**Solution** The following error messages are displayed when initial validation checks fail when the image is not present and ISSU is aborted:

#### When Image is Not Present

```
user@host> ...0120914_srx_12q1_major2.2-539764-domestic.tgz reboot
Chassis ISSU Started
Chassis ISSU Started
ISSU: Validating Image
Initiating in-service-upgrade
Initiating in-service-upgrade
Fetching package...
error: File does not exist:
/var/tmp/junos-srx1k3k-12.1I20120914_srx_12q1_major2.2-539764-domestic.tgz
error: Couldn't retrieve package
/var/tmp/junos-srx1k3k-12.1I20120914_srx_12q1_major2.2-539764-domestic.tgz
Exiting in-service-upgrade window
Exiting in-service-upgrade window
Chassis ISSU Aborted
Chassis ISSU Aborted
Chassis ISSU Aborted
ISSU: IDLE
ISSU aborted; exiting ISSU window.
```

#### When Image File is Corrupted

```
user@host> ...junos-srx1k3k-11.4X9-domestic.tgz_1 reboot
```

Chassis ISSU Started

node1:

-----  
Chassis ISSU Started

ISSU: Validating Image

Initiating in-service-upgrade

node1:

-----  
Initiating in-service-upgrade

ERROR: Cannot use /var/tmp/junos-srx1k3k-11.4X9-domestic.tgz\_1:

gzip: stdin: invalid compressed data--format violated

tar: Child returned status 1

tar: Error exit delayed from previous errors

ERROR: It may have been corrupted during download.

ERROR: Please try again, making sure to use a binary transfer.

Exiting in-service-upgrade window

node1:

-----  
Exiting in-service-upgrade window

Chassis ISSU Aborted

Chassis ISSU Aborted

node1:

-----  
Chassis ISSU Aborted

ISSU: IDLE

ISSU aborted; exiting ISSU window.

{primary:node0}

The primary node validates the device configuration to ensure that it can be committed using the new software version. If anything goes wrong, ISSU aborts and error messages are displayed.

## Chassis Configuration Statement Hierarchy

Use the statements in the **chassis** configuration hierarchy to configure alarms, aggregated devices, clusters, the Routing Engine, and other chassis properties.

```
chassis {
  aggregated-devices {
    ethernet {
      device-count number;
      lacp {
        link-protection {
          non-revertive;
        }
        system-priority number;
      }
    }
    sonet {
      device-count number;
    }
  }
  alarm {
    ds1 {
      ais (ignore | red | yellow);
      ylw (ignore | red | yellow);
    }
    ethernet {
      link-down (ignore | red | yellow);
    }
    integrated-services {
      failure (ignore | red | yellow);
    }
    management-ethernet {
      link-down (ignore | red | yellow);
    }
    serial {
      cts-absent (ignore | red | yellow);
      dcd-absent (ignore | red | yellow);
      dsr-absent (ignore | red | yellow);
      loss-of-rx-clock (ignore | red | yellow);
      loss-of-tx-clock (ignore | red | yellow);
    }
    services {
      hw-down (ignore | red | yellow);
      linkdown (ignore | red | yellow);
      pic-hold-reset (ignore | red | yellow);
      pic-reset (ignore | red | yellow);
      rx-errors (ignore | red | yellow);
      sw-down (ignore | red | yellow);
      tx-errors (ignore | red | yellow);
    }
  }
  t3 {
    ais (ignore | red | yellow);
  }
}
```

```
    exz (ignore | red | yellow);
    ferf (ignore | red | yellow);
    idle (ignore | red | yellow);
    lcv (ignore | red | yellow);
    lof (ignore | red | yellow);
    los (ignore | red | yellow);
    pll (ignore | red | yellow);
    ylw (ignore | red | yellow);
  }
}

## Accounting-Options Configuration Statement Hierarchy

Use the statements in the **accounting-options** configuration hierarchy to collect and log data about basic system operations and services on the device.

```
accounting-options {
  class-usage-profile profile-name {
    destination-classes {
      destination-class-name;
    }
    file filename;
    interval minutes;
    source-classes {
      source-class-name;
    }
  }
  file filename {
    archive-sites url {
      password password;
    }
    files number;
    nonpersistent;
    size bytes;
    start-time yyyy-mm-dd.hh:mm;
    transfer-interval minutes;
  }
  filter-profile profile-name {
    counters {
      counter-name;
    }
    file filename;
    interval minutes;
  }
  interface-profile profile-name {
    fields {
```

```

        field-name;
    }
    file filename;
    interval minutes;
}
mib-profile profile-name {
    file filename;
    interval minutes;
    object-names {
        mib-object-name;
    }
    operation (get | get-next | walk) ;
}
periodic-refresh disable;
routing-engine-profile profile-name {
    fields {
        field-name ;
    }
    file filename;
    interval minutes;
}
}

```

## action-profile

**Syntax** `action-profile profile-name {`  
     `event (jexec | lbt | lt-enter | lt-leave | mac-egress | mac-ingress | np-egress | np-ingress |`  
     `pot) {`  
         `count;`  
         `packet-dump;`  
         `packet-summary;`  
         `trace;`  
     `}`  
     `module {`  
         `flow {`  
             `flag {`  
                 `all;`  
             `}`  
         `}`  
     `}`  
     `preserve-trace-order;`  
     `record-pic-history;`  
`}`

**Hierarchy Level** [edit security datapath-debug]

**Release Information** Command introduced in Junos OS Release 10.0.

**Description** Configure the action profile options for data path debugging.

- Options**
- ***action-profile name*** — Name of the action profile.
  - **event**—Enable the events to trace the packet when the packet hit the events (jexec, lbt, lt-enter, lt-leave, mac-egress, mac-ingress, np-egress, np-ingress, pot)
    - **count**—Number of times a packet hits the specified event.
    - **packet-dump**—Capture the packet that hits the specified event.
    - **packet-summary**—Print the source/destination IP address details with protocol number and IP length details along with trace message for the specified event.
    - **trace**—Print the standard trace message when the packet hits the specified event.
  - **module**—Turn on the flow session related trace messages.
    - **flow**—Trace flow session related messages.
    - **flag**—Specify which flow message needs to be traced.
    - **all**—Trace all possible flow trace messages.
    - **trace**—Print the standard trace message when the packet hits the specified event.
  - **preserve-trace-order**—Preserve trace order.
  - **record-pic-history**—Record the PICs in which the packet has been processed.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

---

## archive-sites

---

**Syntax** archive-sites {  
    *site-name*;  
}

**Hierarchy Level** [edit accounting-options [file](#) *filename*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.

**Description** Configure an archive site. If more than one site name is configured, an ordered list of archive sites for the accounting-data log files is created. When a file is archived, the router or switch attempts to transfer the file to the first URL in the list, moving to the next site only if the transfer does not succeed. The log file is stored at the archive site with a filename of the format *router-name\_log-filename\_timestamp*.

**Options** *site-name*—Any valid FTP/SCP URL to a destination.

**Required Privilege Level** snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 7.5.<br>Support at the [edit services rpm twamp client control-connection <i>control-client-name</i> ] hierarchy level introduced in Junos OS Release 15.1 for MX Series routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | <p>On M Series and T Series routers, specify a services (<b>sp-</b>) interface that adds a timestamp to RPM probe messages. This feature is supported only with <b>icmp-ping</b>, <b>icmp-ping-timestamp</b>, <b>udp-ping</b>, and <b>udp-ping-timestamp</b> probe types. You must also configure the <b>rpm</b> statement on the <b>sp-</b> interface and include the <b>unit 0 family inet</b> statement with a <b>/32</b> address.</p> <p>On M Series, MX Series, and T Series routers, specify a multiservices (<b>ms-</b>) interface that adds a timestamp to RPM probe messages. This feature is supported only with <b>icmp-ping</b>, <b>icmp-ping-timestamp</b>, <b>udp-ping</b>, and <b>udp-ping-timestamp</b> probe types. You must also configure the <b>rpm</b> statement on the <b>ms-</b> interface and include the <b>unit 0 family inet</b> statement with a <b>/32</b> address.</p> <p>The inline service interface (<b>si-</b> interface) is a virtual physical service interface that resides on the Packet Forwarding Engine to provide L2TP services without a special services PIC. The inline service interface is supported only by MPCs on MX Series routers. Four inline service interfaces are configurable per MPC-occupied chassis slot. Specify a multiservices (<b>si-</b>) interface that adds a timestamp to TWAMP probe messages. You must also configure the <b>rpm twamp-client</b> or <b>twamp-server</b> statement on the <b>si-</b> interface and include the <b>unit 0 family inet</b> statement with a <b>/32</b> address.</p> <p>To enable RPM for the extension-provider packages on the adaptive services interface, configure the <b>object-cache-size</b>, <b>policy-db-size</b>, and <b>package</b> statements at the [edit chassis fpc <i>slot-number</i> pic <i>pic-number</i> adaptive-services service-package extension-provider] hierarchy level. For the extension-provider package, <i>package-name</i> in the <b>package</b> <i>package-name</i> statement is <b>jservices-rpm</b>.</p> |
| <b>Options</b>                  | <i>interface-name</i> —Name of the adaptive services interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Hierarchy Level** [edit security]

**Release Information** Statement modified in Junos OS Release 9.5.

**Description** Determine how the device manages packet flow. The device can regulate packet flow in the following ways:

- Enable or disable DNS replies when there is no matching DNS request.
- Set the initial session-timeout values.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Description</b>              | Specify the relative importance of all IP address monitored objects to the operation of the redundancy group. Every monitored IP address is assigned a weight. If the monitored address becomes unreachable, the weight of the object is deducted from the global-threshold of IP monitoring objects in its redundancy group. When the global-threshold reaches 0, the global-weight is deducted from the redundancy group. Every redundancy group has a default threshold of 255. If the threshold reaches 0, a failover is triggered. Failover is triggered even if the redundancy group is in manual failover mode and preemption is not enabled. |
| <b>Options</b>                  | <p><b><i>number</i></b> —Combined weight assigned to all monitored IP addresses. A higher weight value indicates a greater importance.</p> <p><b>Range:</b> 0 through 255</p> <p><b>Default:</b> 255</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## ip-monitoring

```
Syntax  ip-monitoring {
        family {
            inet {
                ipv4-address {
                    interface {
                        logical-interface-name;
                        secondary-ip-address ip-address;
                    }
                    weight number;
                }
            }
        }
        global-threshold number;
        global-weight number;
        retry-count number;
        retry-interval seconds;
    }
```

**Hierarchy Level** [edit chassis cluster redundancy-group *group-number* ]

**Release Information** Statement updated in Junos OS Release 10.1.

**Description** Specify a global IP address monitoring threshold and weight, and the interval between pings (**retry-interval**) and the number of consecutive ping failures (**retry-count**) permitted before an IP address is considered unreachable for all IP addresses monitored by the redundancy group. Also specify IP addresses, a monitoring weight, a redundant Ethernet interface number, and a secondary IP monitoring ping source for each IP address, for the redundancy group to monitor.

**Options** **family inet IPv4 address**—The address to be continually monitored for reachability.

**NOTE:** All monitored object failures, including IP monitoring, are deducted from the redundancy group threshold priority. Other monitored objects include interface monitor, SPU monitor, cold-sync monitor, and NPC monitor (on supported platforms).

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## mib-profile

**Syntax** `mib-profile profile-name {  
     file filename;  
     interval minutes;  
     object-names {  
         mib-object-name;  
     }  
     operation operation-name;  
 }`

**Hierarchy Level** [edit accounting-options]

**Release Information** Statement introduced in Junos OS Release 8.2.  
 Statement introduced in Junos OS Release 9.0 for EX Series switches.

**Description** Create a MIB profile to collect selected MIB statistics and write them to a file in the `/var/log` directory.

**NOTE:** Do not configure MIB objects related to interface octets or packets for a MIB profile, because it can cause the SNMP walk or a CLI show command to time out.

**Options** *profile-name*—Name of the MIB statistics profile.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
 interface-control—To add this statement to the configuration.

## mpls (Security Forwarding Options)

|                            |                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>mpls {<br/>    mode packet-based;<br/>}</code>                              |
| <b>Hierarchy Level</b>     | [edit security forwarding-options family]                                         |
| <b>Release Information</b> | Statement introduced in Junos OS Release 9.0.                                     |
| <b>Description</b>         | Enable the forwarding of MPLS traffic. By default, the device drops MPLS traffic. |

**CAUTION:** Because MPLS operates in packet mode, security services are not available.

**NOTE:** Packet-based processing is not supported on the following SRX Series devices: SRX1500, SRX5600, and SRX5800.

|                                 |                                                                                                                       |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|

```

**Hierarchy Level** [edit services rpm]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.3 for EX Series switches.

**Description** Specify an owner name. The owner name combined with the test name represent a single RPM configuration instance.

**Options** *owner*—Specify an owner name up to 32 characters in length.

The remaining statements are explained separately.

```

**Hierarchy Level** [edit chassis cluster]

**Release Information** Statement introduced in Junos OS Release 9.0.

**Description** Define a redundancy group. Except for redundancy group 0, a redundancy group is a logical interface consisting of two physical Ethernet interfaces, one on each chassis. One interface is active, and the other is on standby. When the active interface fails, the standby interface becomes active. The logical interface is called a redundant Ethernet interface (**reth**).

Redundancy group 0 consists of the two Routing Engines in the chassis cluster and controls which Routing Engine is primary. You must define redundancy group 0 in the chassis cluster configuration.

**Options** *group-number* —Redundancy group identification number.

**Range:** 0 through 128

**NOTE:** The maximum number of redundancy groups is equal to the number of redundant Ethernet interfaces that you configure.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

---

## retry-interval (Chassis Cluster)

---

**Syntax** `retry-interval interval;`

**Hierarchy Level** [edit chassis cluster redundancy-group *group-number* ip-monitoring ]

**Release Information** Statement introduced in Junos OS Release 10.1.

**Description** Specify the ping packet send frequency (in seconds) for each IP address monitored by the redundancy group. (See **retry-count** for a related IP address monitoring configuration variable.)

**Options** *interval*—Pause time between each ping sent to each IP address monitored by the redundancy group.

**Range:** 1 to 30 seconds

**Default:** 1 second

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, unified threat management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

- [\[edit security address-book\] Hierarchy Level](#)
- [\[edit security alarms\] Hierarchy Level on page 1419](#)

- [\[edit security alg\] Hierarchy Level](#)

| <b>Description</b>              | Specify thresholds used for the probes. A system log message is generated when the configured threshold is exceeded. Likewise, an SNMP trap (if configured) is generated when a threshold is exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>                  | <p><b>thresholds</b>—Specify one or more threshold measurements. The following options are supported:</p> <ul style="list-style-type: none"> <li>• <b>egress-time</b>—Measures maximum source-to-destination time per probe.</li> <li>• <b>ingress-time</b>—Measures maximum destination-to-source time per probe.</li> <li>• <b>jitter-egress</b>—Measures maximum source-to-destination jitter per test.</li> <li>• <b>jitter-ingress</b>—Measures maximum destination-to- source jitter per test.</li> <li>• <b>jitter-rtt</b>—Measures maximum jitter per test, from 0 through 60,000,000 microseconds.</li> <li>• <b>rtt</b>—Measures maximum round-trip time per probe, in microseconds.</li> <li>• <b>std-dev-egress</b>—Measures maximum source-to-destination standard deviation per test.</li> <li>• <b>std-dev-ingress</b>—Measures maximum destination-to-source standard deviation per test.</li> <li>• <b>std-dev-rtt</b>—Measures maximum standard deviation per test, in microseconds.</li> <li>• <b>successive-loss</b>—Measures successive probe loss count, indicating probe failure.<br/>Default: 1</li> <li>• <b>total-loss</b>—Measures total probe loss count indicating test failure, from 0 through 15.<br/>Default: 1</li> </ul> |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b> | Command introduced in Junos OS Release 9.6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>         | Sets the trace options for datapath-debug.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li>• <b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</li> <li>• <b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li>• <b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li>• <b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the trace-file again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p> <p>Range: 10 KB through 1 GB</p> <p>Default: 128 KB</p> |

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option
  - **no-remote-trace**—Set remote tracing as disabled.
- Required Privilege Level** trace—To view this statement in the configuration.  
trace-control—To add this statement to the configuration.

---

## transfer-interval

---

- Syntax** transfer-interval *minutes*;
- Hierarchy Level** [edit accounting-options [file](#) *filename*]
- Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.
- Description** Specify the length of time the file remains open and receives new statistics before it is closed and transferred to an archive site.
- Options** *minutes*—Time the file remains open and receives new statistics before it is closed and transferred to an archive site.  
**Range:** 5 through 2880 minutes  
**Default:** 30 minutes
- Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>         | Set the trap bit to generate traps for probes. Traps are sent if the configured threshold is met or exceeded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>             | <p><b>traps</b>—Specify one or more traps. The following options are supported:</p> <ul style="list-style-type: none"> <li>• <b>control-connection-closed</b>—Generate traps when the control connection is closed.</li> <li>• <b>egress-jitter-exceeded</b>—Generate traps when the jitter in egress time threshold is met or exceeded.</li> <li>• <b>egress-std-dev-exceeded</b>—Generate traps when the egress time standard deviation threshold is met or exceeded.</li> <li>• <b>egress-time-exceeded</b>—Generate traps when the maximum egress time threshold is met or exceeded.</li> <li>• <b>ingress-jitter-exceeded</b>—Generate traps when the jitter in ingress time threshold is met or exceeded.</li> <li>• <b>ingress-std-dev-exceeded</b>—Generate traps when the ingress time standard deviation threshold is met or exceeded.</li> <li>• <b>ingress-time-exceeded</b>—Generate traps when the maximum ingress time threshold is met or exceeded.</li> <li>• <b>jitter-exceeded</b>—Generate traps when the jitter in round-trip time threshold is met or exceeded.</li> <li>• <b>probe-failure</b>—Generate traps when successive probe loss thresholds are crossed.</li> <li>• <b>rtt-exceeded</b>—Generate traps when the maximum round-trip time threshold is met or exceeded.</li> <li>• <b>std-dev-exceeded</b>—Generate traps when the round-trip time standard deviation threshold is met or exceeded.</li> <li>• <b>test-completion</b>—Generate traps when a test is completed.</li> <li>• <b>test-failure</b>—Generate traps when the total probe loss threshold is met or exceeded.</li> <li>• <b>test-iteration-done</b>—Generate traps when all test sessions under control connections complete one test iteration.</li> </ul> |

**NOTE:** For RPM traps to be generated, you must configure the `remote-operations` SNMP trap category by including the [categories](#) statement at the `[edit snmp trap-group trap-group-name]` hierarchy level.

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 173: monitor list Output Fields**

| Field Name           | Field Description                                  |
|----------------------|----------------------------------------------------|
| <b>monitor start</b> | Indicates the file is being monitored.             |
| <b>"filename"</b>    | Name of the file that is being monitored.          |
| <b>Last changed</b>  | Date and time at which the file was last modified. |

## Sample Output

### monitor list

```
user@host> monitor list
monitor start "vrrpd" (Last changed Dec 03:11:06 20)
monitor start "cli-commands" (Last changed Nov 07:3)
```

## monitor start

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```

## ping mpls l2circuit

**Syntax** ping mpls l2circuit (interface *interface-name* | virtual-circuit *virtual-circuit-id* neighbor *address*)  
 <count *count*>  
 <destination *address*>  
 <detail>  
 <exp *forwarding-class*>  
 <logical-system (all | *logical-system-name*)>  
 reply-mode (application-level-control-channel | ip-udp | no-reply)  
 <size *bytes*>  
 <source *source-address*>  
 <sweep>  
 <v1>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.0 for EX Series switches.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.  
 The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
 The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

**Description** Check the operability of the MPLS Layer 2 circuit connections. Type Ctrl+c to interrupt a ping mpls l2circuit command.

**Options** **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**interface** *interface-name*—Ping an interface configured for the Layer 2 circuit on the egress provider edge (PE) router.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**reply-mode**—(Optional) Reply mode for the ping request. This option has the following suboptions:

**application-level-control-channel**—Reply using an application level control channel.

**ip-udp**—Reply using an IPv4 or IPv6 UDP packet.

**no-reply**—Do not reply to the ping request.

**NOTE:** The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

**size bytes**—(Optional) Size of the label-switched path (LSP) ping request packet (96 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

**source source-address**—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**vt**—(Optional) Use the type 9 Layer 2 circuit type, length, and value (TLV).

**virtual-circuit virtual-circuit-id neighbor address**—Ping the virtual circuit identifier on the egress PE router or switch and the specified neighbor, testing the integrity of the Layer 2 circuit between the ingress and egress PE routers or switches.

**Additional Information** You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls l2circuit interface on page 1486](#)  
[ping mpls l2circuit virtual-circuit detail on page 1486](#)  
[ping mpls l2circuit interface <interface-name> reply-mode on page 1486](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls l2circuit interface

```
user@host> ping mpls l2circuit interface so-1/0/0.1
Request for seq 1, to interface 69, labels <100000, 100208>, packet size 100
Reply for seq 1, return code: Egress-ok, time: 0.439 ms
```

### ping mpls l2circuit virtual-circuit detail

```
user@host> ping mpls l2circuit virtual-circuit 200 neighbor 10.255.245.122/32 detail
Request for seq 1, to interface 68, labels <100048, 100128>, packet size 100

Reply for seq 1, return code: Egress-ok time: 0.539 ms
```

### ping mpls l2circuit interface <interface-name> reply-mode

```
user@host> ping mpls l2circuit interface lt-1/2/0.21 reply-mode application-level-control-channel
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

## ping mpls l2vpn

**Syntax** ping mpls l2vpn (instance *instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number* | interface *interface-name*)  
 <bottom-label-ttl>  
 <count *count*>  
 <destination *address*>  
 <detail>  
 <exp forwarding-class>  
 <logical-system (all | *logical-system-name*)>  
 reply-mode (application-level-control-channel | ip-udp | no-reply)  
 <size *bytes*>  
 <source *source-address*>  
 <sweep>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.0 for EX Series switches.  
 The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
 The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

**Description** Check the operability of MPLS Layer 2 virtual private network (VPN) connections. Type Ctrl+c to interrupt a **ping mpls l2vpn** command.

**Options** **bottom-label-ttl**—(Optional) Display the time-to-live value for the bottom label in the label stack.

**count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp forwarding-class**—(Optional) Value of the forwarding class for the MPLS ping packets.

**instance** *instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number*—Ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the ingress and egress provider edge (PE) routers or switches.

**interface** *interface-name*—Ping an interface configured for the Layer 2 VPN on the egress PE router or switch.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**reply-mode**—(Optional) Reply mode for the ping request. This option has the following suboptions:

**application-level-control-channel**—Reply using an application level control channel.

**ip-udp**—Reply using an IPv4 or IPv6 UDP packet.

**no-reply**—Do not reply to the ping request.

The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

**size bytes**—(Optional) Size of the label-switched path (LSP) ping request packet (96 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

**source source-address**—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Additional Information</b>   | <p>You must configure MPLS at the <b>[edit protocols mpls]</b> hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.</p> <p>In asymmetric MTU scenarios, the echo response might be dropped. ```

### ping mpls l2vpn interface <interface-name> reply-mode

```
user@host> ping mpls l2vpn interface lt-1/2/0.21 reply-mode ip-udp
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

## ping mpls l3vpn

---

**Syntax** ping mpls l3vpn prefix *prefix-name*  
<*l3vpn-name*>  
<bottom-label-ttl>  
<count *count*>  
<destination *address*>  
<detail>  
<exp *forwarding-class*>  
<logical-system (all | *logical-system-name*)>  
<size *bytes*>  
<source *source-address*>  
<sweep>

**Release Information** Command introduced before Junos OS Release 7.4.  
Command introduced in Junos OS Release 9.0 for EX Series switches.  
The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Check the operability of a MPLS Layer 3 virtual private network (VPN) connection. Type Ctrl+c to interrupt a **ping mpls l3vpn** command.

**Options** **bottom-label-ttl**—(Optional) Display the time-to-live value for the bottom label in the label stack.

**count *count***—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through **1,000,000**. The default value is **5**.

**destination *address***—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp *forwarding-class***—(Optional) Value of the forwarding class for the MPLS ping packets.

***l3vpn-name***—(Optional) Layer 3 VPN name.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on the specified logical system.

**prefix *prefix-name***—Ping to test whether a prefix is present in a provider edge (PE) router's or switch's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix. This option does not test the connection between a PE router or switch and a customer edge (CE) router or switch.

**size *bytes***—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

If the Layer 3 VPN traffic transits a route reflector within the network, the **ping mpls l3vpn** command does not work.

**Required Privilege Level** network

**List of Sample Output** [ping mpls l3vpn on page 1491](#)  
[ping mpls l3vpn detail on page 1491](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code these packets are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls l3vpn

```
user@host> ping mpls l3vpn vpn1 prefix 10.255.245.122/32
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

### ping mpls l3vpn detail

Reply for seq 5, return code: Egress-ok
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

## ping mpls ldp

**Syntax** ping mpls ldp *fec*  
 <count *count*>  
 <destination *address*>  
 <detail>  
 <exp *forwarding-class*>  
 <instance *routing-instance-name*>  
 <logical-system (all | *logical-system-name*)>  
 <p2mp root-addr *ip-address* lsp-id *identifier*>  
 <size *bytes*>  
 <source *source-address*>  
 <sweep>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.0 for EX Series switches.  
**size** and **sweep** options introduced in Junos OS Release 9.6.  
**instance** option introduced in Junos OS Release 10.0.  
**p2mp**, **root-address**, and **lsp-id** options introduced in Junos OS Release 11.2.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Check the operability of MPLS LDP-signaled label-switched path (LSP) connections.  
 Type Ctrl+c to interrupt a **ping mpls** command.

**Options** **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**fec**—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

**instance** *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**p2mp root-addr** *ip-address* **lsp-id** *identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

**size** *bytes*—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller

than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

You can configure the ping interval for the **ping mpls ldp** command by specifying a new time in seconds using the **lsp-ping-interval** statement at the **[edit protocols ldp oam]** hierarchy level. For more information, see the *MPLS Feature Guide for Security Devices*.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls ldp fec count on page 1494](#)  
[ping mpls ldp p2mp root-addr lsp-id on page 1494](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls ldp fec count

```

## ping mpls lsp-end-point

---

**Syntax**    ping mpls lsp-end-point *prefix-name*  
              <count *count*>  
              <destination *address*>  
              <detail>  
              <exp *forwarding-class*>  
              <instance *routing-instance-name*>  
              <logical-system (all | *logical-system-name*)>  
              <size *bytes*>  
              <source *source-address*>  
              <sweep>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                          Command introduced in Junos OS Release 9.0 for EX Series switches.  
                          The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
                          The **instance** option was introduced in Junos OS Release 10.0.  
                          Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**    Check the operability of MPLS label-switched path (LSP) endpoint connections. Type Ctrl+c to interrupt a **ping mpls** command.

**Options**    **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**instance** *routing-instance-name*—(Optional) Ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP connection.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**prefix-name**—LDP forwarding equivalence class (FEC) prefix or RSVP LSP endpoint address.

**size** *bytes*—(Optional) Size of the LSP ping request packet. If the endpoint is LDP-based, the minimum size of the packet is 88 bytes. If the endpoint is RSVP-based, the minimum size of the packet is 100 bytes. The maximum size in either case is 65468 bytes.

**source** *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls lsp-end-point detail on page 1497](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

 <standby standby-path-name>  
 <sweep>

**Release Information** Command introduced before Junos OS Release 7.4.  
 The **egress** and **multipoint** options were introduced in Junos OS Release 9.2.  
 The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
 The **dynamic-bypass** and **manual-bypass** options were introduced in Junos OS Release 10.2.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Check the operability of MPLS RSVP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

**Options** **count count**—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination address**—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**NOTE:** When using the **detail** option, the reported time is based on the system time configured on the local and remote routers. Differences in these system times can result in inaccurate one way ping trip times being reported.

In practice, it is difficult to synchronize the system times of independent Juniper Networks routers with sufficient accuracy to provide a meaningful time value for the **detail** option (even when synchronized using NTP).

**dynamic-bypass**—(Optional) Ping dynamically generated bypass LSPs, used for protecting other LSPs.

**egress *egress-address***—(Optional) Only the specified egress router or switch responds to the ping request.

**exp *forwarding-class***—(Optional) Value of the forwarding class for the MPLS ping packets.

**interface**—(Optional) Specify the name of the interface protected by the manual bypass LSP. This option is only available when you have also used the **manual-bypass** option.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on the specified logical system.

***lsp-name***—Ping an RSVP-signaled LSP using an LSP name.

**manual-bypass**—(Optional) Ping manually configured bypass LSPs, used for protecting other LSPs. For this option, you must also specify the interface protected by the manual bypass LSP using the **interface** option.

**multipoint**—(Optional) Send ping requests to each of the egress routers or switches participating in a point-to-multipoint LSP. You can also include the **egress** option to ping a specific egress router or switch participating in a point-to-multipoint LSP.

**size *bytes***—(Optional) Size of the LSP ping request packet (100 through 65468 bytes). Packets are 4-byte aligned. For example, if you enter a size of 101, 102, 103, or 104, the router or switch uses a size value of 104 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 100-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface.

**standby *standby-path-name***—(Optional) Name of the standby path.

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls rsvp \(Echo Reply Received\) on page 1500](#)  
[ping mpls rsvp \(Echo Reply with Error Code\) on page 1500](#)

[ping mpls rsvp detail on page 1500](#)

[ping mpls rsvp multipoint egress detail count on page 1500](#)

[ping mpls rsvp multipoint detail count on page 1500](#)

[ping mpls rsvp destination detail count size on page 1501](#)

[ping mpls rsvp destination detail sweep size on page 1501](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls rsvp (Echo Reply Received)

```
user@host> ping mpls rsvp test1
!!!!!--- lsping statistics ---5 packets transmitted, 5 packets received, 0% packet
loss
```

### ping mpls rsvp (Echo Reply with Error Code)

```
user@host> ping mpls rsvp test2
!!xxx--- lsping statistics ---5 packets transmitted, 2 packets received, 60%
packet loss3 packets received with error status, not counted as received.
```

### ping mpls rsvp detail

```
user@host> ping mpls rsvp to-green detail
Request for seq 1, to interface 67, labels <100095, 0, 0>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 67, labels <100095, 0, 0>
Reply for seq 2, return code: Egress-ok
```

### ping mpls rsvp multipoint egress detail count

```
user@host>ping mpls rsvp sample-lsp multipoint egress 192.168.1.3 detail count 1
Request for seq 1, to interface 70, label 299952
Request for seq 1, to interface 70, no label stack.
Request for seq 1, to interface 67, no label stack.

| <b>Additional Information</b>   | <p>You cannot clear the alarms for chassis components. Instead, you must remedy the cause of the alarm. When a chassis alarm is lit, it indicates that you are running the device in a manner that we do not recommend.</p> <p>On routers, you can manually silence external devices connected to the alarm relay contacts by pressing the alarm cutoff button, located on the craft interface. Silencing the device does not remove the alarm messages from the display (if present on the router) or extinguish the alarm LEDs. In addition, new alarms that occur after you silence an external device reactivate the external device.</p> <p>In Junos OS Release 11.1 and later, alarms for fans also show the slot number of the fans in the CLI output.</p> |

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 176: show chassis alarms Output Fields**

| Field Name  | Field Description                              |
|-------------|------------------------------------------------|
| Alarm time  | Date and time the alarm was first recorded.    |
| Class       | Severity class for this alarm: Minor or Major. |
| Description | Information about the alarm.                   |

## Sample Output

### show chassis alarms

```
user@host> show chassis alarms
```

4 alarms currently active

| Alarm time              | Class | Description                                      |
|-------------------------|-------|--------------------------------------------------|
| 2012-05-29 16:47:18 UTC | Major | /var partition usage crossed critical threshold  |
| 2012-05-29 16:47:18 UTC | Minor | /var partition usage crossed high threshold      |
| 2012-05-29 16:47:18 UTC | Major | /root partition usage crossed critical threshold |
| 2012-05-29 16:47:18 UTC | Minor | /root partition usage crossed high threshold     |

| <b>Release Information</b> | Command introduced before Junos OS Release 7.4.<br>Command introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>         | Display the configuration that currently is running on the router or switch, which is the last committed configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | <p><b>none</b>—Display the entire configuration.</p> <p><b>statement-path</b>—(Optional) Display one of the following hierarchies in a configuration. (Each <b>statement-path</b> option has additional suboptions not described here. See the appropriate feature guide or EX Series switch documentation for more information.)</p> <ul style="list-style-type: none"><li>• <b>access</b>—Network access configuration.</li><li>• <b>access-profile</b>—Access profile configuration.</li><li>• <b>accounting-options</b>—Accounting data configuration.</li><li>• <b>applications</b>—Applications defined by protocol characteristics.</li><li>• <b>apply-groups</b>—Groups from which configuration data is inherited.</li><li>• <b>chassis</b>—Chassis configuration.</li><li>• <b>chassis network-services</b>—Current running mode.</li><li>• <b>class-of-service</b>—Class-of-service configuration.</li><li>• <b>diameter</b>—Diameter base protocol layer configuration.</li><li>• <b>ethernet-switching-options</b>—(EX Series switch only) Ethernet switching configuration.</li><li>• <b>event-options</b>—Event processing configuration.</li><li>• <b>firewall</b>—Firewall configuration.</li><li>• <b>forwarding-options</b>—Options that control packet sampling.</li><li>• <b>groups</b>—Configuration groups.</li><li>• <b>interfaces</b>—Interface configuration.</li><li>• <b>jsrc</b>—JSRC partition configuration.</li><li>• <b>jsrc-partition</b>—JSRC partition configuration.</li><li>• <b>logical-systems</b>—Logical system configuration.</li><li>• <b>poe</b>—(EX Series switch only) Power over Ethernet configuration.</li><li>• <b>policy-options</b>—Routing policy option configuration.</li><li>• <b>protocols</b>—Routing protocol configuration.</li></ul> |

- **routing-instances**—Routing instance configuration.
- **routing-options**—Protocol-independent routing option configuration.
- **security**—Security configuration.
- **services**—Service PIC applications configuration.
- **snmp**—Simple Network Management Protocol configuration.
- **system**—System parameters configuration.
- **virtual-chassis**—(EX Series switch only) Virtual Chassis configuration.
- **vlan**—(EX Series switch only) VLAN configuration.

**Additional Information** The portions of the configuration that you can view depend on the user class that you belong to and the corresponding permissions. If you do not have permission to view a portion of the configuration, the text **ACCESS-DENIED** is substituted for that portion of the configuration. If you do not have permission to view authentication keys and passwords in the configuration, because the **secret** permission bit is not set for your user account, the text **SECRET-DATA** is substituted for that portion of the configuration. If an identifier in the configuration contains a space, the identifier is displayed in quotation marks.

Likewise, when you issue the **show configuration** command with the **| display set** pipe option to view the configuration as **set** commands, those portions of the configuration that you do not have permissions to view are substituted with the text **ACCESS-DENIED**.

**Required Privilege Level** view

**Table 177: show chassis cluster ip-monitoring status Output Fields**

| Field Name               | Field Description                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Redundancy-group</b>  | ID number (0 - 255) of a redundancy group in the cluster.                                                                                                                                                                                          |
| <b>Global threshold</b>  | Failover value for all IP addresses monitored by the redundancy group.                                                                                                                                                                             |
| <b>Current threshold</b> | Value equal to the global threshold minus the total weight of the unreachable IP address.                                                                                                                                                          |
| <b>IP Address</b>        | Monitored IP address in the redundancy group.                                                                                                                                                                                                      |
| <b>Status</b>            | <p>Current reachability state of the monitored IP address.</p> <p>Values for this field are: <b>reachable</b>, <b>unreachable</b>, and <b>unknown</b>. The status is "unknown" if Packet Forwarding Engines (PFEs) are not yet up and running.</p> |
| <b>Failure count</b>     | Number of attempts to reach an IP address.                                                                                                                                                                                                         |
| <b>Reason</b>            | Explanation for the reported status. See <a href="#">Table 178</a> .                                                                                                                                                                               |

Table 177: show chassis cluster ip-monitoring status Output Fields (*continued*)

| Field Name    | Field Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Weight</b> | Combined weight (0 - 255) assigned to all monitored IP addresses. A higher weight value indicates greater importance. |

Expanded reason output fields for unreachable IP addresses added in Junos OS Release 10.1. You might see any of the following reasons displayed.

Table 178: show chassis cluster ip-monitoring status redundancy group Reason Fields

| Reason                                | Reason Description                                                                                                                                               |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>No route to host</b>               | The router could not resolve the ARP, which is needed to send the ICMP packet to the host with the monitored IP address.                                         |
| <b>No auxiliary IP found</b>          | The redundant Ethernet interface does not have an auxiliary IP address configured.                                                                               |
| <b>Reth child not up</b>              | A child interface of a redundant Ethernet interface is down.                                                                                                     |
| <b>redundancy-group state unknown</b> | Unable to obtain the state (primary, secondary, secondary-hold, disable) of a redundancy-group.                                                                  |
| <b>No reth child MAC address</b>      | Could not extract the MAC address of the redundant Ethernet child interface.                                                                                     |
| <b>Secondary link not monitored</b>   | The secondary link might be down (the secondary child interface of a redundant Ethernet interface is either down or non-functional).                             |
| <b>Unknown</b>                        | The IP address has just been configured and the router still does not know the status of this IP.<br><br>or<br><br>Do not know the exact reason for the failure. |

## Sample Output

### show chassis cluster ip-monitoring status

```

user@host> show chassis cluster ip-monitoring status
node0:
-----

Redundancy group: 1
Global threshold: 200
Current threshold: -120

IP address      Status      Failure count  Reason  Weight
10.254.5.44     reachable   0              n/a     220
2.2.2.1         reachable   0              n/a     100

node1:
-----

```

Redundancy group: 1  
 Global threshold: 200  
 Current threshold: -120

| IP address  | Status    | Failure count | Reason | Weight |
|-------------|-----------|---------------|--------|--------|
| 10.254.5.44 | reachable | 0             | n/a    | 220    |
| 2.2.2.1     | reachable | 0             | n/a    | 100    |

## Sample Output

### show chassis cluster ip-monitoring status redundancy-group

```
user@host> show chassis cluster ip-monitoring status redundancy-group 1
node0:
```

-----

Redundancy group: 1

| IP address  | Status    | Failure count | Reason |
|-------------|-----------|---------------|--------|
| 10.254.5.44 | reachable | 0             | n/a    |
| 2.2.2.1     | reachable | 0             | n/a    |
| 1.1.1.5     | reachable | 0             | n/a    |
| 1.1.1.4     | reachable | 0             | n/a    |
| 1.1.1.1     | reachable | 0             | n/a    |

node1:

-----

Redundancy group: 1

| IP address  | Status    | Failure count | Reason |
|-------------|-----------|---------------|--------|
| 10.254.5.44 | reachable | 0             | n/a    |
| 2.2.2.1     | reachable | 0             | n/a    |
| 1.1.1.5     | reachable | 0             | n/a    |
| 1.1.1.4     | reachable | 0             | n/a    |
| 1.1.1.1     | reachable | 0             | n/a    |

## show interfaces (SRX Series)

**Syntax** show interfaces {  
     <brief | detail | extensive | terse>  
     controller *interface-name*  
     descriptions *interface-name*  
     destination-class (all | *destination-class-name logical-interface-name*)  
     diagnostics optics *interface-name*  
     far-end-interval *interface-fpc/pic/port*  
     filters *interface-name*  
     flow-statistics *interface-name*  
     interval *interface-name*  
     load-balancing (detail | *interface-name*)  
     mac-database mac-address *mac-address*  
     mc-ae id *identifier* unit *number* revertive-info  
     media *interface-name*  
     policers *interface-name*  
     queue both-ingress-egress egress forwarding-class *forwarding-class* ingress l2-statistics  
     redundancy (detail | *interface-name*)  
     routing brief detail summary *interface-name*  
     routing-instance (all | *instance-name*)  
     snmp-index *snmp-index*  
     source-class (all | *destination-class-name logical-interface-name*)  
     statistics *interface-name*  
     switch-port *switch-port number*  
     transport pm (all | optics | otn) (all | current | currentday | interval | previousday) (all |  
         *interface-name*)  
     zone *interface-name*  
 }

**Release Information** Command modified in Junos OS Release 9.5.

**Description** Display status information and statistics about interfaces on SRX Series appliance running Junos OS.

On SRX Series appliance, on configuring identical IPs on a single interface, you will not see a warning message; instead, you will see a syslog message.

- Options**
- **interface-name**—(Optional) Display standard information about the specified interface. Following is a list of typical interface names. Replace pim with the PIM slot and port with the port number.
    - **at-*pim*/0/*port***—ATM-over-ADSL or ATM-over-SHDSL interface.
    - **ce1-*pim*/0/ *port***—Channelized E1 interface.
    - **cl-0/0/8**—3G wireless modem interface for SRX320 devices.
    - **ct1-*pim*/0/*port***—Channelized T1 interface.
    - **dl0**—Dialer Interface for initiating ISDN and USB modem connections.
    - **e1-*pim*/0/*port***—E1 interface.
    - **e3-*pim*/0/*port***—E3 interface.

- **fe-pim/0/port**—Fast Ethernet interface.
- **ge-pim/0/port**—Gigabit Ethernet interface.
- **se-pim/0/port**—Serial interface.
- **t1-pim/0/port**—T1 (also called DS1) interface.
- **t3-pim/0/port**—T3 (also called DS3) interface.
- **wx-slot/0/0**—WAN acceleration interface, for the WXC Integrated Services Module (ISM 200).
- **brief | detail | extensive | terse**—(Optional) Display the specified level of output.
- **controller**—(Optional) Show controller information.
- **descriptions**—(Optional) Display interface description strings.
- **destination-class**—(Optional) Show statistics for destination class.
- **diagnostics**—(Optional) Show interface diagnostics information.
- **far-end-interval**—(Optional) Show far end interval statistics.
- **filters**—(Optional) Show interface filters information.
- **flow-statistics**—(Optional) Show security flow counters and errors.
- **interval**—(Optional) Show interval statistics.
- **load-balancing**—(Optional) Show load-balancing status.
- **mac-database**—(Optional) Show media access control database information.
- **mc-ae**—(Optional) Show MC-AE configured interface information.
- **media**—(Optional) Display media information.
- **policers**—(Optional) Show interface policers information.
- **queue**—(Optional) Show queue statistics for this interface.
- **redundancy**—(Optional) Show redundancy status.
- **routing**—(Optional) Show routing status.
- **routing-instance**—(Optional) Name of routing instance.
- **snmp-index**—(Optional) SNMP index of interface.
- **source-class**—(Optional) Show statistics for source class.
- **statistics**—(Optional) Display statistics and detailed output.
- **switch-port**—(Optional) Front end port number (0..15).
- **transport**—(Optional) Show interface transport information.
- **zone**—(Optional) Interface's zone.

| Output Fields         | Table 179 lists the output fields for the <b>show interfaces</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Physical Interface</b> |                                                                                                                                                                                                                                                     |                              |
| <b>Physical interface</b> | Name of the physical interface.                                                                                                                                                                                                                     | All levels                   |
| <b>Enabled</b>            | State of the interface.                                                                                                                                                                                                                             | All levels                   |
| <b>Interface index</b>    | Index number of the physical interface, which reflects its initialization sequence.                                                                                                                                                                 | <b>detail extensive none</b> |
| <b>SNMP ifIndex</b>       | SNMP index number for the physical interface.                                                                                                                                                                                                       | <b>detail extensive none</b> |
| <b>Link-level type</b>    | Encapsulation being used on the physical interface.                                                                                                                                                                                                 | All levels                   |
| <b>Generation</b>         | Unique number for use by Juniper Networks technical support only.                                                                                                                                                                                   | <b>detail extensive</b>      |
| <b>MTU</b>                | Maximum transmission unit size on the physical interface.                                                                                                                                                                                           | All levels                   |
| <b>Link mode</b>          | Link mode: Full-duplex or Half-duplex.                                                                                                                                                                                                              |                              |
| <b>Speed</b>              | Speed at which the interface is running.                                                                                                                                                                                                            | All levels                   |
| <b>BPDU error</b>         | Bridge protocol data unit (BPDU) error: Detected or None                                                                                                                                                                                            |                              |
| <b>Loopback</b>           | Loopback status: <b>Enabled</b> or <b>Disabled</b> . If loopback is enabled, type of loopback: <b>Local</b> or <b>Remote</b> .                                                                                                                      | All levels                   |
| <b>Source filtering</b>   | Source filtering status: <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                        | All levels                   |
| <b>Flow control</b>       | Flow control status: <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                            | All levels                   |
| <b>Auto-negotiation</b>   | (Gigabit Ethernet interfaces) Autonegotiation status: <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                           | All levels                   |
| <b>Remote-fault</b>       | (Gigabit Ethernet interfaces) Remote fault status: <ul style="list-style-type: none"> <li>• <b>Online</b>—Autonegotiation is manually configured as online.</li> <li>• <b>Offline</b>—Autonegotiation is manually configured as offline.</li> </ul> | All levels                   |
| <b>Device flags</b>       | Information about the physical device.                                                                                                                                                                                                              | All levels                   |
| <b>Interface flags</b>    | Information about the interface.                                                                                                                                                                                                                    | All levels                   |
| <b>Link flags</b>         | Information about the physical link.                                                                                                                                                                                                                | All levels                   |
| <b>CoS queues</b>         | Number of CoS queues configured.                                                                                                                                                                                                                    | <b>detail extensive none</b> |
| <b>Current address</b>    | Configured MAC address.                                                                                                                                                                                                                             | <b>detail extensive none</b> |

| Field Name                              | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Level of Output              |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| <b>Last flapped</b>                     | Date, time, and how long ago the interface went from down to up. The format is <b>Last flapped: year-month-day hour:minute:second:timezone (hour:minute:second ago)</b> . For example, <b>Last flapped: 2002-04-26 10:52:40 PDT (04:33:20 ago)</b> .                                                                                                                                                                                                                                                                          | <b>detail extensive none</b> |
| <b>Input Rate</b>                       | Input rate in bits per second (bps) and packets per second (pps).                                                                                                                                                                                                                                                                                                                                                                                                                                                             | None                         |
| <b>Output Rate</b>                      | Output rate in bps and pps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | None                         |
| <b>Active alarms and Active defects</b> | <p>Ethernet-specific defects that can prevent the interface from passing packets. When a defect persists for a certain amount of time, it is promoted to an alarm. These fields can contain the value <b>None</b> or <b>Link</b>.</p> <ul style="list-style-type: none"> <li>• <b>None</b>—There are no active defects or alarms.</li> <li>• <b>Link</b>—Interface has lost its link state, which usually means that the cable is unplugged, the far-end system has been turned off, or the PIC is malfunctioning.</li> </ul> | <b>detail extensive none</b> |
| <b>Statistics last cleared</b>          | Time when the statistics for the interface were last set to zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <b>detail extensive</b>      |
| <b>Traffic statistics</b>               | <p>Number and rate of bytes and packets received and transmitted on the physical interface.</p> <ul style="list-style-type: none"> <li>• <b>Input bytes</b>—Number of bytes received on the interface.</li> <li>• <b>Output bytes</b>—Number of bytes transmitted on the interface.</li> <li>• <b>Input packets</b>—Number of packets received on the interface.</li> <li>• <b>Output packets</b>—Number of packets transmitted on the interface.</li> </ul>                                                                  | <b>detail extensive</b>      |

Table 179: show interfaces Output Fields (*continued*)

| Field Name           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Level of Output  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>Input errors</b>  | <p>Input errors on the interface.</p> <ul style="list-style-type: none"> <li>• <b>Errors</b>—Sum of the incoming frame aborts and FCS errors.</li> <li>• <b>Drops</b>—Number of packets dropped by the input queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism.</li> <li>• <b>Framing errors</b>—Number of packets received with an invalid frame checksum (FCS).</li> <li>• <b>Runts</b>—Number of frames received that are smaller than the runt threshold.</li> <li>• <b>Policed discards</b>—Number of frames that the incoming packet match code discarded because they were not recognized or not of interest. Usually, this field reports protocols that Junos OS does not handle.</li> <li>• <b>L3 incompletes</b>—Number of incoming packets discarded because they failed Layer 3 (usually IPv4) sanity checks of the header. For example, a frame with less than 20 bytes of available IP header is discarded. L3 incomplete errors can be ignored by configuring the <b>ignore-l3-incompletes</b> statement.</li> <li>• <b>L2 channel errors</b>—Number of times the software did not find a valid logical interface for an incoming frame.</li> <li>• <b>L2 mismatch timeouts</b>—Number of malformed or short packets that caused the incoming packet handler to discard the frame as unreadable.</li> <li>• <b>FIFO errors</b>—Number of FIFO errors in the receive direction that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning.</li> <li>• <b>Resource errors</b>—Sum of transmit drops.</li> </ul>                                                                                                                                                    | <b>extensive</b> |
| <b>Output errors</b> | <p>Output errors on the interface.</p> <ul style="list-style-type: none"> <li>• <b>Carrier transitions</b>—Number of times the interface has gone from <b>down</b> to <b>up</b>. This number does not normally increment quickly, increasing only when the cable is unplugged, the far-end system is powered down and then up, or another problem occurs. If the number of carrier transitions increments quickly (perhaps once every 10 seconds), the cable, the far-end system, or the PIC or PIM is malfunctioning.</li> <li>• <b>Errors</b>—Sum of the outgoing frame aborts and FCS errors.</li> <li>• <b>Drops</b>—Number of packets dropped by the output queue of the I/O Manager ASIC. If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism.</li> <li>• <b>Collisions</b>—Number of Ethernet collisions. The Gigabit Ethernet PIC supports only full-duplex operation, so for Gigabit Ethernet PICs, this number should always remain 0. If it is nonzero, there is a software bug.</li> <li>• <b>Aged packets</b>—Number of packets that remained in shared packet SDRAM so long that the system automatically purged them. The value in this field should never increment. If it does, it is most likely a software bug or possibly malfunctioning hardware.</li> <li>• <b>FIFO errors</b>—Number of FIFO errors in the send direction as reported by the ASIC on the PIC. If this value is ever nonzero, the PIC is probably malfunctioning.</li> <li>• <b>HS link CRC errors</b>—Number of errors on the high-speed links between the ASICs responsible for handling the interfaces.</li> <li>• <b>MTU errors</b>—Number of packets whose size exceeded the MTU of the interface.</li> <li>• <b>Resource errors</b>—Sum of transmit drops.</li> </ul> | <b>extensive</b> |

Table 179: show interfaces Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Level of Output         |

| <b>MAC statistics</b>                  | <p>Receive and Transmit statistics reported by the PIC's MAC subsystem, including the following:</p> <ul style="list-style-type: none"> <li>• <b>Total octets and total packets</b>—Total number of octets and packets.</li> <li>• <b>Unicast packets, Broadcast packets, and Multicast packets</b>—Number of unicast, broadcast, and multicast packets.</li> <li>• <b>CRC/Align errors</b>—Total number of packets received that had a length (excluding framing bits, but including FCS octets) of between 64 and 1518 octets, inclusive, and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).</li> <li>• <b>FIFO error</b>—Number of FIFO errors that are reported by the ASIC on the PIC. If this value is ever nonzero, the PIC or a cable is probably malfunctioning.</li> <li>• <b>MAC control frames</b>—Number of MAC control frames.</li> <li>• <b>MAC pause frames</b>—Number of MAC control frames with <b>pause</b> operational code.</li> <li>• <b>Oversized frames</b>—There are two possible conditions regarding the number of oversized frames: <ul style="list-style-type: none"> <li>• Packet length exceeds 1518 octets, or</li> <li>• Packet length exceeds MRU</li> </ul> </li> <li>• <b>Jabber frames</b>—Number of frames that were longer than 1518 octets (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition in which any packet exceeds 20 ms. The allowed range to detect jabber is from 20 ms to 150 ms.</li> <li>• <b>Fragment frames</b>—Total number of packets that were less than 64 octets in length (excluding framing bits, but including FCS octets) and had either an FCS error or an alignment error. Fragment frames normally increment because both runts (which are normal occurrences caused by collisions) and noise hits are counted.</li> <li>• <b>VLAN tagged frames</b>—Number of frames that are VLAN tagged. The system uses the TPID of 0x8100 in the frame to determine whether a frame is tagged or not.</li> <li>• <b>Code violations</b>—Number of times an event caused the PHY to indicate "Data reception error" or "invalid data symbol error."</li> </ul> | <b>extensive</b>        |

Table 179: show interfaces Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Level of Output |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Filter statistics                      | <p>Receive and Transmit statistics reported by the PIC's MAC address filter subsystem. The filtering is done by the content-addressable memory (CAM) on the PIC. The filter examines a packet's source and destination MAC addresses to determine whether the packet should enter the system or be rejected.</p> <ul style="list-style-type: none"> <li>• <b>Input packet count</b>—Number of packets received from the MAC hardware that the filter processed.</li> <li>• <b>Input packet rejects</b>—Number of packets that the filter rejected because of either the source MAC address or the destination MAC address.</li> <li>• <b>Input DA rejects</b>—Number of packets that the filter rejected because the destination MAC address of the packet is not on the accept list. It is normal for this value to increment. When it increments very quickly and no traffic is entering the device from the far-end system, either there is a bad ARP entry on the far-end system, or multicast routing is not on and the far-end system is sending many multicast packets to the local device (which the router is rejecting).</li> <li>• <b>Input SA rejects</b>—Number of packets that the filter rejected because the source MAC address of the packet is not on the accept list. The value in this field should increment only if source MAC address filtering has been enabled. If filtering is enabled, if the value increments quickly, and if the system is not receiving traffic that it should from the far-end system, it means that the user-configured source MAC addresses for this interface are incorrect.</li> <li>• <b>Output packet count</b>—Number of packets that the filter has given to the MAC hardware.</li> <li>• <b>Output packet pad count</b>—Number of packets the filter padded to the minimum Ethernet size (60 bytes) before giving the packet to the MAC hardware. Usually, padding is done only on small ARP packets, but some very small IP packets can also require padding. If this value increments rapidly, either the system is trying to find an ARP entry for a far-end system that does not exist or it is misconfigured.</li> <li>• <b>Output packet error count</b>—Number of packets with an indicated error that the filter was given to transmit. These packets are usually aged packets or are the result of a bandwidth problem on the FPC hardware. On a normal system, the value of this field should not increment.</li> <li>• <b>CAM destination filters, CAM source filters</b>—Number of entries in the CAM dedicated to destination and source MAC address filters. There can only be up to 64 source entries. If source filtering is disabled, which is the default, the values for these fields should be 0.</li> </ul> | extensive       |
| Autonegotiation information            | <p>Information about link autonegotiation.</p> <ul style="list-style-type: none"> <li>• <b>Negotiation status:</b> <ul style="list-style-type: none"> <li>• <b>Incomplete</b>—Ethernet interface has the speed or link mode configured.</li> <li>• <b>No autonegotiation</b>—Remote Ethernet interface has the speed or link mode configured, or does not perform autonegotiation.</li> <li>• <b>Complete</b>—Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process is successful.</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | extensive       |

| <b>Transit statistics</b>                             | Number and rate of bytes and packets transiting the switch.<br><br><b>NOTE:</b> For Gigabit Ethernet intelligent queuing 2 (IQ2) interfaces, the logical interface egress statistics might not accurately reflect the traffic on the wire when output shaping is applied. Traffic management output shaping might drop packets after they are tallied by the <b>Output bytes</b> and <b>Output packets</b> interface counters. However, correct values display for both of these egress statistics when per-unit scheduling is enabled for the Gigabit Ethernet IQ2 physical interface, or when a single logical interface is actively using a shared scheduler. | <b>extensive</b>             |

## Sample Output

### show interfaces Gigabit Ethernet

```
user@host> show interfaces ge-0/0/1
```

```

Physical interface: ge-0/0/1, Enabled, Physical link is Down
  Interface index: 135, SNMP ifIndex: 510
  Link-level type: Ethernet, MTU: 1514, Link-mode: Full-duplex, Speed: 1000mbps,

  BPDU Error: None, MAC-REWRITE Error: None, Loopback: Disabled,
  Source filtering: Disabled, Flow control: Enabled, Auto-negotiation: Enabled,
  Remote fault: Online
  Device flags   : Present Running Down
  Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
  Link flags     : None
  CoS queues     : 8 supported, 8 maximum usable queues
  Current address: 00:1f:12:e4:b1:01, Hardware address: 00:1f:12:e4:b1:01
  Last flapped   : 2015-05-12 08:36:59 UTC (1w1d 22:42 ago)
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  Active alarms  : LINK
  Active defects : LINK
  Interface transmit statistics: Disabled

Logical interface ge-0/0/1.0 (Index 71) (SNMP ifIndex 514)
  Flags: Device-Down SNMP-Traps 0x0 Encapsulation: ENET2
  Input packets : 0
  Output packets: 0
  Security: Zone: public
  Protocol inet, MTU: 1500
    Flags: Sendbroadcast-pkt-to-re
    Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
      Destination: 1.1.1/24, Local: 1.1.1.1, Broadcast: 1.1.1.255

```

## Sample Output

### show interfaces brief (Gigabit Ethernet)

```

user@host> show interfaces ge-3/0/2 brief
Physical interface: ge-3/0/2, Enabled, Physical link is Up
  Link-level type: 52, MTU: 1522, Speed: 1000mbps, Loopback: Disabled,
  Source filtering: Disabled, Flow control: Enabled, Auto-negotiation: Enabled,
  Remote fault: Online
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Link flags     : None

Logical interface ge-3/0/2.0
  Flags: SNMP-Traps 0x4000
  VLAN-Tag [ 0x8100.512 0x8100.513 ] In(pop-swap 0x8100.530) Out(swap-push
  0x8100.512 0x8100.513)
  Encapsulation: VLAN-CCC
  ccc

Logical interface ge-3/0/2.32767
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2

```

## Sample Output

### show interfaces detail (Gigabit Ethernet)

```

user@host> show interfaces ge-0/0/1 detail
Physical interface: ge-0/0/1, Enabled, Physical link is Down
  Interface index: 135, SNMP ifIndex: 510, Generation: 138
  Link-level type: Ethernet, MTU: 1514, Link-mode: Full-duplex, Speed: 1000mbps,
  BPDU Error: None, MAC-REWRITE Error: None, Loopback: Disabled, Source filtering:

| <b>Release Information</b>      | Command introduced in Junos OS Release 9.5.                                                                                                                                                                                                 |
| <b>Description</b>              | Display the status of Power over Ethernet (PoE) ports.                                                                                                                                                                                      |
| <b>Options</b>                  | <ul style="list-style-type: none"> <li><b>none</b>—Display the status of all PoE ports on the SRX Series device.</li> <li><b>ge-fpc/pic/port</b>— (Optional) Display the status of a specific PoE port on the SRX Series device.</li> </ul> |
| <b>Required Privilege Level</b> | View                                                                                                                                                                                                                                        |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"> <li><i>Example: Configuring PoE on All Interfaces</i></li> </ul>                                                                                                                                         |
| <b>Output Fields</b>            | Table 180 lists the output fields for the <b>show poe interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                        |

Table 180: show poe interface Output Fields

| Field name        | Field Description                                                                 |
|-------------------|-----------------------------------------------------------------------------------|
| PoE Interface     | Specifies the interface name.                                                     |
| Admin Status      | Specifies whether PoE capabilities are enabled or disabled.                       |
| Oper status       | Specifies the operational status of the port.                                     |
| Max-power         | Specifies the maximum power configured on the port.                               |
| Priority          | Specifies whether the port is high priority or low priority.                      |
| Power-consumption | Specifies how much power is being used by the port.                               |
| Class             | Indicates the class of the powered device as defined by the IEEE 802 AF standard. |

## Sample Output

### show poe interface

```
user@host>show poe interface
```

```

| <b>Output Fields</b>            | Table 181 lists the output fields for the <b>show poe telemetries interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                           |

Table 181: show poe telemetries interface Output Fields

| Field name | Field Description                                                                 |
|------------|-----------------------------------------------------------------------------------|
| S1 No      | Number of the record for the specified port. The last record is the most recent.  |
| Timestamp  | Time that the power-consumption data was gathered.                                |
| Power      | Amount of power provided by the specified port at the time the data was gathered. |
| Voltage    | Voltage on the specified port at the time the data was gathered.                  |

## Sample Output

### show poe telemetries interface

```
user@host>show poe telemetries interface ge-0/0/1 count 8
```

| S1 No | Timestamp                | Power | Voltage |
|-------|--------------------------|-------|---------|
| 1     | Fri Jan 04 11:41:15 2009 | 6.6 W | 47.2 V  |
| 2     | Fri Jan 04 11:40:15 2009 | 6.6 W | 47.2 V  |

| <b>Output Fields</b>            | Table 182 lists the output fields for the <b>show pppoe interfaces</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 182: show pppoe interfaces Output Fields

| Field Name         | Field Description                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------|
| Index              | Index number of the logical interface, which reflects its initialization sequence.              |
| State              | State of the logical interface: <b>up</b> or <b>down</b> .                                      |
| Session ID         | Session ID.                                                                                     |
| Service name       | Type of service required (can be used to indicate an ISP name, a class, or quality of service). |
| Configured AC name | Configured access concentrator name.                                                            |
| Session AC name    | Name of the access concentrator.                                                                |

Table 182: show pppoe interfaces Output Fields (*continued*)

| Field Name                              | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Remote MAC address or Remote MAC</b> | MAC address of the remote side of the connection, either the access concentrator or the PPPoE client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Auto-reconnect timeout</b>           | Timeout value for reconnecting after a PPPoE session is terminated (in seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Idle timeout</b>                     | Length of time (in seconds) that a connection can be idle before disconnecting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Session uptime</b>                   | Length of time the session has been up, in <i>hh:mm:ss</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Ignore End-Of-List tag</b>           | Disables the <b>End-of-List</b> tag to continue processing of other tags after the <b>End-of-List</b> tag in a PPPoE Active Discovery Offer (PADO) packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Underlying interface</b>             | Interface on which PPPoE is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Packet Type</b>                      | <p>Number of packets sent and received during the PPPoE session, categorized by packet type and packet errors:</p> <ul style="list-style-type: none"> <li>• <b>PADI</b>—PPPoE Active Discovery Initiation packets.</li> <li>• <b>PADO</b>—PPPoE Active Discovery Offer packets.</li> <li>• <b>PADR</b>—PPPoE Active Discovery Request packets.</li> <li>• <b>PADS</b>—PPPoE Active Discovery Session-Confirmation packets.</li> <li>• <b>PADT</b>—PPPoE Active Discovery Termination packets.</li> <li>• <b>Service name error</b>—Packets for which the Service-Name request could not be honored.</li> <li>• <b>AC system error</b>—Packets for which the access concentrator experienced an error in performing the host request. For example, the host had insufficient resources to create a virtual circuit.</li> <li>• <b>Generic error</b>—Packets that indicate an unrecoverable error occurred.</li> <li>• <b>Malformed packets</b>—Malformed or short packets that caused the packet handler to discard the frame as unreadable.</li> <li>• <b>Unknown packets</b>—Unrecognized packets.</li> </ul> |
| <b>Timeout</b>                          | <p>Timeouts that occur during the PPPoE session:</p> <ul style="list-style-type: none"> <li>• <b>PADI</b>—No PADI packets received within the timeout period.</li> <li>• <b>PADO</b>—No PADO packets received within the timeout period. (This value is always zero and is not supported.)</li> <li>• <b>PADR</b>—No PADR packets received within the timeout period.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Receive Error Counters</b>           | <p>Error counters received during the PPPoE session:</p> <ul style="list-style-type: none"> <li>• <b>PADI</b>—No PADI error counters received during the session.</li> <li>• <b>PADO</b>—No PADO error counters received during the session.</li> <li>• <b>PADR</b>—No PADR error counters received during the session.</li> <li>• <b>PADS</b>—No PADS error counters received during the session.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Sample Output

### show pppoe interfaces

```
user@host> show pppoe interfaces
pp0.0 Index 71
  State: Session up, Session ID: 4,
  Service name: None,
  Session AC name: srx-pppoe-ac, Configured AC name: None,
  Remote MAC address: b0:c6:9a:74:5e:c1,
  Session uptime: 5d 15:21 ago,
  Auto-reconnect timeout: Never, Idle timeout: Never,
  Underlying interface: ge-0/0/1.0 Index 70
```

### show pppoe interfaces brief

```
user@host> show pppoe interfaces brief
```

| Interface | Underlying<br>interface | State      | Session<br>ID | Remote<br>MAC     |
|-----------|-------------------------|------------|---------------|-------------------|
| pp0.0     | ge-0/0/1.0              | Session up | 4             | b0:c6:9a:74:5e:c1 |

### show pppoe interfaces detail

```
user@host> show pppoe interfaces detail
pp0.0 Index 71
  State: Session up, Session ID: 4,
  Service name: None,
  Session AC name: srx-pppoe-ac, Configured AC name: None,

| Active PPPoE sessions | Total number of active PPPoE sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Packet Type           | Number of packets sent and received during the PPPoE session, categorized by packet type and packet errors: <ul style="list-style-type: none"> <li>• <b>PADI</b>—PPPoE Active Discovery Initiation packets.</li> <li>• <b>PADO</b>—PPPoE Active Discovery Offer packets.</li> <li>• <b>PADR</b>—PPPoE Active Discovery Request packets.</li> <li>• <b>PADS</b>—PPPoE Active Discovery Session-Confirmation packets.</li> <li>• <b>PADT</b>—PPPoE Active Discovery Termination packets.</li> <li>• <b>Service name error</b>—Packets for which the Service-Name request could not be honored.</li> <li>• <b>AC system error</b>—Packets for which the access concentrator experienced an error in performing the host request. For example, the host had insufficient resources to create a virtual circuit.</li> <li>• <b>Generic error</b>—Packets that indicate an unrecoverable error occurred.</li> <li>• <b>Malformed packets</b>—Malformed or short packets that caused the packet handler to discard the frame as unreadable.</li> <li>• <b>Unknown packets</b>—Unrecognized packets.</li> </ul> |

Table 183: show pppoe statistics Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Timeout</b>                | <p>Timeouts that occur during the PPPoE session:</p> <ul style="list-style-type: none"> <li>• <b>PADI</b>—No PADI packets received within the timeout period.</li> <li>• <b>PADO</b>—No PADO packets received within the timeout period. (This value is always zero and is not supported.)</li> <li>• <b>PADR</b>—No PADR packets received within the timeout period.</li> </ul>                              |
| <b>Receive Error Counters</b> | <p>Error counters received during the PPPoE session:</p> <ul style="list-style-type: none"> <li>• <b>PADI</b>—No PADI error counters received during the session.</li> <li>• <b>PADO</b>—No PADO error counters received during the session.</li> <li>• <b>PADR</b>—No PADR error counters received during the session.</li> <li>• <b>PADS</b>—No PADS error counters received during the session.</li> </ul> |

## Sample Output

### show pppoe statistics

```

user@host> show pppoe statistics
Active PPPoE sessions: 0

      PacketType          Sent      Received
      PADI                0          0
      PADO                0          0
      PADR                0          0
      PADS                0          0
      PADT                0          0
      Service name error  0          0
      AC system error     0          0
      Generic error       0          0
      Malformed packets   0          0
      Unknown packets     0          0
      Timeout
      PADI                0
      PADO                0
      PADR                0
      Receive Error Counters
      PADI                0
      PADO                0
      PADR                0
      PADS                0

```

## show security alarms

**Syntax** show security alarms  
 <detail>  
 <alarm-id *id-number*>  
 <alarm-type [ *types* ]>  
 <newer-than YYYY-MM-DD.HH:MM:SS>  
 <older-than YYYY-MM-DD.HH:MM:SS>  
 <process *process*>  
 <severity *severity*>

**Release Information** Command introduced in Junos OS Release 11.2.

**Description** Display the alarms that are active on the device. Run this command when the CLI prompt indicates that a security alarm has been raised, as shown here:

```
[1 SECURITY ALARM] user@host#
```

**Options** **none**—Display all active alarms.

**detail**—(Optional) Display detailed output.

**alarm-id *id-number***—(Optional) Display the specified alarm.

**alarm-type [ *types* ]**—(Optional) Display the specified alarm type or a set of types.

You can specify one or more of the following alarm types:

- authentication
- cryptographic-self-test
- decryption-failures
- encryption-failures
- ike-phase1-failures
- ike-phase2-failures
- key-generation-self-test
- non-cryptographic-self-test
- policy
- replay-attacks

**newer-than YYYY-MM-DD.HH:MM:SS**—(Optional) Display active alarms that were raised after the specified date and time.

**older-than YYYY-MM-DD.HH:MM:SS**—(Optional) Display active alarms that were raised before the specified date and time.

**process *process***—(Optional) Display active alarms that were raised by the specified system process.

**severity severity**—(Optional) Display active alarms of the specified severity.

You can specify the following severity levels:

- **alert**
- **crit**
- **debug**
- **emerg**
- **err**
- **info**
- **notice**
- **warning**

**Required Privilege Level** security—To view this statement in the configuration.

**Related Documentation**

- *clear security alarms*
- *Example: Generating a Security Alarm in Response to Policy Violations*

**List of Sample Output**

[show security alarms on page 1555](#)  
[show security alarms detail on page 1555](#)  
[show security alarms alarm-id on page 1555](#)  
[show security alarms alarm-type authentication on page 1555](#)  
[show security alarms newer-than <time> on page 1556](#)  
[show security alarms older-than <time> on page 1556](#)  
[show security alarms process <process> on page 1556](#)  
[show security alarms severity <severity> on page 1556](#)

**Output Fields** [Table 184](#) lists the output fields for the **show security alarms** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used.

**Table 184: show security alarms**

| Field Name        | Field Description                                                                                        | Level of Output |
|-------------------|----------------------------------------------------------------------------------------------------------|-----------------|
| <b>ID</b>         | Identification number of the alarm.                                                                      | All levels      |
| <b>Alarm time</b> | Date and time the alarm was raised..                                                                     | All levels      |
| <b>Message</b>    | Information about the alarm, including the alarm type, username, IP address, and port number.            | All levels      |
| <b>Process</b>    | System process (For example, login or sshd) and process identification number associated with the alarm. | <b>detail</b>   |

Table 184: show security alarms (*continued*)

| Field Name | Field Description            | Level of Output |
|------------|------------------------------|-----------------|
| Severity   | Severity level of the alarm. | detail          |

## Sample Output

### show security alarms

```
[3 SECURITY ALARMS] user@router> show security alarms
```

```

ID      Alarm time      Message
1      2010-01-19 13:41:36 PST  SSHD_LOGIN_FAILED_LIMIT: Specified number of login
failures (1) for user 'user' reached from '10.17.0.1'
2      2010-01-19 13:41:52 PST  SSHD_LOGIN_FAILED_LIMIT: Specified number of login
failures (1) for user 'user' reached from '10.17.0.1'
3      2010-01-19 13:42:13 PST  SSHD_LOGIN_FAILED_LIMIT: Specified number of login
failures (1) for user 'user' reached from '10.17.0.1'

| <b>Output Fields</b>            | <a href="#">Table 185</a> lists the output fields for the <b>show security monitoring fpc <i>fpc-number</i></b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 185: show security monitoring fpc fpc-number Output Fields**

| Field Name             | Field Description                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FPC                    | Slot number in which the FPC is installed.                                                                                                                       |
| PIC                    | Slot number in which the PIC is installed.                                                                                                                       |
| CPU Utilization (%)    | Total percentage of CPU being used by the PIC's processors.                                                                                                      |
| Memory Utilization (%) | Percentage of heap space (dynamic memory) being used by the PIC's processor. If this number exceeds 80 percent, there might be a software problem (memory leak). |

Table 185: show security monitoring fpc fpc-number Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Current flow session</b>   | The current number of flow sessions. When SRX Series devices operate in packet mode, flow sessions will not be created and this field will remain zero. |
| <b>Max flow session</b>       | The maximum number of flow sessions allowed. This number will differ from one device to another.                                                        |
| <b>SPU current cp session</b> | The current number of cp sessions for the SPU (on SRX5600, and SRX5800 devices only).                                                                   |
| <b>SPU max cp session</b>     | The maximum number of cp sessions allowed for the SPU (on SRX5600, and SRX5800 devices only).                                                           |

## Sample Output

### show security monitoring fpc 0

```

user@host> show security monitoring fpc 0
FPC 0
  PIC 0
    CPU utilization      :    0 %
    Memory utilization   :   82 %
    Current flow session :    0
    Max flow session     :    0
    Current CP session   :    0
    Max CP session       : 12000000
  Session Creation Per Second (for last 96 seconds on average):    0
  PIC 1
    CPU utilization      :    0 %
    Memory utilization   :   54 %
    Current flow session :    0
    Max flow session     : 819200
    Current CP session   :    0
    Max CP session       :    0
  Session Creation Per Second (for last 96 seconds on average):    0

```

## Sample Output

### show security monitoring fpc 1

```

user@host> show security monitoring fpc 1
FPC 1
  PIC 0
    CPU utilization      :    0 %
    Memory utilization   :   21 %
    Current flow session :    0
    Max flow session     : 524288
    Current CP session   :    0
    Max CP session       : 1048576
  Session Creation Per Second (for last 96 seconds on average):    0

```

## Sample Output

### show security monitoring fpc 8

```
user@host> show security monitoring fpc 5
FPC 5
  PIC 0
    CPU utilization      :    0 %
    Memory utilization   :   64 %
    Current flow session :    0
    Max flow session     : 524288
    Current CP session   :    0
    Max CP session       : 2359296
  Session Creation Per Second (for last 96 seconds on average):    0
  PIC 1
    CPU utilization      :    0 %
    Memory utilization   :   65 %
    Current flow session :    0
    Max flow session     : 1048576
    Current CP session   :    0
    Max CP session       :    0
  Session Creation Per Second (for last 96 seconds on average):    0
```

## show security monitoring performance session

**Syntax** show security monitoring performance session

<fpc slot-number>

<pic slot-number>

**Release Information** Command introduced in Junos OS Release of 10.2.

**Description** Display the current session (total number of sessions at that time) for the last 60 seconds.

- Options**
- **fpc slot-number** — Display information about the FPC slot. Use this option to filter the output based on the slot number.
  - **pic slot-number** — Display information about existing PIMs or Mini-PIMs in a particular PIC slot. Use this option to filter the output based on PIC slot.

**NOTE:** The **fpc slot-number** and **pic slot-number** options are not available on SRX300, SRX320, and SRX340 devices.

## show security monitoring performance spu

**Syntax** show security monitoring performance spu

<fpc slot-number>

<pic slot-number>

**Release Information** Command introduced in Junos OS Release 10.2.

**Description** Display the services processing unit (SPU) percent utilization for all FPC slots over the last 60 seconds. Use this command to track the percent utilization statistics per second for the past 60 seconds for each FPC slot and PIC.

- Options**
- **fpc slot-number** — Display information about the FPC slot. Use this option to filter the output based on the slot number.
  - **pic slot-number** — Display information about existing PIMs or Mini-PIMs in a particular PIC slot. Use this option to filter the output based on PIC slot.

**NOTE:** The **fpc slot-number** and **pic slot-number** options are not available on SRX300, SRX320, or SRX340 devices or on vSRX instances.

| <b>Output Fields</b>            | Table 186 lists the output fields for the <b>show services ip-monitoring status</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                        |

**Table 186: show services ip-monitoring status Output Fields**

| Field Name              | Field Description                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Policy</b>           | Name of the policy configured.                                                                                                |
| <b>Probe Name</b>       | Name of the probe configured.                                                                                                 |
| <b>Address</b>          | Displays the configured target address.                                                                                       |
| <b>Status</b>           | Displays the status of the probe on the target address. If the status is PASS, then the target address is reached.            |
| <b>Route-Action</b>     | Displays route injection information configured for the policy and its failover status.                                       |
| <b>Route-Instance</b>   | Displays the routing instance of the route to be injected during failover.                                                    |
| <b>Route</b>            | Routing address of the route to be injected during failover.                                                                  |
| <b>Next-Hop</b>         | Specifies the next-hop address of the route to be injected during failover. P2P interfaces only.                              |
| <b>State</b>            | Display the state of the route injection action. If the state is APPLIED, then the ip-monitoring policy is in failover state. |
| <b>Interface Action</b> | Displays the interface action type as enable or disable.                                                                      |

Table 186: show services ip-monitoring status Output Fields (*continued*)

| Field Name    | Field Description                                     |
|---------------|-------------------------------------------------------|
| Policy Action | Displays the policy action type as enable or disable. |
| Admin State   | Displays the current admin state of the interface.    |
| Action Status | Displays the current action status of the interface.  |

## Sample Output

### show services ip-monitoring status

```
user@host> show services ip-monitoring status
```

```
Policy - policy1 (Non-preemptive. Status: FAIL)
```

```
RPM Probes:
```

| Probe name | Test Name | Address   | Status |
|------------|-----------|-----------|--------|
| probe_a    | a1        | 15.1.1.10 | FAIL   |
| probe_a    | a2        | 200.1.1.1 | FAIL   |

```
Route-Action:
```

| route-instance | route     | next-hop  | State   |
|----------------|-----------|-----------|---------|
| inet.0         | 200.1.1.0 | 150.1.1.1 | APPLIED |

```
Interface-Action:
```

| interface  | policy action | admin state | action status |
|------------|---------------|-------------|---------------|
| fe-0/0/5.2 | Enable        | UP          | FAILOVER      |
| fe-0/0/5.4 | Disable       | DOWN        | FAILOVER      |
| t1-1/0/0   | Enable        | UP          | FAILOVER      |
| d10        | Enable        | UP          | FAILOVER      |
| ge-0/0/1   | Enable        | UP          | FAILOVER      |

## Sample Output

### show services ip-monitoring status

In this example, the policy is in the failback state, and the no-preempt option is not configured.

```
user@host> show services ip-monitoring status
```

```
Policy - policy1 (Status: PASS)
```

```
RPM Probes:
```

| Probe name | Test Name | Address  | Status |
|------------|-----------|----------|--------|
| probe1     | a1        | 99.1.1.2 | PASS   |

```
Route-Action:
```

| route-instance | route    | next-hop   | state       |
|----------------|----------|------------|-------------|
| inet.0         | 99.1.1.0 | 12.12.12.2 | NOT-APPLIED |

```
Interface-Action:
```

| interface | policy action | admin state | action status |
|-----------|---------------|-------------|---------------|
|           |               |             |               |

|            |        |      |             |
|------------|--------|------|-------------|
| at-2/0/0   | Enable | DOWN | MARKED-DOWN |
| ge-0/0/2.2 | Enable | DOWN | MARKED-DOWN |
| ge-0/0/2.3 | Enable | DOWN | MARKED-DOWN |

## Sample Output

### show services ip-monitoring status

In this example, the policy is in the failover state, and the primary is restored. The no-preempt option is configured.

```
user@host> show services ip-monitoring status
```

Policy - policy1 (Non-preemptive. Status: FAILOVER-NO-PREEMPT)

RPM Probes:

| Probe name | Test Name | Address  | Status |
|------------|-----------|----------|--------|
| probe1     | a1        | 99.1.1.2 | PASS   |

Route-Action:

| route-instance | route    | next-hop   | state   |
|----------------|----------|------------|---------|
| inet.0         | 99.1.1.0 | 12.12.12.2 | APPLIED |

Interface-Action:

| interface  | policy action | admin state | action status |
|------------|---------------|-------------|---------------|
| at-2/0/0   | Enable        | UP          | FAILOVER      |
| ge-0/0/2.2 | Enable        | UP          | FAILOVER      |
| ge-0/0/2.3 | Enable        | UP          | FAILOVER      |

## Sample Output

### show services ip-monitoring status

When the probe succeeds and the policy is not applied, the output is as follows:

```
user@host> show services ip-monitoring status
```

Policy payment (Status: PASS)

RPM Probes:

| Probe name           | Test Name | Address | Status |
|----------------------|-----------|---------|--------|
| Probe-Payment-Server | paysvr    | 9.9.9.2 | PASS   |

Route-Action:

| route-instance | route      | next-hop   | state       |
|----------------|------------|------------|-------------|
| inet.0         | 9.9.9.0/24 | e1-6/0/0.0 | NOT-APPLIED |

## Sample Output

### show services ip-monitoring status

When the probe fails and the policy is applied, the output is as follows:

```
user@host> show services ip-monitoring status
```

Policy payment (Status: FAIL)

RPM Probes:

| Probe name           | Test Name | Address | Status |
|----------------------|-----------|---------|--------|
| Probe-Payment-Server | paysvr    | 9.9.9.2 | FAIL   |

Route-Action:

| route-instance | route | next-hop | state |
|----------------|-------|----------|-------|
|----------------|-------|----------|-------|

```
-----  
inet.0          9.9.9.0/24          e1-6/0/0.0      APPLIED
```

## show services rpm probe-results (View)

| <b>Output Fields</b>            | <a href="#">Table 187</a> lists the output fields for the <b>show services rpm probe-results</b> command. Output fields are listed in the approximate order in which they appear.                                                                          |

**Table 187: show services rpm probe-results Output Fields**

| Field Name                  | Field Description                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Owner</b>                | Owner name. When you configure the probe owner statement at the <b>[edit services rpm]</b> hierarchy level, this field displays the configured owner name. When you configure BGP neighbor discovery through RPM, the output for this field is <b>Rpm-Bgp-Owner</b> .                                                                                                     |
| <b>Test</b>                 | Name of a test representing a collection of probes. When you configure the test test-name statement at the <b>[edit services rpm probe owner]</b> hierarchy level, the field displays the configured test name. When you configure BGP neighbor discovery through RPM, the output for this field is <b>Rpm-BGP-Test-<i>n</i></b> , where <i>n</i> is a cumulative number. |
| <b>Target address</b>       | Destination IPv4 address used for the probes.                                                                                                                                                                                                                                                                                                                             |
| <b>Target inet6-address</b> | Destination IPv6 address used for the probes. This field is displayed when the probes are sent to the configured IPv6 targets or RPM servers.                                                                                                                                                                                                                             |
| <b>Source address</b>       | Source address used for the probes.                                                                                                                                                                                                                                                                                                                                       |
| <b>Probe type</b>           | Protocol configured on the receiving probe server: <b>http-get</b> , <b>http-metadata-get</b> , <b>icmp-ping</b> , <b>icmp6-ping</b> , <b>icmp-ping-timestamp</b> , <b>tcp-ping</b> , <b>udp-ping</b> , or <b>udp-ping-timestamp</b> .                                                                                                                                    |
| <b>Test size</b>            | Number of probes within a test.                                                                                                                                                                                                                                                                                                                                           |

Table 187: show services rpm probe-results Output Fields (*continued*)

| Field Name                       | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Routing Instance Name</b>     | <p>(BGP neighbor discovery) Name of the configured (if any) routing instance, logical system name, or both, in which the probe is configured:</p> <ul style="list-style-type: none"> <li>When a routing instance is defined within a logical system, the logical system name is followed by the routing instance name. A slash ( / ) is used to separate the two entities. For example, if the routing instance called <b>R1</b> is configured within the logical system called <b>LS</b>, the name in the output field is <b>LS/R1</b>.</li> <li>When a routing instance is configured but the default logical system is used, the name in the output field is the name of the routing instance.</li> <li>When a logical system is configured but the default routing instance is used, the name in the output field is the name of the logical system followed by <b>default</b>. A slash ( / ) is used to separate the two entities. For example, <b>LS/default</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Probe results</b>             | <p>Raw measurement of a particular probe sample done by a remote host. This data is provided separately from the calculated results. The following information is contained in the raw measurement:</p> <ul style="list-style-type: none"> <li><b>Response received</b>—Timestamp when the probe result was determined.</li> <li><b>Client and server hardware timestamps</b>—If timestamps are configured, an entry appears at this point.</li> <li><b>Rtt</b>—Average ping round-trip time (RTT), in microseconds.</li> <li><b>Egress jitter</b>—Egress jitter, in microseconds.</li> <li><b>Ingress jitter</b>—Ingress jitter, in microseconds.</li> <li><b>Round trip jitter</b>—Round-trip jitter, in microseconds.</li> <li><b>Egress interarrival jitter</b>—Egress interarrival jitter, in microseconds.</li> <li><b>Ingress interarrival jitter</b>—Ingress interarrival jitter, in microseconds.</li> <li><b>Round trip interarrival jitter</b>—Round-trip interarrival jitter, in microseconds.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Results over current test</b> | <p>Probes are grouped into tests, and the statistics are calculated for each test. If a test contains 10 probes, the average, minimum, and maximum results are calculated from the results of those 10 probes. If the command is issued while the test is in progress, the statistics use information from the completed probes.</p> <ul style="list-style-type: none"> <li><b>Probes sent</b>—Number of probes sent within the current test.</li> <li><b>Probes received</b>—Number of probe responses received within the current test.</li> <li><b>Loss percentage</b>—Percentage of lost probes for the current test.</li> <li><b>Measurement</b>—Measurement type. Possible values are round-trip time, positive round-trip jitter, negative round-trip jitter, egress time, positive egress jitter, negative egress jitter, ingress time, positive ingress jitter, negative ingress jitter, and, for the probe type <b>icmp-ping-timestamp</b>, the egress delay and ingress delay.</li> </ul> <p>For each measurement type, the following individual calculated results are provided:</p> <ul style="list-style-type: none"> <li><b>Samples</b>—Number of probes.</li> <li><b>Minimum</b>—Minimum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Maximum</b>—Maximum RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Average</b>—Average RTT, ingress delay, or egress delay measured over the course of the current test.</li> <li><b>Peak to peak</b>—Peak-to-peak difference, in microseconds.</li> <li><b>Stddev</b>—Standard deviation, in microseconds.</li> <li><b>Sum</b>—Statistical sum.</li> </ul> |

Table 187: show services rpm probe-results Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Sample Output

### show services rpm probe-results (IPv4 Targets)

```
user@host> show services rpm probe-results
```

```
Owner: probe_a, Test: a1
Target address: 200.1.1.2, Probe type: icmp-ping
Destination interface name: ge-0/0/6.0
Test size: 10 probes
Probe results:
  Response received, Sat Jul 30 11:52:21 2011, No hardware timestamps
  Rtt: 1897 usec
Results over current test:
  Probes sent: 8, Probes received: 8, Loss percentage: 0
  Measurement: Round trip time
    Samples: 8, Minimum: 1897 usec, Maximum: 7205 usec, Average: 2848 usec,
    Peak to peak: 5308 usec, Stddev: 1715 usec, Sum: 22783 usec
Results over last test:
  Probes sent: 10, Probes received: 10, Loss percentage: 0
  Test completed on Sat Jul 30 11:52:01 2011
  Measurement: Round trip time
    Samples: 10, Minimum: 1907 usec, Maximum: 8201 usec, Average: 3111 usec,
    Peak to peak: 6294 usec, Stddev: 2306 usec, Sum: 31106 usec
Results over all tests:
  Probes sent: 598, Probes received: 327, Loss percentage: 45
  Measurement: Round trip time
    Samples: 327, Minimum: 1878 usec, Maximum: 133729 usec,
    Average: 3304 usec, Peak to peak: 131851 usec, Stddev: 7561 usec,
    Sum: 1080434 usec
```

### show services rpm probe-results (IPv6 Targets)

```
user@host> show services rpm probe-results
```

```
Owner: p, Test: t1
Target inet6-address: 2001:db8:0:1:2a0:a502:0:1da,
Target Port : 34567 Test size: 1000000 probes
Probe results:
  Response received, Mon May 18 10:48:07 2015, No hardware timestamps
  Rtt: 236 usec, Round trip jitter: -10 usec, Round trip interarrival jitter:
484 usec
Results over current test:
  Probes sent: 10, Probes received: 10, Loss percentage: 0
  Measurement: Round trip time
    Samples: 10, Minimum: 231 usec, Maximum: 298 usec, Average: 268 usec,
Peak to peak: 67 usec, Stddev: 24 usec, Sum: 2682 usec
  Measurement: Positive round trip jitter
    Samples: 3, Minimum: 15 usec, Maximum: 1841 usec, Average: 750 usec, Peak
to peak: 1826 usec, Stddev: 787 usec, Sum: 2251 usec
  Measurement: Negative round trip jitter
    Samples: 7, Minimum: 10 usec, Maximum: 1244 usec, Average: 709 usec, Peak
to peak: 1234 usec, Stddev: 466 usec, Sum: 4961 usec
Results over last test:
  Probes sent: 10, Probes received: 10, Loss percentage: 0
  Test completed on Mon Dec 16 10:48:07 2013
  Measurement: Round trip time
    Samples: 10, Minimum: 231 usec, Maximum: 298 usec, Average: 268 usec,
Peak to peak: 67 usec, Stddev: 24 usec, Sum: 2682 usec
  Measurement: Positive round trip jitter
```

Samples: 3, Minimum: 15 usec, Maximum: 1841 usec, Average: 750 usec, Peak to peak: 1826 usec, Stddev: 787 usec, Sum: 2251 usec  
Measurement: Negative round trip jitter  
Samples: 7, Minimum: 10 usec, Maximum: 1244 usec, Average: 709 usec, Peak to peak: 1234 usec, Stddev: 466 usec, Sum: 4961 usec  
Results over all tests(From start of current control session):  
Probes sent: 490, Probes received: 488, Loss percentage: 0  
Measurement: Round trip time  
Samples: 488, Minimum: 231 usec, Maximum: 306 usec, Average: 270 usec, Peak to peak: 75 usec, Stddev: 16 usec, Sum: 131586 usec  
Measurement: Positive round trip jitter  
Samples: 254, Minimum: 0 usec, Maximum: 10151 usec, Average: 157 usec, Peak to peak: 10151 usec, Stddev: 873 usec, Sum: 39817 usec  
Measurement: Negative round trip jitter  
Samples: 233, Minimum: 1 usec, Maximum: 10170 usec, Average: 171 usec, Peak to peak: 10169 usec, Stddev: 888 usec, Sum: 39889 usec

## show system alarms

---

|                                 |                                                                                                                                                                                                                                                              |

**Release Information**   Command introduced before Junos OS Release 7.4.  
                   Command introduced in Junos OS Release 9.0 for EX Series switches.  
                   **mpls** option introduced in Junos OS Release 9.2.  
                   **propagate-ttl** option introduced in Junos OS Release 12.1.  
                   Command introduced in Junos OS Release 11.1 for the QFX Series.

**Description**   Display the route that packets take to a specified network host. Use **traceroute** as a debugging tool to locate points of failure in a network.

**Options**   **host**—IP address or name of remote host.

**as-number-lookup**—(Optional) Display the autonomous system (AS) number of each intermediate hop on the path from the host to the destination.

**bypass-routing**—(Optional) Bypass the normal routing tables and send requests directly to a system on an attached network. If the system is not on a directly attached

network, an error is returned. Use this option to display a route to a local system through an interface that has no route through it.

**clns**—(Optional) Trace the route belonging to Connectionless Network Service (CLNS).

**gateway address**—(Optional) Address of a router or switch through which the route transits.

**inet | inet6**—(Optional) Trace the route belonging to IPv4 or IPv6, respectively.

**interface *interface-name***—(Optional) Name of the interface over which to send packets.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**monitor *host***—(Optional) Display real-time monitoring information for the specified host.

**monitor *host***—(Optional) Perform this operation to display real-time monitoring information.

**monitor *host***—(Optional) Perform this operation to display real-time monitoring information.

**mpls (ldp *FEC address* | rsvp *label-switched-path name*)**—(Optional).

**no-resolve**—(Optional) Do not attempt to determine the hostname that corresponds to the IP address.

**propagate-ttl**—(Optional) On the PE router, use this option to view locally-generated Routing Engine transit traffic. This is applicable for MPLS L3VPN traffic only. Use for troubleshooting, when you want to view hop-by-hop information from the local provider router to the remote provider router, when TTL decrementing is disabled on the core network using the **no-propagate-ttl** configuration statement.

**NOTE:** Using **propagate-ttl** with **traceroute** on the CE router does not show hop-by-hop information.

**routing-instance *routing-instance-name***—(Optional) Name of the routing instance for the traceroute attempt.

**source *source-address***—(Optional) Source address of the outgoing traceroute packets.

**tos *value***—(Optional) Value to include in the IP type-of-service (ToS) field. The range of values is 0 through 255.

**ttl *value***—(Optional) Maximum time-to-live value to include in the traceroute request. The range of values is 0 through 128.

**wait *seconds***—(Optional) Maximum time to wait for a response to the traceroute request.

**Required Privilege Level** network

**List of Sample Output** [traceroute on page 1578](#)  
[traceroute as-number-lookup host on page 1578](#)  
[traceroute no-resolve on page 1578](#)  
[traceroute propagate-ttl on page 1579](#)  
[traceroute \(Between CE Routers, Layer 3 VPN\) on page 1579](#)  
[traceroute \(Through an MPLS LSP\) on page 1579](#)

**Output Fields** [Table 188](#) describes the output fields for the **traceroute** command. Output fields are listed in the approximate order in which they appear.

**Table 188: traceroute Output Fields**

| Field Name             | Field Description                                             |
|------------------------|---------------------------------------------------------------|
| <b>traceroute to</b>   | IP address of the receiver.                                   |
| <b>hops max</b>        | Maximum number of hops allowed.                               |
| <b>byte packets</b>    | Size of packets being sent.                                   |
| <i>number-of-hops</i>  | Number of hops from the source to the named router or switch. |
| <i>router-name</i>     | Name of the router or switch for this hop.                    |
| <i>address</i>         | Address of the router or switch for this hop.                 |
| <b>Round trip time</b> | Average round-trip time, in milliseconds (ms).                |

## Sample Output

### traceroute

```
user@host> traceroute santacruz
traceroute to host1.example.com (10.156.169.254), 30 hops max, 40 byte packets
 1 blue23 (10.168.1.254) 2.370 ms 2.853 ms 0.367 ms
 2 red14 (10.168.255.250) 0.778 ms 2.937 ms 0.446 ms
 3 yellow (10.156.169.254) 7.737 ms 89.905 ms 0.834 ms
```

### traceroute as-number-lookup host

```
user@host> traceroute as-number-lookup 10.100.1.1
traceroute to 10.100.1.1 (10.100.1.1), 30 hops max, 40 byte packets
 1 10.39.1.1 (10.39.1.1) 0.779 ms 0.728 ms 0.562 ms
 2 10.39.1.6 (10.39.1.6) [AS 32] 0.657 ms 0.611 ms 0.617 ms
 3 10.100.1.1 (10.100.1.1) [AS 10, 40, 50] 0.880 ms 0.808 ms 0.774 ms
```

### traceroute no-resolve

```
user@host> traceroute santacruz no-resolve
```

```
traceroute to host1.example.com (10.156.169.254), 30 hops max, 40 byte packets
```

```
1 10.168.1.254 0.458 ms 0.370 ms 0.365 ms
2 10.168.255.250 0.474 ms 0.450 ms 0.444 ms
3 10.156.169.254 0.931 ms 0.876 ms 0.862 ms
```

### traceroute propogate-ttl

```
user@host> traceroute propogate-ttl 100.200.2.2 routing-instance VPN-A
traceroute to 100.200.2.2 (100.200.2.2) from 1.1.0.2, 30 hops max, 40 byte packets
```

```
1 1.2.0.2 (1.2.0.2) 2.456 ms 1.753 ms 1.672 ms
   MPLS Label=299776 CoS=0 TTL=1 S=0
   MPLS Label=299792 CoS=0 TTL=1 S=1
2 1.3.0.2 (1.3.0.2) 1.213 ms 1.225 ms 1.166 ms
   MPLS Label=299792 CoS=0 TTL=1 S=1
3 100.200.2.2 (100.200.2.2) 1.422 ms 1.521 ms 1.443 ms
```

### traceroute (Between CE Routers, Layer 3 VPN)

```
user@host> traceroute vpn09
traceroute to host2.example.com (10.255.14.179), 30 hops max, 40
byte packets
1 10.39.10.21 (10.39.10.21) 0.598 ms 0.500 ms 0.461 ms
2 10.39.1.13 (10.39.1.13) 0.796 ms 0.775 ms 0.806 ms
   MPLS Label=100006 CoS=0 TTL=1 S=1
3 host2.example.com (10.255.14.179) 0.783 ms 0.716 ms 0.686
```

### traceroute (Through an MPLS LSP)

```
user@host> traceroute mpls1
traceroute to 10.168.1.224 (10.168.1.224), 30 hops max, 40 byte packets
1 mpls1-sr0.company.net (10.168.200.101) 0.555 ms 0.393 ms 0.367 ms
   MPLS Label=1024 CoS=0 TTL=1
2 mpls5-lo0.company.net (10.168.1.224) 0.420 ms 0.394 ms 0.401 ms
```

- [Junos OS Default System Log Settings on page 1586](#)
- [Junos OS Platform-Specific Default System Log Messages on page 1587](#)

## Junos OS System Log Overview

The Junos OS generates system log messages (also called *syslog messages*) to record events that occur on the device, including the following:

- Routine operations, such as creation of an Open Shortest Path First (OSPF) protocol adjacency or a user login to the configuration database
- Failure and error conditions, such as failure to access a configuration file or unexpected closure of a connection to a peer process
- Emergency or critical conditions, such as router power-down due to excessive temperature

Each system log message identifies the Junos OS process that generated the message and briefly describes the operation or error that occurred. For detailed information about specific system log messages, see the *Junos OS System Log Reference for Security Devices*.

**NOTE:** This topic describes system log messages for Junos OS processes and libraries and not the system logging services on a Physical Interface Card (PIC) such as the Adaptive Services PIC.

## Junos OS System Logging Facilities and Message Severity Levels

Table 189 lists the Junos OS system logging facilities that you can specify in configuration statements at the `[edit system syslog]` hierarchy level.

**Table 189: Junos OS System Logging Facilities**

| Facility                    | Type of Event or Error                                                                                                                            |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>any</b>                  | All (messages from all facilities)                                                                                                                |
| <b>authorization</b>        | Authentication and authorization attempts                                                                                                         |
| <b>change-log</b>           | Changes to the Junos OS configuration                                                                                                             |
| <b>conflict-log</b>         | Specified configuration is invalid on the router type                                                                                             |
| <b>daemon</b>               | Actions performed or errors encountered by system processes                                                                                       |
| <b>dfc</b>                  | Events related to dynamic flow capture                                                                                                            |
| <b>firewall</b>             | Packet filtering actions performed by a firewall filter                                                                                           |
| <b>ftp</b>                  | Actions performed or errors encountered by the FTP process                                                                                        |
| <b>interactive-commands</b> | Commands issued at the Junos OS command-line interface (CLI) prompt or by a client application such as a Junos XML protocol or NETCONF XML client |
| <b>kernel</b>               | Actions performed or errors encountered by the Junos OS kernel                                                                                    |
| <b>pfe</b>                  | Actions performed or errors encountered by the Packet Forwarding Engine                                                                           |
| <b>user</b>                 | Actions performed or errors encountered by user-space processes                                                                                   |

Table 190 lists the severity levels that you can specify in configuration statements at the `[edit system syslog]` hierarchy level. The levels from **emergency** through **info** are in order from highest severity (greatest effect on functioning) to lowest.

Unlike the other severity levels, the **none** level disables logging of a facility instead of indicating how seriously a triggering event affects routing functions. For more information, see “Disabling the System Logging of a Facility” on page 1597.

**Table 190: System Log Message Severity Levels**

| Severity Level | Description                                                  |
|----------------|--------------------------------------------------------------|
| <b>any</b>     | Includes all severity levels                                 |
| <b>none</b>    | Disables logging of the associated facility to a destination |

Table 190: System Log Message Severity Levels (*continued*)

| Severity Level   | Description                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>emergency</b> | System panic or other condition that causes the router to stop functioning                                              |
| <b>alert</b>     | Conditions that require immediate correction, such as a corrupted system database                                       |
| <b>critical</b>  | Critical conditions, such as hard errors                                                                                |
| <b>error</b>     | Error conditions that generally have less serious consequences than errors at the emergency, alert, and critical levels |
| <b>warning</b>   | Conditions that warrant monitoring                                                                                      |
| <b>notice</b>    | Conditions that are not errors but might warrant special handling                                                       |
| <b>info</b>      | Events or nonerror conditions of interest                                                                               |

- [Junos OS System Log Overview on page 1583](#)
- [Junos OS Platform-Specific Default System Log Messages on page 1587](#)

## Junos OS Platform-Specific Default System Log Messages

The following messages are generated by default on specific routers. To view any of these types of messages, you must configure at least one destination for messages as described in “[Junos OS Minimum System Logging Configuration](#)” on page 1585.

- To log the kernel process message on an M Series, MX Series, or T Series router, include the **kernel info** statement at the appropriate hierarchy level:

```
[edit system syslog]
(console | file filename | host destination | user username) {
  kernel info;
}
```

- On a routing matrix composed of a TX Matrix router and T640 routers, the master Routing Engine on each T640 router forwards all messages with a severity of **info** and higher to the master Routing Engine on the TX Matrix router. This is equivalent to the following configuration statement included on the TX Matrix router:

```
[edit system syslog]
host scc-master {
  any info;
}
```

- Likewise, on a routing matrix composed of a TX Matrix Plus router with connected T1600 or T4000 routers, the master Routing Engine on each T1600 or T4000 LCC forwards to the master Routing Engine on the TX Matrix Plus router all messages with a severity of **info** and higher. This is equivalent to the following configuration statement included on the TX Matrix Plus router:

**NOTE:** From the perspective of the user interface, the routing matrix appears as a single router. The TX Matrix Plus router controls all the T1600 or T4000 routers connected to it in the routing matrix.

```
[edit system syslog]
host sfc0-master {
```

```
    any info;  
}
```

### Specifying the Facility and Severity of Messages to Include in the Log

Each system log message belongs to a *facility*, which is a group of messages that are either generated by the same software process or concern a similar condition or activity (such as authentication attempts). Each message is also preassigned a *severity level*, which indicates how seriously the triggering event affects router functions.

When you configure logging for a facility and destination, you specify a severity level for each facility. Messages from the facility that are rated at that level or higher are logged to the destination:

```
[edit system syslog]
(console | file filename | host destination | user username) {
  facility severity;
```

```
}
```

**Related Documentation**

- [Junos OS System Logging Facilities and Message Severity Levels on page 1584](#)

- [Examples: Configuring System Logging on page 1597](#)

## Directing System Log Messages to a Log File

To direct system log messages to a file in the `/var/log` directory of the local Routing Engine, include the **file** statement at the **[edit system syslog]** hierarchy level:

```
[edit system syslog]
file filename {
  facility severity;
  archive <archive-sites (ftp-url <password password>)> <files number> <size size>
    <start-time "YYYY-MM-DD.hh:mm"> <transfer-interval minutes> <world-readable |
    no-world-readable>;
  explicit-priority;
  match "regular-expression";
  structured-data {
    brief;
  }
}
```

For the list of facilities and severity levels, see *Specifying the Facility and Severity of Messages to Include in the Log*.

To prevent log files from growing too large, the Junos OS system logging utility by default writes messages to a sequence of files of a defined size. By including the **archive** statement, you can configure the number of files, their maximum size, and who can read them, either for all log files or for a certain log file. For more information, see *Specifying Log File Size, Number, and Archiving Properties*.

For information about the following statements, see the indicated sections:

- **explicit-priority**—See “Including Priority Information in System Log Messages” on page 1592
- **match**—See “Using Regular Expressions to Refine the Set of Logged Messages” on page 1595
- **structured-data**—See “Logging Messages in Structured-Data Format” on page 1591

**Related Documentation**

- [Single-Chassis System Logging Configuration Overview](#)
- [Overview of Junos OS System Log Messages](#)
- [Logging Messages in Structured-Data Format on page 1591](#)
- [Examples: Configuring System Logging on page 1597](#)

## Logging Messages in Structured-Data Format

You can log messages to a file in structured-data format instead of the standard Junos OS format. Structured-data format provides more information without adding significant length, and makes it easier for automated applications to extract information from a message.

The structured-data format complies with Internet draft draft-ietf-syslog-protocol-23, *The syslog Protocol*, which is at <http://tools.ietf.org/html/draft-ietf-syslog-protocol-23>. The draft establishes a standard message format regardless of the source or transport protocol for logged messages.

To output messages to a file in structured-data format, include the **structured-data** statement at the **[edit system syslog file filename]** hierarchy level:

```
[edit system syslog file filename]
facility severity;
structured-data {
  brief;
}
```

The optional **brief** statement suppresses the English-language text that appears by default at the end of a message to describe the error or event. For information about the fields in a structured-data format message, see the *Junos OS System Log Reference for Security Devices*.

The structured format is used for all messages logged to the file that are generated by a Junos OS process or software library.

**NOTE:** If you include either or both of the **explicit-priority** and **time-format** statements along with the **structured-data** statement, they are ignored. These statements apply to the standard Junos OS system log format, not to structured-data format.

### Related Documentation

- *Single-Chassis System Logging Configuration Overview*
- [Examples: Configuring System Logging on page 1597](#)

## Directing System Log Messages to a User Terminal

To direct system log messages to the terminal session of one or more specific users (or all users) when they are logged in to the local Routing Engine, include the **user** statement at the **[edit system syslog]** hierarchy level:

```
[edit system syslog]
user (username | *) {
  facility severity;
  match "regular-expression";
}
```

Specify one or more Junos OS usernames, separating multiple values with spaces, or use the asterisk (\*) to indicate all users who are logged in to the local Routing Engine.

For the list of logging facilities and severity levels, see *Specifying the Facility and Severity of Messages to Include in the Log*. For information about the **match** statement, see [“Using Regular Expressions to Refine the Set of Logged Messages” on page 1595](#).

- Related Documentation**
- [Single-Chassis System Logging Configuration Overview](#)
  - [Examples: Configuring System Logging on page 1597](#)

## Directing System Log Messages to the Console

To direct system log messages to the console of the local Routing Engine, include the **console** statement at the **[edit system syslog]** hierarchy level:

```
[edit system syslog]
console {
  facility severity;
}
```

For the list of logging facilities and severity levels, see *Specifying the Facility and Severity of Messages to Include in the Log*.

- Related Documentation**
- [Single-Chassis System Logging Configuration Overview](#)
  - [Examples: Configuring System Logging on page 1597](#)

## Including Priority Information in System Log Messages

The facility and severity level of a message are together referred to as its *priority*. By default, messages logged in the standard Junos OS format do not include information about priority. To include priority information in standard-format messages directed to a file, include the **explicit-priority** statement at the **[edit system syslog file filename]** hierarchy level:

```
[edit system syslog file filename]
facility severity;
explicit-priority;
```

**NOTE:** Messages logged in structured-data format include priority information by default. If you include the **structured-data** statement at the **[edit system syslog file filename]** hierarchy level along with the **explicit-priority** statement, the **explicit-priority** statement is ignored and messages are logged in structured-data format.

For information about the **structured-data** statement, see [“Logging Messages in Structured-Data Format” on page 1591](#). For information about the contents of a structured-data message, see the *Junos OS System Log Reference for Security Devices*.

To include priority information in messages directed to a remote machine or the other Routing Engine, include the **explicit-priority** statement at the **[edit system syslog host (*hostname* | other-routing-engine)]** hierarchy level:

```
[edit system syslog host (hostname | other-routing-engine)]
  facility severity;
  explicit-priority;
```

**NOTE:** The **other-routing-engine** option does not apply to the QFX Series.

The priority recorded in a message always indicates the original, local facility name. If the **facility-override** statement is included for messages directed to a remote destination, the Junos OS system logging utility still uses the alternative facility name for the messages themselves when directing them to the remote destination. For more information, see *Changing the Alternative Facility Name for Remote System Log Messages*.

When the **explicit-priority** statement is included, the Junos OS logging utility prepends codes for the facility name and severity level to the message tag name, if the message has one:

```
FACILITY-severity[-TAG]
```

(The tag is a unique identifier assigned to some Junos OS system log messages.)

In the following example, the **CHASSISD\_PARSE\_COMPLETE** message belongs to the **daemon** facility and is assigned severity **info** (6):

```
Aug 21 12:36:30 router1 chassisd[522]: %DAEMON-6-CHASSISD_PARSE_COMPLETE:
  Using new configuration
```

When the **explicit-priority** statement is not included, the priority does not appear in the message:

```
Aug 21 12:36:30 router1 chassisd[522]: CHASSISD_PARSE_COMPLETE: Using new
  configuration
```

For more information about message formatting, see the *Junos OS System Log Reference for Security Devices*.

## System Log Default Facilities for Messages Directed to a Remote Destination

[Table 193](#) lists the default alternative facility name next to the Junos OS-specific facility name for which it is used. For facilities that are not listed, the default alternative name is the same as the local facility name.

**Table 193: Default Facilities for Messages Directed to a Remote Destination**

| Junos OS—specific Local Facility | Default Facility When Directed to Remote Destination |
|----------------------------------|------------------------------------------------------|
| change-log                       | local6                                               |
| conflict-log                     | local5                                               |
| dfc                              | local1                                               |
| firewall                         | local3                                               |
| interactive-commands             | local7                                               |
| pfe                              | local4                                               |

**Related Documentation**

- *Single-Chassis System Logging Configuration Overview*

**Including the Year or Millisecond in Timestamps**

By default, the timestamp recorded in a standard-format system log message specifies the month, date, hour, minute, and second when the message was logged, as in the following example:

```
Aug 21 12:36:30
```

To include the year, the millisecond, or both in the timestamp, include the **time-format** statement at the **[edit system syslog]** hierarchy level:

```
[edit system syslog]
time-format (year | millisecond | year millisecond);
```

However, the timestamp for traceoption messages is specified in milliseconds by default, and is independent of the **[edit system syslog time-format]** statement.

The modified timestamp is used in messages directed to each destination configured by a **file**, **console**, or **user** statement at the **[edit system syslog]** hierarchy level, but not to destinations configured by a **host** statement.

The following example illustrates the format for a timestamp that includes both the millisecond (401) and the year (2006):

```
Aug 21 12:36:30.401 2006
```

**NOTE:** Messages logged in structured-data format include the year and millisecond by default. If you include the structured-data statement at the [edit system syslog file *filename*] hierarchy level along with the time-format statement, the time-format statement is ignored and messages are logged in structured-data format.

For information about the structured-data statement, see “[Logging Messages in Structured-Data Format](#)” on page 1591. For information about the contents of a structured-data message, see the *Junos OS System Log Reference for Security Devices*.

- [Examples: Configuring System Logging on page 1597](#)

## Using Regular Expressions to Refine the Set of Logged Messages

The predefined facilities group together related messages, but you can also use regular expression matching to specify more exactly which messages from a facility are logged to a file, a user terminal, or a remote destination.

To specify the text string that must (or must not) appear in a message for the message to be logged to a destination, include the **match** statement and specify the regular expression which the text string must match:

```
match "regular-expression";
```

You can include this statement at the following hierarchy levels:

- [edit system syslog file *filename*] (for a file)
- [edit system syslog user (*username* | \*)] (for a specific user session or for all user sessions on a terminal)
- [edit system syslog host (*hostname* | other-routing-engine)] (for a remote destination)

In specifying the regular expression, use the notation defined in POSIX Standard 1003.2 for extended (modern) UNIX regular expressions. Explaining regular expression syntax is beyond the scope of this document, but POSIX standards are available from the Institute of Electrical and Electronics Engineers (IEEE, <http://www.ieee.org>).

Table 194 specifies which character or characters are matched by some of the regular expression operators that you can use in the match statement. In the descriptions, the term *term* refers to either a single alphanumeric character or a set of characters enclosed in square brackets, parentheses, or braces.

**NOTE:** The match statement is not case-sensitive.

Table 194: Regular Expression Operators for the match Statement

| Operator                     | Matches                                                                                                                                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| . (period)                   | One instance of any character except the space.                                                                                                                                                                                      |
| * (asterisk)                 | Zero or more instances of the immediately preceding term.                                                                                                                                                                            |
| + (plus sign)                | One or more instances of the immediately preceding term.                                                                                                                                                                             |
| ? (question mark)            | Zero or one instance of the immediately preceding term.                                                                                                                                                                              |
| (pipe)                       | One of the terms that appears on either side of the pipe operator.                                                                                                                                                                   |
| ! (exclamation point)        | Any string except the one specified by the expression, when the exclamation point appears at the start of the expression. Use of the exclamation point is Junos OS-specific.                                                         |
| ^ (caret)                    | Start of a line, when the caret appears outside square brackets.<br><br>One instance of any character that does not follow it within square brackets, when the caret is the first character inside square brackets.                  |
| \$ (dollar sign)             | End of a line.                                                                                                                                                                                                                       |
| [ ] (paired square brackets) | One instance of one of the enclosed alphanumeric characters. To indicate a range of characters, use a hyphen ( - ) to separate the beginning and ending characters of the range. For example, [a-z0-9] matches any letter or number. |
| ( ) (paired parentheses)     | One instance of the evaluated value of the enclosed term. Parentheses are used to indicate the order of evaluation in the regular expression.                                                                                        |

#### Using Regular Expressions

Filter messages that belong to the **interactive-commands** facility, directing those that include the string **configure** to the terminal of the root user:

```
[edit system syslog]
user root {
  interactive-commands any;
  match ".*configure.*";
}
```

Messages like the following appear on the **root** user's terminal when a user issues a **configure** command to enter configuration mode:

```
timestamp router-name mgd[PID]: UI_CMDLINE_READ_LINE: User 'user', command
'configure private'
```

Filter messages that belong to the **daemon** facility and have a severity of **error** or higher, directing them to the file **/var/log/process-errors**. Omit messages generated by the SNMP process (snmpd), instead directing them to the file **/var/log/snmpd-errors**:

```
[edit system syslog]
file process-errors {
  daemon error;
```

```

match "!(.*snmpd.*)";
}
file snmpd-errors {
  daemon error;
  match ".*snmpd.*";
}

```

- Related Documentation**
- *Single-Chassis System Logging Configuration Overview*
  - [Examples: Configuring System Logging on page 1597](#)

## Disabling the System Logging of a Facility

To disable the logging of messages that belong to a particular facility, include the **facility none** statement in the configuration. This statement is useful when, for example, you want to log messages that have the same severity level and belong to all but a few facilities. Instead of including a statement for each facility you want to log, you can include the **any severity** statement and then a **facility none** statement for each facility that you do not want to log. For example, the following logs all messages at the **error** level or higher to the console, except for messages from the **daemon** and **kernel** facilities. Messages from those facilities are logged to the file **>/var/log/internals** instead:

```

[edit system syslog]
console {
  any error;
  daemon none;
  kernel none;
}
file internals {
  daemon info;
  kernel info;
}

```

- Related Documentation**
- *Single-Chassis System Logging Configuration Overview*

## Examples: Configuring System Logging

The following example shows how to configure the logging of messages about all commands entered by users at the CLI prompt or invoked by client applications such as Junos OS XML protocol or NETCONF client applications, and all authentication or authorization attempts, both to the file **cli-commands** and to the terminal of any user who is logged in:

```

[edit system]
syslog {
  file cli-commands {
    interactive-commands info;
    authorization info;
  }
  user * {
    interactive-commands info;
    authorization info;
  }
}

```

```
}
```

The following example shows how to configure the logging of all changes in the state of alarms to the file `/var/log/alarms`:

```
[edit system]
syslog {
  file alarms {
    kernel warning;
  }
}
```

The following example shows how to configure the handling of messages of various types, as described in the comments. Information is logged to two files, to the terminal of user `alex`, to a remote machine, and to the console:

```
[edit system]
syslog {
  /* write all security-related messages to file /var/log/security */
  file security {
    authorization info;
    interactive-commands info;
  }
  /* write messages about potential problems to file /var/log/messages: */
  /* messages from "authorization" facility at level "notice" and above, */
  /* messages from all other facilities at level "warning" and above */
  file messages {
    authorization notice;
    any warning;
  }
  /* write all messages at level "critical" and above to terminal of user "alex" if */
  /* that user is logged in */
  user alex {
    any critical;
  }
  /* write all messages from the "daemon" facility at level "info" and above, and */
  /* messages from all other facilities at level "warning" and above, to the */
  /* machine monitor.mycompany.com */
  host monitor.mycompany.com {
    daemon info;
    any warning;
  }
  /* write all messages at level "error" and above to the system console */
  console {
    any error;
  }
}
```

The following example shows how to configure the handling of messages generated when users issue Junos OS CLI commands, by specifying the **interactive-commands** facility at the following severity levels:

- **info**—Logs a message when users issue any command at the CLI operational or configuration mode prompt. The example writes the messages to the file `/var/log/user-actions`.

- **notice**—Logs a message when users issue the configuration mode commands **rollback** and **commit**. The example writes the messages to the terminal of user **philip**.
- **warning**—Logs a message when users issue a command that restarts a software process. The example writes the messages to the console.

```
[edit system]
syslog {
  file user-actions {
    interactive-commands info;
  }
  user philip {
    interactive-commands notice;
  }
  console {
    interactive-commands warning;
  }
}
```

## Directing System Log Messages to a Remote Destination

- [Adding a Text String to System Log Messages on page 1599](#)
- [Adding a String on page 1600](#)
- [Examples: Assigning an Alternative Facility on page 1600](#)

### Adding a Text String to System Log Messages

To add a text string to every system log message directed to a remote machine or to the other Routing Engine, include the **log-prefix** statement at the **[edit system syslog host]** hierarchy level:

```
[edit system syslog host (hostname | other-routing-engine)]
facility severity;
log-prefix string;
```

The string can contain any alphanumeric or special character except the equal sign ( = ) and the colon ( : ). It also cannot include the space character; do not enclose the string in quotation marks ( " ") in an attempt to include spaces in it.

The Junos OS system logging utility automatically appends a colon and a space to the specified string when the system log messages are written to the log. The string is inserted after the identifier for the Routing Engine that generated the message.

The following example shows how to add the string M120 to all messages to indicate that the router is an M120 router, and direct the messages to the remote machine hardware-logger.mycompany.com:

```
[edit system syslog]
host hardware-logger.mycompany.com {
  any info;
  log-prefix M120;
```

```
}
```

When these configuration statements are included on an M120 router called `origin1`, a message in the system log on `hardware-logger.mycompany.com` looks like the following:

```
Mar 9 17:33:23 origin1 M120: mgd[477]: UI_CMDLINE_READ_LINE: user 'root', command 'run
show version'
```

**Related  
Documentation**

- *Single-Chassis System Logging Configuration Overview*
- *Specifying Log File Size, Number, and Archiving Properties*

## Adding a String

Add the string `M120` to all messages to indicate that the router is an M120 router, and direct the messages to the remote machine `hardware-logger.mycompany.com`:

```
[edit system syslog]
host hardware-logger.mycompany.com {
  any info;
  log-prefix M120;
}
```

When these configuration statements are included on an M120 router called `origin1`, a message in the system log on **`hardware-logger.mycompany.com`** looks like the following:

```
Mar 9 17:33:23 origin1 M120: mgd[477]: UI_CMDLINE_READ_LINE: user 'root', command 'run
show version'
```

## Examples: Assigning an Alternative Facility

Log all messages generated on the local routing platform at the error level or higher to the **`local0`** facility on the remote machine called **`monitor.mycompany.com`**:

```
[edit system syslog]
host monitor.mycompany.com {
  any error;
  facility-override local0;
}
```

Configure routing platforms located in California and routing platforms located in New York to send messages to a single remote machine called **`central-logger.mycompany.com`**. The messages from California are assigned alternative facility **`local0`** and the messages from New York are assigned to alternative facility **`local2`**.

- Configure California routing platforms to aggregate messages in the **`local0`** facility:

```
[edit system syslog]
host central-logger.mycompany.com {
  change-log info;
  facility-override local0;
}
```

- Configure New York routing platforms to aggregate messages in the **`local2`** facility:

```
[edit system syslog]
host central-logger.mycompany.com {
```

```
change-log info;
facility-override local2;
}
```

On **central-logger**, you can then configure the system logging utility to write messages from the **local0** facility to the file **california-config** and the messages from the **local2** facility to the file **new-york-config**.

## Displaying System Log Files

- [Displaying a Log File from a Single-Chassis System on page 1601](#)
- [Examples: Displaying a Log File on page 1601](#)

### Displaying a Log File from a Single-Chassis System

To display a log file stored on a single-chassis system, enter Junos OS CLI operational mode and issue either of the following commands:

```
user@host> show log log-filename
user@host> file show log-file-pathname
```

By default, the commands display the file stored on the local Routing Engine. To display the file stored on a particular Routing Engine, prefix the file or pathname with the string **re0** or **re1** and a colon. The following examples both display the **/var/log/messages** file stored on the Routing Engine in slot 1:

```
user@host> show log re1:messages
user@host> file show re1:/var/log/messages
```

For information about the fields in a log message, see *Interpreting Messages Generated in Standard Format by a Junos Process or Library*, “[Interpreting Messages Generated in Standard Format by Services on a PIC](#)” on page 1609, and “[Interpreting Messages Generated in Structured-Data Format](#)” on page 1604. For examples, see “[Examples: Displaying a Log File](#)” on page 1601.

### Examples: Displaying a Log File

Display the contents of the **/var/log/messages** file stored on the local Routing Engine. (The **/var/log** directory is the default location for log files, so you do not need to include it in the filename. The **messages** file is a commonly configured destination for system log messages.)

```
user@host> show log messages Apr 11 10:27:25 router1 mgd[3606]:
  UI_DBASE_LOGIN_EVENT: User 'barbara' entering configuration mode
Apr 11 10:32:22 router1 mgd[3606]: UI_DBASE_LOGOUT_EVENT: User 'barbara' exiting
  configuration mode
Apr 11 11:36:15 router1 mgd[3606]: UI_COMMIT: User 'root' performed commit: no comment
Apr 11 11:46:37 router1 mib2d[2905]: SNMP_TRAP_LINK_DOWN: ifIndex 82, ifAdminStatus
  up(1), ifOperStatus down(2), ifName at-1/0/0
```

Display the contents of the file `/var/log/processes`, which has been previously configured to include messages from the **daemon** facility. When issuing the **file show** command, you must specify the full pathname of the file:

```
user@host> file show /var/log/processes Feb 22 08:58:24 router1 snmpd[359]:
SNMPD_TRAP_WARM_START: trap_generate_warm: SNMP trap: warm start
Feb 22 20:35:07 router1 snmpd[359]: SNMPD_THROTTLE_QUEUE_DRAINED:
trap_throttle_timer_handler: cleared all throttled traps
Feb 23 07:34:56 router1 snmpd[359]: SNMPD_TRAP_WARM_START: trap_generate_warm:
SNMP trap: warm start
Feb 23 07:38:19 router1 snmpd[359]: SNMPD_TRAP_COLD_START: trap_generate_cold:
SNMP trap: cold start
```

Display the contents of the file `/var/log/processes` when the **explicit-priority** statement is included at the `[edit system syslog file processes]` hierarchy level:

```
user@host> file show /var/log/processes Feb 22 08:58:24 router1 snmpd[359]:
%DAEMON-3-SNMPD_TRAP_WARM_START: trap_generate_warm: SNMP trap: warm
start
Feb 22 20:35:07 router1 snmpd[359]:
%DAEMON-6-SNMPD_THROTTLE_QUEUE_DRAINED: trap_throttle_timer_handler: cleared
all throttled traps
Feb 23 07:34:56 router1 snmpd[359]:
%DAEMON-3-SNMPD_TRAP_WARM_START: trap_generate_warm: SNMP trap: warm
start
Feb 23 07:38:19 router1 snmpd[359]:
%DAEMON-2-SNMPD_TRAP_COLD_START: trap_generate_cold: SNMP trap: cold start
```

## Displaying and Interpreting System Log Message Descriptions

This reference lists the messages available at the time of its publication. To display the list of messages that applies to the version of the Junos OS that is running on a routing platform, enter Junos OS CLI operational mode and issue the following command:

```
user@host> help syslog ?
```

To display the list of available descriptions for tags whose names begin with a specific character string, substitute the string (in all capital letters) for the variable **TAG-PREFIX** (there is no space between the prefix and the question mark):

```
user@host> help syslog TAG-PREFIX?
```

To display the complete descriptions for tags whose name includes a regular expression, substitute a Perl-based expression for the variable **regex**. The match is not case-sensitive.

For information about Perl-based regular expressions, consult a Perl reference manual or website such as <http://perldoc.perl.org>.

```
user@host> help syslog regex
```

To display the complete description of a particular message, substitute its name for the variable **TAG** (in all capital letters):

```
user@host> help syslog TAG
```

[Table 195](#) describes the fields in a system log message description in this reference or in the CLI.

**Table 195: Fields in System Log Message Descriptions**

| Field Name in Reference   | Field Name in CLI  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| —                         | <b>Name</b>        | The message tag in all capital letters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>System Log Message</b> | <b>Message</b>     | <p>Text of the message written to the system log. In the log, a specific value is substituted for each variable that appears in italics in this reference or in angle brackets (&lt; &gt;) in the CLI.</p> <p>In this reference, the message text appears on the second line of the <b>System Log Message</b> field. The first line is the message tag (the same text as in the <b>CLI Name</b> field). The prefix on each tag identifies the message source and the rest of the tag indicates the specific event or error.</p> |
| —                         | <b>Help</b>        | Short description of the message, which also appears in the right-hand column of CLI output for the <b>help syslog</b> command when the output lists multiple messages.                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>        | <b>Description</b> | More detailed explanation of the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Type</b>               | <b>Type</b>        | <p>Category to which the message belongs:</p> <ul style="list-style-type: none"> <li>• <b>Error:</b> The message reports an error or failure condition that might require corrective action.</li> <li>• <b>Event:</b> The message reports a condition or occurrence that does not generally require corrective action.</li> </ul>                                                                                                                                                                                               |

Table 195: Fields in System Log Message Descriptions (*continued*)

| Field Name in Reference | Field Name in CLI | Description                                                                                                                                                                                                      |
|-------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Severity                | Severity          | Message severity level as described in Table: <b>System Log Message Severity Levels</b> in <i>Specifying the Facility and Severity of Messages to Include in the Log</i> .                                       |
| Cause                   | Cause             | (Optional) Possible cause for message generation. There can be more than one cause.                                                                                                                              |
| Action                  | Action            | (Optional) Action you can perform to resolve the error or failure condition described in the message. If this field does not appear in an entry, either no action is required or the action is self-explanatory. |

## Interpreting Messages Generated in Structured-Data Format

Beginning in Junos OS Release 8.3, when the **structured-data** statement is included in the configuration for a log file, Junos OS processes and software libraries write messages to the file in structured-data format instead of the standard Junos OS format. For information about the **structured-data** statement, see “[Logging Messages in Structured-Data Format](#)” on page 1591.

Structured-format makes it easier for automated applications to extract information from the message. In particular, the standardized format for reporting the value of variables (elements in the English-language message that vary depending on the circumstances that triggered the message) makes it easy for an application to extract those values. In standard format, the variables are interspersed in the message text and not identified as variables.

The structured-data format for a message includes the following fields (which appear here on two lines only for legibility):

```
<priority code>version timestamp hostname process processID TAG [junos@2636.platform
variable-value-pairs] message-text
```

Table 196 describes the fields. If the system logging utility cannot determine the value in a particular field, a hyphen ( - ) appears instead.

Table 196: Fields in Structured-Data Messages

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Examples                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;priority code&gt;</b> | Number that indicates the message's facility and severity. It is calculated by multiplying the facility number by 8 and then adding the numerical value of the severity. For a mapping of the numerical codes to facility and severity, see Table: <b>Facility and Severity Codes in the priority-code Field</b> in <i>Specifying the Facility and Severity of Messages to Include in the Log</i> .                                                                                                   | <165> for a message from the <b>pfe</b> facility (facility=20) with severity <b>notice</b> (severity=5).                                                                     |
| <b>version</b>               | Version of the Internet Engineering Task Force (IETF) system logging protocol specification.                                                                                                                                                                                                                                                                                                                                                                                                          | 1 for the initial version                                                                                                                                                    |
| <b>timestamp</b>             | Time when the message was generated, in one of two representations: <ul style="list-style-type: none"> <li><b>YYYY-MM-DDTHH:MM:SS.MSZ</b> is the year, month, day, hour, minute, second and millisecond in Universal Coordinated Time (UTC)</li> <li><b>YYYY-MM-DDTHH:MM:SS.MS+/-HH:MM</b> is the year, month, day, hour, minute, second and millisecond in local time; the hour and minute that follows the plus sign (+) or minus sign (-) is the offset of the local time zone from UTC</li> </ul> | 2007-02-15T09:17:15.719Z is 9:17 AM UTC on 15 February 2007.<br>2007-02-15T01:17:15.719-08:00 is the same timestamp expressed as Pacific Standard Time in the United States. |
| <b>hostname</b>              | Name of the host that originally generated the message.                                                                                                                                                                                                                                                                                                                                                                                                                                               | router1                                                                                                                                                                      |
| <b>process</b>               | Name of the Junos OS process that generated the message.                                                                                                                                                                                                                                                                                                                                                                                                                                              | mgd                                                                                                                                                                          |
| <b>processID</b>             | UNIX process ID (PID) of the Junos OS process that generated the message.                                                                                                                                                                                                                                                                                                                                                                                                                             | 3046                                                                                                                                                                         |
| <b>TAG</b>                   | Junos OS system log message tag, which uniquely identifies the message.                                                                                                                                                                                                                                                                                                                                                                                                                               | UI_DBASE_LOGOUT_EVENT                                                                                                                                                        |
| <b>junos@2636.platform</b>   | An identifier for the type of hardware platform that generated the message. The junos@2636 prefix indicates that the platform runs Junos OS. It is followed by a dot-separated numerical identifier for the platform type. For a list of the identifiers, see <a href="#">Table 198</a> .                                                                                                                                                                                                             | junos@2636.1.1.1.2.18 for the M120 router                                                                                                                                    |
| <b>variable-value-pairs</b>  | A variable-value pair for each element in the <i>message-text</i> string that varies depending on the circumstances that triggered the message. Each pair appears in the format <b>variable = "value"</b> .                                                                                                                                                                                                                                                                                           | username="user"                                                                                                                                                              |

Table 196: Fields in Structured-Data Messages (*continued*)

| Field               | Description                                                                                                                                                                                                                                                      | Examples                               |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| <b>message-text</b> | English-language description of the event or error (omitted if the brief statement is included at the [edit system syslog file <i>filename</i> structured-data] hierarchy level). For the text for each message, see the chapters following System Log Messages. | User 'user' exiting configuration mode |

By default, the structured-data version of a message includes English text at the end, as in the following example (which appears on multiple lines only for legibility):

```
<165>1 2007-02-15T09:17:15.719Z router1 mgd 3046 UI_DBASE_LOGOUT_EVENT
[junos@2636.1.1.1.2.18 username="user"] User 'user' exiting configuration mode
```

When the brief statement is included at the [edit system syslog file *filename* structured-data ] hierarchy level, the English text is omitted, as in this example:

```
<165>1 2007-02-15T09:17:15.719Z router1 mgd 3046 UI_DBASE_LOGOUT_EVENT
[junos@2636.1.1.1.2.18 username="user"]
```

Table 197 maps the codes that appear in the **priority-code** field to facility and severity level.

**NOTE:** Not all of the facilities and severities listed in Table 197 can be included in statements at the [edit system syslog] hierarchy level (some are used by internal processes). For a list of the facilities and severity levels that can be included in the configuration, see *Specifying the Facility and Severity of Messages to Include in the Log*.

Table 197: Facility and Severity Codes in the priority-code Field

| Facility (number) | Severity emergency | alert | critical | error | warning | notice | info | debug |
|-------------------|--------------------|-------|----------|-------|---------|--------|------|-------|
| kernel (0)        | 1                  | 1     | 2        | 3     | 4       | 5      | 6    | 7     |
| user (1)          | 8                  | 9     | 10       | 11    | 12      | 13     | 14   | 15    |
| mail (2)          | 16                 | 17    | 18       | 19    | 20      | 21     | 22   | 23    |
| daemon (3)        | 24                 | 25    | 26       | 27    | 28      | 29     | 30   | 31    |
| authorization (4) | 32                 | 33    | 34       | 35    | 36      | 37     | 38   | 39    |
| syslog (5)        | 40                 | 41    | 42       | 43    | 44      | 45     | 46   | 47    |
| printer (6)       | 48                 | 49    | 50       | 51    | 52      | 53     | 54   | 55    |
| news (7)          | 56                 | 57    | 58       | 59    | 60      | 61     | 62   | 63    |

Table 197: Facility and Severity Codes in the priority-code Field (*continued*)

| Facility (number)             | Severity<br>emergency | alert | critical | error | warning | notice | info | debug |
|-------------------------------|-----------------------|-------|----------|-------|---------|--------|------|-------|
| uucp (8)                      | 64                    | 65    | 66       | 67    | 68      | 69     | 70   | 71    |
| clock (9)                     | 72                    | 73    | 74       | 75    | 76      | 77     | 78   | 79    |
| authorization-private<br>(10) | 80                    | 81    | 82       | 83    | 84      | 85     | 86   | 87    |
| ftp (11)                      | 88                    | 89    | 90       | 91    | 92      | 93     | 94   | 95    |
| ntp (12)                      | 96                    | 97    | 98       | 99    | 100     | 101    | 102  | 103   |
| security (13)                 | 104                   | 105   | 106      | 107   | 108     | 109    | 110  | 111   |

| local0 (16)                   | 128                   | 129   | 130      | 131   | 132     | 133    | 134  | 135   |
| dfc (17)                      | 136                   | 137   | 138      | 139   | 140     | 141    | 142  | 143   |
| local2 (18)                   | 144                   | 145   | 146      | 147   | 148     | 149    | 150  | 151   |
| firewall (19)                 | 152                   | 153   | 154      | 155   | 156     | 157    | 158  | 159   |
| pfe (20)                      | 160                   | 161   | 162      | 163   | 164     | 165    | 166  | 167   |
| conflict-log (21)             | 168                   | 169   | 170      | 171   | 172     | 173    | 174  | 175   |
| change-log (22)               | 176                   | 177   | 178      | 179   | 180     | 181    | 182  | 183   |
| interactive-commands<br>(23)  | 184                   | 185   | 186      | 187   | 188     | 189    | 190  | 191   |

Table 198 lists the numerical identifiers for routing platforms that appear in the **platform** field. The identifier is derived from the platform's SNMP object identifier (OID) as defined in the Juniper Networks routing platform MIB. For more information about OIDs, see the *SNMP MIBs and Traps Monitoring and Troubleshooting Guide for Security Devices*.

Table 198: Platform Identifiers in the platform Field

| Identifier | Platform Name |
|------------|---------------|
| 1.1.1.2.1  | M40 router    |
| 1.1.1.2.2  | M20 router    |
| 1.1.1.2.3  | M160 router   |
| 1.1.1.2.4  | M10 router    |

Table 198: Platform Identifiers in the platform Field (*continued*)

| Identifier | Platform Name           |
|------------|-------------------------|
| 1.1.1.2.5  | M5 router               |
| 1.1.1.2.6  | T640 routing node       |
| 1.1.1.2.7  | T320 router             |
| 1.1.1.2.8  | M40e router             |
| 1.1.1.2.9  | M320 router             |
| 1.1.1.2.10 | M7i router              |
| 1.1.1.2.11 | M10i router             |
| 1.1.1.2.13 | J2300 Services Router   |
| 1.1.1.2.14 | J4300 Services Router   |
| 1.1.1.2.15 | J6300 Services Router   |
| 1.1.1.2.17 | TX Matrix platform      |
| 1.1.1.2.18 | M120 router             |
| 1.1.1.2.19 | J4350 Services Router   |
| 1.1.1.2.20 | J6350 Services Router   |
| 1.1.1.2.23 | J2320 Services Router   |
| 1.1.1.2.27 | T1600 router            |
| 1.1.1.2.37 | TX Matrix Plus platform |
| 1.1.1.2.83 | T4000 router            |

### The message-source Field on a Single-Chassis System

The format of the **message-source** field in a message on a single-chassis system depends on whether the message was generated on the local Routing Engine or the other Routing Engine (on a system with two Routing Engines installed and operational). Messages from the other Routing Engine appear only if its configuration includes the **other-routing-engine** statement at the [edit system syslog host] hierarchy level.

- When the local Routing Engine generated the message, there are two subfields:  
*hostname process[process-ID]*
- When the other Routing Engine generated the message, there are three subfields:

*hostname reX process[process-ID]*

**hostname** is the hostname of the local Routing Engine.

**process[process-ID]** is the name and PID of the process that generated the message. If the **reX** field also appears, the process is running on the other Routing Engine. If a process does not report its PID, the **[process-ID]** part does not appear.

**reX** indicates that the other Routing Engine generated the message (X is 0 or 1).

## Interpreting Messages Generated in Standard Format by Services on a PIC

Standard-format system log messages generated by services on a PIC, such as the Adaptive Services (AS) PIC, have the following syntax:

*timestamp* (FPC Slot *fpc-slot*, PIC Slot *pic-slot*) {*service-set*} [*SERVICE*]:  
*optional-string* TAG: *message-text*

**NOTE:** System logging for services on PICs is not configured at the [edit system syslog] hierarchy level as discussed in this chapter. For configuration information, see the *Junos Services Interfaces Configuration Guide*.

The (FPC Slot *fpc-slot*, PIC Slot *pic-slot*) field appears only when the standard system logging utility that runs on the Routing Engine writes the messages to the system log. When the PIC writes the message directly, the field does not appear.

Table 199 describes the message fields.

**Table 199: Fields in Messages Generated by a PIC**

| Field                  | Description                                                                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>timestamp</i>       | Time at which the message was logged.                                                                                                                                                                                                                               |
| <i>fpc-slot</i>        | Slot number of the Flexible PIC Concentrator (FPC) that houses the PIC that generated the message.                                                                                                                                                                  |
| <i>pic-slot</i>        | Number of the PIC slot on the FPC in which the PIC that generated the message resides.                                                                                                                                                                              |
| <i>service-set</i>     | Name of the service set that generated the message.                                                                                                                                                                                                                 |
| <i>SERVICE</i>         | Code representing the service that generated the message. The codes include the following: <ul style="list-style-type: none"> <li>FWNAT—Network Address Translation (NAT) service</li> <li>IDS—Intrusion detection service</li> </ul>                               |
| <i>optional-string</i> | A text string that appears if the configuration for the PIC includes the log-prefix statement at the [edit interfaces interface-name services-options syslog] hierarchy level. For more information, see the <i>Junos Services Interfaces Configuration Guide</i> . |

Table 199: Fields in Messages Generated by a PIC (*continued*)

| Field               | Description                                                                                                                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TAG</b>          | Text string that uniquely identifies the message, in all uppercase letters and using the underscore (_) to separate words. The tag name begins with a prefix that indicates the generating PIC. The entries in this reference are ordered alphabetically by this prefix. |
| <b>message-text</b> | Text of the message. For the text of each message, see System Log Messages.                                                                                                                                                                                              |

## Examples: Displaying System Log Message Descriptions

Display the list of all currently available system log message descriptions:

```
user@host> help syslog ?

Possible completions:
<syslog-tag>   Syslog tag
. . . . .
BOOTPD_ARG_ERR   Command-line option was invalid
BOOTPD_BAD_ID    Request failed because assembly ID was unknown
BOOTPD_BOOTSTRING tnp.bootpd provided boot string
BOOTPD_CONFIG_ERR tnp.bootpd could not parse configuration file;
                  used default settings
BOOTPD_CONF_OPEN tnp.bootpd could not open configuration file
BOOTPD_DUP_REV   Extra boot string definitions for revision were
                  ignored
---(more 4%)---
```

Display the list of all currently available system log message descriptions for tags that begin with the letters **ACCT** (there is no space between **ACCT** and the question mark, and some descriptions are shortened for legibility):

```
user@host> help syslog ACCT?

Possible completions:
<syslog-tag>      System log tag or regular expression
ACCT_ACCOUNTING_FERROR Error occurred during file processing
ACCT_ACCOUNTING_FOPEN_ERROR Open operation failed on file
ACCT_ACCOUNTING_SMALL_FILE_SIZE Maximum file size is smaller than ...
ACCT_BAD_RECORD_FORMAT Record format does not match accounting profile
ACCT_CU_RTSLIB_ERROR Error occurred obtaining current class usage ...
ACCT_FORK_ERR      Could not create child process
ACCT_FORK_LIMIT_EXCEEDED Could not create child process because of limit
ACCT_GETHOSTNAME_ERROR gethostname function failed
ACCT_MALLOC_FAILURE Memory allocation failed
ACCT_UNDEFINED_COUNTER_NAME Filter profile used undefined counter name
ACCT_XFER_FAILED   Attempt to transfer file failed
ACCT_XFER_POPEN_FAIL File transfer failed
```

Display the description of the **UI\_CMDLINE\_READ\_LINE** message:

```
user@host> help syslog UI_CMDLINE_READ_LINE

Name:      UI_CMDLINE_READ_LINE
Message:   User '<users>', command '<input>'
Help:     User entered command at CLI prompt
```

Description: The indicated user typed the indicated command at the CLI prompt and pressed the Enter key, sending the command string to the management process (mgd).

Type: Event: This message reports an event, not an error

Severity: info

---

## Configuring System Logging for a Security Device

## Understanding System Logging for Security Devices

Junos OS supports configuring and monitoring of system log messages (also called *syslog messages*). You can configure files to log system messages and also assign attributes, such as severity levels, to messages. Reboot requests are recorded to the system log files, which you can view with the **show log** command.

This section contains the following topics:

- [Control Plane and Data Plane Logs on page 1611](#)
- [Redundant System Log Server on page 1612](#)

---

### Control Plane and Data Plane Logs

---

Junos OS generates separate log messages to record events that occur on the system's control and data planes.

- The control plane logs, also called system logs, include events that occur on the routing platform. The system sends control plane events to the **eventd** process on the Routing Engine, which then handles the events by using Junos OS policies, by generating system log messages, or both. You can choose to send control plane logs to a file, user terminal, routing platform console, or remote machine. To generate control plane logs, use the **syslog** statement at the **[system]** hierarchy level.
- The data plane logs, also called *security logs*, primarily include security events that are handled inside the data plane. Security logs can be in text or binary format, and they can be saved locally (event mode) or sent to an external server (stream mode). Binary format is required for stream mode and recommended to conserve log space in event mode.

Note the following:

- Security logs can be saved locally (on box) or externally (off box), but not both.
- SRX1500, SRX5600, and SRX5800 devices default to stream mode. To specify binary format and an external server, see [“Configuring Off-Box Binary Security Log Files” on page 1615](#).

**NOTE:** Logs might be dropped if you configure event mode logging on these devices.

- Other devices default to event mode and text format. Data plane events are written to system log files in a similar manner to control plane events. To specify binary format for the security logs, see [“Configuring On-Box Binary Security Log Files” on page 1614](#).

---

### Redundant System Log Server

Security system logging traffic intended for remote servers is sent through the network interface ports, which support two simultaneous system log destinations. Each system logging destination must be configured separately. When two system log destination addresses are configured, identical logs are sent to both destinations. While two destinations can be configured on any device that supports the feature, adding a second destination is primarily useful as a redundant backup for standalone and active/backup configured chassis cluster deployments.

The following redundant server information is available:

- Facility: **cron**
- Description: cron scheduling process
- Severity Level (from highest to lowest severity): **debug**
- Description: Software debugging messages

### Understanding Stream Logging for Security Devices

Junos OS supports forwarding logs using stream mode and event mode. All the categories can be configured for sending specific category logs to different log servers for stream mode log forwarding.

Stream mode log forwarding includes the following steps:

- An RTLOG system log message is generated by the data plane and is sent out from the Packet Forwarding Engine.
- An RTLOG system log message is generated by fpe process and is sent from Packet Forwarding Engine.
- An RTLOG system log message is generated by the Routing Engine unified threat management (utmd) process and is sent by rtlogd process from the Routing Engine.

For stream mode log forwarding, the transport protocol used between Packet Forwarding Engine and the log server can be UDP, TCP, or TLS, and these fields are configurable. The transport protocol used between the Routing Engine and the log server can only be UDP.

- [Monitoring System Log Messages with the J-Web Event Viewer on page 1618](#)

## Understanding Binary Format for Security Logs

The Junos OS generates separate log messages to record events that occur on the system's control plane and data plane. The control plane monitors events that occur on the routing platform. Such events are recorded in system log messages. To generate system log messages, use the **syslog** statement at the **[system]** hierarchy level.

Data plane log messages, referred to as security log messages, record security events that the system handles directly inside the data plane. To generate security log messages, use the **log** statement at the **[security]** hierarchy level.

System log messages are maintained in log files in text-based formats, such as BSD Syslog, Structured Syslog, and WebTrends Enhanced Log Format (WELF).

Security log messages can also be maintained in text-based formats. Because security logging can produce large amounts of data, however, text-based log files can quickly consume storage and CPU resources. Depending on your implementation of security logging, a log file in a binary-based format can provide more efficient use of on-box or off-box storage and improved CPU utilization. Binary format for security log messages is available on all SRX Series devices.

When configured in event mode, security log messages generated in the data plane are directed to the control plane and stored locally on the device. Security log messages stored in binary format are maintained in a log file separate from that used to maintain system log messages. Events stored in a binary log file are not accessible with advanced log-scripting commands intended for text-based log files. A separate CLI operational command supports decoding, converting, and viewing binary log files that are stored locally on the device.

When configured in stream mode, security log messages generated in the data plane are streamed to a remote device. When these messages are stored in binary format, they are streamed directly to an external log collection server in a Juniper-specific binary format. Externally-stored binary log files can only be read using Juniper Secure Analytics (JSA) or Security Threat Response Manager (STRM).

For information about configuring on-box (event-mode) binary security logs, please see [“Configuring On-Box Binary Security Log Files” on page 1614](#). For information about

configuring off-box (stream-mode) binary security logs, please see [“Configuring Off-Box Binary Security Log Files” on page 1615](#).

**Related Documentation**

- [Understanding System Logging for Security Devices on page 1611](#)

## Configuring On-Box Binary Security Log Files

SRX Series devices have two types of log: system logs and security logs. System logs record control plane events, for example admin login to the device. For more about system logs, please see [“Junos OS System Log Overview” on page 1583](#). Security logs, also known as traffic logs, record data plane events regarding specific traffic handling, for example when a security policy denies certain traffic due to some violation of the policy. For more information about security logs, please see [“Understanding System Logging for Security Devices” on page 1611](#).

The two types of log can be collected and saved either on-box or off-box. The procedure below explains how to configure security logs in binary format for on-box (event-mode) logging.

You can configure security files in binary format using the **log** statement at the **[security]** hierarchy level.

The following procedure specifies binary format for event-mode security logging, and defines the log filename, path, and log file characteristics. For stream-mode, off-box security logging, please see [“Configuring Off-Box Binary Security Log Files” on page 1615](#).

1. Specify the logging mode and the format for the log file. For on-box, event-mode logging:

```
set security log mode event
set security log format binary
```

**NOTE:** If system logging has been set to send system logs to an external destination, security logs will also be sent to that destination when using security log event-mode. More information about sending system logs to an external destination is available here [“Examples: Configuring System Logging” on page 1597](#).

**NOTE:** Off-box and on-box security logging modes cannot be enabled simultaneously.

2. Optionally, define a log filename and a path. By default, the file `bin_messages` is created in the `/var/log` directory.

```
set security log file name security-binary-log
set security log file path security/log-folder
```

3. Optionally, change the maximum size of the log file and the maximum number of log files that can be archived. By default the maximum size of the log file is 3 MB, and a total of three log files can be archived.

```
set security log file size 5
set security log file files 5
```

4. Optionally, select the hpl flag to enable diagnostic traces for binary logging. The prefix smf\_hpl identifies all binary logging traces.

```
set security log traceoptions flag hpl
```

5. View the content of the event-mode log file stored on the device.

```
show security log file
```

**NOTE:** The `show security log` command displays event-mode security log messages if they are in a text-based format. The `show security log file` command displays event-mode security log messages if they are in binary format.

Use the following command to clear the content of the binary event-mode security log file.

```
clear security log file
```

- [Setting the System to Send All Log Messages Through eventd on page 1617](#)

## Configuring Off-Box Binary Security Log Files

SRX Series devices have two types of log: system logs and security logs. System logs record control plane events, for example admin login to the device. For more about system logs, please see “[Junos OS System Log Overview](#)” on page 1583. Security logs, also known as traffic logs, record data plane events regarding specific traffic handling, for example when a security policy denies certain traffic due to some violation of the policy. For more information about security logs, please see “[Understanding System Logging for Security Devices](#)” on page 1611.

The two types of log can be collected and saved either on-box or off-box. The procedure below explains how to configure security logs in binary format for off-box (stream-mode) logging.

You can configure security files in binary format using the `log` statement at the `[security]` hierarchy level.

The following procedure specifies binary format for stream-mode security logging, and defines the log filename, path, and log file characteristics. For event-mode, on-box security logging, please see “[Configuring On-Box Binary Security Log Files](#)” on page 1614.

1. Specify the logging mode and the format for the log file. For off-box, stream-mode logging:

```
set security log mode stream
set security log stream test-stream format binary host 1.3.54.22
```

**NOTE:** Off-box and on-box security logging modes cannot be enabled simultaneously.

- For off-box security logging, specify the source address, which identifies the SRX Series device that generated the log messages. The source address is required.

```
set security log source-address 2.3.45.66
```

- Optionally, define a log filename and a path. By default, the file `bin_messages` is created in the `/var/log` directory.

```
set security log file name security-binary-log
set security log file path security/log-folder
```

- Optionally, change the maximum size of the log file and the maximum number of log files that can be archived. By default the maximum size of the log file is 3 MB, and a total of three log files can be archived.

```
set security log file size 5
set security log file files 5
```

- Optionally, select the `hpl` flag to enable diagnostic traces for binary logging. The prefix `smf_hpl` identifies all binary logging traces.

```
set security log traceoptions flag hpl
```

- View the content of the event-mode log file stored on the device using either Juniper Secure Analytics (JSA) or Security Threat Response Manager (STRM).

#### Related Documentation

- [Understanding Binary Format for Security Logs on page 1613](#)
- [Setting the System to Send All Log Messages Through eventd on page 1617](#)
- [Setting the System to Stream Security Logs Through Revenue Ports on page 1618](#)

## Sending System Log Messages to a File

You can direct system log messages to a file on the CompactFlash (CF) card. The default directory for log files is `/var/log`. To specify a different directory on the CF card, include the complete pathname.

Create a file named **security**, and send log messages of the **authorization** class at the severity level **info** to the file.

To set the filename, the facility, and severity level:

```
{primary:node0}
user@host# set system syslog file security authorization info
```

## Setting the System to Send All Log Messages Through eventd

The **eventd** process of logging configuration is most commonly used for Junos OS. In this configuration, control plane logs and data plane, or security, logs are forwarded from the data plane to the Routing Engine control plane **rtlogd** process. The **rtlogd** process then either forwards syslog or sd-syslog-formatted logs to the **eventd** process or the WELF-formatted logs to the external or remote WELF log collector.

To send all log messages through **eventd**:

1. Set the **eventd** process to handle security logs and send them to a remote server.

```
{primary:node0}
user@host# set security log mode event
```

2. Configure the server that will receive the system log messages.

```
{primary:node0}
user@host# set system syslog host hostname any any
```

where **hostname** is the fully qualified hostname or IP address of the server that will receive the logs.

**NOTE:** To send duplicate logs to a second remote server, repeat the command with a new fully qualified **hostname** or IP address of a second server.

If your deployment is an active/active chassis cluster, you can also configure security logging on the active node to be sent to separate remote servers to achieve logging redundancy.

To rename or redirect one of the logging configurations, you need to delete and recreate it. To delete a configuration:

```
{primary:node0}
user@host# delete security log mode event
```

- [Monitoring System Log Messages with the J-Web Event Viewer on page 1618](#)

## Setting the System to Stream Security Logs Through Revenue Ports

You can increase the number of data plane, or security, logs that are sent by modifying the manner in which they are sent. When the logging mode is set to **stream**, security logs generated in the data plane are streamed out a revenue traffic port directly to a remote server.

To use the **stream** mode, enter the following commands:

```
{primary:node0}
user@host# set security log mode stream source-address source-address
user@host# set security log stream streamname format (syslog|sd-syslog|welf) category
(all|content-security) host ipaddr
```

where *source-address* is the IP address of the source machine; **syslog**, **sd-syslog** (structured system logging messages) and **welf** are logging formats; **all** and **content-security** are the categories of logging; and *ipaddr* is the IP address of the server to which the logs will be streamed.

**NOTE:** WELF logs must be streamed through a revenue port because the **eventd** process does not recognize the WELF format. The category must be set to **content-security**. For example:

```
{primary:node0}
user@host# set security log stream securitylog1 format
welf category content-security host 10.121.23.5
```

To send duplicate logs to a second remote server, repeat the command with a new *ipaddr*. If your deployment is an active/active chassis cluster, you can also configure security logging on the active node to be sent to separate remote servers to achieve logging redundancy.

## Monitoring System Log Messages with the J-Web Event Viewer

**Purpose** Monitor errors and events that occur on the device.

**Action** Select **Monitor>Events and Alarms>View Events** in the J-Web user interface.

The J-Web View Events page displays the following information about each event:

- **Process**—System process that generated the error or event.
- **Severity**— A severity level indicates how seriously the triggering event affects routing platform functions. Only messages from the facility that are rated at that level or higher are logged. Possible severities and their corresponding color code are:
  - **Debug/Info/Notice (Green)**—Indicates conditions that are not errors but are of interest or might warrant special handling.
  - **Warning (Yellow)**—Indicates conditions that warrant monitoring.
  - **Error (Blue)**—Indicates standard error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels.
  - **Critical (Pink)**—Indicates critical conditions, such as hard drive errors.
  - **Alert (Orange)**—Indicates conditions that require immediate correction, such as a corrupted system database.
  - **Emergency (Red)**—Indicates system panic or other conditions that cause the routing platform to stop functioning.
- **Event ID**—Unique ID of the error or event. The prefix on each code identifies the generating software process. The rest of the code indicates the specific event or error.
- **Event Description**—Displays a more detailed explanation of the message.
- **Time**—Time that the error or event occurred.

To control which errors and events are displayed in the list, use the following options:

- **System Log File**—Specify the name of the system log file that records the errors and events.
- **Process**—Specify the system processes that generate the events you want to display. To view all the processes running on your system, enter the **show system processes** CLI command.
- **Date From**—Specify the beginning of the date range that you want to monitor. Set the date using the calendar pick tool.
- **To**—Specify the end of the date range that you want to monitor. Set the date using the calendar pick tool.
- **Event ID**—Specify the specific ID of the error or event that you want to monitor.
- **Description**—Enter a description for the errors or events.
- **Search**—Fetches the errors and events specified in the search criteria.
- **Reset**—Clears the cache of errors and events that were previously selected.
- **Generate Report**—Creates an HTML report based on the specified parameters.

## Security Configuration Statement Hierarchy

Use the statements in the **security** configuration hierarchy to configure actions, certificates, dynamic virtual private networks (VPNs), firewall authentication, flow, forwarding options, group VPNs, Intrusion Detection Prevention (IDP), Internet Key Exchange (IKE), Internet Protocol Security (IPsec), logging, Network Address Translation (NAT), public key infrastructure (PKI), policies, resource manager, rules, screens, secure shell known hosts, trace options, user identification, unified threat management (UTM), and zones. Statements that are exclusive to the SRX Series devices running Junos OS are described in this section.

Each of the following topics lists the statements at a sub-hierarchy of the **[edit security]** hierarchy.

- *[edit security address-book] Hierarchy Level*
- [\[edit security alarms\] Hierarchy Level](#) on page 1419
- *[edit security alg] Hierarchy Level*
- *[edit security analysis] Hierarchy Level*
- *[edit security application-firewall] Hierarchy Level*
- *[edit security application-tracking] Hierarchy Level*
- [\[edit security certificates\] Hierarchy Level](#) on page 899
- [\[edit security datapath-debug\] Hierarchy Level](#) on page 1420
- *[edit security dynamic-vpn] Hierarchy Level*
- *[edit security firewall-authentication] Hierarchy Level*
- *[edit security flow] Hierarchy Level*
- *[edit security forwarding-options] Hierarchy Level*

- *[edit security forwarding-process] Hierarchy Level*

| <b>Description</b>         | Configure archiving properties for all system log files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>             | <p><b>files <i>number</i></b>—Maximum number of archived log files to retain. When the Junos OS logging utility has written a defined maximum amount of data to a log file <b>logfile</b>, it closes the file, compresses it, and renames it <b>logfile.0.gz</b> (the amount of data is determined by the <b>size</b> statement at this hierarchy level). The utility then opens and writes to a new file called <b>logfile</b>. When the new file reaches the maximum size, the <b>logfile.0.gz</b> file is renamed to <b>logfile.1.gz</b>, and the new file is closed, compressed, and renamed <b>logfile.0.gz</b>. By default, the logging facility creates up to ten archive files in this manner. Once the maximum number of archive files exists, each time the active log file reaches the maximum size, the contents of the oldest archive file are lost (overwritten by the next oldest file).</p> <p><b>Range:</b> 1 through 1000</p> <p><b>Default:</b> 10 files</p> <p><b>size <i>size</i></b>—Maximum amount of data that the Junos OS logging utility writes to a log file <b>logfile</b> before archiving it (closing it, compressing it, and changing its name to <b>logfile.0.gz</b>). The utility then opens and writes to a new file called <b>logfile</b>.</p> <p><b>Syntax:</b> <i>x k</i> to specify the number of kilobytes, <i>x m</i> for the number of megabytes, or <i>x g</i> for the number of gigabytes</p> <p><b>Range:</b> 64 KB through 1 GB</p> <p><b>Default:</b></p> <ul style="list-style-type: none"> <li>• 128 KB for EX Series switches</li> <li>• 1 MB for M Series, MX Series, and T Series routers, and the QFX3500 switch</li> <li>• 10 MB for TX Matrix and TX Matrix Plus routers</li> </ul> <p><b>binary-data   no-binary-data</b>—Mark file as containing binary data. This allows proper archiving of binary files, such as WTMP files (login records for UNIX based systems)..</p> <p><b>Default:</b> no-binary-data</p> <p><b>world-readable   no-world-readable</b>—Grant all users permission to read archived log files, or restrict the permission only to the <b>root</b> user and users who have the Junos OS <b>maintenance</b> permission.</p> <p><b>Default:</b> no-world-readable</p> |

**Required Privilege Level** system—To view this statement in the configuration.  
system-control—To add this statement to the configuration.

## cache (Security Log)

---

**Syntax**

```
cache {  
  exclude exclude-name {  
    destination-address destination-address;  
    destination-port destination-port;  
    event-id event-id;  
    failure;  
    interface-name interface-name;  
    policy-name policy-name;  
    process process-name;  
    protocol protocol;  
    source-address source-address;  
    source-port source-address;  
    success;  
    user-name user-name;  
  }  
  limit value;  
}
```

**Hierarchy Level** [edit security log]

**Release Information** Statement modified in Junos OS Release 9.2.

**Description** Cache security log events in the audit log buffer.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Hierarchy Level</b>     | <code>[edit security log stream <i>stream-name</i>]</code>                                                                                                  |
| <b>Release Information</b> | Statement introduced in Junos OS Release 10.0. Statement modified in Junos OS Release 15.1X49-D40.                                                          |
| <b>Description</b>         | Set the category of logging to <b>all</b> or <b>content-security</b> . Note that for the WELF format, the category must be set to <b>content-security</b> . |

**NOTE:** On SRX5600 and SRX5800 devices, if the stream configuration does not specify a destination port, the default destination port will be the system log port. If you specify a destination port in the stream configuration, then that port will be used instead.

| <b>Description</b>              | Configure the logging of system messages to a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>                  | <p><b><i>facility</i></b>—Class of messages to log. To specify multiple classes, include multiple <b><i>facility severity</i></b> statements. For a list of the facilities, see <a href="#">Table 189</a>.</p> <p><b><i>file filename</i></b>—File in the <code>/var/log</code> directory in which to log messages from the specified facility. To log messages to more than one file, include more than one <b><i>file</i></b> statement.</p> <p><b><i>severity</i></b>—Severity of the messages that belong to the facility specified by the paired <b><i>facility</i></b> name. Messages with severities of the specified level and higher are logged. For a list of the severities, see <a href="#">Table 190</a>.</p> <p>The remaining statements are explained separately.</p> |
| <b>Required Privilege Level</b> | <p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | Configure the maximum number of archived log files to retain. When the Junos OS logging utility has written a defined maximum amount of data to a log file <i>logfile</i> , it closes the file, compresses it, and renames it to <i>logfile.0.gz</i> (for information about the maximum file size, see <a href="#">size</a> ). The utility then opens and writes to a new file called <i>logfile</i> . When the new file reaches the maximum size, the <i>logfile.0.gz</i> file is renamed to <i>logfile.1.gz</i> , and the new file is closed, compressed, and renamed <i>logfile.0.gz</i> . By default, the logging facility creates up to ten archive files in this manner. Once the maximum number of archive files exists, each time the active log file reaches the maximum size, the contents of the oldest archive file are lost (overwritten by the next oldest file). |
| <b>Options</b>                  | <i>number</i> —Maximum number of archived files.<br><b>Range:</b> 1 through 1000<br><b>Default:</b> 10 files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                          |
| <b>Description</b>              | Configure the maximum amount of data that the Junos OS logging utility writes to a log file <b>logfile</b> before archiving it (closing it, compressing it, and changing its name to <b>logfile.0.gz</b> ). The utility then opens and writes to a new file called <b>logfile</b> . For information about the number of archive files that the utility creates in this way, see <a href="#">files</a> . |
| <b>Options</b>                  | <p><b>size</b>—Maximum size of each system log file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).</p> <p><b>Syntax:</b> <b>xk</b> to specify the number of kilobytes, <b>xm</b> for the number of megabytes, or <b>xg</b> for the number of gigabytes</p> <p><b>Range:</b> 64 KB through 1 GB</p> <p><b>Default:</b> 1 MB for MX Series routers and the QFX Series</p>                         |

| <b>Description</b>              | <p>Include the year, the millisecond, or both, in the timestamp on every standard-format system log message. The additional information is included for messages directed to each destination configured by a <b>file</b>, <b>console</b>, or <b>user</b> statement at the <code>[edit system syslog]</code> hierarchy level. As of Junos OS Release 11.4, the additional time information is also sent to destinations configured by a <b>host</b> statement.</p> <p>By default, the timestamp specifies the month, date, hour, minute, and second when the message was logged—for example, <b>Aug 21 12:36:30</b>. However, the timestamp for traceoption messages is specified in milliseconds by default, and is independent of the <code>[edit system syslog time-format]</code> statement.</p> |
|                                 | <p> <b>NOTE:</b> When the <b>structured-data</b> statement is included at the <code>[edit system syslog file filename]</code> hierarchy level, this statement is ignored for the file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>         | Configure security log tracing options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>             | <ul style="list-style-type: none"> <li>• <b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li>• <b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. By default, the name of the file is the name of the process being traced.</li> <li>• <b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li>• <b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li>• <b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the <b>trace-file</b> again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the <b>files</b> option and a filename.</p> <p>Syntax: <b>x K</b> to specify KB, <b>x m</b> to specify MB, or <b>x g</b> to specify GB</p> <p>Range: 10 KB through 1 GB</p> |

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Trace operation to perform. To specify more than one trace operation, include multiple **flag** statements.
  - **all**—Trace with all flags enabled
  - **configuration**—Trace configuration events
  - **hpl**— Trace HPL logging
  - **report**— Trace HPL logging
  - **source**—Communicate with security log forwarder
- **no-remote-trace**—Set remote tracing as disabled.

| Release Information      | Statement introduced in Junos OS Release 9.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description              | <p>Configure the router to enable remote tracing to a specified host IP address. The default setting is disabled.</p> <p>The following processes are supported:</p> <ul style="list-style-type: none"><li>• <b>chassisd</b>—Chassis-control process</li><li>• <b>eventd</b>—Event-processing process</li><li>• <b>cosd</b>—Class-of-service process</li><li>• <b>spd</b>—Adaptive-services process</li></ul> <p>You can use the <b>no-remote-trace</b> statement, under the [edit system process-name traceoptions] hierarchy, to disable remote tracing.</p> |
| Options                  | <b>destination-override syslog host <i>ip-address</i></b> —Overrides the global config under <b>system tracing</b> and has no effect if <b>system tracing</b> is not configured.                                                                                                                                                                                                                                                                                                                                                                              |
| Required Privilege Level | <b>system</b> —To view this statement in the configuration.<br><b>system-control</b> —To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Sample Output

### clear log

The following sample commands list log file information, clear the contents of a log file, and then display the updated log file information:

```

user@host> file list lcc0-re0:/var/log/sampled detail
lcc0-re0:
-----
-rw-r-----  1 root  wheel          26450 Jun 23 18:47 /var/log/sampled
total 1

user@host> clear log lcc0-re0:sampled
lcc0-re0:
-----

user@host> file list lcc0-re0:/var/log/sampled detail
lcc0-re0:
-----
-rw-r-----  1 root  wheel           57 Sep 15 03:44 /var/log/sampled
total 1

```

## clear security log

---

**Syntax** clear security log  
<all>  
<destination-address>  
<destination-port>  
<event-id>  
<failure>  
<interface-name>  
<newer-than>  
<older-than>  
<process>  
<protocol>  
<severity>  
<source-address>  
<source-port>  
<success>  
<username>

**Release Information** Command introduced in Junos OS Release 11.2.

**Description** Deletes the event log.

**Options** **all**—Clears all audit event logs stored in the device memory.

**destination-address**—Clears audit event logs with the specified destination address.

**destination-port**—Clears audit event logs with the specified destination port.

**event-id**—Clears audit event logs with the specified event identification number.

**failure**—Clears failed audit event logs.

**interface-name**—Clears audit event logs with the specified interface.

**newer-than**—Clears audit event logs newer than the specified date and time.

**older-than**—Clears audit event logs older than the specified date and time.

**process**—Clears audit event logs with the specified process that generated the event.

**protocol**—Clears audit event logs generated through the specified protocol.

**severity**—Clears audit event logs generated with the specified severity.

**source-address**—Clears audit event logs with the specified source address.

**source-port**—Clears audit event logs with the specified source port.

**success**—Clears successful audit event logs.

**username**—Clears audit event logs generated for the specified user.

**Required Privilege Level**    clear

**Table 200: monitor list Output Fields**

| Field Name           | Field Description                                  |
|----------------------|----------------------------------------------------|
| <b>monitor start</b> | Indicates the file is being monitored.             |
| <b>"filename"</b>    | Name of the file that is being monitored.          |
| <b>Last changed</b>  | Date and time at which the file was last modified. |

## Sample Output

### monitor list

```
user@host> monitor list
monitor start "vrrpd" (Last changed Dec 03:11:06 20)
monitor start "cli-commands" (Last changed Nov 07:3)
```

## monitor start

| <b>Description</b>                        | List log files, display log file contents, or display information about users who have logged in to the router or switch.                                                                                                                                                                                                                                                                                    |

**NOTE:** On MX Series routers, modifying a configuration to replace a service interface with another service interface is treated as a catastrophic event. When you modify a configuration, the entire configuration associated with the service interface—including NAT pools, rules, and service sets—is deleted and then re-created for the newly specified service interface. If there are active sessions associated with the service interface that is being replaced, these sessions are deleted and the NAT pools are then released, which leads to the generation of the NAT\_POOL\_RELEASE system log messages. However, because NAT pools are already deleted as a result of the catastrophic configuration change and no longer exist, the NAT\_POOL\_RELEASE system log messages are not generated for the changed configuration.

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b> | <p><b>none</b>—List all log files.</p> <p><b>&lt;all-lcc   lcc <i>number</i>   scc&gt;</b>—(Routing matrix only) (Optional) Display logging information about all T640 routers (or line-card chassis) or a specific T640 router (replace <i>number</i> with a value from 0 through 3) connected to a TX Matrix router. Or, display logging information about the TX Matrix router (or switch-card chassis).</p> <p><b>device-type</b>—(QFabric system only) (Optional) Display log messages for only one of the following device types:</p> |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- **director-device**—Display logs for Director devices.
- **infrastructure-device**—Display logs for the logical components of the QFabric system infrastructure, including the diagnostic Routing Engine, fabric control Routing Engine, fabric manager Routing Engine, and the default network Node group and its backup (NW-NG-0 and NW-NG-0-backup).
- **interconnect-device**—Display logs for Interconnect devices.
- **node-device**—Display logs for Node devices.

**NOTE:** If you specify the **device-type** optional parameter, you must also specify either the **device-id** or **device-alias** optional parameter.

**(device-id | device-alias)**—If a device type is specified, display logs for a device of that type. Specify either the device ID or the device alias (if configured).

**filename**—(Optional) Display the log messages in the specified log file. For the routing matrix, the filename must include the chassis information.

**user <username>**—(Optional) Display logging information about users who have recently logged in to the router or switch. If you include **username**, display logging information about the specified user.

**Output Fields** Table 202 lists the output fields for the **show security log** command. Output fields are listed in the approximate order in which they appear.

**Table 202: show security log Output Fields**

| Field Name | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event time | The timestamp of the events received.<br><br>On SRX Series devices, security logs were always timestamped using the UTC time zone by running <b>set system time-zone utc</b> and <b>set security log utc-timestamp</b> CLI commands. Now, time zone can be defined using the local time zone by running the <b>set system time-zone time-zone</b> command to specify the local time zone that the system should use when timestamping the security logs. |
| Message    | Security events are listed.                                                                                                                                                                                                                                                                                                                                                                                                                              |

## show security log file

|                                 |                                                                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | show security log file                                                                                                                                   |
| <b>Release Information</b>      | Command introduced in Junos OS Release 12.1.                                                                                                             |
| <b>Description</b>              | Enables customers to view event-mode log files stored on the device in binary format.                                                                    |
| <b>Required Privilege Level</b> | view                                                                                                                                                     |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"> <li><a href="#">show security log on page 1665</a></li> </ul>                                                         |
| <b>List of Sample Output</b>    | <a href="#">show security log file on page 1668</a>                                                                                                      |
| <b>Output Fields</b>            | Table 203 lists the output fields for the <b>show security log file</b> command. Output fields are listed in the approximate order in which they appear. |

Table 203: show security log file Output Fields

| Field Name | Field Description                                   |
|------------|-----------------------------------------------------|
| Event time | The timestamp when the security event was received. |
| Message    | The message describing the security event.          |

## Sample Output

## CHAPTER 66

# Overview

- [Introduction to Device Management on page 1673](#)

### Introduction to Device Management

---

- [Understanding Device Management Functions in Junos OS on page 1673](#)
- [Understanding the Integrated Local Management Interface on page 1675](#)

### Understanding Device Management Functions in Junos OS

After you have installed a device into your network, you need to manage the device within your network. Device management can be divided into five tasks:

- Fault management—Monitor the device; detect and fix faults.
- Configuration management—Configure device attributes.
- Accounting management—Collect statistics for accounting purposes.
- Performance management—Monitor and adjust device performance.
- Security management—Control device access and authenticate users.

The Junos OS network management features work in conjunction with an operations support system (OSS) to manage the devices within the network. Junos OS can assist you in performing these management tasks, as described in [Table 205](#).

Table 205: Device Management Features in Junos OS

| Task                     | Junos OS Feature                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fault management         | <p>Monitor and see faults using:</p> <ul style="list-style-type: none"> <li>Operational mode commands—For more information about operational mode commands, see the <i>CLI User Guide</i>.</li> <li>SNMP MIBs—For more information about SNMP MIBs supported by Junos OS, see “<a href="#">Standard SNMP MIBs Supported by Junos OS</a>” on page 1681 and “<a href="#">Juniper Networks Enterprise-Specific MIBs</a>” on page 1700.</li> <li>Standard SNMP traps—For more information about standard SNMP traps, see the “<a href="#">Standard SNMP Traps Supported on Devices Running Junos OS</a>” on page 1763.</li> <li>Enterprise-specific SNMP traps—For more information about enterprise-specific traps, see “<a href="#">Juniper Networks Enterprise-Specific SNMP Traps</a>” on page 1748.</li> <li>System log messages—For more information about how to configure system log messages, see <i>System Log Monitoring and Troubleshooting Guide for Security Devices</i>.</li> </ul> |
| Configuration management | <ul style="list-style-type: none"> <li>Configure device attributes using the command-line interface (CLI). For more information about configuring the device using the CLI, see the <i>CLI User Guide</i>.</li> <li>Configuration Management MIB—For more information about the Configuration Management MIB, see the <i>Configuration Management MIB</i>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Accounting management    | <p>Perform the following accounting-related tasks:</p> <ul style="list-style-type: none"> <li>Collect statistics for interfaces, firewall filters, destination classes, source classes, and the Routing Engine. For more information about collecting statistics, see “<a href="#">Accounting Options Configuration</a>” on page 1151.</li> <li>Use interface-specific traffic statistics and other counters, available in the Standard Interfaces MIB, Juniper Networks enterprise-specific extensions to the Interfaces MIB, and media-specific MIBs, such as the enterprise-specific ATM MIB.</li> <li>Count packets as part of a firewall filter. For more information about firewall filter policies, see “<a href="#">Juniper Networks Enterprise-Specific MIBs</a>” on page 1700 and the <i>Junos OS Routing Protocols Library for Security Devices</i>.</li> </ul>                                                                                                                     |
| Performance management   | <p>Monitor performance in the following ways:</p> <ul style="list-style-type: none"> <li>Use operational mode commands. For more information about monitoring performance using operational mode commands, see the <i>CLI User Guide</i>.</li> <li>Use firewall filters. For more information about performance monitoring using firewall filters, see the <i>Junos OS Routing Protocols Library for Security Devices</i>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Understanding the Integrated Local Management Interface

The Integrated Local Management Interface (ILMI) provides a mechanism for Asynchronous Transfer Mode (ATM)-attached devices, such as hosts, routers, and ATM switches, to transfer management information. ILMI provides bidirectional exchange of management information between two ATM interfaces across a physical connection. ILMI information is exchanged over a direct encapsulation of SNMP version 1 (RFC 1157, *A Simple Network Management Protocol*) over ATM Adaptation Layer 5 (AAL5) using a virtual path identifier/virtual channel identifier (VPI/VCI) value (VPI=0, VCI=16).

Junos OS supports only two ILMI MIB variables: **atmfMYIPNmAddress** and **atmfPortMyIfname**. For ATM1 and ATM2 intelligent queuing (IQ) interfaces, you can configure ILMI to communicate directly with an attached ATM switch to enable querying of the switch’s IP address and port number.

For more information about the ILMI MIB, see the ATM Forum at <http://www.atmforum.com/>.

## SNMP MIBs Overview

---

- [Understanding the SNMP Implementation in Junos OS on page 1677](#)

## Understanding the SNMP Implementation in Junos OS

SNMP enables the monitoring of network devices from a central location. This topic provides an overview of SNMP and describes how SNMP is implemented in the Junos OS.

This topic includes the following sections:

- [SNMP Architecture on page 1677](#)
- [Junos OS SNMP Agent Features on page 1680](#)

### SNMP Architecture

---

The SNMP agent exchanges network management information with SNMP manager software running on a network management system (NMS), or host. The agent responds to requests for information and actions from the manager. The agent also controls access to the agent's MIB, the collection of objects that can be viewed or changed by the SNMP manager.

The SNMP manager collects information about network connectivity, activity, and events by polling managed devices.

Communication between the agent and the manager occurs in one of the following forms:

- **Get, GetBulk, and GetNext** requests—The manager requests information from the agent; the agent returns the information in a **Get** response message.
- **Set** requests—The manager changes the value of a MIB object controlled by the agent; the agent indicates status in a **Set** response message.
- **Traps** notification—The agent sends traps to notify the manager of significant events that occur on the network device.

This topic contains the following sections:

- [SNMP MIBs on page 1678](#)
- [SNMP Traps and Informs on page 1678](#)

### ***SNMP MIBs***

A MIB is a hierarchy of information used to define managed objects in a network device. The MIB structure is based on a tree structure, which defines a grouping of objects into related sets. Each object in the MIB is associated with an object identifier (OID), which names the object. The “leaf” in the tree structure is the actual managed object instance, which represents a resource, event, or activity that occurs in your network device.

MIBs are either standard or enterprise-specific. Standard MIBs are created by the Internet Engineering Task Force (IETF) and documented in various RFCs. Depending on the vendor, many standard MIBs are delivered with the NMS software. You can also download the standard MIBs from the IETF website, [www.ietf.org](http://www.ietf.org), and compile them into your NMS, if necessary.

For a list of standard supported MIBs, see “[Standard SNMP MIBs Supported by Junos OS](#)” on page 1681.

Enterprise-specific MIBs are developed and supported by a specific equipment manufacturer. If your network contains devices that have enterprise-specific MIBs, you must obtain them from the manufacturer and compile them into your network management software.

For a list of Juniper Networks enterprise-specific supported MIBs, see “[Juniper Networks Enterprise-Specific MIBs](#)” on page 1700.

### ***SNMP Traps and Informs***

Routers can send notifications to SNMP managers when significant events occur on a network device, most often errors or failures. SNMP notifications can be sent as traps or inform requests. SNMP traps are unconfirmed notifications. SNMP informs are confirmed notifications.

SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. The standard traps are compiled into the network management software. You can also download the standard traps from the IETF website, [www.ietf.org](http://www.ietf.org).

For more information about standard traps supported by the Junos OS, see [“Standard SNMP Traps Supported on Devices Running Junos OS” on page 1763](#).

Enterprise-specific traps are developed and supported by a specific equipment manufacturer. If your network contains devices that have enterprise-specific traps, you must obtain them from the manufacturer and compile them into your network management software.

For more information about enterprise-specific traps supported by the Junos OS, see [“Juniper Networks Enterprise-Specific SNMP Traps” on page 1748](#). For information about system logging severity levels for SNMP traps, see [“System Logging Severity Levels for SNMP Traps” on page 1680](#).

With traps, the receiver does not send any acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. To increase reliability, SNMP informs are supported in SNMPv3. An SNMP manager that receives an inform acknowledges the message with a response. For information about SNMP informs, see [“Configuring SNMP Informs” on page 1818](#).

### ***SNMP Trap Queuing***

The Junos OS supports trap queuing to ensure that traps are not lost because of temporary unavailability of routes. Two types of queues, destination queues and a throttle queue, are formed to ensure delivery of traps and to control the trap traffic.

The Junos OS forms a destination queue when a trap to a particular destination is returned because the host is not reachable, and adds the subsequent traps to the same destination to the queue. The Junos OS checks for availability of routes every 30 seconds and sends the traps from the destination queue in a round-robin fashion. If the trap delivery fails, the trap is added back to the queue, and the delivery attempt counter and the next delivery attempt timer for the queue are reset. Subsequent attempts occur at progressive intervals of 1 minute, 2 minutes, 4 minutes, and 8 minutes. The maximum delay between the attempts is 8 minutes, and the maximum number of attempts is 10. After 10 unsuccessful attempts, the destination queue and all the traps in the queue are deleted.

The Junos OS also has a throttle mechanism to control the number of traps (**throttle threshold**; default value of 500 traps) sent during a particular time period (**throttle interval**; default of 5 seconds) and to ensure consistency in trap traffic, especially when a large number of traps are generated because of interface status changes. The throttle interval period begins when the first trap arrives at the throttle. All traps within the trap threshold are processed, and the traps beyond the threshold limit are queued. The maximum size of trap queues (that is, the throttle queue and the destination queue combined) is 40,000 traps. However, on EX Series switches, the maximum size of the trap queue is 1000 traps. The maximum size of any one queue is 20,000 traps for devices other than EX Series switches. On EX Series switches, the maximum size of one queue is 500 traps. If a trap is sent from a destination queue when the throttle queue has exceeded the maximum size, the trap is added back to the top of the destination queue, and all subsequent attempts from the destination queue are stopped for a 30-second period, after which the destination queue restarts sending the traps.

**NOTE:** Users cannot configure the Junos OS for trap queuing. Users cannot view any information about trap queues except what is available in the syslog.

---

### ***System Logging Severity Levels for SNMP Traps***

For some traps, when a trap condition occurs, regardless of whether the SNMP agent sends a trap to an NMS, the trap is logged if the system logging is configured to log an event with that system logging severity level. For more information about system logging severity levels, see the *System Log Monitoring and Troubleshooting Guide for Security Devices*.

For more information about system logging severity levels for standard traps, see [“Standard SNMP Version 1 Traps” on page 1764](#) and [“Standard SNMP Version 2 Traps” on page 1767](#). For more information about system logging severity levels for enterprise-specific traps, see [“Juniper Networks Enterprise-Specific SNMP Version 1 Traps” on page 1749](#) and [“Juniper Networks Enterprise-Specific SNMP Version 2 Traps” on page 1756](#).

### **Junos OS SNMP Agent Features**

---

The Junos OS SNMP agent software consists of an SNMP master agent that delegates all SNMP requests to subagents. Each subagent is responsible for the support of a specific set of MIBs.

The Junos OS supports the following versions of SNMP:

- **SNMPv1**—The initial implementation of SNMP that defines the architecture and framework for SNMP.
- **SNMPv2c**—The revised protocol, with improvements to performance and manager-to-manager communications. Specifically, SNMPv2c implements community strings, which act as passwords when determining who, what, and how the SNMP clients can access the data in the SNMP agent. The community string is contained in SNMP **Get**, **GetBulk**, **GetNext**, and **Set** requests. The agent might require a different community string for **Get**, **GetBulk**, and **GetNext** requests (**read-only** access) than it does for **Set** requests (**read-write** access).
- **SNMPv3**—The most up-to-date protocol focuses on security. SNMPv3 defines a security model, user-based security model (USM), and a view-based access control model (VACM). SNMPv3 USM provides data integrity, data origin authentication, message replay protection, and protection against disclosure of the message payload. SNMPv3 VACM provides access control to determine whether a specific type of access (read or write) to the management information is allowed.

In addition, the Junos OS SNMP agent software accepts IPv4 and IPv6 addresses for transport over IPv4 and IPv6. For IPv6, the Junos OS supports the following features:

- SNMP data over IPv6 networks
- IPv6-specific MIB data
- SNMP agents for IPv6

## Standard SNMP MIBs Supported by Junos OS

Table 206 contains the list of standard SNMP MIBs and RFCs that are supported on various devices running Junos OS. RFCs can be found at <http://www.ietf.org>.

**NOTE:** In this table, a value of 1 in any of the platform columns (M, T, MX, EX, and SRX) denotes that the corresponding MIB is supported on that particular platform, and a value of 0 denotes that the MIB is not supported on the platform.

Table 206: Standard MIBs Supported on Devices Running Junos OS

| MIB/RFC                                                                                                                                                                                                                                                                                                                                                         | Platforms |   |   |    |    |         |           |          |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |           |   |   |    |    | Low-End | Mid-Range | High-End |   |
| RFC 1850, <i>OSPF Version 2 Management Information Base</i> (except for the <b>ospfOriginateNewLsas</b> and <b>ospfRxNewLsas</b> objects, the Host Table, and the traps <b>ospfOriginateLSA</b> , <b>ospfLsdbOverflow</b> , and <b>ospfLsdbApproachingOverflow</b> )                                                                                                                                                                                                      | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 0 |
| RFC 1901, <i>Introduction to Community-based SNMPv2</i>                                                                                                                                                                                                                                                                                                                                                                                                                   | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 1        | 1 |
| RFC 2011, <i>SNMPv2 Management Information Base for the Internet Protocol Using SMIv2</i>                                                                                                                                                                                                                                                                                                                                                                                 | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 0 |
| RFC 2012, <i>SNMPv2 Management Information Base for the Transmission Control Protocol Using SMIv2</i>                                                                                                                                                                                                                                                                                                                                                                     | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| RFC 2013, <i>SNMPv2 Management Information Base for the User Datagram Protocol Using SMIv2</i>                                                                                                                                                                                                                                                                                                                                                                            | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| RFC 2024, <i>Definitions of Managed Objects for Data Link Switching Using SMIv2</i> (except for the <b>dlswInterface</b> and <b>dlswSdlc</b> object groups; the <b>dlswDirLocateMacTable</b> , <b>dlswDirNBTable</b> , and <b>dlswDirLocateNBTable</b> tables; the <b>dlswCircuitDiscReasonLocal</b> and <b>dlswCircuitDiscReasonRemote</b> tabular objects; and the <b>dlswDirMacCacheNextIndex</b> and <b>dlswDirNBCacheNextIndex</b> scalar objects; read-only access) | 0         | 1 | 1 | 1  | 0  | 0       | 0         | 0        | 0 |
| RFC 2096, <i>IP Forwarding Table MIB</i> (The <b>ipCidrRouteTable</b> has been extended to include the tunnel name when the next hop is through an RSVP-signaled LSP.)<br><br><b>NOTE:</b> RFC 2096 has been replaced by RFC 4292. However, Junos OS currently supports both RFC 2096 and RFC 4292.                                                                                                                                                                       | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 1 |
| RFC 2115, <i>Management Information Base for Frame Relay DTEs Using SMIv2</i> ( <b>frDlcmiTable</b> only; <b>frCircuitTable</b> and <b>frErrTable</b> are not supported)                                                                                                                                                                                                                                                                                                  | 0         | 1 | 1 | 1  | 0  | 0       | 1         | 0        | 0 |

Table 206: Standard MIBs Supported on Devices Running Junos OS (*continued*)

| MIB/RFC                                                                                                                                                                                                                                                           | Platforms |   |   |    |    |         |           |          |   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---|---|----|----|---------|-----------|----------|---|
|                                                                                                                                                                                                                                                                   | ACX       | M | T | MX | EX | SRX     |           |          |   |
|                                                                                                                                                                                                                                                                   |           |   |   |    |    | Low-End | Mid-Range | High-End |   |
| RFC 2233, <i>The Interfaces Group MIB Using SMIv2</i>                                                                                                                                                                                                             | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| <b>NOTE:</b> RFC 2233 has been replaced by RFC 2863, IF MIB. However, Junos OS supports both RFC 2233 and RFC 2863.                                                                                                                                               |           |   |   |    |    |         |           |          |   |
| RFC 2287, <i>Definitions of System-Level Managed Objects for Applications</i> (only the objects <b>sysApplInstallPkgTable</b> , <b>sysApplInstallElmtTable</b> , <b>sysApplElmtRunTable</b> , and <b>sysApplMapTable</b> )                                        | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| RFC 2465, <i>Management Information Base for IP Version 6: Textual Conventions and General Group</i> (except for IPv6 interface statistics)                                                                                                                       | 1         | 1 | 1 | 1  | 0  | 1       | 1         | 0        | 0 |
| RFC 2495, <i>Definitions of Managed Objects for the DS1, E1, DS2, and E2 Interface Types</i> (except for <b>dsx1FarEndConfigTable</b> , <b>dsx1FarEndCurrentTable</b> , <b>dsx1FarEndIntervalTable</b> , <b>dsx1FarEndTotalTable</b> , and <b>dsx1FracTable</b> ) | 1         | 1 | 1 | 0  | 0  | 0       | 1         | 0        | 0 |
| RFC 2515, <i>Definitions of Managed Objects for ATM Management</i> (except <b>atmVpCrossConnectTable</b> , <b>atmVcCrossConnectTable</b> , and <b>aal5VccTable</b> )                                                                                              | 1         | 1 | 1 | 0  | 0  | 0       | 0         | 0        | 0 |
| RFC 2570, <i>Introduction to Version 3 of the Internet-standard Network Management Framework</i>                                                                                                                                                                  | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 1 |
| RFC 2571, <i>An Architecture for Describing SNMP Management Frameworks</i> (read-only access)                                                                                                                                                                     | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| <b>NOTE:</b> RFC 2571 has been replaced by RFC 3411. However, Junos OS supports both RFC 2571 and RFC 3411.                                                                                                                                                       |           |   |   |    |    |         |           |          |   |
| RFC 2572, <i>Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)</i> (read-only access)                                                                                                                                          | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| <b>NOTE:</b> RFC 2572 has been replaced by RFC 3412. However, Junos OS supports both RFC 2572 and RFC 3412.                                                                                                                                                       |           |   |   |    |    |         |           |          |   |

Table 206: Standard MIBs Supported on Devices Running Junos OS (*continued*)

| MIB/RFC                                                                                                                                                                                                                     | Platforms |   |   |    |    |         |           |          |   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---|---|----|----|---------|-----------|----------|---|
|                                                                                                                                                                                                                             | ACX       | M | T | MX | EX | SRX     |           |          |   |
|                                                                                                                                                                                                                             |           |   |   |    |    | Low-End | Mid-Range | High-End |   |
| RFC 2576, <i>Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework</i>                                                                                              | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| <b>NOTE:</b> RFC 2576 has been replaced by RFC 3584. However, Junos OS supports both RFC 2576 and RFC 3584.                                                                                                                 |           |   |   |    |    |         |           |          |   |
| RFC 2578, <i>Structure of Management Information Version 2 (SMIv2)</i>                                                                                                                                                      | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 1 |
| RFC 2579, <i>Textual Conventions for SMIv2</i>                                                                                                                                                                              | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 1 |
| RFC 2580, <i>Conformance Statements for SMIv2</i>                                                                                                                                                                           | 1         | 1 | 1 | 1  | 1  | 1       | 0         | 0        | 1 |
| RFC 2662, <i>Definitions of Managed Objects for ADSL Lines</i> (All MIB tables, objects, and traps are applicable for the ADSL ATU-R agent.)                                                                                | 0         | 1 | 1 | 1  | 0  | 0       | 1         | 0        | 0 |
| RFC 2665, <i>Definitions of Managed Objects for the Ethernet-like Interface Types</i>                                                                                                                                       | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |
| <b>NOTE:</b> For M, T and MX Series, the SNMP counters do not count the Ethernet header and frame check sequence (FCS). Therefore, the Ethernet header bytes and the FCS bytes are not included in the following four OIDs: |           |   |   |    |    |         |           |          |   |
| <ul style="list-style-type: none"><li>• ifInOctets</li><li>• ifOutOctets</li><li>• ifHCInOctets</li><li>• ifHCOctets</li></ul>                                                                                              |           |   |   |    |    |         |           |          |   |
| However, the EX switches adhere to RFC 2665.                                                                                                                                                                                |           |   |   |    |    |         |           |          |   |
| <b>NOTE:</b> The list of managed objects specified in RFC 2665 has been updated by RFC 3635 by including information useful for the management of 10 Gigabit per second Ethernet interfaces.                                |           |   |   |    |    |         |           |          |   |
| RFC 2787, <i>Definitions of Managed Objects for the Virtual Router Redundancy Protocol</i> (except row creation, the <b>Set</b> operation, and the object <b>vrpStatsPacketLengthErrors</b> )                               | 1         | 1 | 1 | 1  | 1  | 1       | 1         | 0        | 1 |

Table 206: Standard MIBs Supported on Devices Running Junos OS (*continued*)

| MIB/RFC                                                                                                                                                                                                                                                                                                                                                                  | Platforms |   |   |    |    |         |           |          |   |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---|---|----|----|---------|-----------|----------|---|
|                                                                                                                                                                                                                                                                                                                                                                          | ACX       | M | T | MX | EX | SRX     |           |          |   |

## Juniper Networks Enterprise-Specific MIBs

The Junos OS supports the following enterprise-specific MIBs:

- **AAA Objects MIB**—Provides support for monitoring user authentication, authorization, and accounting through the RADIUS, LDAP, SecurID, and local authentication servers. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt)

For more information, see *AAA Objects MIB*.

- **Access Authentication Objects MIB**—Provides support for monitoring firewall authentication, including data about the users trying to access firewall-protected resources and the firewall authentication service itself. This MIB is currently supported

by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt).

For more information, see *Access Authentication Objects MIB*.

- Alarm MIB—Provides support for alarms from the router. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt).

For more information, see *Alarm MIB*.

- DHCP Objects MIB— Provides SNMP support (get and trap) for DHCP local server and relay configurations. It also provides support for bindings and leases tables, and for statistics. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-jdhcp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-jdhcp.txt).

For more information, see *DHCP MIB*.

- Digital Optical Monitoring MIB—Provides support for the **SNMP Get** request for statistics and **SNMP Trap** notifications for alarms. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-dom.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-dom.txt).

For more information, see *Digital Optical Monitoring MIB*.

- DNS Objects MIB—Provides support for monitoring DNS proxy queries, requests, responses, and failures. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt).

For more information, see *DNS Objects MIB*.

- Firewall MIB—Provides support for monitoring firewall filter counters. Routers must have the Internet Processor II ASIC to perform firewall monitoring. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt).

For more information, see *Firewall MIB*.

- Flow Collection Services MIB—Provides statistics on files, records, memory, FTP, and error states of a monitoring services interface. It also provides SNMP traps for unavailable destinations, unsuccessful file transfers, flow overloading, and memory overloading. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-coll.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-coll.txt).

For more information, see *Flow Collection Services MIB*.

- Host Resources MIB—Extends the **hrStorageTable** object, providing a measure of the usage of each file system on the router in percentage format. Previously, the objects in the **hrStorageTable** measured the usage in allocation units—**hrStorageUsed** and **hrStorageAllocationUnits**—only. Using the percentage measurement, you can more easily monitor and apply thresholds on usage. For a downloadable version of this MIB,

see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt).

For more information, see *Host Resources MIB*.

- IDP Objects MIB—Provides support for monitoring SNMP IDP queries, requests, responses, and failures. This MIB defines the key monitoring and threshold crossing trap support, IDP database update status and trap support, attack-related monitoring and trap support for all SRX Series devices. This MIB models IDP attributes specific to the appropriate Juniper Networks implementation. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-idp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-idp.txt).

For more information, see *IDP MIB*.

- Interface MIB—Extends the standard **ifTable** (RFC 2863) with additional statistics and Juniper Networks enterprise-specific chassis information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt).

For more information, see *Interface MIB*.

- Interface Accounting Forwarding Class MIB—Extends the Juniper Enterprise Interface MIB and provides support for monitoring statistics data for interface accounting and IETF standardization. This MIB is currently supported by Junos OS for M Series and MX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-accounting.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-accounting.txt)

For more information, see *Interface Accounting Forwarding Class MIB*.

- IP Forward MIB—Extends the standard IP Forwarding Table MIB (RFC 2096) to include CIDR forwarding information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt).

For more information, see *IP Forward MIB*.

- IPsec Generic Flow Monitoring Object MIB—Based on **jnx-ipsec-monitor-mib**, this MIB provides support for monitoring IPsec and IPsec VPN management objects. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt).

For more information, see *IPsec Generic Flow Monitoring Object MIB*.

- IPsec Monitoring MIB—Provides operational and statistical information related to the IPsec and IKE tunnels on Juniper Networks routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt).

For more information, see *IPsec Monitoring MIB*.

- IPsec VPN Objects MIB—Provides support for monitoring IPsec and IPsec VPN management objects for Juniper security product lines. This MIB is an extension of **jnx-ipsec-flow-mon.mib**. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see

[http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-ipsec-vpn.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-ipsec-vpn.txt) .

For more information, see *IPsec VPN Objects MIB*.

- IPv4 MIB—Provides additional Internet Protocol version 4 (IPv4) address information, supporting the assignment of identical IPv4 addresses to separate interfaces. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt) .

For more information, see *IPv4 MIB*.

- IPv6 and ICMPv6 MIB—Provides IPv6 and Internet Control Message Protocol version 6 (ICMPv6) statistics. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv6.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv6.txt) .

For more information, see *IPv6 MIB*.

- L2ALD MIB—Contains information about the Layer 2 Address Learning Daemon (L2ALD) and related traps, such as the routing instance MAC limit trap and the interface MAC limit trap. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2ald.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2ald.txt) .

For more information, see *L2ALD MIB*.

- L2CP MIB—Provides information about Layer 2 Control Protocols (L2CP) based features on MX Series 3D Universal Edge Routers . Currently, Junos OS supports only the **jnxDot1dStpPortRootProtectEnabled**, **jnxDot1dStpPortRootProtectState**, and **jnxPortRootProtectStateChangeTrap** objects. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2cp-features.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2cp-features.txt) .

For more information, see *L2CP MIB*.

- L2TP MIB—Provides information about Layer 2 Transport Protocol (L2TP) tunnels and sessions. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2tp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-l2tp.txt) .

For more information, see *L2TP MIB*.

- LDP MIB—Provides LDP statistics and defines LDP label-switched path (LSP) notifications. LDP traps support only IPv4 standards. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ldp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ldp.txt) .

For more information, see *LDP MIB*.

- License MIB—Extends SNMP support to licensing information, and introduces SNMP traps that alert users when the licenses are about to expire, expire, or when the total number of users exceeds the number specified in the license. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt) .

For more information, see *License MIB*.

- Logical Systems MIBs—Extend SNMP support to logical systems security profile through various MIBs defined under **jnxLsysSecurityProfile**. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt).

For more information about logical systems MIBs and downloadable versions of the MIBs, see *Logical Systems MIB*.

- NAT Objects MIB—Provides support for monitoring network address translation (NAT). This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt).

For more information, see *NAT Objects MIB*.

- Power Supply Unit MIB—Enables monitoring and managing of the power supply on a device running the Junos OS. This MIB is currently supported only on EX Series Ethernet Switches. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-power-supply-unit.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-power-supply-unit.txt).

For more information, see *Power Supply Unit MIB*.

- PPP MIB—Provides SNMP support for PPP-related information such as the type of authentication used, interface characteristics, status, and statistics. This MIB is currently supported only on M Series and MX Series routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ppp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ppp.txt).

For more information, see *PPP MIB*.

- PPPoE MIB—Provides SNMP support for PPPoE-related information such as the type of authentication used, interface characteristics, status, and statistics. This MIB is currently supported only on M Series and MX Series routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-pppoe.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-pppoe.txt).

For more information, see *PPPoE MIB*.

- Pseudowire TDM MIB—Extends the standard Pseudowire MIB, and contains information about configuration and statistics for specific pseudowire types. The enterprise-specific Pseudowire TDM MIB is the Juniper Networks implementation of the standard Managed Objects for TDM over Packet Switched Network MIB (draft-ietf-pwe3-tdm-mib-08.txt). For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-pwtdm.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-pwtdm.txt).
- SONET APS MIB—Monitors any SONET interface that participates in Automatic Protection Switching (APS). For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-sonetaps.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-sonetaps.txt).

For more information, see *SONET APS MIB*.

- SONET/SDH Interface Management MIB—Monitors the current alarm for each SONET/SDH interface. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-sonet.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-sonet.txt).

For more information, see *SONET/SDH Interface Management MIB*.

- Source Class Usage MIB—Counts packets sent to customers by performing a lookup on the IP source address and the IP destination address. The Source Class Usage (SCU) MIB makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt).

For more information, see *Source Class Usage MIB*.

- SPU Monitoring MIB—Provides support for monitoring SPUs on all high-end SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt).

For more information, see *SPU Monitoring Objects MIB*.

- Structure of Management Information MIB—Contains object identifiers (OIDs) for the security branch of the MIBs used in Junos OS for SRX Series devices, services, and traps. This MIB is currently supported by Junos OS for SRX Series devices only.

Explains how the Juniper Networks enterprise-specific MIBs are structured. For a downloadable version of this MIB, see

[http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-smi.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-smi.txt).

For more information, see *Structure of Management Information MIB*.

## List of SRX300, SRX320, SRX340, SRX550, and SRX1500 Services Gateways Supported Enterprise-Specific MIBs

Junos OS supports the following enterprise-specific MIBs:

- Structure of Management Information MIB—Contains object identifiers (OIDs) for the security branch of the MIBs used in Junos OS for SRX Series devices product, services and traps. This MIB is currently supported only by Junos OS for SRX Series devices. It also explains how the Juniper Networks enterprise-specific MIBs are structured. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-smi.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-smi.txt). For more information, see *Structure of Management Information MIB*.
- Access Authentication Objects MIB—Provides support for monitoring firewall authentication, including data about the users trying to access firewall-protected resources and the firewall authentication service itself. This MIB is currently supported

only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt).

For more information, see *Access Authentication Objects MIB*.

- Alarm MIB—Provides support for alarms from the router. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt).

For more information, see *Alarm MIB*.

- BGP4 V2 MIB—Contains objects used to monitor BGP peer-received prefix counters. It is based upon similar objects in the MIB documented in Internet draft draft-ietf-idr-bgp4-mibv2-03.txt, Definitions of Managed Objects for the Fourth Version of BGP (BGP-4), Second Version. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt).

For more information, see *BGP4 V2 MIB*.

- BFD MIB—Provides support for monitoring Bidirectional Forwarding Detection (BFD) sessions. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt).

For more information, see *Bidirectional Forwarding Detection MIB*.

- Chassis MIB—Provides support for environmental monitoring (power supply state, board voltages, fans, temperatures, and air flow) and inventory support for the chassis, System Control Board (SCB), System and Switching Board (SSB), Switching and Forwarding Model (SFM), Flexible PIC Concentrators (FPCs), and PICs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt).

For more information, see *Chassis MIBs*.

- Configuration Management MIB—Provides notification for configuration changes as SNMP traps. Each trap contains the time at which the configuration change was committed, the name of the user who made the change, and the method by which the change was made. A history of the last 32 configuration changes is kept in **jnxCmChgEventTable**. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt).

For more information, see *Configuration Management MIB*.

- Ethernet MAC MIB—Monitors media access control (MAC) statistics on Gigabit Ethernet intelligent queuing (IQ) interfaces. It collects MAC statistics; for example, **inOctets**, **inFrames**, **outOctets**, and **outFrames** on each source MAC address and virtual LAN (VLAN) ID for each Ethernet port. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-mac.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-mac.txt).

For more information, see *Ethernet MAC MIB*.

- Event MIB—Defines a generic trap that can be generated using an op script or event policy. This MIB provides the ability to specify a system log string and raise a trap if that system log string is found. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt).

For more information, see *Event MIB*.

- Firewall MIB—Provides support for monitoring firewall filter counters. Routers must have the Internet Processor II ASIC to perform firewall monitoring. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt).

For more information, see *Firewall MIB*.

- Host Resources MIB—Extends the **hrStorageTable** object, providing a measure of the usage of each file system on the router in percentage. Previously, the objects in the **hrStorageTable** measured the usage in allocation units—**hrStorageUsed** and **hrStorageAllocationUnits**—only. Using the percentage measurement, you can more easily monitor and apply thresholds on usage. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt).

For more information, see *Host Resources MIB*.

- Interface MIB—Extends the standard ifTable (RFC 2863) with additional statistics and Juniper Networks enterprise-specific chassis information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt).

For more information, see *Interface MIB*.

- IP Forward MIB—Extends the standard IP Forwarding Table MIB (RFC 2096) to include CIDR forwarding information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt).

For more information, see *IP Forward MIB*.

- IPsec Monitoring MIB—Provides operational and statistical information related to the IPsec and IKE tunnels on Juniper Networks routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt).

For more information, see *IPsec Monitoring MIB*.

- IPsec Generic Flow Monitoring Object MIB—Based on **jnx-ipsec-monitor-mib**, this MIB provides support for monitoring IPsec and IPsec VPN management objects. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt).

For more information, see *IPsec Generic Flow Monitoring Object MIB*.

- IPv4 MIB—Provides additional Internet Protocol version 4 (IPv4) address information, supporting the assignment of identical IPv4 addresses to separate interfaces. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt).

For more information, see *IPv4 MIB*.

- License MIB—Extends SNMP support to licensing information, and introduces SNMP traps that alert users when the licenses are about to expire, expire, or when the total number of users exceeds the number specified in the license. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt).

For more information, see *License MIB*.

- Network Address Translation (NAT) Objects MIB—Provides support for monitoring network address translation (NAT). This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt).

For more information, see *NAT Objects MIB*.

- Packet Forwarding Engine MIB—Provides notification statistics for Packet Forwarding Engines. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt).

For more information, see *Packet Forwarding Engine MIB*.

- Ping MIB—Extends the standard Ping MIB control table (RFC 2925). Items in this MIB are created when entries are created in pingCtlTable of the Ping MIB. Each item is indexed exactly as it is in the Ping MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt).

For more information, see *PING MIB*.

- Policy Objects MIB—Provides support for monitoring the security policies that control the flow of traffic from one zone to another. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt).

For more information, see *Policy Objects MIB*.

- Reverse-Path-Forwarding MIB—Monitors statistics for traffic that is rejected because of reverse-path-forwarding (RPF) processing. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt).

**NOTE:** The enterprise-specific RPF MIB is not supported on EX Series Ethernet Switches.

For more information, see *Reverse Path Forwarding MIB*.

- **RMON Events and Alarms MIB**—Supports the Junos extensions to the standard Remote Monitoring (RMON) Events and Alarms MIB (RFC 2819). The extension augments alarmTable with additional information about each alarm. Two new traps are also defined to indicate when problems are encountered with an alarm. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt).

For more information, see *RMON Events and Alarms MIB*.

- **Security Interface Extension Objects MIB**—Provides support for the security management of interfaces. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt).

For more information, see *Security Interface Extension Objects MIB*.

- **SNMP IDP Objects MIB**—Provides support for monitoring SNMP IDP queries, requests, responses, and failures. This MIB defines the key monitoring and threshold crossing trap support, IDP database update status and trap support, attack-related monitoring and trap support for SRX300, SRX320, SRX340, SRX550, and SRX1500 Services Gateways. This MIB models IDP attributes specific to the appropriate Juniper Networks implementation. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-idp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-idp.txt).

For more information, see *SNMP IDP MIB*.

- **System Log MIB**—Enables notification of an SNMP trap-based application when an important system log message occurs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt).

For more information, see *System Log MIB*.

- **Traceroute MIB**—Supports the Junos extensions of traceroute and remote operations. Items in this MIB are created when entries are created in the traceRouteCtlTable of the Traceroute MIB. Each item is indexed exactly the same way as it is in the Traceroute MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt).

For more information, see *Traceroute MIB*.

- **Utility MIB**—Provides SNMP support for exposing Junos data and has tables that contain information on each type of data, such as integer and string. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt).

For more information, see *Utility MIB*.

- VPN Certificate Objects MIB—Provides support for monitoring the local and CA certificates loaded on the router. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt).

For more information, see *VPN Certificate Objects MIB*.

- *Structure of Management Information MIB*

## List of SRX1500 Services Gateways Supported Enterprise-Specific MIBs

Junos OS supports the following enterprise-specific MIBs:

- Structure of Management Information MIB—Contains object identifiers (OIDs) for the security branch of the MIBs used in Junos OS for SRX Series devices product, services and traps. This MIB is currently supported only by Junos OS for SRX Series devices. It also explains how the Juniper Networks enterprise-specific MIBs are structured. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-smi.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-smi.txt). For more information, see *Structure of Management Information MIB*.
- AAA Objects MIB—Provides support for monitoring user authentication, authorization, and accounting through the RADIUS, LDAP, SecurID, and local authentication servers. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt).

For more information, see *AAA Objects MIB*.

- Access Authentication Objects MIB—Provides support for monitoring firewall authentication, including data about the users trying to access firewall-protected resources and the firewall authentication service itself. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt).

For more information, see *Access Authentication Objects MIB*.

- Alarm MIB—Provides support for alarms from the router. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt).

For more information, see *Alarm MIB*.

- ATM CoS MIB—Provides support for monitoring Asynchronous Transfer Mode, version 2 (ATM2) virtual circuit (VC) class-of-service (CoS) configurations. It also provides

CoS queue statistics for all VCs that have CoS configured. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-atm-cos.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-atm-cos.txt).

For more information, see *ATM Class-of-Service MIB*.

- BGP4 V2 MIB—Contains objects used to monitor BGP peer-received prefix counters. It is based upon similar objects in the MIB documented in Internet draft draft-ietf-idr-bgp4-mibv2-03.txt, Definitions of Managed Objects for the Fourth Version of BGP (BGP-4), Second Version. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt).

For more information, see *BGP4 V2 MIB*.

- BFD MIB—Provides support for monitoring Bidirectional Forwarding Detection (BFD) sessions. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt).

For more information, see *Bidirectional Forwarding Detection MIB*.

- Chassis MIB—Provides support for environmental monitoring (power supply state, board voltages, fans, temperatures, and air flow) and inventory support for the chassis, System Control Board (SCB), System and Switching Board (SSB), Switching and Forwarding Model (SFM), Flexible PIC Concentrators (FPCs), and PICs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt).

For more information, see *Chassis MIBs*.

- Chassis Cluster MIB—Provides information about objects that are used whenever the state of the control link interfaces or fabric link interfaces changes (up to down or down to up) in a chassis cluster deployment. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-jsrpd.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-jsrpd.txt).

For more information, see *Chassis Cluster MIB*.

- Configuration Management MIB—Provides notification for configuration changes as SNMP traps. Each trap contains the time at which the configuration change was committed, the name of the user who made the change, and the method by which the change was made. A history of the last 32 configuration changes is kept in `jnxCmChgEventTable`. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt).

For more information, see *Configuration Management MIB*.

- Destination Class Usage MIB—Provides support for monitoring packet counts based on the ingress and egress points for traffic transiting your networks. Ingress points are identified by input interface. Egress points are identified by destination prefixes grouped into one or more sets, known as destination classes. One counter is managed per interface per destination class, up to a maximum of 16 counters per interface. For a

downloadable version of this MIB, see

[http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-dcu.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-dcu.txt).

For more information, see *Destination Class Usage MIB*.

- DNS Objects MIB—Provides support for monitoring DNS proxy queries, requests, responses, and failures. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt).

For more information, see *DNS Objects MIB*.

- Ethernet MAC MIB—Monitors media access control (MAC) statistics on Gigabit Ethernet intelligent queuing (IQ) interfaces. It collects MAC statistics; for example, **inocets**, **inframes**, **outocets**, and **outframes** on each source MAC address and virtual LAN (VLAN) ID for each Ethernet port. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-mac.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-mac.txt).

For more information, see *Ethernet MAC MIB*.

- Event MIB—Defines a generic trap that can be generated using an op script or event policy. This MIB provides the ability to specify a system log string and raise a trap if that system log string is found. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt).

For more information, see *Event MIB*.

- Firewall MIB—Provides support for monitoring firewall filter counters. Routers must have the Internet Processor II ASIC to perform firewall monitoring. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt).

For more information, see *Firewall MIB*.

- Host Resources MIB—Extends the **hrStorageTable** object, providing a measure of the usage of each file system on the router in percentage. Previously, the objects in the **hrStorageTable** measured the usage in allocation units—**hrStorageUsed** and **hrStorageAllocationUnits**—only. Using the percentage measurement, you can more easily monitor and apply thresholds on usage. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt).

For more information, see *Host Resources MIB*.

- Interface MIB—Extends the standard ifTable (RFC 2863) with additional statistics and Juniper Networks enterprise-specific chassis information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt).

For more information, see *Interface MIB*.

- IP Forward MIB—Extends the standard IP Forwarding Table MIB (RFC 2096) to include CIDR forwarding information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt).

For more information, see *IP Forward MIB*.

- IPsec Monitoring MIB—Provides operational and statistical information related to the IPsec and IKE tunnels on Juniper Networks routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt).

For more information, see *IPsec Monitoring MIB*.

- IPsec Generic Flow Monitoring Object MIB—Based on **jnx-ipsec-monitor-mib**, this MIB provides support for monitoring IPsec and IPsec VPN management objects. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt).

For more information, see *IPsec Generic Flow Monitoring Object MIB*.

- IPv4 MIB—Provides additional Internet Protocol version 4 (IPv4) address information, supporting the assignment of identical IPv4 addresses to separate interfaces. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt).

For more information, see *IPv4 MIB*.

- License MIB—Extends SNMP support to licensing information, and introduces SNMP traps that alert users when the licenses are about to expire, expire, or when the total number of users exceeds the number specified in the license. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt).

For more information, see *License MIB*.

- Logical Systems MIB—Provides support for logical systems security profile. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt).

For more information, see *Logical Systems MIB*.

- NAT Objects MIB—Provides support for monitoring network address translation (NAT). This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt).

For more information, see *NAT Objects MIB*.

- Packet Forwarding Engine MIB—Provides notification statistics for Packet Forwarding Engines. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt).

For more information, see *Packet Forwarding Engine MIB*.

- Ping MIB—Extends the standard Ping MIB control table (RFC 2925). Items in this MIB are created when entries are created in **pingCtlTable** of the Ping MIB. Each item is indexed exactly as it is in the Ping MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt).

For more information, see *PING MIB*.

- Policy Objects MIB—Provides support for monitoring the security policies that control the flow of traffic from one zone to another. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt).

For more information, see *Policy Objects MIB*.

- Reverse-Path-Forwarding MIB—Monitors statistics for traffic that is rejected because of reverse-path-forwarding (RPF) processing. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt).

**NOTE:** The enterprise-specific RPF MIB is not supported on EX Series Ethernet Switches.

For more information, see *Reverse Path Forwarding MIB*.

- RMON Events and Alarms MIB—Supports the Junos OS extensions to the standard Remote Monitoring (RMON) Events and Alarms MIB (RFC 2819). The extension augments **alarmTable** with additional information about each alarm. Two new traps are also defined to indicate when problems are encountered with an alarm. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt).

For more information, see *RMON Events and Alarms MIB*.

- Security Interface Extension Objects MIB—Provides support for the security management of interfaces. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt).

For more information, see *Security Interface Extension Objects MIB*.

- Security Screening Objects MIB—Defines the MIB for the Juniper Networks Enterprise Firewall screen functionality. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-screening.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-screening.txt).

For more information, see *Security Screening Objects MIB*.

- **Source Class Usage MIB**—Counts packets sent to customers by performing a lookup on the IP source address and the IP destination address. The Source Class Usage (SCU) MIB makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt).

For more information, see *Source Class Usage MIB*.

- **SPU Monitoring MIB**—Provides support for monitoring SPUs on SRX5600 and SRX5800 devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt).

For more information, see *SPU Monitoring Objects MIB*.

- **System Log MIB**—Enables notification of an SNMP trap-based application when an important system log message occurs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt).

For more information, see *System Log MIB*.

- **Traceroute MIB**—Supports the Junos OS extensions of traceroute and remote operations. Items in this MIB are created when entries are created in the **traceRouteCtlTable** of the Traceroute MIB. Each item is indexed exactly the same way as it is in the Traceroute MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt).

For more information, see *Traceroute MIB*.

- **Utility MIB**—Provides SNMP support for exposing Junos OS data and has tables that contain information about each type of data, such as integer and string. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt).

For more information, see *Utility MIB*.

- **VPN Certificate Objects MIB**—Provides support for monitoring the local and CA certificates loaded on the router. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt).

For more information, see *VPN Certificate Objects MIB*.

#### Related Documentation

- *Structure of Management Information MIB*

### List of SRX5400, SRX5600 and SRX5800 Services Gateways Supported Enterprise-Specific MIBs

Junos OS supports the following enterprise-specific MIBs:

- Structure of Management Information MIB—Contains object identifiers (OIDs) for the security branch of the MIBs used in Junos OS for SRX Series devices product, services and traps. This MIB is currently supported only by Junos OS for SRX Series devices. It also explains how the Juniper Networks enterprise-specific MIBs are structured. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-smi.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-smi.txt) . For more information, see *Structure of Management Information MIB*.

- AAA Objects MIB—Provides support for monitoring user authentication, authorization, and accounting through the RADIUS, LDAP, SecurID, and local authentication servers. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-user-aaa.txt) .

For more information, see *AAA Objects MIB*.

- Access Authentication Objects MIB—Provides support for monitoring firewall authentication, including data about the users trying to access firewall-protected resources and the firewall authentication service itself. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-auth.txt) .

For more information, see *Access Authentication Objects MIB*.

- Alarm MIB—Provides support for alarms from the router. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis-alarm.txt) .

For more information, see *Alarm MIB*.

- ATM CoS MIB—Provides support for monitoring Asynchronous Transfer Mode, version 2 (ATM2) virtual circuit (VC) class-of-service (CoS) configurations. It also provides CoS queue statistics for all VCs that have CoS configured. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-atm-cos.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-atm-cos.txt) .

For more information, see *ATM Class-of-Service MIB*.

- BGP4 V2 MIB—Contains objects used to monitor BGP peer-received prefix counters. It is based upon similar objects in the MIB documented in Internet draft draft-ietf-idr-bgp4-mibv2-03.txt, Definitions of Managed Objects for the Fourth Version of BGP (BGP-4), Second Version. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bgpmib2.txt) .

For more information, see *BGP4 V2 MIB*.

- BFD MIB—Provides support for monitoring Bidirectional Forwarding Detection (BFD) sessions. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-bfd.txt) .

For more information, see *Bidirectional Forwarding Detection MIB*.

- Chassis MIB—Provides support for environmental monitoring (power supply state, board voltages, fans, temperatures, and air flow) and inventory support for the chassis, System Control Board (SCB), System and Switching Board (SSB), Switching and Forwarding Model (SFM), Flexible PIC Concentrators (FPCs), and PICs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-chassis.txt).

For more information, see *Chassis MIBs*.

- Chassis Cluster MIB—Provides information about objects that are used whenever the state of the control link interfaces or fabric link interfaces changes (up to down or down to up) in a chassis cluster deployment. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-jsrpd.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-jsrpd.txt).

For more information, see *Chassis Cluster MIB*.

- Configuration Management MIB—Provides notification for configuration changes as SNMP traps. Each trap contains the time at which the configuration change was committed, the name of the user who made the change, and the method by which the change was made. A history of the last 32 configuration changes is kept in **jnxCmChgEventTable**. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-cfgmgmt.txt).

For more information, see *Configuration Management MIB*.

- Destination Class Usage MIB—Provides support for monitoring packet counts based on the ingress and egress points for traffic transiting your networks. Ingress points are identified by input interface. Egress points are identified by destination prefixes grouped into one or more sets, known as destination classes. One counter is managed per interface per destination class, up to a maximum of 16 counters per interface. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-dcu.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-dcu.txt).

For more information, see *Destination Class Usage MIB*.

- DNS Objects MIB—Provides support for monitoring DNS proxy queries, requests, responses, and failures. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-dns.txt).

For more information, see *DNS Objects MIB*.

- Ethernet MAC MIB—Monitors media access control (MAC) statistics on Gigabit Ethernet intelligent queuing (IQ) interfaces. It collects MAC statistics; for example, **inocets**, **inframes**, **outocets**, and **outframes** on each source MAC address and virtual LAN (VLAN) ID for each Ethernet port. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/jnx-mac.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/jnx-mac.txt).

For more information, see *Ethernet MAC MIB*.

- Event MIB—Defines a generic trap that can be generated using an op script or event policy. This MIB provides the ability to specify a system log string and raise a trap if that system log string is found. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-event.txt).

For more information, see *Event MIB*.

- Firewall MIB—Provides support for monitoring firewall filter counters. Routers must have the Internet Processor II ASIC to perform firewall monitoring. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-firewall.txt).

For more information, see *Firewall MIB*.

- Host Resources MIB—Extends the **hrStorageTable** object, providing a measure of the usage of each file system on the router in percentage. Previously, the objects in the **hrStorageTable** measured the usage in allocation units—**hrStorageUsed** and **hrStorageAllocationUnits**—only. Using the percentage measurement, you can more easily monitor and apply thresholds on usage. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-hostresources.txt).

For more information, see *Host Resources MIB*.

- Interface MIB—Extends the standard ifTable (RFC 2863) with additional statistics and Juniper Networks enterprise-specific chassis information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-if-extensions.txt).

For more information, see *Interface MIB*.

- IP Forward MIB—Extends the standard IP Forwarding Table MIB (RFC 2096) to include CIDR forwarding information. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipforward.txt).

For more information, see *IP Forward MIB*.

- IPsec Generic Flow Monitoring Object MIB—Based on **jnx-ipsec-monitor-mib**, this MIB provides support for monitoring IPsec and IPsec VPN management objects. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt).

For more information, see *IPsec Generic Flow Monitoring Object MIB*.

- IPsec Monitoring MIB—Provides operational and statistical information related to the IPsec and IKE tunnels on Juniper Networks routers. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt).

For more information, see *IPsec Monitoring MIB*.

- IPv4 MIB—Provides additional Internet Protocol version 4 (IPv4) address information, supporting the assignment of identical IPv4 addresses to separate interfaces. For a

downloadable version of this MIB, see

[http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ipv4.txt).

For more information, see *IPv4 MIB*.

- License MIB—Extends SNMP support to licensing information, and introduces SNMP traps that alert users when the licenses are about to expire, expire, or when the total number of users exceeds the number specified in the license. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-license.txt).

For more information, see *License MIB*.

- Logical Systems MIB—Provides support for logical systems security profile. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt).

For more information, see *Logical Systems MIB*.

- Network Address Translation (NAT) Objects MIB—Provides support for monitoring network address translation (NAT). This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-nat.txt).

For more information, see *NAT Objects MIB*.

- Packet Forwarding Engine MIB—Provides notification statistics for Packet Forwarding Engines. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-pfe.txt).

For more information, see *Packet Forwarding Engine MIB*.

- Ping MIB—Extends the standard Ping MIB control table (RFC 2925). Items in this MIB are created when entries are created in pingCtlTable of the Ping MIB. Each item is indexed exactly as it is in the Ping MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-ping.txt).

For more information, see *PING MIB*.

- Policy Objects MIB—Provides support for monitoring the security policies that control the flow of traffic from one zone to another. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-policy.txt).

For more information, see *Policy Objects MIB*.

- Reverse-Path-Forwarding MIB—Monitors statistics for traffic that is rejected because of reverse-path-forwarding (RPF) processing. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rpf.txt).

**NOTE:** The enterprise-specific RPF MIB is not supported on EX Series Ethernet Switches.

For more information, see *Reverse Path Forwarding MIB*.

- RMON Events and Alarms MIB—Supports the Junos OS extensions to the standard Remote Monitoring (RMON) Events and Alarms MIB (RFC 2819). The extension augments alarmTable with additional information about each alarm. Two new traps are also defined to indicate when problems are encountered with an alarm. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-rmon.txt).

For more information, see *RMON Events and Alarms MIB*.

- Security Interface Extension Objects MIB—Provides support for the security management of interfaces. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-if-ext.txt).

For more information, see *Security Interface Extension Objects MIB*.

- Security Screening Objects MIB—Defines the MIB for the Juniper Networks Enterprise Firewall screen functionality. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-screening.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-screening.txt).

For more information, see *Security Screening Objects MIB*.

- Source Class Usage MIB—Counts packets sent to customers by performing a lookup on the IP source address and the IP destination address. The Source Class Usage (SCU) MIB makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-scu.txt).

For more information, see *Source Class Usage MIB*.

- SPU Monitoring MIB—Provides support for monitoring SPUs on SRX5600 and SRX5800 devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt).

For more information, see *SPU Monitoring Objects MIB*.

- System Log MIB—Enables notification of an SNMP trap-based application when an important system log message occurs. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-syslog.txt).

For more information, see *System Log MIB*.

- Traceroute MIB—Supports the Junos OS extensions of traceroute and remote operations. Items in this MIB are created when entries are created in the traceRouteCtlTable of the Traceroute MIB. Each item is indexed exactly the same way as it is in the Traceroute MIB. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-traceroute.txt).

For more information, see *Traceroute MIB*.

- Utility MIB—Provides SNMP support for exposing Junos OS data and has tables that contain information on each type of data, such as integer and string. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-util.txt).

For more information, see *Utility MIB*.

- VPN Certificate Objects MIB—Provides support for monitoring the local and CA certificates loaded on the router. This MIB is currently supported only by Junos OS for SRX Series devices. For a downloadable version of this MIB, see [http://www.juniper.net/techpubs/en\\_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt](http://www.juniper.net/techpubs/en_US/junos15.1x49/topics/reference/mibs/mib-jnx-js-cert.txt).

For more information, see *VPN Certificate Objects MIB*.

## Enterprise-Specific MIBs and Supported Devices

Table 207 lists the enterprise-specific MIBs that are supported on various devices running the Junos OS.

**NOTE:** In this table, a value of 1 in any of the platform columns (M, MX, T, EX, J, and SRX) denotes that the corresponding MIB is supported on that particular platform. A value of 0 denotes that the MIB is not supported on the platform.

**NOTE:** This topic uses the following classification for SRX Series devices: Low-End (SRX300, SRX320, and SRX340), Mid-Range (SRX550), and High-End (SRX1500, SRX5400, SRX5600, and SRX5800).

Table 207: Enterprise-Specific MIBs and Supported Devices

| Enterprise-Specific MIB                                                                                                                                                                                                                      | Platforms |   |   |   |    |    |     | SRX     |           |          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---|---|---|----|----|-----|---------|-----------|----------|
|                                                                                                                                                                                                                                              | ACX       | M | T | J | MX | EX | PTX | Low-End | Mid-Range | High-End |
|                                                                                                                                                                                                                                              |           |   |   |   |    |    |     |         |           |          |

## MIB Support Details

Table 208 shows enterprise-specific MIB objects supported by Junos OS and provides notes detailing how they are handled when a routing instance is specified in an SNMP request. An en dash (–) indicates that the item is not applicable.

Table 208: MIB Support for Routing Instances (Juniper Networks MIBs)

| Object                         | Support Class | Description/Notes                                                                                                            |
|--------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------|
| jnxProducts(1)                 | –             | Product Object IDs                                                                                                           |
| jnxServices(2)                 | –             | Services                                                                                                                     |
| jnxMibs(3)<br>jnxBoxAnatomy(1) | Class 3       | Objects are exposed only for the default logical system.                                                                     |
| mpls(2)                        | Class 2       | All instances within a logical system are exposed. Data will not be segregated down to the routing instance level.           |
| ifJnx(3)                       | Class 1       | Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed. |

**Table 208: MIB Support for Routing Instances (Juniper Networks MIBs) (continued)**

| Object                                                                                                                                   | Support Class | Description/Notes                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>jnxAlarms(4)</b>                                                                                                                      | Class 3       | Objects are exposed only for the default logical system.                                                                                                  |
| <b>jnxFirewalls(5)</b>                                                                                                                   | Class 4       | Data is not segregated by routing instance. All instances are exposed.                                                                                    |
| <b>jnxDCUs(6)</b>                                                                                                                        | Class 1       | Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.                              |
| <b>jnxPingMIB(7)</b>                                                                                                                     | Class 3       | Objects are exposed only for the default logical system.                                                                                                  |
| <b>jnxTraceRouteMIB(8)</b>                                                                                                               | Class 3       | Objects are exposed only for the default logical system.                                                                                                  |
| <b>jnxATM(10)</b>                                                                                                                        | Class 1       | Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.                              |
| <b>jnxIpv6(11)</b>                                                                                                                       | Class 4       | Data is not segregated by routing instance. All instances are exposed.                                                                                    |
| <b>jnxIpv4(12)</b>                                                                                                                       | Class 1       | <b>jnxIpv4AddrTable(1)</b> . Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed. |
| <b>jnxRmon(13)</b>                                                                                                                       | Class 3       | <b>jnxRmonAlarmTable(1)</b> . Objects are exposed only for the default logical system.                                                                    |
| <b>jnxLdp(14)</b>                                                                                                                        | Class 2       | <b>jnxLdpTrapVars(1)</b> . All instances within a logical system are exposed. Data will not be segregated down to the routing instance level.             |

|         | rfc1907.mib           | snmpModules                                                     |
|         | snmpModules           | Examples:<br>snmpMIB snmpFrameworkMIB                           |

Table 212 shows Class 4 MIB objects (standard and enterprise-specific MIBs) supported by Junos OS. With Class 4 objects, data is not segregated by routing instance. All instances are exposed.

Table 212: Class 4 MIB Objects (Standard and Juniper MIBs)

| Class   | MIB              | Objects                                 |
|---------|------------------|-----------------------------------------|
| Class 4 | system           | Example: sysORTable                     |
|         | rfc2011a.mib     | ip (ipDefaultTTL, ipInReceives)<br>icmp |
|         | rfc2012a.mib     | tcp<br>tcpConnTable<br>ipv6TcpConnTable |
|         | rfc2013a.mib     | udp<br>udpTable<br>ipv6UdpTable         |
|         | rfc2790a.mib     | hrSystem                                |
|         | rfc2287a.mib     | sysApplOBJ                              |
|         | jnx-firewall.mib | jnxFirewalls                            |
|         | jnx-ipv6.mib     | jnxIpv6                                 |

## SNMP MIB Objects Supported by Junos OS for the Set Operation

Table 213 lists the SNMP MIB objects that are supported by Junos OS for the **snmp set** operation.

Table 213: SNMP MIB Objects

| Object Name           | Object Identifier |
|-----------------------|-------------------|
| RFC 1907              |                   |
| sysContact            | 1.3.6.1.2.1.1.4   |
| sysName               | 1.3.6.1.2.1.1.5   |
| sysLocation           | 1.3.6.1.2.1.1.6   |
| snmpEnableAuthenTraps | 1.3.6.1.2.1.11.30 |

Table 213: SNMP MIB Objects (*continued*)

| Object Name               | Object Identifier       |
|---------------------------|-------------------------|
| RFC 2819a                 |                         |
| alarmInterval             | 1.3.6.1.2.1.16.3.1.1.2  |
| alarmVariable             | 1.3.6.1.2.1.16.3.1.1.2  |
| alarmSampleType           | 1.3.6.1.2.1.16.3.1.1.4  |
| alarmStartupAlarm         | 1.3.6.1.2.1.16.3.1.1.6  |
| alarmRisingThreshold      | 1.3.6.1.2.1.16.3.1.1.7  |
| alarmFallingThreshold     | 1.3.6.1.2.1.16.3.1.1.8  |
| alarmRisingEventIndex     | 1.3.6.1.2.1.16.3.1.1.9  |
| alarmFallingEventIndex    | 1.3.6.1.2.1.16.3.1.1.10 |
| alarmOwner                | 1.3.6.1.2.1.16.3.1.1.11 |
| alarmStatus               | 1.3.6.1.2.1.16.3.1.1.12 |
| eventDescription          | 1.3.6.1.2.1.16.9.1.1.2  |
| eventType                 | 1.3.6.1.2.1.16.9.1.1.3  |
| eventCommunity            | 1.3.6.1.2.1.16.9.1.1.4  |
| eventOwner                | 1.3.6.1.2.1.16.9.1.1.6  |
| eventStatus               | 1.3.6.1.2.1.16.9.1.1.7  |
| RFC 2925a                 |                         |
| pingMaxConcurrentRequests | 1.3.6.1.2.1.80.1.1      |
| pingCtlTargetAddressType  | 1.3.6.1.2.1.80.1.2.1.3  |
| pingCtlTargetAddress      | 1.3.6.1.2.1.80.1.2.1.4  |
| pingCtlDataSize           | 1.3.6.1.2.1.80.1.2.1.5  |
| pingCtlTimeOut            | 1.3.6.1.2.1.80.1.2.1.6  |
| pingCtlProbeCount         | 1.3.6.1.2.1.80.1.2.1.7  |
| pingCtlAdminStatus        | 1.3.6.1.2.1.80.1.2.1.8  |

Table 213: SNMP MIB Objects (*continued*)

| Object Name                     | Object Identifier       |
|---------------------------------|-------------------------|
| pingCtlDataFill                 | 1.3.6.1.2.1.80.1.2.1.9  |
| pingCtlFrequency                | 1.3.6.1.2.1.80.1.2.1.10 |
| pingCtlMaxRows                  | 1.3.6.1.2.1.80.1.2.1.11 |
| pingCtlStorageType              | 1.3.6.1.2.1.80.1.2.1.12 |
| pingCtlTrapGeneration           | 1.3.6.1.2.1.80.1.2.1.13 |
| pingCtlTrapProbeFailureFilter   | 1.3.6.1.2.1.80.1.2.1.14 |
| pingCtlTrapTestFailureFilter    | 1.3.6.1.2.1.80.1.2.1.15 |
| pingCtlType                     | 1.3.6.1.2.1.80.1.2.1.16 |
| pingCtlDescr                    | 1.3.6.1.2.1.80.1.2.1.17 |
| pingCtlSourceAddressType        | 1.3.6.1.2.1.80.1.2.1.18 |
| pingCtlSourceAddress            | 1.3.6.1.2.1.80.1.2.1.19 |
| pingCtlIfIndex                  | 1.3.6.1.2.1.80.1.2.1.20 |
| pingCtlByPassRouteTable         | 1.3.6.1.2.1.80.1.2.1.21 |
| pingCtlDSField                  | 1.3.6.1.2.1.80.1.2.1.22 |
| pingCtlRowStatus                | 1.3.6.1.2.1.80.1.2.1.23 |
| RFC 2925B                       |                         |
| traceRouteMaxConcurrentRequests | 1.3.6.1.2.1.81.1.1      |
| traceRouteCtlTargetAddressType  | 1.3.6.1.2.1.81.1.2.1.3  |
| traceRouteCtlTargetAddress      | 1.3.6.1.2.1.81.1.2.1.4  |
| traceRouteCtlByPassRouteTable   | 1.3.6.1.2.1.81.1.2.1.5  |
| traceRouteCtlDataSize           | 1.3.6.1.2.1.81.1.2.1.6  |
| traceRouteCtlTimeOut            | 1.3.6.1.2.1.81.1.2.1.7  |
| traceRouteCtlProbesPerHop       | 1.3.6.1.2.1.81.1.2.1.8  |
| traceRouteCtlPort               | 1.3.6.1.2.1.81.1.2.1.9  |

Table 213: SNMP MIB Objects (*continued*)

| Object Name                    | Object Identifier            |
|--------------------------------|------------------------------|
| traceRouteCtlMaxTtl            | 1.3.6.1.2.1.81.1.2.1.10      |
| traceRouteCtlDSField           | 1.3.6.1.2.1.81.1.2.1.11      |
| traceRouteCtlSourceAddressType | 1.3.6.1.2.1.81.1.2.1.12      |
| traceRouteCtlSourceAddress     | 1.3.6.1.2.1.81.1.2.1.13      |
| traceRouteCtlIfIndex           | 1.3.6.1.2.1.81.1.2.1.14      |
| traceRouteCtlMiscOptions       | 1.3.6.1.2.1.81.1.2.1.15      |
| traceRouteCtlMaxFailure        | 1.3.6.1.2.1.81.1.2.1.16      |
| traceRouteCtlDontFragment      | 1.3.6.1.2.1.81.1.2.1.17      |
| traceRouteCtlInitialTtl        | 1.3.6.1.2.1.81.1.2.1.18      |
| traceRouteCtlFrequency         | 1.3.6.1.2.1.81.1.2.1.19      |
| traceRouteCtlStorageType       | 1.3.6.1.2.1.81.1.2.1.20      |
| traceRouteCtlAdminStatus       | 1.3.6.1.2.1.81.1.2.1.21      |
| traceRouteCtlDescr             | 1.3.6.1.2.1.81.1.2.1.22      |
| traceRouteCtlMaxRows           | 1.3.6.1.2.1.81.1.2.1.23      |
| traceRouteCtlTrapGeneration    | 1.3.6.1.2.1.81.1.2.1.24      |
| traceRouteCtlCreateHopEntries  | 1.3.6.1.2.1.81.1.2.1.25      |
| traceRouteCtlType              | 1.3.6.1.2.1.81.1.2.1.26      |
| traceRouteCtlRowStatus         | 1.3.6.1.2.1.81.1.2.1.27      |
| Enterprise-Specific PING MIB   |                              |
| jnxPingCtlIfName               | 1.3.6.1.4.1.2636.3.7.1.2.1.3 |

## Juniper Networks Enterprise-Specific SNMP Traps

This topic provides pointers to the enterprise-specific SNMP traps supported by the Junos OS.

**NOTE:** All enterprise-specific SNMP traps supported by the Junos OS can be sent in version 1, 2, and 3 formats.

## Juniper Networks Enterprise-Specific SNMP Version 1 Traps

The Junos OS supports enterprise-specific SNMP version 1 traps shown in [Table 214](#). The traps are organized first by trap category and then by trap name. The system logging severity levels are listed for those traps that have them. Traps that do not have corresponding system logging severity levels are marked with an en dash (–).

For more information about system log messages, see the *Junos OS System Log Reference for Security Devices*. To view the Juniper Networks enterprise-specific SNMP version 2 traps, see “[Juniper Networks Enterprise-Specific SNMP Version 2 Traps](#)” on [page 1756](#). For more information about chassis traps, see *Chassis Traps*.

## Juniper Networks Enterprise-Specific SNMP Version 2 Traps

The Junos OS supports the enterprise-specific SNMP version 2 traps shown in [Table 215](#). The traps are organized first by trap category and then by trap name. The system logging severity levels are listed for those traps that have them. Traps that do not have corresponding system logging severity levels are marked with an en dash (–).

For more information about system messages, see the [System Log Explorer](#). For more information about configuring system logging, see the [Junos OS Administration Library for Routing Devices](#). To view the Juniper Networks enterprise-specific SNMP version 1 traps, see “[Juniper Networks Enterprise-Specific SNMP Version 1 Traps](#)” on page 1749. For more information about chassis traps, see [Chassis Traps](#).

**Standard SNMP Traps Supported on Devices Running Junos OS**

This topic provides pointers to the standard SNMP traps supported by the Junos OS.

**NOTE:** For scalability reasons, the MPLS traps are generated by the ingress router only.

## Standard SNMP Version 1 Traps

[Table 216](#) provides an overview of the standard traps for SNMPv1. The traps are organized first by trap category and then by trap name, and include their enterprise ID, generic trap number, and specific trap number. The system logging severity levels are listed for those traps that have them with their corresponding system log tag. Traps that do not have corresponding system logging severity levels are marked with an en dash (–) in the table.

For more information about system log messages, see the [System Log Explorer](#). For more information about configuring system logging, see the *Junos OS System Basics Configuration Guide*.

**Table 216: Standard Supported SNMP Version 1 Traps**

| Defined in                                                            | Trap Name                    | Enterprise ID    | Generic Trap Number | Specific Trap Number | System Logging Severity Level | Syslog Tag             | Supported On                  |

## Standard SNMP Version 2 Traps

[Table 217](#) provides an overview of the standard SNMPv2 traps supported by the Junos OS. The traps are organized first by trap category and then by trap name and include their **snmpTrapOID**. The system logging severity levels are listed for those traps that have them with their corresponding system log tag. Traps that do not have corresponding system logging severity levels are marked with an en dash (–) in the table.

For more information about system log messages, see *System Log Monitoring and Troubleshooting Guide for Security Devices*.

The Junos OS also supports the following standard SNMP version 2 traps:

- [SNMP Version 2 MPLS Traps on page 1771](#)
- [SNMP Version 2 L3VPN Traps on page 1772](#)

### SNMP Version 2 MPLS Traps

The Junos OS supports the MPLS SNMP version 2 traps defined in RFC 3812, *Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Management Information Base*.

You can disable the MPLS traps by including the **no-trap** option at the **[edit protocol mpls log-updown]** hierarchy level. For information about disabling the generation of MPLS traps, see the *MPLS Feature Guide for Security Devices*.

The Junos OS supports the following MPLS traps:

- **mplsTunnelUp**—Generated when an **mplsTunnelOperStatus** object for one of the configured tunnels leaves the **down** state and transitions into another state, other than the **notPresent** state.
- **mplsTunnelDown**—Generated when an **mplsTunnelOperStatus** object for one of the configured tunnels enters the **down** state from a state other than the **notPresent** state.

**NOTE:** When an LSP flaps, only the ingress and egress routers of that LSP generate the **mplsTunnelUp** and **mplsTunnelDown** traps. Previously, all the routers associated with an LSP—that is, the ingress, egress, and transit routers—used to generate the traps when the LSP flaps.

- **mplsTunnelRerouted**—Generated when a tunnel is rerouted.
- **mplsTunnelReoptimized**—Generated when a tunnel is reoptimized.

**NOTE:** In Junos OS Release 8.3 and earlier, `mplsTunnelReoptimized` was generated every time the optimization timer expired; that is, when the optimization timer exceeded the value set for the `optimize-timer` statement at the `[edit protocols mpls label-switched-path path-name]` hierarchy level. However, in Release 8.4 and later, this trap is generated only when the path is reoptimized, and not when the optimization timer expires.

### SNMP Version 2 L3VPN Traps

The Junos OS also supports the following L3VPN SNMP version 2 traps defined in RFC 4382, *MPLS/BGP Layer 3 Virtual Private Network (VPN)*:

- **mplsL3VpnVrfUp**—Generated when:
  - No interface is associated with this VRF, and the first (and only first) interface associated with it has its **ifOperStatus** change to **up**.
  - Only one interface is associated with this VRF, and the **ifOperStatus** of this interface changes to **up**.
  - Multiple interfaces are associated with this VRF, and the **ifOperStatus** of all interfaces is **down**, and the first of those interfaces has its **ifOperStatus** change to **up**.
- **mplsL3VpnVrfDown**—Generated when:
  - One interface is associated with this VRF, and the **ifOperStatus** of this interface changes from **up** to **down**.
  - Multiple interfaces are associated with this VRF, and the **ifOperStatus** of all except one of these interfaces is equal to **up**, and the **ifOperStatus** of that interface changes from **up** to **down**.
  - The last interface with **ifOperStatus** equal to **up** is disassociated from a VRF.
- **mplsL3VpnVrfRouteMidThreshExceeded**—Generated when the number of routes contained by the specified VRF exceeds the value indicated by **mplsL3VpnVrfMidRouteThreshold**.

You can configure the **mplsL3VpnVrfMidRouteThreshold** value as follows:

```
[edit routing-instances <instance-name>]
user@R1# set routing-options maximum-paths <limit> threshold <threshold-value>
```

This configuration sets the **mplsL3VpnVrfMidRouteThreshold** value to **<threshold-value>** % of **<limit>**. This value can also be calculated as  $(\text{<limit>} * \text{<threshold-value>}) / 100$ .

- **mplsL3VpnVrfNumVrfRouteMaxThreshExceeded**—Generated when the number of routes contained by the specified VRF exceeds or attempts to exceed the maximum allowed value as indicated by **mplsL3VpnVrfMaxRouteThreshold**.

- **mplsL3VpnNumVrfSecIllegalLblThreshExcd**—Generated when the number of illegal label violations on a VRF as indicated by **mplsL3VpnVrfSecIllegalLblVltnsh** has exceeded **mplsL3VpnIllegalLblRcvThresh**.
- **mplsL3VpnNumVrfRouteMaxThreshCleared**—Generated only after the number of routes contained by the specified VRF exceeds or attempts to exceed the maximum allowed value as indicated by **mplsVrfMaxRouteThreshold**, and then falls below this value.

## Unsupported Standard SNMP Traps

Standard SNMP traps that are defined in MIBs supported by the Junos OS but are not generated by the Junos OS are shown in [Table 218](#).

Table 218: Unsupported Standard SNMP Traps

| MIB         | Trap Name                            | Description                                                                                                                                                                                               |
|-------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| isismib.mib | isisDatabaseOverload                 | Generated when the system enters or leaves the overload state.                                                                                                                                            |
|             | isisManualAddressDrops               | Generated when one of the manual <b>areaAddresses</b> assigned to the system is ignored when computing routes.                                                                                            |
|             | isisCorruptedLSPDetected             | Generated when an LSP stored in memory becomes corrupted.                                                                                                                                                 |
|             | isisAttemptToExceedMaxSequence       | Generated when the sequence number on a generated LSP wraps the 32-bit sequence counter and the number is purged.                                                                                         |
|             | isisIDLenMismatch                    | Generated when a protocol data unit (PDU) is received with a different value for the system ID length. This trap includes an index to identify the circuit where the PDU was received and the PDU header. |
|             | isisMaxAreaAddressesMismatch         | Generated when a PDU with a different value for the maximum area addresses is received.                                                                                                                   |
|             | isisOwnLSPPurge                      | Generated when a PDU is received with a system ID and zero age. This notification includes the circuit index if available.                                                                                |
|             | isisSequenceNumberSkip               | Generated when an LSP is received with a system ID and different contents, indicating the LSP might require a higher sequence number.                                                                     |
|             | isisAuthenticationTypeFailure        | Generated when a PDU with the wrong authentication type field is received.                                                                                                                                |
|             | isisAuthenticationFailure            | Generated when a PDU with an incorrect authentication information field is received.                                                                                                                      |
|             | isisVersionSkew                      | Generated when a hello PDU from an IS running a different version of the protocol is received.                                                                                                            |
|             | isisAreaMismatch                     | Generated when a hello PDU from an IS which does not share any area address is received.                                                                                                                  |
|             | isisRejectedAdjacency                | Generated when a hello PDU from an IS is received, but no adjacency is established because of a lack of resources.                                                                                        |
|             | isisLSPTooLargeToPropagate           | Generated when a link-state PDU that is larger than the <b>dataLinkBlockSize</b> for a circuit is attempted, but not propagated.                                                                          |
|             | isisOriginatingLSPBufferSizeMismatch |                                                                                                                                                                                                           |

Table 218: Unsupported Standard SNMP Traps (*continued*)

| MIB           | Trap Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                         | Generated when a Level 1 link-state PDU or Level 2 link-state PDU is received that is larger than the local value for originating <b>L1LSPBufferSize</b> or originating <b>L2LSPBufferSize</b> , respectively, or when a Level 1 link-state PDU or Level 2 link-state PDU is received containing the originating <b>LSPBufferSize</b> option and the value in the PDU option field does not match the local value for originating <b>L1LSPBufferSize</b> or originating <b>L2LSPBufferSize</b> , respectively. |
|               | <b>isisProtocolsSupportedMismatch</b>   | Generated when a nonpseudonode, segment 0 link-state PDU is received that has no matching protocols.                                                                                                                                                                                                                                                                                                                                                                                                           |
| l3vpn-mib.mib | <b>mplsVrflfUp</b>                      | Generated when the <b>ifOperStatus</b> of an interface associated with a VRF table changes to the <b>up(1)</b> state, or when an interface with <b>ifOperStatus = up(1)</b> is associated with a VRF table.                                                                                                                                                                                                                                                                                                    |
|               | <b>mplsVrflfDown</b>                    | Generated when the <b>ifOperStatus</b> of an interface associated with a VRF table changes to the <b>down(1)</b> state, or when an interface with <b>ifOperStatus = up(1)</b> state is disassociated from a VRF table.                                                                                                                                                                                                                                                                                         |
|               | <b>mplsNumVrfRouteMidThreshExceeded</b> | Generated when the number of routes contained by the specified VRF table exceeds the value indicated by <b>mplsVrfMidRouteThreshold</b> .                                                                                                                                                                                                                                                                                                                                                                      |
|               | <b>mplsNumVrfRouteMaxThreshExceeded</b> | Generated when the number of routes contained by the specified VRF table reaches or attempts to exceed the maximum allowed value as indicated by <b>mplsVrfMaxRouteThreshold</b> .                                                                                                                                                                                                                                                                                                                             |
|               | <b>mplsNumVrfSecIllegalLblThrshExcd</b> | Generated when the number of illegal label violations on a VRF table as indicated by <b>mplsVpnVrfSecIllegalLblVltns</b> has exceeded <b>mplsVpnVrfSecIllegalLblRcvThrsh</b> .                                                                                                                                                                                                                                                                                                                                 |
| msdp-mib.mib  | <b>msdpEstablished</b>                  | Generated when the Multicast Source Discovery Protocol (MSDP) finite state machine (FSM) enters the <b>Established</b> state.                                                                                                                                                                                                                                                                                                                                                                                  |
|               | <b>msdpBackwardTransition</b>           | Generated when the MSDP FSM moves from a higher numbered state to a lower numbered state.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ospf2trap-mib | <b>ospfOriginateLsa</b>                 | Generated when a new LSA is originated by the router because of a topology change.                                                                                                                                                                                                                                                                                                                                                                                                                             |
|               | <b>ospfLsdbOverflow</b>                 | Generated when the number of LSAs in the router's link-state database exceeds the value of <b>ospfExtLsdbLimit</b> .                                                                                                                                                                                                                                                                                                                                                                                           |
|               | <b>ospfLsdbApproachingOverflow</b>      | Generated when the number of LSAs in the router's link-state database exceeds 90% of the value of <b>ospfExtLsdbLimit</b> .                                                                                                                                                                                                                                                                                                                                                                                    |

Table 218: Unsupported Standard SNMP Traps (*continued*)

| MIB          | Trap Name                    | Description                                                                                                                                            |
|--------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| rfc1747.mib  | sdlcPortStatusChange         | Generated when the state of an SDLC port transitions to active or inactive.                                                                            |
|              | sdlcLSStatusChange           | Generated when the state of an SDLC link station transitions to contacted or disconnected.                                                             |
| rfc2115a.mib | frDLCIStatusChange           | Generated when a virtual circuit changes state (has been created or invalidated, or has toggled between the active and inactive states).               |
| rfc2662.mib  | adslAtucRateChangeTrap       | Generated when the ATUCs transmit rate has changed (RADSL mode only).                                                                                  |
|              | adslAtucPerfLofsThreshTrap   | Generated when the loss of framing 15-minute interval threshold is reached.                                                                            |
|              | adslAtucInitFailureTrap      | Generated when ATUC initialization fails.                                                                                                              |
|              | adslAturPerfLprsThreshTrap   | Generated when the loss of power 15-minute interval threshold is reached.                                                                              |
|              | adslAturRateChangeTrap       | Generated when the ATURs transmit rate changes (RADSL mode only).                                                                                      |
| rfc3020.mib  | mfrMibTrapBundleLinkMismatch | Generated when a bundle link mismatch is detected.                                                                                                     |
| rfc3813.mib  | mplsXCUp                     | Generated when <b>mplsXCOperStatus</b> for one or more contiguous entries in <b>mplsXCTable</b> enters the <b>up(1)</b> state from some other state.   |
|              | mplsXCDown                   | Generated when <b>mplsXCOperStatus</b> for one or more contiguous entries in <b>mplsXCTable</b> enters the <b>down(2)</b> state from some other state. |

## Loading MIB Files to a Network Management System

For your network management system (NMS) to identify and understand the MIB objects used by the Junos OS, you must first load the MIB files to your NMS using a MIB compiler. A MIB compiler is a utility that parses the MIB information such as the MIB object name, IDs, and data type for the NMS.

You can download the Junos MIB package from the **Enterprise-Specific MIBs and Traps** section of the Junos OS Technical Publications index page at <http://www.juniper.net/techpubs/software/junos/index.html>. The Junos MIB package is available in .zip and .tar packages. You can download the appropriate format based on your requirements.

The Junos MIB package contains two folders: **StandardMibs** and **JuniperMibs**. The **StandardMibs** folder contains the standard MIBs and RFCs that are supported on devices running the Junos OS, whereas the **JuniperMibs** folder contains the Juniper Networks enterprise-specific MIBs.

To load MIB files that are required for managing and monitoring devices running the Junos OS:

1. Go to the Junos OS Technical Publications index page (<http://www.juniper.net/techpubs/software/junos/index.html>).
2. Click the tab that corresponds to the Junos OS Release for which you want to download the MIB files.
3. On the selected tab, click the + (plus) sign that corresponds to the **Enterprise-Specific MIBs and Traps** section to expand the section.
4. Click the **TAR** or **ZIP** link that corresponds to the **Enterprise MIBs** link under the **Enterprise-Specific MIBs and Traps** section to download the Junos MIB package.
5. Decompress the file (.tar or .zip) using an appropriate utility.
6. Load the standard MIB files (from the **StandardMibs** folder) in the following order:

**NOTE:** Some of the MIB compilers that are commonly used have the standard MIBs preloaded on them. If the standard MIBs are already loaded on the MIB compiler that you are using, skip this step and proceed to Step 7.

- a. mib-SNMPv2-SMI.txt
- b. mib-SNMPv2-TC.txt
- c. mib-IANAifType-MIB.txt
- d. mib-IANA-RTPROTO-MIB.txt
- e. mib-rfc1907.txt
- f. mib-rfc2011a.txt

- g. `mib-rfc2012a.txt`
- h. `mib-rfc2013a.txt`
- i. `mib-rfc2863a.txt`

7. Load the remaining standard MIB files.

**NOTE:** You must follow the order specified in this procedure, and ensure that all standard MIBs are loaded before you load the enterprise-specific MIBs. There might be dependencies that require a particular MIB to be present on the compiler before loading some other MIB. You can find such dependencies listed in the **IMPORT** section of the MIB file.

8. Load the Juniper Networks enterprise-specific SMI MIB, `mib-jnx-smi.txt`, and the following optional SMI MIBs based on your requirements:
  - `mib-jnx-js-smi.txt`—(Optional) For Juniper Security MIB tree objects
  - `mib-jnx-ex-smi.txt`—(Optional) For EX Series Ethernet Switches
  - `mib-jnx-exp.txt`—(Recommended) For Juniper Networks experimental MIB objects
9. Load the remaining enterprise-specific MIBs from the **JuniperMibs** folder.

**TIP:** While loading a MIB file, if the compiler returns an error message saying that any of the objects is undefined, open the MIB file using a text editor and ensure that all the MIB files listed in the **IMPORT** section are loaded on the compiler. If any of the MIB files listed in the **IMPORT** section is not loaded on the compiler, load that MIB file, and then try to load the MIB file that failed to load.

For example, the enterprise-specific PING MIB, `mib-jnx-ping.txt`, has dependencies on RFC 2925, DiSMAN-PING-MIB, `mib-rfc2925a.txt`. If you try to load `mib-jnx-ping.txt` before loading `mib-rfc2925a.txt`, the compiler returns an error message saying that certain objects in `mib-jnx-ping.txt` are undefined. Load `mib-rfc2925a.txt`, and then try to load `mib-jnx-ping.txt`. The enterprise-specific PING MIB, `mib-jnx-ping.txt`, then loads without any issue.

## Configuring SNMP on a Device Running Junos OS

By default, SNMP is disabled on devices running Junos OS. To enable SNMP on a router or switch, you must include the SNMP configuration statements at the **[edit snmp]** hierarchy level.

To configure the minimum requirements for SNMP, include the following statements at the **[edit snmp]** hierarchy level of the configuration:

```
[edit]
snmp {
  community public;
}
```

The community defined here as **public** grants read access to all MIB data to any client.

To configure complete SNMP features, include the following statements at the **[edit snmp]** hierarchy level:

```
snmp {
  client-list client-list-name {
    ip-addresses;
  }
  community community-name {
    authorization authorization;
    client-list-name client-list-name;
    clients {
      address restrict;
    }
    routing-instance routing-instance-name {
      clients {
        addresses;
      }
    }
  }
}
```

```

    }
  }
  logical-system logical-system-name {
    routing-instance routing-instance-name {
      clients {
        addresses;
      }
    }
  }
  view view-name;
}
contact contact;
description description;
engine-id {
  (local engine-id | use-mac-address | use-default-ip-address);
}
filter-duplicates;
health-monitor {
  falling-threshold integer;
  interval seconds;
  rising-threshold integer;
}
interface [ interface-names ];
location location;
name name;
nonvolatile {
  commit-delay seconds;
}
rmon {
  alarm index {
    description text-description;
    falling-event-index index;
    falling-threshold integer;
    falling-threshold-interval seconds;
    interval seconds;
    request-type (get-next-request | get-request | walk-request);
    rising-event-index index;
    sample-type type;
    startup-alarm alarm;
    syslog-subtag syslog-subtag;
    variable oid-variable;
  }
  event index {
    community community-name;
    description text-description;
    type type;
  }
}
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable> <match
    regular-expression>;
  flag flag;
}
trap-group group-name {
  categories {
    category;
  }
}

```

```

    }
    destination-port port-number;
    routing-instance instance;
    targets {
        address;
    }
    version (all | v1 | v2);
}
trap-options {
    agent-address outgoing-interface;
    source-address address;
}
view view-name {
    oid object-identifier (include | exclude);
}
}

```

## Configuring the System Contact on a Device Running Junos OS

You can specify an administrative contact for each system being managed by SNMP. This name is placed into the MIB II **sysContact** object. To configure a contact name, include the **contact** statement at the **[edit snmp]** hierarchy level:

```

[edit snmp]
contact contact;

```

If the name contains spaces, enclose it in quotation marks (" ").

To define a system contact name that contains spaces:

```

[edit]
snmp {
    contact "Juniper Berry, (650) 555-1234";
}

```

  - [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)

## Configuring the System Location for a Device Running Junos OS

You can specify the location of each system being managed by SNMP. This string is placed into the MIB II **sysLocation** object. To configure a system location, include the **location** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
location location;
```

If the location contains spaces, enclose it in quotation marks (" ").

To specify the system location:

```
[edit]
snmp {
  location "Row 11, Rack C";
}
```

## Configuring the System Description on a Device Running Junos OS

You can specify a description for each system being managed by SNMP. This string is placed into the MIB II **sysDescription** object. To configure a description, include the **description** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
description description;
```

If the description contains spaces, enclose it in quotation marks (" ").

To specify the system description:

```
[edit]
snmp {
  description "M40 router with 8 FPCs";
}
```

## Configuring the System Name

Junos OS enables you to override the system name by including the **name** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
name name;
```

If the name contains spaces, enclose it in quotation marks (" ").

To specify the system name override:

```
[edit]
snmp {
  name "snmp 1";
}
```

## Configuring the Commit Delay Timer

When a router or switch first receives an SNMP nonvolatile **Set** request, a Junos OS XML protocol session opens and prevents other users or applications from changing the candidate configuration (equivalent to the command-line interface [CLI]

**configure exclusive** command). If the router does not receive new SNMP **Set** requests within 5 seconds (the default value), the candidate configuration is committed and the Junos OS XML protocol session closes (the configuration lock is released). If the router receives new SNMP **Set** requests while the candidate configuration is being committed, the SNMP **Set** request is rejected and an error is generated. If the router receives new SNMP **Set** requests before 5 seconds have elapsed, the commit-delay timer (the length of time between when the last SNMP request is received and the commit is requested) resets to 5 seconds.

By default, the timer is set to 5 seconds. To configure the timer for the SNMP **Set** reply and start of the commit, include the **commit-delay** statement at the **[edit snmp nonvolatile]** hierarchy level:

```
[edit snmp nonvolatile]
commit-delay seconds;
```

**seconds** is the length of the time between when the SNMP request is received and the commit is requested for the candidate configuration. For more information about the **configure exclusive** command and locking the configuration, see the *CLI User Guide*.

## Configuring the SNMP Community String

Configuring the SNMP agent in Junos OS is a straightforward task that shares many familiar settings common to other managed devices in your network. For example, you need to configure Junos OS with an SNMP community string and a destination for traps. Community strings are administrative names that group collections of devices and the agents that are running on them together into common management domains. If a manager and an agent share the same community, they can communicate with each other. An SNMP community defines the level of authorization granted to its members, such as which MIB objects are available, which operations (read-only or read-write) are valid for those objects, and which SNMP clients are authorized, based on their source IP addresses.

The SNMP community string defines the relationship between an SNMP server system and the client systems. This string acts like a password to control the clients' access to the server. To configure a community string in a Junos OS configuration, include the **community** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
community name {
  authorization authorization;
  clients {
    default restrict;
    address restrict;
  }
  view view-name;
}
```

If the community name contains spaces, enclose it in quotation marks (" ").

Community names must be unique.

**NOTE:** You cannot configure the same community name at the **[edit snmp community]** and **[edit snmp v3 snmp-community community-index]** hierarchy levels.

```
[edit groups global]
user@host# set snmp community name
```

This example uses the standard name **public** to create a community that gives limited read-only access.

```
[edit groups global]
user@host# set snmp community public
```

1. Define the authorization level for the community.

The default authorization level for a community is **read-only**. To allow **Set** requests within a community, you need to define that community as **authorization read-write**. For **Set** requests, you also need to include the specific MIB objects that are accessible with read-write privileges using the **view** statement. The default view includes all supported MIB objects that are accessible with read-only privileges; no MIB objects

are accessible with read-write privileges. For more information about the **view** statement, see [“Configuring MIB Views” on page 1789](#).

```
[edit groups global snmp community name]
user@host# set authorization authorization
```

This example confines the public community to read-only access. Any SNMP client (for example, an SNMP management system) that belongs to the public community can read MIB variables but cannot set (change) them.

```
[edit groups global snmp community public]
user@host# set authorization read-only
```

2. Define a list of clients in the community who are authorized to communicate with the SNMP agent in Junos OS.

The **clients** statement lists the IP addresses of the clients (community members) that are allowed to use this community. If no **clients** statement is present, all clients are allowed. For **address**, you must specify an IPv4 or IPv6 address, not a hostname. Include the **default restrict** option to deny access to all SNMP clients for which access is not explicitly granted. We recommend that you always include the **default restrict** option to limit SNMP client access to the local router.

**NOTE:** Community names must be unique. You cannot configure the same community name at the [edit snmp community] and [edit snmp v3 snmp-community *community-index*] hierarchy levels.

- [Examples: Configuring the SNMP Community String on page 1785](#)

## Examples: Configuring the SNMP Community String

Grant read-only access to all clients. With the following configuration, the system responds to SNMP **Get**, **GetNext**, and **GetBulk** requests that contain the community string **public**:

```
[edit]
snmp {
  community public {
    authorization read-only;
  }
}
```

Grant all clients read-write access to the ping MIB and **jnxPingMIB**. With the following configuration, the system responds to SNMP **Get**, **GetNext**, **GetBulk**, and **Set** requests that contain the community string **private** and specify an OID contained in the ping MIB or **jnxPingMIB** hierarchy:

```
[edit]
snmp {
```

```

view ping-mib-view {
  oid pingMIB include;
  oid jnxPingMIB include;
  community private {
    authorization read-write;
    view ping-mib-view;
  }
}

```

The following configuration allows read-only access to clients with IP addresses in the range 1.2.3.4/24, and denies access to systems in the range fe80::1:2:3:4/64:

```

[edit]
snmp {
  community field-service {
    authorization read-only;
    clients {
      default restrict; # Restrict access to all SNMP clients not explicitly
                        # listed on the following lines.
      1.2.3.4/24; # Allow access by all clients in 1.2.3.4/24 except
      fe80::1:2:3:4/64 restrict; # fe80::1:2:3:4/64.
    }
  }
}

```

**Related Documentation**

- [Configuring the SNMP Community String on page 1784](#)

## Filtering Duplicate SNMP Requests

By default, filtering duplicate **get**, **getNext**, and **getBulk** SNMP requests is disabled on devices running Junos OS. If a network management station retransmits a **Get**, **GetNext**, or **GetBulk** SNMP request too frequently to the router, that request might interfere with the processing of previous requests and slow down the response time of the agent. Filtering these duplicate requests improves the response time of the SNMP agent. Junos OS uses the following information to determine if an SNMP request is a duplicate:

- Source IP address of the SNMP request
- Source UDP port of the SNMP request
- Request ID of the SNMP request

To filter duplicate SNMP requests, include the **filter-duplicates** statement at the **[edit snmp]** hierarchy level:

```

[edit snmp]
filter-duplicates;

```

**Related Documentation**

- [Filtering Interface Information Out of SNMP Get and GetNext Output on page 1787](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)

## Configuring the Interfaces on Which SNMP Requests Can Be Accepted

By default, all router or switch interfaces have SNMP access privileges. To limit the access through certain interfaces only, include the **interface** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
interface [ interface-names ];
```

Specify the names of any logical or physical interfaces that should have SNMP access privileges. Any SNMP requests entering the router or switch from interfaces not listed are discarded.

### Related Documentation

- [Configuring SNMP on a Device Running Junos OS on page 1779](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)
- [Example: Configuring Secured Access List Checking on page 1787](#)

## Example: Configuring Secured Access List Checking

SNMP access privileges are granted to only devices on interfaces **so-0/0/0** and **at-1/0/1**. The following example does this by configuring a list of logical interfaces:

```
[edit]
snmp {
  interface [ so-0/0/0.0 so-0/0/0.1 at-1/0/1.0 at-1/0/1.1 ];
}
```

The following example grants the same access by configuring a list of physical interfaces:

```
[edit]
snmp {
  interface [ so-0/0/0 at-1/0/1 ];
}
```

## Filtering Interface Information Out of SNMP Get and GetNext Output

Junos OS enables you to filter out information related to specific interfaces from the output of SNMP **Get** and **GetNext** requests performed on interface-related MIBs such as IF MIB, ATM MIB, RMON MIB, and the Juniper Networks enterprise-specific IF MIB.

You can use the following options of the **filter-interfaces** statement at the **[edit snmp]** hierarchy level to specify the interfaces that you want to exclude from SNMP **Get** and **GetNext** queries:

- **interfaces**—Interfaces that match the specified regular expressions.

- **all-internal-interfaces**—Internal interfaces.

```
[edit]
snmp {
  filter-interfaces {
    interfaces {
      interface1;
      interface2;
    }
    all-internal-interfaces;
  }
}
```

Starting with Release 12.1, Junos OS provides an except option (! operator) that enables you to filter out all interfaces except those interfaces that match all the regular expressions prefixed with the ! mark.

For example, to filter out all interfaces except the **ge** interfaces from the SNMP **get** and **get-next** results, enter the following command:

```
[edit snmp]
user@host# set filter-interfaces interfaces "!~ge-.*"
user@host# commit
```

When this is configured, Junos OS filters out all interfaces except the **ge** interfaces from the SNMP **get** and **get-next** results.

**NOTE:** The ! mark is supported only as the first character of the regular expression. If it appears anywhere else in a regular expression, Junos OS considers the regular expression invalid, and returns an error.

---

However, note that these settings are limited to SNMP operations, and the users can continue to access information related to the interfaces (including those hidden using the **filter-interfaces** options) using the appropriate Junos OS command-line interface (CLI) commands.

**Related  
Documentation**

## Configuring MIB Views

SNMPv3 defines the concept of MIB views in RFC 3415, *View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)*. MIB views provide an agent better control over who can access specific branches and objects within its MIB tree. A view consists of a name and a collection of SNMP object identifiers, which are either explicitly included or excluded. Once defined, a view is then assigned to an SNMPv3 group or SNMPv1/v2c community (or multiple communities), automatically masking which parts of the agent's MIB tree members of the group or community can (or cannot) access.

By default, an SNMP community grants read access and denies write access to all supported MIB objects (even communities configured as **authorization read-write**). To restrict or grant read or write access to a set of MIB objects, you must configure a MIB view and associate the view with a community.

To configure MIB views, include the **view** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
view view-name {
  oid object-identifier (include | exclude);
}
```

The **view** statement defines a MIB view and identifies a group of MIB objects. Each MIB object of a view has a common object identifier (OID) prefix. Each object identifier represents a subtree of the MIB object hierarchy. The subtree can be represented either by a sequence of dotted integers (such as **1.3.6.1.2.1.2**) or by its subtree name (such as **interfaces**). A configuration statement uses a view to specify a group of MIB objects on which to define access. You can also use a wildcard character asterisk (\*) to include OIDs that match a particular pattern in the SNMP view. To enable a view, you must associate the view with a community.

**NOTE:** To remove an OID completely, use the **delete view all oid *oid-number*** command but omit the include parameter.

To associate MIB views with a community, include the **view** statement at the **[edit snmp community *community-name*]** hierarchy level:

```
[edit snmp community community-name]
view view-name;
```

For more information about the Ping MIB, see RFC 2925 and the *PING MIB* topic.

### Related Documentation

- [PING MIB](#)
- [Configuring SNMP on a Device Running Junos OS on page 1779](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)
- [Example: Ping Proxy MIB on page 1790](#)
- [view \(Configuring a MIB View\) on page 1979](#)

- [view \(Associating MIB View with a Community\)](#)
- [oid on page 1936](#)

### Example: Ping Proxy MIB

Restrict the **ping-mib** community to read and write access of the Ping MIB and **jnxpingMIB** only. Read or write access to any other MIB using this community is not allowed.

```
[edit snmp]
view ping-mib-view {
  oid 1.3.6.1.2.1.80 include; #pingMIB
  oid jnxPingMIB include; #jnxPingMIB
}
community ping-mib {
  authorization read-write;
  view ping-mib-view;
}
```

The following configuration prevents the **no-ping-mib** community from accessing Ping MIB and **jnxPingMIB** objects. However, this configuration does not prevent the **no-ping-mib** community from accessing any other MIB object that is supported on the device.

```
[edit snmp]
view no-ping-mib-view {
  oid 1.3.6.1.2.1.80 exclude; # deny access to pingMIB objects
  oid jnxPingMIB exclude; # deny access to jnxPingMIB objects
}
community no-ping-mib {
  authorization read-write;
  view ping-mib-view;
}
```

### Configuring SNMP Trap Options and Groups on a Device Running Junos OS

Some carriers have more than one trap receiver that forwards traps to a central NMS. This allows for more than one path for SNMP traps from a router to the central NMS through different trap receivers. A device running Junos OS can be configured to send the same copy of each SNMP trap to every trap receiver configured in the trap group.

The source address in the IP header of each SNMP trap packet is set to the address of the outgoing interface by default. When a trap receiver forwards the packet to the central NMS, the source address is preserved. The central NMS, looking only at the source address of each SNMP trap packet, assumes that each SNMP trap came from a different source.

In reality, the SNMP traps came from the same router, but each left the router through a different outgoing interface.

The statements discussed in the following sections are provided to allow the NMS to recognize the duplicate traps and to distinguish SNMPv1 traps based on the outgoing interface.

To configure SNMP trap options and trap groups, include the **trap-options** and **trap-group** statements at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
  source-address address;
}
trap-group group-name {
  categories {
    category;
  }
  destination-port port-number;
  targets {
    address;
  }
  version (all | v1 | v2);
}
```

#### Related Documentation

- [Configuring SNMP Trap Groups on page 1795](#)
- [Configuring SNMP on a Device Running Junos OS on page 1779](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)

## Configuring SNMP Trap Options

Using SNMP trap options, you can set the source address of every SNMP trap packet sent by the router to a single address regardless of the outgoing interface. In addition, you can set the agent address of the SNMPv1 traps. For more information about the contents of SNMPv1 traps, see RFC 1157.

**NOTE:** SNMP cannot be associated with any routing instances other than the master routing instance.

To configure SNMP trap options, include the **trap-options** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
  enterprise-oid
  logical-system
  routing-instance
```

```

    source-address address;
}

```

You must also configure a trap group for the trap options to take effect. For information about trap groups, see [“Configuring SNMP Trap Groups” on page 1795](#).

This topic contains the following sections:

- [Configuring the Source Address for SNMP Traps on page 1792](#)
- [Configuring the Agent Address for SNMP Traps on page 1794](#)
- [Adding snmpTrapEnterprise Object Identifier to Standard SNMP Traps on page 1794](#)

### Configuring the Source Address for SNMP Traps

You can configure the source address of trap packets in many ways: **lo0**, a valid IPv4 address configured on one of the router interfaces, a logical-system address, or the address of a routing-instance. The value **lo0** indicates that the source address of the SNMP trap packets is set to the lowest loopback address configured on the interface **lo0**.

You can configure the source address of trap packets in one of the following formats:

- a valid IPv4 address configured on one of the router interfaces
- **lo0**; that is the lowest loopback address configured on the interface **lo0**.
- a logical-system name
- a routing-instance name

#### A valid IPv4 Address As the Source Address

To specify a valid interface address as the source address for SNMP traps on one of the router interfaces, include the **source-address** statement at the **[edit snmp trap-options]** hierarchy level:

```

[edit snmp trap-options]
source-address address;

```

**address** is a valid IPv4 address configured on one of the router interfaces.

#### The Lowest Loopback Address As the Source Address

To specify the source address of the SNMP traps so that they use the lowest loopback address configured on the interface **lo0** as the source address, include the **source-address** statement at the **[edit snmp trap-options]** hierarchy level:

```

[edit snmp trap-options]
source-address lo0;

```

To enable and configure the loopback address, include the **address** statement at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level:

```

[edit interfaces]
lo0 {
  unit 0 {
    family inet {
      address ip-address;
    }
  }
}

```

```
}
```

To configure the loopback address as the source address of trap packets:

```
[edit snmp]
trap-options {
  source-address lo0;
}
trap-group "urgent-dispatcher" {
  version v2;
  categories link startup;
  targets {
    192.168.10.22;
    172.17.1.2;
  }
}
[edit interfaces]
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
      address 127.0.0.1/32;
    }
  }
}
```

In this example, the IP address **10.0.0.1** is the source address of every trap sent from this router.

**Logical System Name  
as the Source Address**

To specify a logical system name as the source address of SNMP traps, include the **logical-system *logical-system-name*** statement at the **[edit snmp trap-options]** hierarchy level.

For example, the following configuration sets logical system name **ls1** as the source address of SNMP traps:

```
[edit snmp]
  trap-options {
    logical-system ls1;
  }
```

**Routing Instance  
Name as the Source  
Address**

To specify a routing instance name as the source address of SNMP traps, include the **routing-instance *routing-instance-name*** statement at the **[edit snmp trap-options]** hierarchy level.

For example, the following configuration sets the routing instance name **ri1** as the source address for SNMP traps:

```
[edit snmp]
  trap-options {
    routing-instance ri1;
  }
```

### Configuring the Agent Address for SNMP Traps

---

The agent address is only available in SNMPv1 trap packets (see RFC 1157). By default, the router's default local address is used in the agent address field of the SNMPv1 trap. To configure the agent address, include the **agent-address** statement at the **[edit snmp trap-options]** hierarchy level. Currently, the agent address can only be the address of the outgoing interface:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
}
```

To configure the outgoing interface as the agent address:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
}
trap-group "urgent-dispatcher" {
  version v1;
  categories link startup;
  targets {
    192.168.10.22;
    172.17.1.2;
  }
}
```

In this example, each SNMPv1 trap packet sent has its agent address value set to the IP address of the outgoing interface.

### Adding snmpTrapEnterprise Object Identifier to Standard SNMP Traps

---

The **snmpTrapEnterprise** object helps you identify the enterprise that has defined the trap. Typically, the **snmpTrapEnterprise** object appears as the last varbind in enterprise-specific SNMP version 2 traps. However, starting Release 10.0, Junos OS enables you to add the **snmpTrapEnterprise** object identifier to standard SNMP traps as well.

To add **snmpTrapEnterprise** to standard traps, include the **enterprise-oid** statement at the **[edit snmp trap-options]** hierarchy level. If the **enterprise-oid** statement is not included in the configuration, **snmpTrapEnterprise** is added only for enterprise-specific traps.

```
[edit snmp]
trap-options {
  enterprise-oid;
}
```

#### Related Documentation

- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1894](#)

## Configuring SNMP Trap Groups

You can create and name a group of one or more types of SNMP traps and then define which systems receive the group of SNMP traps. The trap group must be configured for SNMP traps to be sent. To create an SNMP trap group, include the **trap-group** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-group group-name {
  categories {
    category;
  }
  destination-port port-number;
  routing-instance instance;
  targets {
    address;
  }
  version (all | v1 | v2);
}
```

The trap group name can be any string and is embedded in the community name field of the trap. To configure your own trap group port, include the **destination-port** statement. The default destination port is port 162.

For each trap group that you define, you must include the **target** statement to define at least one system as the recipient of the SNMP traps in the trap group. Specify the IPv4 or IPv6 address of each recipient, not its hostname.

Specify the types of traps the trap group can receive in the **categories** statement. For information about the category to which the traps belong, see the [“Standard SNMP Traps Supported on Devices Running Junos OS” on page 1763](#) and [“Juniper Networks Enterprise-Specific SNMP Traps” on page 1748](#) topics.

Specify the routing instance used by the trap group in the **routing-instance** statement. All targets configured in the trap group use this routing instance.

A trap group can receive the following categories:

- **authentication**—Authentication failures
- **chassis**—Chassis or environment notifications
- **configuration**—Configuration notifications
- **link**—Link-related notifications (up-down transitions, DS-3 and DS-1 line status change, IPv6 interface state change, and Passive Monitoring PIC overload)

**NOTE:** To send Passive Monitoring PIC overload interface traps, select the **link** trap category.

- **remote-operations**—Remote operation notifications
- **rmon-alarm**—Alarm for RMON events

- **routing**—Routing protocol notifications
- **sonet-alarms**—SONET/SDH alarms

**NOTE:** If you omit the SONET/SDH subcategories, all SONET/SDH trap alarm types are included in trap notifications.

- **loss-of-light**—Loss of light alarm notification
- **pll-lock**—PLL lock alarm notification
- **loss-of-frame**—Loss of frame alarm notification
- **loss-of-signal**—Loss of signal alarm notification
- **severely-errored-frame**—Severely errored frame alarm notification
- **line-ais**—Line alarm indication signal (AIS) alarm notification
- **path-ais**—Path AIS alarm notification
- **loss-of-pointer**—Loss of pointer alarm notification
- **ber-defect**—SONET/SDH bit error rate alarm defect notification
- **ber-fault**—SONET/SDH error rate alarm fault notification
- **line-remote-defect-indication**—Line remote defect indication alarm notification
- **path-remote-defect-indication**—Path remote defect indication alarm notification
- **remote-error-indication**—Remote error indication alarm notification
- **unequipped**—Unequipped alarm notification
- **path-mismatch**—Path mismatch alarm notification
- **loss-of-cell**—Loss of cell delineation alarm notification
- **vt-ais**—Virtual tributary (VT) AIS alarm notification
- **vt-loss-of-pointer**—VT loss of pointer alarm notification
- **vt-remote-defect-indication**—VT remote defect indication alarm notification
- **vt-unequipped**—VT unequipped alarm notification
- **vt-label-mismatch**—VT label mismatch error notification
- **vt-loss-of-cell**—VT loss of cell delineation notification
- **startup**—System warm and cold starts
- **timing-events**—Timing events and defects notification
- **vrrp-events**—Virtual Router Redundancy Protocol (VRRP) events such as new-master or authentication failures

- **startup**—System warm and cold starts
- **vrrp-events**—Virtual Router Redundancy Protocol (VRRP) events such as new-master or authentication failures

If you include SONET/SDH subcategories, only those SONET/SDH trap alarm types are included in trap notifications.

The **version** statement allows you to specify the SNMP version of the traps sent to targets of the trap group. If you specify **v1** only, SNMPv1 traps are sent. If you specify **v2** only, SNMPv2 traps are sent. If you specify **all**, both an SNMPv1 and an SNMPv2 trap are sent for every trap condition. For more information about the **version** statement, see [version](#).

### Example: Configuring SNMP Trap Groups

Set up a trap notification list named **urgent-dispatcher** for link and startup traps. This list is used to identify the network management hosts (**1.2.3.4** and **fe80::1:2:3:4**) to which traps generated by the local router should be sent. The name specified for a trap group is used as the SNMP community string when the agent sends traps to the listed targets.

```
[edit]
snmp {
  trap-group "urgent-dispatcher" {
    version v2;
    categories link startup;
    targets {
      1.2.3.4;
      fe80::1:2:3:4;
    }
  }
}
```

### Configuring the Trap Notification Filter

SNMPv3 uses the notify filter to define which traps (or which objects from which traps) are sent to the network management system (NMS). The trap notification filter limits the type of traps that are sent to the NMS.

Each object identifier represents a subtree of the MIB object hierarchy. The subtree can be represented either by a sequence of dotted integers (such as **1.3.6.1.2.1.2**) or by its subtree name (such as **interfaces**). You can also use the wildcard character asterisk (\*) in the object identifier (OID) to specify object identifiers that match a particular pattern.

To configure the trap notifications filter, include the **notify-filter** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
  notify-filter profile-name;
```

**profile-name** is the name assigned to the notify filter.

By default, the OID is set to **include**. To define access to traps (or objects from traps), include the **oid** statement at the **[edit snmp v3 notify-filter profile-name]** hierarchy level:

```
[edit snmp v3 notify-filter profile-name]
  oid oid (include | exclude);
```

**oid** is the object identifier. All MIB objects represented by this statement have the specified OID as a prefix. It can be specified either by a sequence of dotted integers or by a subtree name.

- **include**—Include the subtree of MIB objects represented by the specified OID.
- **exclude**—Exclude the subtree of MIB objects represented by the specified OID.

## SNMPv3 Overview

In contrast to SNMP version 1 (SNMPv1) and SNMP version 2 (SNMPv2), SNMP version 3 (SNMPv3) supports authentication and encryption. SNMPv3 uses the user-based security model (USM) for message security and the view-based access control model (VACM) for access control. USM specifies authentication and encryption. VACM specifies access-control rules.

USM uses the concept of a user for which security parameters (levels of security, authentication, privacy protocols, and keys) are configured for both the agent and the manager. Messages sent using USM are better protected than messages sent with community strings, where passwords are sent in the clear. With USM, messages exchanged between the manager and the agent can have data integrity checking and data origin authentication. USM protects against message delays and message replays by using time indicators and request IDs. Encryption is also available.

To complement the USM, SNMPv3 uses the VACM, a highly granular access-control model for SNMPv3 applications. Based on the concept of applying security policies to the name of the groups querying the agent, the agent decides whether the group is allowed to view or change specific MIB objects. VACM defines collections of data (called views), groups of data users, and access statements that define which views a particular group of users can use for reading, writing, or receiving traps.

Trap entries in SNMPv3 are created by configuring the notify, notify filter, target address, and target parameters. The **notify** statement specifies the type of notification (trap) and

contains a single tag. The tag defines a set of target addresses to receive a trap. The notify filter defines access to a collection of trap object identifiers (OIDs). The target address defines a management application's address and other attributes to be used in sending notifications. Target parameters define the message processing and security parameters to be used in sending notifications to a particular management target.

To configure SNMPv3, perform the following tasks:

- [Creating SNMPv3 Users on page 1800](#)
- [Configuring MIB Views on page 1789](#)
- [Defining Access Privileges for an SNMP Group on page 1809](#)
- [Configuring SNMPv3 Traps on a Device Running Junos OS on page 1819](#)
- [Configuring SNMP Informs on page 1818](#)

#### Related Documentation

- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

## Creating SNMPv3 Users

For each SNMPv3 user, you can specify the username, authentication type, authentication password, privacy type, and privacy password. After a user enters a password, a key based on the engine ID and password is generated and is written to the configuration file. After the generation of the key, the password is deleted from this configuration file.

**NOTE:** You can configure only one encryption type for each SNMPv3 user.

To create users, include the **user** statement at the **[edit snmp v3 usm local-engine]** hierarchy level:

```
[edit snmp v3 usm local-engine]
user username;
```

**username** is the name that identifies the SNMPv3 user.

To configure user authentication and encryption, include the following statements at the **[edit snmp v3 usm local-engine user username]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
authentication-md5 {
  authentication-password authentication-password;
}
authentication-sha {
  authentication-password authentication-password;
}
authentication-none;
privacy-aes128 {
  privacy-password privacy-password;
}
privacy-des {
```

```

    privacy-password privacy-password;
}
privacy-3des {
    privacy-password privacy-password;
}
privacy-none;

```

- [Example: SNMPv3 Configuration on page 1801](#)

## Example: SNMPv3 Configuration

Define an SNMPv3 configuration:

```

[edit snmp]
engine-id {
    use-mac-address;
}
view jnxAlarms {
    oid 1.3.6.1.4.1.2636.3.4 include;
}
view interfaces {
    oid 1.3.6.1.2.1.2 include;
}
view ping-mib {
    oid 1.3.6.1.2.1.80 include;
}
[edit snmp v3]
notify n1 {
    tag router1; # Identifies a set of target addresses
    type trap; # Defines type of notification
}
notify n2 {
    tag host1;
    type trap;
}
notify-filter nf1 {
    oid .1 include; # Defines which traps to send
} # In this case, includes all traps
notify-filter nf2 {
    oid 1.3.6.1.4.1 include; # Sends enterprise-specific traps only
}
notify-filter nf3 {
    oid 1.3.6.1.2.1.1.5 include; # Sends BGP traps only
}
snmp-community index1 {
    community-name "$ABC123"; # SECRET-DATA
    security-name john; # Matches the security name at the target parameters
    tag host1; # Finds the addresses that are allowed to be used with
}
target-address ta1 { # Associates the target address with the group

```

```
        # san-francisco.
    address 10.1.1.1;
    address-mask 255.255.255.0; # Defines the range of addresses
    port 162;
    tag-list router1;
    target-parameters tp1; # Applies configured target parameters
}
target-address ta2 {
    address 10.1.1.2;
    address-mask 255.255.255.0;
    port 162;
    tag-list host1;
    target-parameters tp2;
}
target-address ta3 {
    address 10.1.1.3;
    address-mask 255.255.255.0;
    port 162;
    tag-list "router1 host1";
    target-parameters tp3;
}
target-parameters tp1 { # Defines the target parameters
    notify-filter nf1; # Specifies which notify filter to apply
    parameters {
        message-processing-model v1;
        security-model v1;
        security-level none;
        security-name john; # Matches the security name configured at the
    } # [edit snmp v3 snmp-community community-index hierarchy level.
}
target-parameters tp2 {
    notify-filter nf2;
    parameters {
        message-processing-model v1;
        security-model v1;
        security-level none;
        security-name john;
    }
}
target-parameters tp3 {
    notify-filter nf3;
    parameters {
        message-processing-model v1;
        security-model v1;
        security-level none;
        security-name john;
    }
}
usm {
    local-engine { #Defines authentication and encryption for SNMPv3 users
        user user1 {
            authentication-md5 {
                authentication-password authentication-password;
            }
            privacy-des {
                privacy-password privacy-password;
            }
        }
    }
}
```

```

    }
  }
  user user2 {
    authentication-sha {
      authentication-password authentication-password;
    }
    privacy-none;
  }
  user user3 {
    authentication-none;
    privacy-none;
  }
  user user4 {
    authentication-sha {
      authentication-password authentication-password;
    }
    privacy-aes128 {
      privacy-password privacy-password;
    }
  }
  user user5 {
    authentication-sha {
      authentication-password authentication-password;
    }
    privacy-none;
  }
}
}
vacm {
  access {
    group san-francisco { #Defines the access privileges for the group
      default-context-prefix { # called san-francisco
        security-model v1 {
          security-level none {
            notify-view ping-mib;
            read-view interfaces;
            write-view jnxAlarms;
          }
        }
      }
    }
  }
}
security-to-group {
  security-model v1 {
    security-name john { # Assigns john to the security group
      group san-francisco; # called san-francisco
    }
    security-name bob {
      group new-york;
    }
    security-name elizabeth {
      group chicago;
    }
  }
}
}
}

```

### Example: Creating SNMPv3 Users Configuration

Define SNMPv3 users:

```
[edit]
snmp {
  v3 {
    usm {
      local-engine {
        user user1 {
          authentication-md5 {
            authentication-password authentication-password;
          }
          privacy-des {
            privacy-password password;
          }
        }
        user user2 {
          authentication-sha {
            authentication-password authentication-password;
          }
          privacy-none;
        }
        user user3 {
          authentication-none;
          privacy-none;
        }
        user user4 {
          authentication-md5 {
            authentication-password authentication-password;
          }
          privacy-des {
            privacy-password authentication-password;
          }
        }
        user user5 {
          authentication-sha {
            authentication-password authentication-password;
          }
          privacy-aes128 {
            privacy-password authentication-password;
          }
        }
      }
    }
  }
}
```

## Minimum SNMPv3 Configuration on a Device Running Junos OS

To configure the minimum requirements for SNMPv3, include the following statements at the `[edit snmp v3]` and `[edit snmp]` hierarchy levels:

**NOTE:** You must configure at least one view (notify, read, or write) at the `[edit snmp view-name]` hierarchy level.

```
[edit snmp]
view view-name {
  oid object-identifier (include | exclude);
}
[edit snmp v3]
notify name {
  tag tag-name;
}
notify-filter profile-name {
  oid object-identifier (include | exclude);
}
snmp-community community-index {
  security-name security-name;
}
target-address target-address-name {
  address address;
  target-parameters target-parameters-name;
}
target-parameters target-parameters-name {
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
usm {
  local-engine {
    user username {
    }
  }
}
vacm {
  access {
    group group-name {
      (default-context-prefix | context-prefix context-prefix){
        security-model (any | usm | v1 | v2c) {
          security-level (authentication | none | privacy) {
            notify-view view-name;
            read-view view-name;
            write-view view-name;
          }
        }
      }
    }
  }
}
```

```
    }  
  }  
  security-to-group {  
    security-model (usm | v1 | v2c) {  
      security-name security-name {  
        group group-name;  
      }  
    }  
  }  
}
```

## Configuring the SNMPv3 Authentication Type

By default, in a Junos OS configuration the SNMPv3 authentication type is set to none.

This topic includes the following sections:

- [Configuring MD5 Authentication on page 1806](#)
- [Configuring SHA Authentication on page 1807](#)
- [Configuring No Authentication on page 1807](#)

### Configuring MD5 Authentication

---

To configure the message digest algorithm (MD5) as the authentication type for an SNMPv3 user, include the **authentication-md5** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
authentication-md5 {  
  authentication-password authentication-password;  
}
```

***authentication-password*** is the password used to generate the key used for authentication.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

### Configuring SHA Authentication

To configure the secure hash algorithm (SHA) as the authentication type for an SNMPv3 user, include the **authentication-sha** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
authentication-sha {
  authentication-password authentication-password;
}
```

***authentication-password*** is the password used to generate the key used for authentication.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

### Configuring No Authentication

To configure no authentication for an SNMPv3 user, include the **authentication-none** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
authentication-none;
```

#### Related Documentation

- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

### Configuring the Encryption Type

By default, encryption is set to none.

**NOTE:** Before you configure encryption, you must configure MD5 or SHA authentication.

Before you configure the **privacy-des**, **privacy-3des** and **privacy-aes128** statements, you must install the **jcrypto** package, and either restart the SNMP process or reboot the router.

This topic includes the following sections:

- [Configuring the Advanced Encryption Standard Algorithm on page 1808](#)
- [Configuring the Data Encryption Algorithm on page 1808](#)
- [Configuring Triple DES on page 1808](#)
- [Configuring No Encryption on page 1809](#)

---

### Configuring the Advanced Encryption Standard Algorithm

To configure the Advanced Encryption Standard (AES) algorithm for an SNMPv3 user, include the **privacy-aes128** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
  privacy-aes128 {  
    privacy-password privacy-password;  
  }
```

***privacy-password*** is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

---

### Configuring the Data Encryption Algorithm

To configure the data encryption algorithm (DES) for an SNMPv3 user, include the **privacy-des** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
  privacy-des {  
    privacy-password privacy-password;  
  }
```

***privacy-password*** is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

---

### Configuring Triple DES

To configure triple DES for an SNMPv3 user, include the **privacy-3des** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
  privacy-3des {
```

```

    privacy-password privacy-password;
}

```

*privacy-password* is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

### Configuring No Encryption

To configure no encryption for an SNMPv3 user, include the **privacy-none** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```

[edit snmp v3 usm local-engine user username]
  privacy-none;

```

## Defining Access Privileges for an SNMP Group

The SNMP version 3 (SNMPv3) uses the view-based access control model (VACM), which allows you to configure the access privileges granted to a group. Access is controlled by filtering the MIB objects available for a specific operation through a predefined view. You assign views to determine the objects that are visible for read, write, and notify operations for a particular group, using a particular context, a particular security model (v1, v2c, or usm), and particular security level (authenticated, privacy, or none). For information about how to configure views, see [“Configuring MIB Views” on page 1789](#).

You define user access to management information at the **[edit snmp v3 vacm]** hierarchy level. All access control within VACM operates on groups, which are collections of users as defined by USM, or community strings as defined in the SNMPv1 and SNMPv2c security models. The term **security-name** refers to these generic end users. The group to which a specific security name belongs is configured at the **[edit snmp v3 vacm security-to-group]** hierarchy level. That security name can be associated with a group defined at the **[edit snmp v3 vacm security-to-group]** hierarchy level. A group identifies a collection of SNMP users that share the same access policy. You then define the access privileges associated with a group at the **[edit snmp v3 vacm access]** hierarchy level. Access privileges are defined using views. For each group, you can apply different views depending on the SNMP operation; for example, read (**get**, **getNext**, or **getBulk**) write (**set**), notifications,

the security level used (authentication, privacy, or none), and the security model (v1, v2c, or usm) used within an SNMP request.

You configure members of a group with the **security-name** statement. For v3 packets using USM, the security name is the same as the username. For SNMPv1 or SNMPv2c packets, the security name is determined based on the community string. Security names are specific to a security model. If you are also configuring VACM access policies for SNMPv1 or SNMPv2c packets, you must assign security names to groups for each security model (SNMPv1 or SNMPv2c) at the **[edit snmp v3 vacm security-to-group]** hierarchy level. You must also associate a security name with an SNMP community at the **[edit snmp v3 snmp-community community-index]** hierarchy level.

To configure the access privileges for an SNMP group, include statements at the **[edit snmp v3 vacm]** hierarchy level:

```
[edit snmp v3 vacm]
access {
  group group-name {
    (default-context-prefix | context-prefix context-prefix){
      security-model (any | usm | v1 | v2c) {
        security-level (authentication | none | privacy) {
          notify-view view-name;
          read-view view-name;
          write-view view-name;
        }
      }
    }
  }
}
security-to-group {
  security-model (usm | v1 | v2c) {
    security-name security-name {
      group group-name;
    }
  }
}
```

#### Related Documentation

- [Configuring the SNMPv3 Authentication Type on page 1806](#)
- [Configuring the Access Privileges Granted to a Group on page 1810](#)
- [Assigning Security Model and Security Name to a Group on page 1814](#)
- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

## Configuring the Access Privileges Granted to a Group

This topic includes the following sections:

- [Configuring the Group on page 1811](#)
- [Configuring the Security Model on page 1811](#)

- [Configuring the Security Level on page 1811](#)
- [Associating MIB Views with an SNMP User Group on page 1812](#)

### Configuring the Group

To configure the access privileges granted to a group, include the **group** statement at the **[edit snmp v3 vacm access]** hierarchy level:

```
[edit snmp v3 vacm access]
group group-name;
```

**group-name** is a collection of SNMP users that belong to a common SNMP list that defines an access policy. Users belonging to a particular SNMP group inherit all access privileges granted to that group.

### Configuring the Security Model

To configure the security model, include the **security-model** statement at the **[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
context-prefix)]
security-model (any | usm | v1 | v2c);
```

- **any**—Any security model
- **usm**—SNMPv3 security model
- **v1**—SNMPv1 security model
- **v2c**—SNMPv2c security model

### Configuring the Security Level

To configure the access privileges granted to packets with a particular security level, include the **security-level** statement at the **[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name default-context-prefix security-model (any
| usm | v1 | v2c)]
security-level (authentication | none | privacy);
```

- **none**—Provides no authentication and no encryption.
- **authentication**—Provides authentication but no encryption.
- **privacy**—Provides authentication and encryption.

**NOTE:** Access privileges are granted to all packets with a security level equal to or greater than that configured. If you are configuring the SNMPv1 or SNMPv2c security model, use **none** as your security level. If you are configuring the SNMPv3 security model (USM), use the **authentication**, **none**, or **privacy** security level.

## Associating MIB Views with an SNMP User Group

MIB views define access privileges for members of a group. Separate views can be applied for each SNMP operation (read, write, and notify) within each security model (usm, v1, and v2c) and each security level (authentication, none, and privacy) supported by SNMP.

To associate MIB views with an SNMP user group, include the following statements at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
  context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
  | privacy)]
  notify-view view-name;
  read-view view-name;
  write-view view-name;
```

**NOTE:** You must associate at least one view (notify, read, or write) at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level.

You must configure the MIB view at the `[edit snmp view view-name]` hierarchy level. For information about how to configure MIB views, see [“Configuring MIB Views” on page 1789](#).

This section describes the following topics related to this configuration:

- [Configuring the Notify View on page 1812](#)
- [Configuring the Read View on page 1813](#)
- [Configuring the Write View on page 1813](#)

### Configuring the Notify View

To associate notify access with an SNMP user group, include the `notify-view` statement at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
  context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
  | privacy)]
  notify-view view-name;
```

***view-name*** specifies the notify access, which is a list of notifications that can be sent to each user in an SNMP group. A view name cannot exceed 32 characters.

### Configuring the Read View

To associate a read view with an SNMP group, include the **read-view** statement at the **[edit snmp v3 vacm access group *group-name* (default-context-prefix | context-prefix *context-prefix*) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
    context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
    | privacy)]
  read-view view-name;
```

**view-name** specifies read access for an SNMP user group. A view name cannot exceed 32 characters.

### Configuring the Write View

To associate a write view with an SNMP user group, include the **write-view** statement at the **[edit snmp v3 vacm access group *group-name* (default-context-prefix | context-prefix *context-prefix*) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
    context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
    | privacy)]
  write-view view-name;
```

**view-name** specifies write access for an SNMP user group. A view name cannot exceed 32 characters.

- [Example: Access Privilege Configuration on page 1813](#)

### Example: Access Privilege Configuration

Define access privileges:

```
[edit snmp v3]
access {
  group group1 {
    default-context-prefix {
      security-model usm {          #Define an SNMPv3 security model
        security-level privacy {
          notify-view nv1;
          read-view rv1;
          write-view wv1;
        }
      }
    }
  }
}
```

```

context-prefix lr1/ril { # routing instance ril in logical system lr1
  security-model usm {
    security-level privacy {
      notify-view nv1;
      read-view rv1;
      write-view wv1;
    }
  }
}
}
group group2 {
  default-context-prefix {
    security-model usm {      #Define an SNMPv3 security model
      security-level authentication {
        read-view rv2;
        write-view wv2;
      }
    }
  }
}
group group3 {
  default-context-prefix {
    security-model v1 {      #Define an SNMPv3 security model
      security-level none {
        read-view rv3;
        write-view wv3;
      }
    }
  }
}
}

```

#### Related Documentation

- [Configuring the Access Privileges Granted to a Group on page 1810](#)

## Assigning Security Model and Security Name to a Group

To assign security names to groups, include the following statements at the **[edit snmp v3 vacm security-to-group]** hierarchy level:

```

[edit snmp v3 vacm security-to-group]
security-model (usm | v1 | v2c) {
  security-name security-name {
    group group-name;
  }
}

```

This topic includes the following sections:

- [Configuring the Security Model on page 1815](#)
- [Assigning Security Names to Groups on page 1815](#)
- [Configuring the Group on page 1815](#)

### Configuring the Security Model

To configure the security model, include the **security-model** statement at the **[edit snmp v3 vacm security-to-group]** hierarchy level:

```
[edit snmp v3 vacm security-to-group]
security-model (usm | v1 | v2c);
```

- **usm**—SNMPv3 security model
- **v1**—SNMPv1 security model
- **v2c**—SNMPv2 security model

### Assigning Security Names to Groups

To associate a security name with an SNMPv3 user, or a v1 or v2 community string, include the **security-name** statement at the **[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c)]** hierarchy level:

```
[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c)]
security-name security-name;
```

For SNMPv3, the **security-name** is the username configured at the **[edit snmp v3 usm local-engine user username]** hierarchy level. For SNMPv1 and SNMPv2c, the security name is the community string configured at the **[edit snmp v3 snmp-community community-index]** hierarchy level. For information about configuring usernames, see [“Creating SNMPv3 Users” on page 1800](#). For information about configuring a community string, see [“Configuring the SNMPv3 Community” on page 1828](#).

**NOTE:** The USM security name is separate from the SNMPv1 and SNMPv2c security name. If you support SNMPv1 and SNMPv2c in addition to SNMPv3, you must configure separate security names within the security-to-group configuration at the **[edit snmp v3 vacm access]** hierarchy level.

### Configuring the Group

After you have created SNMPv3 users, or v1 or v2 security names, you associate them with a group. A group is a set of security names belonging to a particular security model. A group defines the access rights for all users belonging to it. Access rights define what SNMP objects can be read, written to, or created. A group also defines what notifications a user is allowed to receive.

If you already have a group that is configured with all of the view and access permissions that you want to give a user, you can add the user to that group. If you want to give a user view and access permissions that no other groups have, or if you do not have any groups configured, create a group and add the user to it.

To configure the access privileges granted to a group, include the **group** statement at the **[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c) security-name security-name]** hierarchy level:

```
[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c) security-name
 security-name]
 group group-name;
```

**group-name** identifies a collection of SNMP security names that share the same access policy. For more information about groups, see “[Defining Access Privileges for an SNMP Group](#)” on page 1809.

### Example: Security Group Configuration

Assign security names to groups:

```
vacm {
  security-to-group {
    security-model usm {
      security-name user1 {
        group group1;
      }
      security-name user2 {
        group group2;
      }
      security-name user3 {
        group group3;
      }
    }
  }
}
```

#### Related Documentation

- [Assigning Security Model and Security Name to a Group on page 1814](#)
- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

### Example: Configuring the Tag List

In the following example, two tag entries (**router1** and **router2**) are defined at the **[edit snmp v3 notify notify-name]** hierarchy level. When an event triggers a notification, Junos OS sends a trap to all target addresses that have **router1** or **router2** configured in their target-address tag list. This results in the first two targets getting one trap each, and the third target getting two traps.

```
[edit snmp v3]
notify n1 {
  tag router1; # Identifies a set of target addresses
  type trap; # Defines the type of notification
}
notify n2 {
  tag router2;
  type trap;
}
target-address ta1 {
```

```

address 10.1.1.1;
address-mask 255.255.255.0;
port 162;
tag-list router1;
target-parameters tp1;
}
target-address ta2 {
address 10.1.1.2;
address-mask 255.255.255.0;
port 162;
tag-list router2;
target-parameters tp2;
}
target-address ta3 {
address 10.1.1.3;
address-mask 255.255.255.0;
port 162;
tag-list "router1 router2"; #Define multiple tags in the target address tag list
target-parameters tp3;
}

```

#### Related Documentation

- [Configuring SNMPv3 Traps on a Device Running Junos OS on page 1819](#)

## Configuring the Local Engine ID

By default, the local engine ID uses the default IP address of the router. The local engine ID is the administratively unique identifier for the SNMPv3 engine. This statement is optional. To configure the local engine ID, include the **engine-id** statement at the **[edit snmp]** hierarchy level:

```

[edit snmp]
engine-id {
(local engine-id-suffix | use-default-ip-address | use-mac-address);
}

```

- **local engine-id-suffix**—The engine ID suffix is explicitly configured.
- **use-default-ip-address**—The engine ID suffix is generated from the default IP address.
- **use-mac-address**—The SNMP engine identifier is generated from the Media Access Control (MAC) address of the management interface on the router.

The local engine ID is defined as the administratively unique identifier of an SNMPv3 engine, and is used for identification, not for addressing. There are two parts of an engine ID: prefix and suffix. The prefix is formatted according to the specifications defined in RFC 3411, *An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks*. You can configure the suffix here.

**NOTE:** SNMPv3 authentication and encryption keys are generated based on the associated passwords and the engine ID. If you configure or change the engine ID, you must commit the new engine ID before you configure SNMPv3 users. Otherwise the keys generated from the configured passwords are based on the previous engine ID. For the engine ID, we recommend using the master IP address of the device if the device has multiple routing engines and has the master IP address configured. Alternatively, you can use the MAC address of the management port if the device has only one Routing Engine.

#### Related Documentation

- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)
- [Example: SNMPv3 Configuration on page 1801](#)

## Configuring SNMP Informs

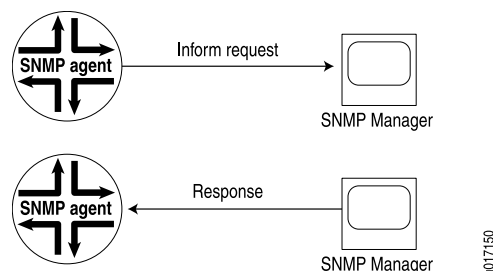

Junos OS supports two types of notifications: traps and informs. With traps, the receiver does not send any acknowledgment when it receives a trap. Therefore, the sender cannot determine if the trap was received. A trap may be lost because a problem occurred during transmission. To increase reliability, an inform is similar to a trap except that the inform is stored and retransmitted at regular intervals until one of these conditions occurs:

- The receiver (target) of the inform returns an acknowledgment to the SNMP agent.
- A specified number of unsuccessful retransmissions have been attempted and the agent discards the inform message.

If the sender never receives a response, the inform can be sent again. Thus, informs are more likely to reach their intended destination than traps are. Informs use the same communications channel as traps (same socket and port) but have different protocol data unit (PDU) types.

Informs are more reliable than traps, but they consume more network, router, and switch resources (see [Figure 31](#)). Unlike a trap, an inform is held in memory until a response is received or the timeout is reached. Also, traps are sent only once, whereas an inform may be retried several times. Use informs when it is important that the SNMP manager receive all notifications. However, if you are more concerned about network traffic, or router and switch memory, use traps.

**Figure 31: Inform Request and Response**

For information about configuring SNMP traps, see [“Configuring SNMPv3 Traps on a Device Running Junos OS” on page 1819](#).

**Related Documentation**

- [Configuring SNMPv3 Traps on a Device Running Junos OS on page 1819](#)

- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

## Configuring SNMPv3 Traps on a Device Running Junos OS

In SNMPv3, you create traps and informs by configuring the **notify**, **target-address**, and **target-parameters** parameters. Traps are unconfirmed notifications, whereas informs are confirmed notifications. This section describes how to configure SNMP traps. For information about configuring SNMP informs, see [“Configuring SNMP Informs” on page 1818](#).

The target address defines a management application's address and parameters to be used in sending notifications. Target parameters define the message processing and security parameters that are used in sending notifications to a particular management target. SNMPv3 also lets you define SNMPv1 and SNMPv2c traps.

**NOTE:** When you configure SNMP traps, make sure your configured access privileges allow the traps to be sent. Access privileges are configured at the `[edit snmp v3 vacm access]` and `[edit snmp v3 vacm security-to-group]` hierarchy levels.

To configure SNMP traps, include the following statements at the `[edit snmp v3]` hierarchy level:

```
[edit snmp v3]
  notify name {
    tag tag-name;
    type trap;
  }
  notify-filter name {
    oid object-identifier (include | exclude);
  }
  target-address target-address-name {
    address address;
    address-mask address-mask;
    logical-system logical-system;
    port port-number;
    routing-instance instance;
    tag-list tag-list;
    target-parameters target-parameters-name;
  }
  target-parameters target-parameters-name {
    notify-filter profile-name;
    parameters {
```

```

    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}

```

#### Related Documentation

## Configuring the SNMPv3 Trap Notification

The **notify** statement specifies the type of notification (trap) and contains a single tag. The tag defines a set of target addresses to receive a trap. The tag list contains one or more tags and is configured at the **[edit snmp v3 target-address target-address-name]** hierarchy level. If the tag list contains this tag, Junos OS sends a notification to all the target addresses associated with this tag.

To configure the trap notifications, include the **notify** statement at the **[edit snmp v3]** hierarchy level:

```

[edit snmp v3]
notify name {
  tag tag-name;
  type trap;
}

```

**name** is the name assigned to the notification.

**tag-name** defines the target addresses to which this notification is sent. This notification is sent to all the target-addresses that have this tag in their tag list. The **tag-name** is not included in the notification.

**trap** is the type of notification.

**NOTE:** Each notify entry name must be unique.

Junos OS supports two types of notification: **trap** and **inform**.

For information about how to configure the tag list, see [“Configuring the Trap Target Address” on page 1823](#).

**Related Documentation**

- [Configuring SNMPv3 Traps on a Device Running Junos OS on page 1819](#)
- [Configuring the Trap Notification Filter on page 1797](#)

- [Configuring SNMP Informs on page 1818](#)
- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

**Example: Configuring SNMPv3 Trap Notification**

Specify three sets of destinations to send traps:

```
[edit snmp v3]
notify n1 {
    tag router1;
    type trap;
}
notify n2 {
    tag router2;
    type trap;
}
notify n3 {
    tag router3;
    type trap;
}
```

**Related Documentation**

- [Complete SNMPv3 Configuration Statements on page 1897](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1805](#)

**Configuring the Trap Target Address**

The target address defines a management application's address and parameters that are used in sending notifications. It can also identify management stations that are allowed to use specific community strings. When you receive a packet with a recognized community string and a tag is associated with it, Junos OS looks up all the target addresses with this tag and verifies that the source address of this packet matches one of the configured target addresses.

**NOTE:** You must configure the address mask when you configure the SNMP community.

To specify where you want the traps to be sent and define what SNMPv1 and SNMPv2cc packets are allowed, include the **target-address** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
  target-address target-address-name;
```

**target-address-name** is the string that identifies the target address.

To configure the target address properties, include the following statements at the **[edit snmp v3 target-address target-address-name]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  address address;
  address-mask address-mask;
  logical-system logical-system;
  port port-number;
  routing-instance instance;
  tag-list tag-list;
  target-parameters target-parameters-name;
```

This section includes the following topics:

- [Configuring the Address on page 1822](#)
- [Configuring the Address Mask on page 1822](#)
- [Configuring the Port on page 1823](#)
- [Configuring the Routing Instance on page 1823](#)
- [Configuring the Trap Target Address on page 1823](#)
- [Applying Target Parameters on page 1824](#)

---

### Configuring the Address

To configure the address, include the **address** statement at the **[edit snmp v3 target-address target-address-name]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  address address;
```

**address** is the SNMP target address.

---

### Configuring the Address Mask

The address mask specifies a set of addresses that are allowed to use a community string and verifies the source addresses for a group of target addresses.

To configure the address mask, include the **address-mask** statement at the **[edit snmp v3 target-address target-address-name]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  address-mask address-mask;
```

**address-mask** combined with the address defines a range of addresses. For information about how to configure the community string, see [“Configuring the SNMPv3 Community” on page 1828](#).

### Configuring the Port

By default, the UDP port is set to 162. To configure a different port number, include the **port** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
port port-number;
```

*port-number* is the SNMP target port number.

### Configuring the Routing Instance

Traps are sent over the default routing instance. To configure the routing instance for sending traps, include the **routing-instance** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
routing-instance instance;
```

*instance* is the name of the routing instance. To configure a routing instance within a logical system, specify the logical system name followed by the routing instance name. Use a slash ( / ) to separate the two names (for example, **test-lr/test-ri**). To configure the default routing instance on a logical system, specify the logical system name followed by **default** (for example, **test-lr/default**).

### Configuring the Trap Target Address

Each **target-address** statement can have one or more tags configured in its tag list. Each tag can appear in more than one tag list. When a significant event occurs on the network device, the tag list identifies the targets to which a notification is sent.

To configure the tag list, include the **tag-list** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
tag-list "tag-list";
```

*tag-list* specifies one or more tags as a space-separated list enclosed within double quotes.

For an example of tag list configuration, see [“Example: Configuring the Tag List” on page 1816](#).

For information about how to specify a tag at the **[edit snmp v3 notify *notify-name*]** hierarchy level, see [“Configuring the SNMPv3 Trap Notification” on page 1820](#).

**NOTE:** When you configure SNMP traps, make sure your configured access privileges allow the traps to be sent. Configure access privileges at the **[edit snmp v3 vacm access]** hierarchy level.

## Applying Target Parameters

The **target-parameters** statement at the **[edit snmp v3]** hierarchy level applies the target parameters configured at the **[edit snmp v3 target-parameters *target-parameters-name*]** hierarchy level.

To reference configured target parameters, include the **target-parameters** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
  target-parameters target-parameters-name;
```

***target-parameters-name*** is the name associated with the message processing and security parameters that are used in sending notifications to a particular management target.

### Related Documentation

- [Configuring SNMPv3 Traps on a Device Running Junos OS on page 1819](#)
- [Configuring the SNMPv3 Trap Notification on page 1820](#)
- [Configuring the Trap Notification Filter on page 1797](#)
- [Defining and Configuring the Trap Target Parameters on page 1824](#)
- [Configuring SNMP Informs on page 1818](#)
- [Complete SNMPv3 Configuration Statements on page 1897](#)

## Defining and Configuring the Trap Target Parameters

Target parameters define the message processing and security parameters that are used in sending notifications to a particular management target.

To define a set of target parameters, include the **target-parameters** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]  
  target-parameters target-parameters-name;
```

***target-parameters-name*** is the name assigned to the target parameters.

To configure target parameter properties, include the following statements at the **[edit snmp v3 target-parameters *target-parameter-name*]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name]  
  notify-filter profile-name;  
  parameters {  
    message-processing-model (v1 | v2c | V3);  
    security-level (authentication | none | privacy);  
    security-model (usm | v1 | v2c);  
    security-name security-name;  
  }
```

This topic includes the following sections:

- [Applying the Trap Notification Filter on page 1825](#)
- [Configuring the Target Parameters on page 1825](#)

### Applying the Trap Notification Filter

To apply the trap notification filter, include the **notify-filter** statement at the **[edit snmp v3 target-parameters *target-parameter-name*]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name]  
  notify-filter profile-name;
```

***profile-name*** is the name of a configured notify filter. For information about configuring notify filters, see “Configuring the Trap Notification Filter” on page 1797.

### Configuring the Target Parameters

To configure target parameter properties, include the following statements at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]  
  message-processing-model (v1 | v2c | v3);  
  security-level (authentication | none | privacy);  
  security-model (usm | v1 | v2c);  
  security-name security-name;
```

This section includes the following topics:

- [Configuring the Message Processing Model on page 1825](#)
- [Configuring the Security Model on page 1825](#)
- [Configuring the Security Level on page 1826](#)
- [Configuring the Security Name on page 1826](#)

#### Configuring the Message Processing Model

The message processing model defines which version of SNMP to use when generating SNMP notifications. To configure the message processing model, include the **message-processing-model** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]  
  message-processing-model (v1 | v2c | v3);
```

- **v1**—SNMPv1 message processing model
- **v2c**—SNMPv2c message processing model
- **v3**—SNMPv3 message processing model

#### Configuring the Security Model

To define the security model to use when generating SNMP notifications, include the **security-model** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]  
  security-model (usm | v1 | v2c);
```

- **usm**—SNMPv3 security model
- **v1**—SNMPv1 security model

- **v2c**—SNMPv2c security model

### Configuring the Security Level

The **security-level** statement specifies whether the trap is authenticated and encrypted before it is sent.

To configure the security level to use when generating SNMP notifications, include the **security-level** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]
  security-level (authentication | none | privacy);
```

- **authentication**—Provides authentication but no encryption.
- **none**—No security. Provides no authentication and no encryption.
- **privacy**—Provides authentication and encryption.

**NOTE:** If you are configuring the SNMPv1 or SNMPv2c security model, use **none** as your security level. If you are configuring the SNMPv3 (USM) security model, use the **authentication** or **privacy** security level.

### Configuring the Security Name

To configure the security name to use when generating SNMP notifications, include the **security-name** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]
  security-name security-name;
```

If the USM security model is used, the **security-name** identifies the user that is used when the notification is generated. If the v1 or v2c security models are used, **security-name** identifies the SNMP community used when the notification is generated.

**NOTE:** The access privileges for the group associated with a security name must allow this notification to be sent.

If you are using the v1 or v2 security models, the security name at the **[edit snmp v3 vacm security-to-group]** hierarchy level must match the security name at the **[edit snmp v3 snmp-community *community-index*]** hierarchy level.

## Adding a Group of Clients to an SNMP Community

Junos OS enables you to add one or more groups of clients to an SNMP community. You can include the **client-list-name** *name* statement at the **[edit snmp community community-name]** hierarchy level to add all the members of the client list or prefix list to an SNMP community.

To define a list of clients, include the **client-list** statement followed by the IP addresses of the clients at the **[edit snmp]** hierarchy level:

```
[edit snmp]
  client-list client-list-name {
    ip-addresses;
  }
```

You can configure a prefix list at the **[edit policy options]** hierarchy level. Support for prefix lists in the SNMP community configuration enables you to use a single list to configure the SNMP and routing policies. For more information about the **prefix-list** statement, see the [Junos OS Routing Protocols Library for Security Devices](#).

To add a client list or prefix list to an SNMP community, include the **client-list-name** statement at the **[edit snmp community community-name]** hierarchy level:

```
[edit snmp community community-name]
  client-list-name client-list-name;
```

**NOTE:** The client list and prefix list must not have the same name.

The following example shows how to define a client list:

```
[edit]
snmp {
  client-list clentlist1 {
    10.1.1.1/32;
    10.2.2.2/32;
  }
}
```

The following example shows how to add a client list to an SNMP community:

```
[edit]
snmp {
  community community1 {
    authorization read-only;
    client-list-name clientlist1;
  }
}
```

The following example shows how to add a prefix list to an SNMP community:

```
[edit]
```

```
policy-options {  
  prefix-list prefixlist {  
    10.3.3.3/32;  
    10.5.5.5/32;  
  }  
}  
snmp {  
  community community2 {  
    client-list-name prefixlist;  
  }  
}
```

**Related Documentation**

- *client-list-name*

## Configuring the SNMPv3 Community

The SNMP community defines the relationship between an SNMP server system and the client systems. This statement is optional.

To configure the SNMP community, include the **snmp-community** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]  
snmp-community community-index;
```

*community-index* is the index for the SNMP community.

To configure the SNMP community properties, include the following statements at the **[edit snmp v3 snmp-community *community-index*]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]  
community-name community-name;  
context context-name;  
security-name security-name;  
tag tag-name;
```

This section includes the following topics:

- [Configuring the Community Name on page 1828](#)
- [Configuring the Context on page 1829](#)
- [Configuring the Security Names on page 1829](#)
- [Configuring the Tag on page 1830](#)

---

### Configuring the Community Name

The community name defines the SNMP community. The SNMP community authorizes SNMPv1 or SNMPv2c clients. The access privileges associated with the configured security name define which MIB objects are available and the operations (read, write, or notify) allowed on those objects.

To configure the SNMP community name, include the **community-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
community-name community-name;
```

**community-name** is the community string for an SNMPv1 or SNMPv2c community.

If unconfigured, it is the same as the community index.

If the community name contains spaces, enclose it in quotation marks (" ").

**NOTE:** Community names must be unique. You cannot configure the same community name at the **[edit snmp community]** and **[edit snmp v3 snmp-community community-index]** hierarchy levels. The configured community name at the **[edit snmp v3 snmp-community community-index]** hierarchy level is encrypted. You cannot view the community name after you have configured it and committed your changes. In the command-line interface (CLI), the community name is concealed.

### Configuring the Context

An SNMP context defines a collection of management information that is accessible to an SNMP entity. Typically, an SNMP entity has access to multiple contexts. A context can be a physical or logical system, a collection of multiple systems, or even a subset of a system. Each context in a management domain has a unique identifier.

To configure an SNMP context, include the **context context-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
context context-name;
```

**NOTE:** To query a routing instance or a logical system,

### Configuring the Security Names

To assign a community string to a security name, include the **security-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
security-name security-name;
```

**security-name** is used when access control is set up. The **security-to-group** configuration at the **[edit snmp v3 vacm]** hierarchy level identifies the group.

**NOTE:** This security name must match the security name configured at the **[edit snmp v3 target-parameters target-parameters-name parameters]** hierarchy level when you configure traps.

## Configuring the Tag

To configure the tag, include the **tag** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
tag tag-name;
```

**tag-name** identifies the address of managers that are allowed to use a community string.

### Related Documentation

## Example: SNMPv3 Community Configuration

Define an SNMP community:

```
[edit snmp v3]
snmp-community index1 {
  community-name "$ABC123"; # SECRET-DATA
  security-name john;
  tag router1; # Identifies managers that are allowed to use
  # a community string
  target-address ta1 {
    address 10.1.1.1;
    address-mask 255.255.255.0; # Defines the range of addresses
    port 162;
    tag-list router1;
    target-parameters tp1; # Applies configured target parameters
  }
}
```

## Configuring the Inform Notification Type and Target Address

To configure the inform notification type and target information, include the following statements at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
notify name {
  tag tag-name;
  type (trap | inform);
}
target-address target-address-name {
  address address;
  address-mask address-mask;
```

```

logical-system logical-system;
port port-number;
retry-count number;
routing-instance instance;
tag-list tag-list;
target-parameters target-parameters-name;
timeout seconds;
}
target-parameters target-parameters-name {
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}

```

**notify *name*** is the name assigned to the notification. Each notify entry name must be unique.

**tag *tag-name*** defines the target addresses that are sent this notification. The notification is sent to all target addresses that have this tag in their tag list. The **tag-name** is not included in the notification. For information about how to configure the tag list, see [“Configuring the Trap Target Address” on page 1823](#).

**type *inform*** is the type of notification.

**target-address *target-address-name*** identifies the target address. The target address defines a management application's address and parameters that are used to respond to informs.

**timeout *seconds*** is the number of seconds to wait for an acknowledgment. If no acknowledgment is received within the timeout period, the inform is retransmitted. The default timeout is 15 seconds.

**retry-count *number*** is the maximum number of times an inform is transmitted if no acknowledgment is received. The default is 3. If no acknowledgment is received after the inform is transmitted the maximum number of times, the inform message is discarded.

**message-processing-model** defines which version of SNMP to use when SNMP notifications are generated. Informs require a **v3** message processing model.

**security-model** defines the security model to use when SNMP notifications are generated. Informs require a **usm** security model.

**security-model** defines the security model to use when SNMP notifications are generated. Informs require a **usm** security model.

**security-level** specifies whether the inform is authenticated and encrypted before it is sent. For the **usm** security model, the security level must be one of the following:

- **authentication**—Provides authentication but no encryption.
- **privacy**—Provides authentication and encryption.

**security-name** identifies the username that is used when generating the inform.

### Example: Configuring the Inform Notification Type and Target Address

In the following example, target **172.17.20.184** is configured to respond to informs. The inform timeout is **30** seconds and the maximum retransmit count is **3**. The inform is sent to all targets in the **tl1** list. The security model for the remote user is **usm** and the remote engine username is **u10**.

```
[edit snmp v3]
  notify n1 {
    type inform;
    tag tl1;
  }
  notify-filter nf1 {
    oid .1.3 include;
  }
  target-address ta1 {
    address 172.17.20.184;
    retry-count 3;
    tag-list tl1;
    address-mask 255.255.255.0;
    target-parameters tp1;
    timeout 30;
  }
  target-parameters tp1 {
    parameters {
      message-processing-model v3;
      security-model usm;
      security-level privacy;
      security-name u10;
    }
    notify-filter nf1;
  }
```

**Related  
Documentation**

## Configuring the Remote Engine and Remote User

To send inform messages to an SNMPv3 user on a remote device, you must first specify the engine identifier for the SNMP agent on the remote device where the user resides. The remote engine ID is used to compute the security digest for authenticating and encrypting packets sent to a user on the remote host. When sending an inform message, the agent uses the credentials of the user configured on the remote engine (inform target).

To configure a remote engine and remote user to receive and respond to SNMP informs, include the following statements at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
usm {
  remote-engine engine-id {
    user username {
      authentication-md5 {
        authentication-key key;
      }
      authentication-none;
      authentication-sha {
        authentication-key key;
      }
      privacy-3des {
        privacy-key key;
      }
      privacy-aes128 {
        privacy-key key;
      }
      privacy-des {
        privacy-key key;
      }
      privacy-none;
    }
  }
}
```

For informs, **remote-engine engine-id** is the identifier for the SNMP agent on the remote device where the user resides.

For informs, **user username** is the user on a remote SNMP engine who receives the informs.

Informs generated can be **unauthenticated**, **authenticated**, or **authenticated\_and\_encrypted**, depending on the security level of the SNMPv3 user configured on the remote engine (the inform receiver). The authentication key is used for generating message authentication code (MAC). The privacy key is used to encrypt the inform PDU part of the message.

- [Example: Configuring the Remote Engine ID and Remote Users on page 1834](#)

## Example: Configuring the Remote Engine ID and Remote Users

This example shows how to configure a remote engine and remote user so you can receive and respond to SNMP inform notifications. Inform notifications can be authenticated and encrypted. They are also more reliable than traps, another type of notification that Junos OS supports. Unlike traps, inform notifications are stored and retransmitted at regular intervals until one of these conditions occurs:

- The target of the inform notification returns an acknowledgment to the SNMP agent.
  - A specified number of unsuccessful retransmissions have been attempted.
- [Requirements on page 1834](#)
  - [Overview on page 1834](#)
  - [Configuration on page 1835](#)
  - [Verification on page 1836](#)

### Requirements

---

No special configuration beyond device initialization is required before configuring this example.

This feature requires the use of plain-text passwords valid for SNMPv3. SNMPv3 has the following special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Although quotation marks are not always required to enclose passwords, it is best to use them. You need quotation marks if the password contains any spaces or possibly in the case of certain special characters or punctuation.

### Overview

---

Inform notifications are supported in SNMPv3 to increase reliability. For example, an SNMP agent receiving an inform notification acknowledges the receipt.

For inform notifications, the remote engine ID identifies the SNMP agent on the remote device where the user resides, and the username identifies the user on a remote SNMP engine who receives the inform notifications.

Consider a scenario in which you have the values in [Table 219](#) to use in configuring the remote engine ID and remote user in this example.

Table 219: Values to Use in Example

| Name of Variable        | Value                      |
|-------------------------|----------------------------|
| username                | u10                        |
| remote engine ID        | 800007E5804089071BC6D10A41 |
| authentication type     | authentication-md5         |
| authentication password | qol67R%?                   |
| encryption type         | privacy-des                |
| privacy password        | m*72Jl9v                   |

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands and paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste these commands into the CLI at the **[edit snmp v3]** hierarchy level, and then enter **commit** from configuration mode.

The following example configures user **u10** located on remote engine **0x800007E5804089071BC6D10A41** and the user's authentication and privacy keys. The keys are autogenerated from the passwords entered by the command-line interface (CLI) user.

1. Configure the remote engine ID, username, and authentication type and password.

```
[edit snmp v3]
user@host# set usm remote-engine 800007E5804089071BC6D10A41 user u10
authentication-md5 authentication-key "qol67R%?"
```

2. Configure the encryption type and privacy password.

You can configure only one encryption type per SNMPv3 user.

```
[edit snmp v3]
user@host# set usm remote-engine 800007E5804089071BC6D10A41 user u10
privacy-des privacy-key "m*72Jl9v"
```

**Results** In configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit snmp v3]
user@ host# show
usm {
  remote-engine 800007E5804089071BC6D10A41 {
    user u10 {
      authentication-md5 {
        authentication-key "$ABC123"
      }
    }
  }
}
```

```

    privacy-des {
      privacy-key "$ABC123"; ## SECRET-DATA
    }
    privacy-des {
      privacy-key "$ABC123"
    }
  }
}

```

After you have confirmed that the configuration is correct, enter **commit** from configuration mode.

### Verification

#### *Verifying the Configuration of the Remote Engine ID and Username*

**Purpose** Verify the status of the engine ID and user information.

**Action** Display information about the SNMPv3 engine ID and user.

```

user@host> show snmp v3
Local engine ID: 80 00 0a 4c 01 0a ff 03 e3
Engine boots:      3
Engine time:       769187 seconds
Max msg size:      65507 bytes

Engine ID: 80 00 07 e5 80 40 89 07 1b c6 d1 0a 41
  User                               Auth/Priv  Storage  Status
  u10                                md5/des   nonvolatile active

```

**Meaning** The output displays the following information:

- Local engine ID and detail about the engine
- Remote engine ID (labeled **Engine ID**)
- Username
- Authentication type and encryption (privacy) type that is configured for the user
- Type of storage for the username, either nonvolatile (configuration saved) or volatile (not saved)
- Status of the new user; only users with an active status can use SNMPv3

- Related Documentation**

## Using the Enterprise-Specific Utility MIB to Enhance SNMP Coverage

Even though Junos OS includes built-in performance metrics and monitoring options, you might need to have customized performance metrics. To make it easier for you to monitor such customized data through a standard monitoring system, Junos OS provides you with an enterprise-specific Utility MIB that can store such data and thus extend SNMP support for managing and monitoring the data of your choice.

The enterprise-specific Utility MIB provides you with container objects of the following types: **32-bit counters**, **64-bit counters**, **signed integers**, **unsigned integers**, and **octet strings**. You can use these container MIB objects to store the data that are otherwise not supported for SNMP operations. You can populate data for these objects either by using CLI commands or with the help of Op scripts and an RPC API that can invoke the CLI commands.

The following CLI commands enable you to set and clear Utility MIB object values:

- `request snmp utility-mib set instance name object-type <counter | counter 64 | integer | string | unsigned integer> object-value value`
- `request snmp utility-mib clear instance name object-type <counter | counter 64 | integer | string | unsigned integer>`

The *instance name* option of the `request snmp utility-mib <set | clear>` command specifies the name of the data instance and is the main identifier of the data. The **object-type** `<counter | counter 64 | integer | string | unsigned integer>` option enables you specify the object type, and the **object-value** *value* option enables you to set the value of the object.

To automate the process of populating Utility MIB data, you can use a combination of an event policy and event script. The following examples show the configuration for an event policy to run `show system buffers` every hour and to store the `show system buffers` data in Utility MIB objects by running an event script (`check-mbufs.slax`).

### Event Policy Configuration

To configure an event policy that runs the `show system buffers` command every hour and invokes `check-mbufs.slax` to store the `show system buffers` data into Utility MIB objects, include the following statements at the `[edit]` hierarchy level:

```
event-options {
  generate-event {
    1-HOUR time-interval 3600;
  }
  policy Mbufs {
    events 1-HOUR;
    then {
      event-script check-mbufs.slax; # script stored at /var/db/scripts/event/
    }
  }
  event-script {
    file check-mbufs.slax;
  }
}
```

**check-mbufs.slax Script** The following example shows the **check-mbufs.slax** script that is stored under **/var/db/scripts/event/**:

```
----- script START -----
version 1.0;

ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";
ns ext = "http://xmlsoft.org/XSLT/namespace";

match / {
  <op-script-results>{
    var $cmd = <command> "show system buffers";
    var $out = jcs:invoke($cmd);

    var $lines = jcs:break_lines($out);
    for-each ($lines) {
      if (contains(., "current/peak/max")) {
        var $pattern = "([0-9]+)/([0-9]+)/([0-9]+) mbufs";
        var $split = jcs:regex($pattern, .);
        var $result = $split[2];

        var $rpc = <request-snmp-utility-mib-set> {
          <object-type> "integer";
          <instance> "current-mbufs";
          <object-value> $result;
        }
        var $res = jcs:invoke($rpc);
      }
    }
  }
}
----- script END -----
```

You can run the following command to check the data stored in the Utility MIB as a result of the event policy and script shown in the preceding examples:

```
user@host> show snmp mib walk jnxUtilData ascii jnxUtilIntegerValue."current-mbufs"
= 0 jnxUtilIntegerTime."current-mbufs" = 07 da 05 0c 03 14 2c 00 2d 07 00
user@host>
```

- [Example: Configuring Interface Settings for a Routing Instance on page 1842](#)
- [Configuring Access Lists for SNMP Access over Routing Instances on page 1844](#)

Understanding SNMP Support for Routing Instances

Junos OS enables SNMP managers for all routing instances to request and manage SNMP data related to the corresponding routing instances and logical system networks.

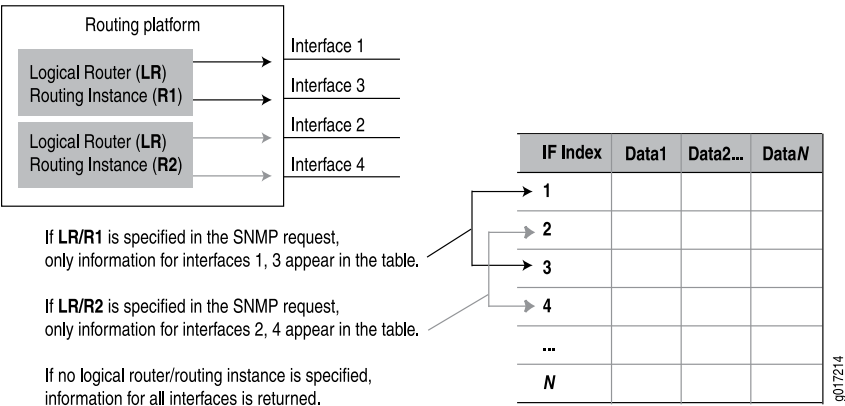

In Junos OS:

- Clients from routing instances other than the default can access MIB objects and perform SNMP operations only on the logical system networks to which they belong.
- Clients from the default routing instance can access information related to all routing instances and logical system networks.

Before Junos OS Release 8.4, only the SNMP manager in the default routing instance (**inet.0**) had access to the MIB objects

With the increase in virtual private network (VPN) service offerings, this feature is useful particularly for service providers who need to obtain SNMP data for specific routing instances (see [Figure 32](#)). Service providers can use this information for their own management needs or export the data for use by their customers.

Figure 32: SNMP Data for Routing Instances

If no routing instance is specified in the request, the SNMP agent operates as before:

- For nonrouting table objects, all instances are exposed.
- For routing table objects, only those associated with the default routing instance are exposed.

**NOTE:** The actual protocol data units (PDUs) are still exchanged over the default (**inet.0**) routing instance, but the data contents returned are dictated by the routing instance specified in the request PDUs.

- Related Documentation

  - [Identifying a Routing Instance on page 1840](#)

- [Enabling SNMP Access over Routing Instances on page 1841](#)
- [Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community on page 1841](#)
- [Configuring Access Lists for SNMP Access over Routing Instances on page 1844](#)

## Trap Support for Routing Instances

You can restrict the trap receivers from receiving traps that are not related to the logical system networks to which they belong. To do this, include the **logical-system-trap-filter** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
logical-system-trap-filter;
```

If the **logical-system-trap-filter** statement is not included in the SNMP configuration, all traps are forwarded to the configured routing instance destinations. However, even when this statement is configured, the trap receiver associated with the default routing instance will receive all SNMP traps.

When configured under the trap-group object, all v1 and v2c traps that apply to routing instances (or interfaces belonging to a routing instance) have the routing instance name encoded in the community string. The encoding is identical to that used in request PDUs.

For traps configured under the v3 framework, the routing instance name is carried in the context field when the v3 message processing model has been configured. For other message processing models (v1 or v2c), the routing instance name is not carried in the trap message header (and not encoded in the community string).

### Related Documentation

- [Understanding SNMP Support for Routing Instances on page 1839](#)
- [MIB Support Details on page 1731](#)

## Identifying a Routing Instance

With this feature, routing instances are identified by either the context field in v3 requests or encoded in the community string in v1 or v2c requests.

When encoded in a community string, the routing instance name appears first and is separated from the actual community string by the @ character.

To avoid conflicts with valid community strings that contain the @ character, the community is parsed only if typical community string processing fails. For example, if a routing instance named **RI** is configured, an SNMP request with **RI@public** is processed within the context of the **RI** routing instance. Access control (views, source address restrictions, access privileges, and so on) is applied according to the actual community string (the set of data after the @ character—in this case **public**). However, if the community string **RI@public** is configured, the protocol data unit (PDU) is processed according to that community and the embedded routing instance name is ignored.

Logical systems perform a subset of the actions of a physical router and have their own unique routing tables, interfaces, policies, and routing instances. When a routing instance is defined within a logical system, the logical system name must be encoded along with

the routing instance using a slash ( / ) to separate the two. For example, if the routing instance **RI** is configured within the logical system **LS**, that routing instance must be encoded within a community string as **LS/RI@public**. When a routing instance is configured outside a logical system (within the default logical system), no logical system name (or / character) is needed.

Also, when a logical system is created, a default routing instance (named **default**) is always created within the logical system. This name should be used when querying data for that routing instance (for example, **LS/default@public**). For v3 requests, the name *logical system/routing instance* should be identified directly in the context field.

**NOTE:** To identify a virtual LAN (VLAN) spanning-tree instance (VSTP on MX Series 3D Universal Edge Routers), specify the routing instance name followed by a double colon (::) and the VLAN ID. For example, to identify VSTP instance for VLAN 10 in the global default routing instance, include **default::10@public** in the context (SNMPv3) or community (SNMPv1 or v2) string.

#### Related Documentation

- [Understanding SNMP Support for Routing Instances on page 1839](#)
- [Enabling SNMP Access over Routing Instances on page 1841](#)
- [Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community on page 1841](#)

## Enabling SNMP Access over Routing Instances

To enable SNMP managers in routing instances other than the default routing instance to access SNMP information, include the **routing-instance-access** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
routing-instance-access;
```

If this statement is not included in the SNMP configuration, SNMP managers from routing instances other than the default routing instance cannot access SNMP information.

#### Related Documentation

## Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community

You can specify the routing instance along with the client information when you add a client to an SNMP community. To specify the routing instance to which a client belongs, include the **routing-instance** statement followed by the routing instance name and client information in the SNMP configuration.

The following example shows the configuration statement to add routing instance **test-ri** to SNMP community **community1**.

**NOTE:** Routing instances specified at the `[edit snmp community community-name]` hierarchy level are added to the default logical system in the community.

```
[edit snmp]
community community1 {
  clients {
    10.209.152.33/32;
  }
  routing-instance test-ri {
    clients {
      10.19.19.1/32;
    }
  }
}
```

If the routing instance is defined within a logical system, include the **routing-instance** statement at the `[edit snmp community community-name logical-system logical-system-name]` hierarchy level, as in the following example:

```
[edit snmp]
community community1 {
  clients {
    10.209.152.33/32;
  }
  logical-system test-LS {
    routing-instance test-ri {
      clients {
        10.19.19.1/32;
      }
    }
  }
}
```

#### Related Documentation

- [Configuring Access Lists for SNMP Access over Routing Instances on page 1844](#)
- [Example: Configuring Interface Settings for a Routing Instance on page 1842](#)

### Example: Configuring Interface Settings for a Routing Instance

This example shows an **802.3ad ae0** interface configuration allocated to a routing instance named **INFrtid**:

```
[edit chassis]
aggregated-devices {
```

```

    ethernet {
        device-count 5;
    }
}
[edit interfaces ae0]
vlan-tagging;
aggregated-ether-options {
    minimum-links 2;
    link-speed 100m;
}
unit 0 {
    vlan-id 100;
    family inet {
        address 10.1.0.1/24;
    }
}
[edit interfaces fe-1/1/0]
fastether-options {
    802.3ad ae0;
}
[edit interfaces fe-1/1/1]
fastether-options {
    802.3ad ae0;
}
[edit routing-instances]
INFrtd {
    instance-type virtual-router;
    interface fe-1/1/0.0;
    interface fe-1/1/1.0;
    interface fe-1/1/5.0;
    interface ae0.0;
    protocols {
        ospf {
            area 0.0.0.0 {
                interface all;
            }
        }
    }
}
}

```

The following **snmpwalk** command shows how to retrieve SNMP-related information from **router1** and the 802.3ae bundle interface belonging to routing instance **INFrtd** with the SNMP community **public**:

```

router# snmpwalk -Os router1 INFrtd@public dot3adAggTable
dot3adAggMACAddress.59 = 0:90:69:92:93:f0
dot3adAggMACAddress.65 = 0:90:69:92:93:f0
dot3adAggActorSystemPriority.59 = 0
dot3adAggActorSystemPriority.65 = 0
dot3adAggActorSystemID.59 = 0:0:0:0:0:0
dot3adAggActorSystemID.65 = 0:0:0:0:0:0
dot3adAggAggregateOrIndividual.59 = true(1)
dot3adAggAggregateOrIndividual.65 = true(1)
dot3adAggActorAdminKey.59 = 0
dot3adAggActorAdminKey.65 = 0
dot3adAggActorOperKey.59 = 0

```

```
dot3adAggActorOperKey.65 = 0
dot3adAggPartnerSystemID.59 = 0:0:0:0:0:0
dot3adAggPartnerSystemID.65 = 0:0:0:0:0:0
dot3adAggPartnerSystemPriority.59 = 0
dot3adAggPartnerSystemPriority.65 = 0
dot3adAggPartnerOperKey.59 = 0
dot3adAggPartnerOperKey.65 = 0
dot3adAggCollectorMaxDelay.59 = 0
dot3adAggCollectorMaxDelay.65 = 0
```

## Configuring Access Lists for SNMP Access over Routing Instances

You can create and maintain access lists to manage access to SNMP information. Access list configuration enables you to allow or deny SNMP access to clients of a specific routing instance.

The following example shows how to create an access list:

```
[edit snmp]
routing-instance-access {
  access-list {
    ri1 restrict;
    ls1/default;
    ls1/ri2;
    ls1*;
  }
}
```

The configuration given in the example:

- Restricts clients in **ri1** from accessing SNMP information.
- Allows clients in **ls1/default**, **ls1/ri2**, and all other routing instances with names starting with **ls1** to access SNMP information.

You can use the wildcard character (\*) to represent a string in the routing instance name.

**NOTE:** You cannot restrict the SNMP manager of the default routing instance from accessing SNMP information.

## Configuring Remote Operations

---

- [SNMP Remote Operations Overview on page 1845](#)
- [Using the Ping MIB for Remote Monitoring Devices Running Junos OS on page 1848](#)
- [Starting a Ping Test on page 1848](#)
- [Monitoring a Running Ping Test on page 1849](#)
- [Gathering Ping Test Results on page 1852](#)
- [Stopping a Ping Test on page 1854](#)
- [Interpreting Ping Variables on page 1854](#)
- [Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS on page 1854](#)

### SNMP Remote Operations Overview

A SNMP remote operation is any process on the router that can be controlled remotely using SNMP. Junos OS currently provides support for two SNMP remote operations: the Ping MIB and Traceroute MIB, defined in RFC 2925. Using these MIBs, an SNMP client in the network management system (NMS) can:

- Start a series of operations on a router
- Receive notification when the operations are complete
- Gather the results of each operation

Junos OS also provides extended functionality to these MIBs in the Juniper Networks enterprise-specific extensions **jnxPingMIB** and **jnxTraceRouteMIB**. For more information about **jnxPingMIB** and **jnxTraceRouteMIB**, see *PING MIB* and *Traceroute MIB*.

This topic covers the following sections:

- [SNMP Remote Operation Requirements on page 1845](#)
- [Setting SNMP Views on page 1845](#)
- [Setting Trap Notification for Remote Operations on page 1846](#)
- [Using Variable-Length String Indexes on page 1847](#)
- [Enabling Logging on page 1847](#)

#### SNMP Remote Operation Requirements

---

To use SNMP remote operations, you should be experienced with SNMP conventions. You must also configure Junos OS to allow the use of the remote operation MIBs.

#### Setting SNMP Views

---

All remote operation MIBs supported by Junos OS require that the SNMP clients have read-write privileges. The default SNMP configuration of Junos OS does not provide clients with a community string with such privileges.

To set read-write privileges for an SNMP community string, include the following statements at the **[edit snmp]** hierarchy level:

```
[edit snmp]
community community-name {
  authorization authorization;
  view view-name;
}
view view-name {
  oid object-identifier (include | exclude);
}
```

#### **Example: Setting SNMP Views**

To create a community named **remote-community** that grants SNMP clients read-write access to the Ping MIB, **jnxPing** MIB, Traceroute MIB, and **jnxTraceRoute** MIB, include the following statements at the **[edit snmp]** hierarchy level:

```
snmp {
  view remote-view {
    oid 1.3.6.1.2.1.80 include; # pingMIB
    oid 1.3.6.1.4.1.2636.3.7 include; # jnxPingMIB
    oid 1.3.6.1.2.1.81 include; # traceRouteMIB
    oid 1.3.6.1.4.1.2636.3.8 include; # jnxTraceRouteMIB
  }
  community remote-community {
    view remote-view;
    authorization read-write;
  }
}
```

For more information about the **community** statement, see [“Configuring the SNMP Community String” on page 1784](#) and [community](#).

For more information about the **view** statement, see [“Configuring MIB Views” on page 1789](#), [view \(Associating a MIB View with a Community\)](#), and [view \(Configuring a MIB View\)](#).

---

### **Setting Trap Notification for Remote Operations**

In addition to configuring the remote operations MIB for trap notification, you must also configure Junos OS. You must specify a target host for remote operations traps.

To configure trap notification for SNMP remote operations, include the **categories** and **targets** statements at the **[edit snmp trap-group group-name]** hierarchy level:

```
[edit snmp trap-group group-name]
categories {
  category;
}
targets {
  address;
}
}
```

**Example: Setting Trap Notification for Remote Operations**

Specify 172.17.12.213 as a target host for all remote operation traps:

```
snmp {
  trap-group remote-traps {
    categories remote-operations;
    targets {
      172.17.12.213;
    }
  }
}
```

For more information about trap groups, see [“Configuring SNMP Trap Groups” on page 1795](#).

**Using Variable-Length String Indexes**

All tabular objects in the remote operations MIBs supported by Junos OS are indexed by two variables of type **SnmpAdminString**. For more information about **SnmpAdminString**, see RFC 2571.

Junos OS does not handle **SnmpAdminString** any differently from the octet string variable type. However, the indexes are defined as variable length. When a variable length string is used as an index, the length of the string must be included as part of the object identifier (OID).

**Example: Set Variable-Length String Indexes**

To reference the **pingCtlTargetAddress** variable of a row in **pingCtlTable** where **pingCtlOwnerIndex** is **bob** and **pingCtlTestName** is **test**, use the following object identifier (OID):

```
pingMIB.pingObjects.pingCtlTable.pingCtlEntry.pingCtlTargetAddress."bob"."test"
1.3.6.1.2.1.80.1.2.1.4.3.98.111.98.4.116.101.115.116
```

For more information about the definition of the Ping MIB, see RFC 2925.

**Enabling Logging**

The SNMP error code returned in response to SNMP requests can only provide a generic description of the problem. The error descriptions logged by the remote operations process can often provide more detailed information about the problem and help you to solve the problem faster. This logging is not enabled by default. To enable logging, include the **flag general** statement at the **[edit snmp traceoptions]** hierarchy level:

```
[edit]
snmp {
  traceoptions {
    flag general;
  }
}
```

For more information about traceoptions, see [“Tracing SNMP Activity on a Device Running Junos OS” on page 1855](#).

If the remote operations process receives an SNMP request that it cannot accommodate, the error is logged in the `/var/log/rmopd` file. To monitor this log file, issue the **monitor start rmopd** command in operational mode of the command-line interface (CLI).

- [Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS on page 1854](#)

## Using the Ping MIB for Remote Monitoring Devices Running Junos OS

A ping test is used to determine whether packets sent from the local host reach the designated host and are returned. If the designated host can be reached, the ping test provides the approximate round-trip time for the packets. Ping test results are stored in **pingResultsTable** and **pingProbeHistoryTable**.

RFC 2925 is the authoritative description of the Ping MIB in detail and provides the ASN.1 MIB definition of the Ping MIB.

**Related Documentation**

- [SNMP Remote Operations Overview on page 1845](#)
- [Starting a Ping Test on page 1848](#)
- [Monitoring a Running Ping Test on page 1849](#)
- [Gathering Ping Test Results on page 1852](#)
- [Stopping a Ping Test on page 1854](#)
- [Interpreting Ping Variables on page 1854](#)

## Starting a Ping Test

Before you start a ping test, configure a Ping MIB view. This allows SNMP **Set** requests on **pingMIB**. To start a ping test, create a row in **pingCtlTable** and set **pingCtlAdminStatus** to **enabled**. The minimum information that must be specified before setting **pingCtlAdminStatus** to **enabled** is:

- **pingCtlOwnerIndexSnmpAdminString**
- **pingCtlTestNameSnmpAdminString**
- **pingCtlTargetAddressInetAddress**
- **pingCtlTargetAddressTypeInetAddressType**
- **pingCtlRowStatusRowStatus**

For all other values, defaults are chosen unless otherwise specified. **pingCtlOwnerIndex** and **pingCtlTestName** are used as the index, so their values are specified as part of the object identifier (OID). To create a row, set **pingCtlRowStatus** to **createAndWait** or **createAndGo** on a row that does not already exist. A value of **active** for **pingCtlRowStatus** indicates that all necessary information has been supplied and the test can begin; **pingCtlAdminStatus** can be set to **enabled**. An SNMP **Set** request that sets **pingCtlRowStatus** to **active** will fail if the necessary information in the row is not specified

or is inconsistent. For information about how to configure a view, see [“Setting SNMP Views” on page 1845](#).

There are two ways to start a ping test:

- [Using Multiple Set Protocol Data Units \(PDUs\) on page 1849](#)
- [Using a Single Set PDU on page 1849](#)

---

### Using Multiple Set Protocol Data Units (PDUs)

You can use multiple **Set** request PDUs (multiple PDUs, with one or more varbinds each) and set the following variables in this order to start the test:

- **pingCtlRowStatus** to **createAndWait**
- All appropriate test variables
- **pingCtlRowStatus** to **active**

Junos OS now verifies that all necessary information to run a test has been specified.

- **pingCtlAdminStatus** to **enabled**

---

### Using a Single Set PDU

You can use a single **Set** request PDU (one PDU, with multiple varbinds) to set the following variables to start the test:

- **pingCtlRowStatus** to **createAndGo**
- All appropriate test variables
- **pingCtlAdminStatus** to **enabled**

## Monitoring a Running Ping Test

When **pingCtlAdminStatus** is successfully set to **enabled**, the following is done before the acknowledgment of the SNMP **Set** request is sent back to the client:

- **pingResultsEntry** is created if it does not already exist.
- **pingResultsOperStatus** transitions to **enabled**.

For more information, see the following sections:

- [pingResultsTable on page 1849](#)
- [pingProbeHistoryTable on page 1851](#)
- [Generating Traps on page 1852](#)

---

### pingResultsTable

While the test is running, **pingResultsEntry** keeps track of the status of the test. The value of **pingResultsOperStatus** is **enabled** while the test is running and **disabled** when it has stopped.

The value of **pingCtlAdminStatus** remains **enabled** until you set it to **disabled**. Thus, to get the status of the test, you must examine **pingResultsOperStatus**.

The **pingCtlFrequency** variable can be used to schedule many tests for one **pingCtlEntry**. After a test ends normally (you did not stop the test) and the **pingCtlFrequency** number of seconds has elapsed, the test is started again just as if you had set **pingCtlAdminStatus** to **enabled**. If you intervene at any time between repeated tests (you set **pingCtlAdminStatus** to **disabled** or **pingCtlRowStatus** to **notInService**), the repeat feature is disabled until another test is started and ends normally. A value of 0 for **pingCtlFrequency** indicates this repeat feature is not active.

**pingResultsIpTgtAddr** and **pingResultsIpTgtAddrType** are set to the value of the resolved destination address when the value of **pingCtlTargetAddressType** is **dns**. When a test starts successfully and **pingResultsOperStatus** transitions to **enabled**:

- **pingResultsIpTgtAddr** is set to null-string.
- **pingResultsIpTgtAddrType** is set to **unknown**.

**pingResultsIpTgtAddr** and **pingResultsIpTgtAddrType** are not set until **pingCtlTargetAddress** can be resolved to a numeric address. To retrieve these values, poll **pingResultsIpTgtAddrType** for any value other than **unknown** after successfully setting **pingCtlAdminStatus** to **enabled**.

At the start of a test, **pingResultsSentProbes** is initialized to 1 and the first probe is sent. **pingResultsSentProbes** increases by 1 each time a probe is sent.

As the test runs, every **pingCtlTimeOut** seconds, the following occur:

- **pingProbeHistoryStatus** for the corresponding **pingProbeHistoryEntry** in **pingProbeHistoryTable** is set to **requestTimedOut**.
- A **pingProbeFailed** trap is generated, if necessary.
- An attempt is made to send the next probe.

**NOTE:** No more than one outstanding probe exists for each test.

---

For every probe, you can receive one of the following results:

- The target host acknowledges the probe with a response.
- The probe times out; there is no response from the target host acknowledging the probe.
- The probe could not be sent.

Each probe result is recorded in **pingProbeHistoryTable**. For more information about **pingProbeHistoryTable**, see "[pingProbeHistoryTable](#)" on page 1851.

When a response is received from the target host acknowledging the current probe:

- **pingResultsProbeResponses** increases by 1.

- The following variables are updated:
  - **pingResultsMinRtt**—Minimum round-trip time
  - **pingResultsMaxRtt**—Maximum round-trip time
  - **pingResultsAverageRtt**—Average round-trip time
  - **pingResultsRttSumOfSquares**—Sum of squares of round-trip times
  - **pingResultsLastGoodProbe**—Timestamp of the last response

**NOTE:** Only probes that result in a response from the target host contribute to the calculation of the round-trip time (RTT) variables.

When a response to the last probe is received or the last probe has timed out, the test is complete.

### pingProbeHistoryTable

An entry in **pingProbeHistoryTable** (**pingProbeHistoryEntry**) represents a probe result and is indexed by three variables:

- The first two variables, **pingCtlOwnerIndex** and **pingCtlTestName**, are the same ones used for **pingCtlTable**, which identifies the test.
- The third variable, **pingProbeHistoryIndex**, is a counter to uniquely identify each probe result.

The maximum number of **pingProbeHistoryTable** entries created for a given test is limited by **pingCtlMaxRows**. If **pingCtlMaxRows** is set to 0, no **pingProbeHistoryTable** entries are created for that test.

Each time a probe result is determined, a **pingProbeHistoryEntry** is created and added to **pingProbeHistoryTable**. **pingProbeHistoryIndex** of the new **pingProbeHistoryEntry** is 1 greater than the last **pingProbeHistoryEntry** added to **pingProbeHistoryTable** for that test. **pingProbeHistoryIndex** is set to 1 if this is the first entry in the table. The same test can be run multiple times, so this index keeps growing.

If **pingProbeHistoryIndex** of the last **pingProbeHistoryEntry** added is 0xFFFFFFFF, the next **pingProbeHistoryEntry** added has **pingProbeHistoryIndex** set to 1.

The following are recorded for each probe result:

- **pingProbeHistoryResponse**—Time to live (TTL)
- **pingProbeHistoryStatus**—What happened and why
- **pingProbeHistoryLastRC**—Return code (RC) value of ICMP packet
- **pingProbeHistoryTime**—Timestamp when probe result was determined

When a probe cannot be sent, **pingProbeHistoryResponse** is set to 0. When a probe times out, **pingProbeHistoryResponse** is set to the difference between the time when the probe was discovered to be timed out and the time when the probe was sent.

### Generating Traps

For any trap to be generated, the appropriate bit of **pingCtlTrapGeneration** must be set. You must also configure a trap group to receive remote operations. A trap is generated under the following conditions:

- A **pingProbeFailed** trap is generated every time **pingCtlTrapProbeFailureFilter** number of consecutive probes fail during the test.
- A **pingTestFailed** trap is generated when the test completes and at least **pingCtlTrapTestFailureFilter** number of probes fail.
- A **pingTestCompleted** trap is generated when the test completes and fewer than **pingCtlTrapTestFailureFilter** probes fail.

**NOTE:** A probe is considered a failure when **pingProbeHistoryStatus** of the probe result is anything besides **responseReceived**.

For information about how to configure a trap group to receive remote operations, see “Configuring SNMP Trap Groups” on page 1795 and “Example: Setting Trap Notification for Remote Operations” on page 1847.

### Gathering Ping Test Results

You can either poll **pingResultsOperStatus** to find out when the test is complete or request that a trap be sent when the test is complete. For more information about **pingResultsOperStatus**, see “[pingResultsTable](#)” on page 1849. For more information about Ping MIB traps, see “[Generating Traps](#)” on page 1852.

The statistics calculated and then stored in **pingResultsTable** include:

- **pingResultsMinRtt**—Minimum round-trip time
- **pingResultsMaxRtt**—Maximum round-trip time
- **pingResultsAverageRtt**—Average round-trip time
- **pingResultsProbeResponses**—Number of responses received
- **pingResultsSentProbes**—Number of attempts to send probes
- **pingResultsRttSumOfSquares**—Sum of squares of round-trip times
- **pingResultsLastGoodProbe**—Timestamp of the last response

You can also consult **pingProbeHistoryTable** for more detailed information about each probe. The index used for **pingProbeHistoryTable** starts at 1, goes to 0xFFFFFFFF, and wraps to 1 again.

For example, if **pingCtlProbeCount** is 15 and **pingCtlMaxRows** is 5, then upon completion of the first run of this test, **pingProbeHistoryTable** contains probes like those in [Table 220](#).

**Table 220: Results in pingProbeHistoryTable: After the First Ping Test**

| pingProbeHistoryIndex | Probe Result                    |
|-----------------------|---------------------------------|
| 11                    | Result of 11th probe from run 1 |
| 12                    | Result of 12th probe from run 1 |
| 13                    | Result of 13th probe from run 1 |
| 14                    | Result of 14th probe from run 1 |
| 15                    | Result of 15th probe from run 1 |

Upon completion of the first probe of the second run of this test, **pingProbeHistoryTable** will contain probes like those in [Table 221](#).

**Table 221: Results in pingProbeHistoryTable: After the First Probe of the Second Test**

| pingProbeHistoryIndex | Probe Result                    |
|-----------------------|---------------------------------|
| 12                    | Result of 12th probe from run 1 |
| 13                    | Result of 13th probe from run 1 |
| 14                    | Result of 14th probe from run 1 |
| 15                    | Result of 15th probe from run 1 |
| 16                    | Result of 1st probe from run 2  |

Upon completion of the second run of this test, **pingProbeHistoryTable** will contain probes like those in [Table 222](#).

**Table 222: Results in pingProbeHistoryTable: After the Second Ping Test**

| pingProbeHistoryIndex | Probe Result                    |
|-----------------------|---------------------------------|
| 26                    | Result of 11th probe from run 2 |
| 27                    | Result of 12th probe from run 2 |
| 28                    | Result of 13th probe from run 2 |
| 29                    | Result of 14th probe from run 2 |
| 30                    | Result of 15th probe from run 2 |

History entries can be deleted from the MIB in two ways:

- More history entries for a given test are added and the number of history entries exceeds **pingCtlMaxRows**. The oldest history entries are deleted to make room for the new ones.
- You delete the entire test by setting **pingCtlRowStatus** to **destroy**.

## Stopping a Ping Test

To stop an active test, set **pingCtlAdminStatus** to **disabled**. To stop the test and remove its **pingCtlEntry**, **pingResultsEntry**, and any **pingHistoryEntry** objects from the MIB, set **pingCtlRowStatus** to **destroy**.

## Interpreting Ping Variables

This section clarifies the ranges for the following variables that are not explicitly specified in the Ping MIB:

- **pingCtlDataSize**—The value of this variable represents the total size of the payload (in bytes) of an outgoing probe packet. This payload includes the timestamp (8 bytes) that is used to time the probe. This is consistent with the definition of **pingCtlDataSize** (maximum value of 65,507) and the standard ping application.

If the value of **pingCtlDataSize** is between 0 and 8 inclusive, it is ignored and the payload is 8 bytes (the timestamp). The Ping MIB assumes all probes are timed, so the payload must always include the timestamp.

For example, if you wish to add an additional 4 bytes of payload to the packet, you must set **pingCtlDataSize** to 12.

- **pingCtlDataFill**—The first 8 bytes of the data segment of the packet is for the timestamp. After that, the **pingCtlDataFill** pattern is used in repetition. The default pattern (when **pingCtlDataFill** is not specified) is (00, 01, 02, 03 ... FF, 00, 01, 02, 03 ... FF, ...).
- **pingCtlMaxRows**—The maximum value is 255.
- **pingMaxConcurrentRequests**—The maximum value is 500.
- **pingCtlTrapProbeFailureFilter** and **pingCtlTrapTestFailureFilter**—A value of 0 for **pingCtlTrapProbeFailureFilter** or **pingCtlTrapTestFailureFilter** is not well defined by the Ping MIB. If **pingCtlTrapProbeFailureFilter** is 0, **pingProbeFailed** traps will not be generated for the test under any circumstances. If **pingCtlTrapTestFailureFilter** is 0, **pingTestFailed** traps will not be generated for the test under any circumstances.

## Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS

A traceroute test approximates the path packets take from the local host to the remote host.

RFC 2925 is the authoritative description of the Traceroute MIB in detail and provides the ASN.1 MIB definition of the Traceroute MIB.

## Tracing SNMP Activity

- [Tracing SNMP Activity on a Device Running Junos OS on page 1855](#)
- [Example: Tracing SNMP Activity on page 1858](#)

### Tracing SNMP Activity on a Device Running Junos OS

SNMP tracing operations track activity for SNMP agents and record the information in log files. The logged error descriptions provide detailed information to help you solve problems faster.

By default, Junos OS does not trace any SNMP activity. If you include the **traceoptions** statement at the **[edit snmp]** hierarchy level, the default tracing behavior is:

- Important activities are logged in files located in the **/var/log** directory. Each log is named after the SNMP agent that generates it. Currently, the following log files are created in the **/var/log** directory when the **traceoptions** statement is used:
  - chassisd
  - craftd
  - ilmid
  - mib2d
  - rmopd
  - serviced
  - snmpd
- When a trace file named **filename** reaches its maximum size, it is renamed **filename.0**, then **filename.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. (For more information about how log files are created, see the *System Log Monitoring and Troubleshooting Guide for Security Devices*.)
- Log files can be accessed only by the user who configured the tracing operation.

You cannot change the directory (**/var/log**) in which trace files are located. However, you can customize the other trace file settings by including the following statements at the **[edit snmp]** hierarchy level:

```
[edit snmp]
traceoptions {
```

```
file <files number> <match regular-expression> <size size> <world-readable |  
no-world-readable>;  
flag flag;  
memory-trace;  
no-remote-trace;  
no-default-memory-trace;  
}
```

These statements are described in the following sections:

- [Configuring the Number and Size of SNMP Log Files on page 1856](#)
- [Configuring Access to the Log File on page 1856](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 1856](#)
- [Configuring the Trace Operations on page 1857](#)

---

### Configuring the Number and Size of SNMP Log Files

By default, when the trace file reaches 128 kilobytes (KB) in size, it is renamed *filename.0*, then *filename.1*, and so on, until there are three trace files. Then the oldest trace file (*filename.2*) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]  
file files number size size;
```

For example, set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation (*filename*) reaches 2 MB, *filename* is renamed *filename.0*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0* is renamed *filename.1* and *filename* is renamed *filename.0*. This process repeats until there are 20 trace files. Then the oldest file (*filename.19*) is overwritten by the newest file (*filename.0*).

The number of files can be from 2 through 1000 files. The file size of each file can be from 10 KB through 1 gigabyte (GB).

---

### Configuring Access to the Log File

By default, log files can be accessed only by the user who configured the tracing operation.

To specify that any user can read all log files, include the **file world-readable** statement at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]  
file world-readable;
```

To explicitly set the default behavior, include the **file no-world-readable** statement at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]  
file no-world-readable;
```

---

### Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged activities.

You can refine the output by including the **match** statement at the **[edit snmp traceoptions file *filename*]** hierarchy level and specifying a regular expression (regex) to be matched:

```
[edit snmp traceoptions]
file filename match regular-expression;
```

### Configuring the Trace Operations

By default, only important activities are logged. You can specify which trace operations are to be logged by including the following **flag** statement (with one or more tracing flags) at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]
flag {
  all;
  configuration;
  database;
  events;
  general;
  interface-stats;
  nonvolatile-sets;
  pdu;
  policy;
  protocol-timeouts;
  routing-socket;
  server;
  subagent;
  timer;
  varbind-error;
}
```

Table 223 describes the meaning of the SNMP tracing flags.

**Table 223: SNMP Tracing Flags**

| Flag                   | Description                                                                 | Default Setting |
|------------------------|-----------------------------------------------------------------------------|-----------------|
| <b>all</b>             | Log all operations.                                                         | Off             |
| <b>configuration</b>   | Log reading of the configuration at the <b>[edit snmp]</b> hierarchy level. | Off             |
| <b>database</b>        | Log events involving storage and retrieval in the events database.          | Off             |
| <b>events</b>          | Log important events.                                                       | Off             |
| <b>general</b>         | Log general events.                                                         | Off             |
| <b>interface-stats</b> | Log physical and logical interface statistics.                              | Off             |
| <b>nonvolatile-set</b> | Log nonvolatile SNMP set request handling.                                  | Off             |
| <b>pdu</b>             | Log SNMP request and response packets.                                      | Off             |

Table 223: SNMP Tracing Flags (*continued*)

| Flag                     | Description                                                  | Default Setting |
|--------------------------|--------------------------------------------------------------|-----------------|
| <b>policy</b>            | Log policy processing.                                       | Off             |
| <b>protocol-timeouts</b> | Log SNMP response timeouts.                                  | Off             |
| <b>routing-socket</b>    | Log routing socket calls.                                    | Off             |
| <b>server</b>            | Log communication with processes that are generating events. | Off             |
| <b>subagent</b>          | Log subagent restarts.                                       | Off             |
| <b>timer</b>             | Log internal timer events.                                   | Off             |
| <b>varbind-error</b>     | Log variable binding errors.                                 | Off             |

To display the end of the log for an agent, issue the **show log agentd | last** operational mode command:

```
[edit]
user@host# run show log agentd | last
```

where **agent** is the name of an SNMP agent.

- [Generating Vital Data from a Screen on page 1866](#)

## Understanding Vital MIB OID Data Collection

MIB object identifier (OID) data is collected and configured for later use in reports. You can configure data collection duration (default is 3 days), dump file size limitation (default is 5 megabytes for branch SRX Series and 10 megabytes for high-end SRX Series), and disk storage limitation (default is 80 percent). The expired dump file is removed automatically. When the dump file exceeds the limited size, a new dump file is created and the old dump file is compressed. When disk utilization exceeds the storage limitation, data collection is skipped but is attempted the next time. If an issue should arise, then the collected data is examined to help identify its cause.

Once you enable a predefined group, the vital data of all OIDs in the group are periodically collected and analyzed. Only critical data is collected when CPU utilization exceeds 60 percent but is within 80 percent.

A maximum of 64 groups per OIDs are supported for branch SRX Series devices and a maximum of 128 groups per OIDs are supported for high-end SRX Series devices.

You can also collect raw MIB OID data. For the format of raw OID output, the first volume is 40 characters and the second volume is 30 characters in length. Any extra characters are stripped.

**TIP:** To make the dump file easily understood, we recommend that you configure short comments for each raw OID.

Use the **set system processes system-log-vital disable** command to manually disable the syslvd process (daemon). Disabling syslvd will not impact the existing data in the dump file. Once all configuration commands are removed, syslvd is disabled automatically. If syslvd is disabled in the middle of a collection, data from the current collection will be lost but data available in the current dump file is retained.

### Related Documentation

- [Generating Raw MIB OID from a Policy on page 1860](#)
- [Generating Readable Raw OID Data Collections on page 1860](#)

## Generating Readable Raw OID Data Collections

You can use the **set system log-vital add oid comment “comment”** command to make raw object identifiers (OIDs) that are lengthy and unreadable easily understood.

```
[edit system]
log-vital {
  add oid {
    comment comment;
  }
}
```

The **OID** parameter can be formatted as `mib-table.index`. For example, `jnxOperating1MinLoadAvg.9.1.0.0` is an OID.

The “comment” parameter describes the OID. If “comment” is present, the comment instead of the OID is generated as the subject of the vital data.

For example, without the “comment” parameter, the output of the **set system log-vital add jnxJsPolicyNumber.0** command in the dump file is:

```
=====
jnxJsPolicyNumber.0          1
=====
```

With the “comment” parameter, the output of the **set system log-vital add jnxJsPolicyNumber.0 comment “Total Policy Number”** command in the dump file is:

```
=====
Total Policy Number          1
=====
```

**NOTE:** For OIDs that are temporarily unavailable, the string **NA** is generated for them and the system continues to get their values for every collection. In this case, the output displayed in the dump file is:

```
=====
Total Policy Number          NA
=====
```

### Related Documentation

- [Generating Raw MIB OID from a Policy on page 1860](#)

## Generating Raw MIB OID from a Policy

You can generate a raw MIB OID from a policy. You can also monitor the session number associated with the policy and other policy MIB tables.

For example, consider a policy called **test**. Monitor the session number associated with the policy.

```
[edit]
```

```

from-zone untrust to-zone trust {
policy test {
  match {
    source-address any;
    destination-address any;
    application any;
  }
  then {
    permit;
    count;
  }
}
}

```

To monitor a session number associated with a policy:

1. Identify the OID of the policy's session number.

```

user@host> show snmp mib walk jnxJsPolicyName | match test
jnxJsPolicyName.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
= test

```

In the above output, the index of the policy is 7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116; the policy name is test; and the MIB table name is jnxJsPolicyName.

2. With the index, verify that both the from-zone and the to-zone match the configuration. Enter the **show snmp mib get** command.

```

user@host> show snmp mib get
jnxJsPolicyFromZone.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
jnxJsPolicyFromZone.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
= untrust

```

```

user@host> show snmp mib get
jnxJsPolicyToZone.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
jnxJsPolicyToZone.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
= trust

```

3. Perform a mandatory from-zone and to-zone match check to avoid a scenario where there is a policy with the same name but the from-zone or the to-zone is different.
4. After performing both the from-zone and the to-zone match checks, ensure that 7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116 is the index of the policy called test in various policy MIB tables.
5. Monitor the session number using the following command:

```

[edit]
user@host# set system log-vital add
jnxJsPolicyStatsNumSessions.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
comment "sess num of policy test"

```

The output of the configuration is:

```

=====
sess num of policy test    100
=====

```

To monitor other policy MIB tables:

1. Combine a MIB table's name with the index.
2. Monitor the session setup rate for the test policy using the command:

```
[edit]
set system log-vital add
jnxJsPolicyStatsSessionRate.7.117.110.116.114.117.115.116.5.116.114.117.115.116.4.116.101.115.116
comment "sess setup rate of policy test"
```

The output of the configuration is:

```
=====
sess setup rate of policy test    233
=====
```

#### Related Documentation

- [Generating Readable Raw OID Data Collections on page 1860](#)

## Generating Vital Data from a Predefined Group

You can use the **set system log-vital group [cluster-counter | idp | operating | storage | spu <spu-name> | screen <zone-name>** command to enable a predefined group.

```
[edit system]
group {
  operating;
  idp;
  storage;
  cluster-counter;
  screen;
  spu;
}
```

**NOTE:** The parameter for **spu-name** must be *fwdd*, *all*, *fpcy.picz* or *nodex.fpcy.picz*.

The predefined groups are operating, SPU, storage, IDP, screen, and cluster-counter. Once a group is enabled, all OIDs in the group are periodically collected and dumped.

The operating group includes state, temperature, current CPU utilization percentage, buffer utilization percentage, heap-utilization percentage, up time, average-load in the last 1 minute, 5 minutes, or 15 minutes, and buffer-pool utilization percentage in the control plane of each operating component in the system.

The IDP group includes IDP data plane memory usage, IDP session usage and policies loaded number.

The storage group includes storage utilization of directory **/var/log**.

The cluster-counter group includes current total session number, total CPS, IPv4 CPS, IPv6 CPS, current total IPv4 session number, and current total IPv6 session number of both node 0 and node 1.

The screen group includes screen statistics of a specified zone.

The SPU group includes CPU usage, memory usage, current flow session number, current CP session number, IPv4 session number, IPv6 session number, CP IPv4 session number, and CP IPv6 session number of the SPU.

**Related Documentation**

- [Generating Raw MIB OID from a Policy on page 1860](#)

## Generating Vital Data from an Interface

You can monitor the statistics of interface ge-0/0/0 by first obtaining the SNMP ifIndex from the interface.

```
user@host> show interfaces ge-0/0/0
```

```
Physical interface: ge-0/0/0, Enabled, Physical link is Up
  Interface index: 134, SNMP ifIndex: 509
```

In this output, the 509 value is the index of ge-0/0/0 in the interface MIB table. By combining this index value with the interface MIB tables, the vital data of the interface can be periodically collected.

For example, combine the 509 index with the ifInErrors interface MIB table to collect the In-Error data of interface ge-0/0/0 by using the following command:

```
[edit]
user@host# set system log-vital add ifInErrors.509 comment "In-Err of ge-0/0/0"
```

The output for the command is:

```
=====
In-Err of ge-0/0/0    100
=====
```

The following interface MIB tables can be used to collect vital data:

- ifInOctets
- ifInUcastPkts
- ifInNUcastPkts
- ifInDiscards
- ifInErrors
- ifInUnknownProtos
- ifOutOctets
- ifOutUcastPkts
- ifOutNUcastPkts

- ifOutDiscards
- ifOutErrors

**Related  
Documentation**

- [Generating Readable Raw OID Data Collections on page 1860](#)

## Generating Vital Data from an IPsec VPN

You can monitor the vital data of an IPsec VPN by first obtaining the index of the VPN in the IPsec VPN MIB table.

For example, consider the following below policy-based VPN configuration, where the name of the policy is test.

```
user@host> show configuration security policies
```

```
from-zone untrust to-zone trust {
  policy test {
    match {
      source-address any;
      destination-address any;
      application any;
    }
    then {
      permit {
        tunnel {
          ipsec-vpn ike-vpn;
        }
      }
    }
  }
}
```

To monitor the error statistics for the VPN, you must first obtain the index of the VPN in the IPsec VPN MIB table. You can obtain this value by using the command:

```
user@host> show snmp mib walk jnxIpSecTunPolicyName | match test
jnxJsIpSecTunPolicyName.1.4.2.2.1.2 = test
```

In the output, 1.4.2.2.1.2 is the index of the IPsec SA associated with the policy called test. By combining the index with various IPsec VPN MIB tables, you can monitor the statistics by using the following commands:

```
[edit]
user@host# set system log-vital add jnxIpSecTunMonReplayDropPkts.1.4.2.2.1.2 comment
"Anti-Replay drop number of VPN policy test"
user@host# set system log-vital add jnxIpSecTunMonBadHeaders.1.4.2.2.1.2 comment "Bad
Header number of VPN policy test"
```

**Related  
Documentation**

- [Generating Vital Data from a Screen on page 1866](#)

## Generating Vital Data from a NAT Rule

You can monitor the vital data from a NAT rule (in this example, `r1`) by first obtaining the MIB index of `r1`.

Consider the following source NAT configuration.

```
user@host> show configuration security nat
```

```
source {
  rule-set rs1 {
    from zone trust;
    to zone untrust;
    rule r1 {
      match {
        source-address 17.0.0.0/8;
        destination-address 0.0.0.0/0;
      }
      then {
        source-nat {
          interface;
        }
      }
    }
  }
}
```

To find the MIB index of `r1`, enter the following command:

```
[edit]
user@host# show snmp mib walk jnxJsNatRuleName | grep r1
jnxJsNatRuleName.2.114.49.1 = r1
```

The output shows that `2.114.49.1` is the MIB index of `r1`.

Therefore, by combining the index with NAT MIB table `jnxJsNatRuleHits`, the session number associated with NAT rule `r1` can be monitored by using the command:

```
[edit]
user@host# set system log-vital add jnxJsNatRuleHits.2.114.49.1 comment "Number of sessions
on NAT rule r1"
```

### Related Documentation

- [Generating Readable Raw OID Data Collections on page 1860](#)

## Generating Vital Data from an Operating Component

You can monitor the vital data of an operating component. For example, to monitor the temperature of the SPC component located at slot 3 of node 0, enter the following command:

```
user@host> show snmp mib walk jnxOperatingDescr | match "SPC @ 3"
```

```
jnxOperatingDescr.7.4.0.0 = node0 FPC: SRX5k SPC @ 3/*/*
jnxOperatingDescr.7.10.0.0 = node1 FPC: SRX5k SPC @ 3/*/*
```

In the output, the SPC index at slot 3 of node 0 in the operating MIB table is 7.4.0.0. By combining the 7.4.0.0 index with operating MIB table `jnxOperatingTemp`, the temperature of SPC at slot 3 of node 0 can be monitored by using the following command:

```
[edit]
user@host# set system log-vital add jnxOperatingTemp.7.4.0.0 comment "Temperature of node0
SPC-3"
```

## Related Documentation

- Generating Vital Data from a Screen on page 1866

## Generating Vital Data from a Screen

The screen group collects all screen statistics of a specified zone. However, it can only collect some of the statistics rather than all statistics.

For example, consider the following screen configuration, where the number of UDP flood attacks in the untrust zone is to be monitored.

```
user@host> show configuration security screen
```

```
ids-option zone-syn-flood {
    tcp {
        syn-flood {
            timeout 20;
        }
    }
}
```

```
user@host> show configuration security zones
```

```
security-zone untrust {
    screen zone-syn-flood;
    ...
    ...
}
```

To monitor the number of UDP flood attacks, you must first obtain the index of the untrust zone in various screen MIB tables.

[illegible]

In the output, the string  
117.110.116.114.117.115.116.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0 is the index of  
the untrust zone in the MIB table.

By combining the index with screen MIB table `jnxJsScreenMonUdpFlood`, the number can be monitored using the following command:

[illegible]

## Related Documentation

- [Generating Vital Data from a NAT Rule on page 1865](#)

## SNMP FAQs

- [Managing Traps and Informs on page 1867](#)

## Managing Traps and Informs

The following sections contain a few tips on managing SNMP notifications:

- [Generating Traps Based on SysLog Events on page 1867](#)
- [Filtering Traps Based on the Trap Category on page 1867](#)
- [Filtering Traps Based on the Object Identifier on page 1868](#)

### Generating Traps Based on SysLog Events

Event policies can include an action that raises traps for events based on system log messages. This feature enables notification of an SNMP trap-based application when an important system log message occurs. You can convert any system log message, for which there is no corresponding trap, into a trap. If you are using network management system traps rather than system log messages to monitor your network, you can use this feature to ensure that you are notified of all the major events.

To configure a policy that raises a trap on receipt of an event, include the following statements at the **[edit event-options policy *policy-name*]** hierarchy level:

```
[edit event-options policy policy-name]
events [ events ];
then {
    raise-trap;
}
```

The following example shows the sample configuration for raising a trap for the event **ui\_mgd\_terminate**:

#### Generating Traps Based on SysLog Events

```
[edit event-options policy p1]
events ui_mgd_terminate;
then {
    raise-trap;
}
```

### Filtering Traps Based on the Trap Category

SNMP traps are categorized into many categories. The Junos OS provides a configuration option, **categories** at the **[edit snmp trap-group *trap-group*]** hierarchy level, that enables you to specify categories of traps that you want to receive on a particular host. You can use this option when you want to monitor only specific modules of the Junos OS.

The following example shows a sample configuration for receiving only **link**, **vrrp-events**, **services**, and **otn-alarms** traps:

```
[edit snmp]
```

```
trap-group jnpr {
  categories {
    link;
    vrrp-events;
    services;
    otn-alarms;
  }
  targets {
    192.168.69.179;
  }
}
```

---

### Filtering Traps Based on the Object Identifier

The Junos OS also provides a more advanced filter option that enables you to filter out specific traps based on their object identifiers. You can use the **notify-filter** option to filter out a specific trap or a group of traps.

The following example shows the sample configuration for excluding Juniper Networks enterprise-specific configuration management traps (note that the SNMPv3 configuration also supports filtering of SNMPv1 and SNMPv2 traps as is shown in the following example):

```
[edit snmp]
v3 {
  vacm {
    security-to-group {
      security-model v2c {
        security-name sn_v2c_trap {
          group gr_v2c_trap;
        }
      }
    }
  }
  access {
    group gr_v2c_trap {
      default-context-prefix {
        security-model v2c {
          security-level none {
            read-view all;
            notify-view all;
          }
        }
      }
    }
  }
}
target-address TA_v2c_trap {
  address 10.209.196.166;
  port 9001;
  tag-list tgl;
  target-parameters TP_v2c_trap;
}
target-parameters TP_v2c_trap {
  parameters {
    message-processing-model v2c;
    security-model v2c;
    security-level none;
  }
}
```

```

        security-name sn_v2c_trap;
    }
    notify-filter nf1;
}
notify v2c_notify {
    type trap;
    tag tg1;
}
notify-filter nf1 {
    oid .1.3.6.1.4.1.2636.4.5 exclude;
    oid .1 include;
}
snmp-community index1 {
    community-name "$ABC123"; ## SECRET-DATA
    security-name sn_v2c_trap;
    tag tg1;
}
view all {
    oid .1 include;
}
}

```

## CHAPTER 68

# Remote Monitoring (RMON) with SNMP

- [RMON Overview on page 1871](#)
- [Configuring RMON Alarms and Events on page 1874](#)
- [Monitoring RMON Alarms and Events on page 1880](#)

## RMON Overview

---

- [Understanding RMON Alarms on page 1871](#)
- [Understanding RMON Events on page 1873](#)

## Understanding RMON Alarms

An RMON alarm identifies:

- A specific MIB object that is monitored.
- The frequency of sampling.
- The method of sampling.
- The thresholds against which the monitored values are compared.

An RMON alarm can also identify a specific **eventTable** entry to be triggered when a threshold is crossed.

Configuration and operational values are defined in **alarmTable** in RFC 2819. Additional operational values are defined in Juniper Networks enterprise-specific extensions to **alarmTable** (**jnxRmonAlarmTable**).

This topic covers the following sections:

- [alarmTable on page 1872](#)
- [jnxRmonAlarmTable on page 1872](#)

## alarmTable

**alarmTable** in the RMON MIB allows you to monitor and poll the following:

- **alarmIndex**—The index value for **alarmTable** that identifies a specific entry.
- **alarmInterval**—The interval, in seconds, over which data is sampled and compared with the rising and falling thresholds.
- **alarmVariable**—The MIB variable that is monitored by the alarm entry.
- **alarmSampleType**—The method of sampling the selected variable and calculating the value to be compared against the thresholds.
- **alarmValue**—The value of the variable during the last sampling period. This value is compared with the rising and falling thresholds.
- **alarmStartupAlarm**—The alarm sent when the entry is first activated.
- **alarmRisingThreshold**—The upper threshold for the sampled variable.
- **alarmFallingThreshold**—The lower threshold for the sampled variable.
- **alarmRisingEventIndex**—The **eventTable** entry used when a rising threshold is crossed.
- **alarmFallingEventIndex**—The **eventTable** entry used when a falling threshold is crossed.
- **alarmStatus**—Method for adding and removing entries from the table. It can also be used to change the state of an entry to allow modifications.

**NOTE:** If this object is not set to valid, the associated event alarm does not take any action.

## jnxRmonAlarmTable

The **jnxRmonAlarmTable** is a Juniper Networks enterprise-specific extension to **alarmTable**. It provides additional operational information and includes the following objects:

- **jnxRmonAlarmGetFailCnt**—The number of times the internal **Get** request for the variable monitored by this entry has failed.
- **jnxRmonAlarmGetFailTime**—The value of **sysUpTime** when an internal **Get** request for the variable monitored by this entry last failed.
- **jnxRmonAlarmGetFailReason**—The reason an internal **Get** request for the variable monitored by this entry last failed.
- **jnxRmonAlarmGetOkTime**—The value of **sysUpTime** when an internal **Get** request for the variable monitored by this entry succeeded and the entry left the **getFailure** state.
- **jnxRmonAlarmState**—The current state of this RMON alarm entry.

To view the Juniper Networks enterprise-specific extensions to the RMON Events and Alarms and Event MIB, see

[http://www.juniper.net/techpubs/en\\_US/junos10.3/topics/reference/mibs/mib-jnx-rmon.txt](http://www.juniper.net/techpubs/en_US/junos10.3/topics/reference/mibs/mib-jnx-rmon.txt).

For more information about the Juniper Networks enterprise-specific extensions to the RMON Events and Alarms MIB, see “*RMON Events and Alarms MIB*” in the *SNMP MIBs and Traps Monitoring and Troubleshooting Guide for Security Devices*.

  - [Configuring an Alarm Entry and Its Attributes on page 1875](#)
  - [Using alarmTable to Monitor MIB Objects](#)

## Understanding RMON Events

An RMON event allows you to log the crossing of thresholds of other MIB objects. It is defined in **eventTable** for the RMON MIB.

This section covers the following topics:

- [eventTable on page 1873](#)

### eventTable

**eventTable** contains the following objects:

- **eventIndex**—An index that uniquely identifies an entry in **eventTable**. Each entry defines one event that is generated when the appropriate conditions occur.
- **eventDescription**—A comment describing the event entry.
- **eventType**—Type of notification that the probe makes about this event.
- **eventCommunity**—Trap group used if an SNMP trap is to be sent. If **eventCommunity** is not configured, a trap is sent to each trap group configured with the **rmon-alarm** category.
- **eventLastTimeSent**—Value of **sysUpTime** when this event entry last generated an event.
- **eventOwner**—Any text string specified by the creating management application or the command-line interface (CLI). Typically, it is used to identify a network manager (or application) and can be used for fine access control between participating management applications.
- **eventStatus**—Status of this event entry.

**NOTE:** If this object is not set to valid, no action is taken by the associated event entry. When this object is set to valid, all previous log entries associated with this entry (if any) are deleted.

## Configuring RMON Alarms and Events

---

- [Understanding RMON Alarms and Events Configuration on page 1874](#)
- [Configuring an Alarm Entry and Its Attributes on page 1875](#)
- [Configuring an Event Entry and Its Attributes on page 1879](#)
- [Example: Configuring an RMON Alarm and Event Entry on page 1879](#)
- [Example: Configuring Health Monitoring on page 1880](#)

### Understanding RMON Alarms and Events Configuration

Junos OS supports monitoring routers from remote devices. These values are measured against thresholds and trigger events when the thresholds are crossed. You configure remote monitoring (RMON) alarm and event entries to monitor the value of a MIB object.

To configure RMON alarm and event entries, you include statements at the **[edit snmp]** hierarchy level of the configuration:

```
[edit snmp]
rmon {
  alarm index {
    description text-description;
    falling-event-index index;
    falling-threshold integer;
    falling-threshold-interval seconds;
    interval seconds;
    rising-event-index index;
    rising-threshold integer;
    request-type (get-next-request | get-request | walk-request);
    sample-type (absolute-value | delta-value);
    startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
    syslog-subtag syslog-subtag;
    variable oid-variable;
    event index {
      community community-name;
      description description;
      type type;
    }
  }
}
```

- [Configuring an Event Entry and Its Attributes on page 1879](#)

## Configuring an Alarm Entry and Its Attributes

An alarm entry monitors the value of a MIB variable. You can configure how often the value is sampled, the type of sampling to perform, and what event to trigger if a threshold is crossed.

This section discusses the following topics:

- [Configuring the Alarm Entry on page 1875](#)
- [Configuring the Description on page 1875](#)
- [Configuring the Falling Event Index or Rising Event Index on page 1876](#)
- [Configuring the Falling Threshold or Rising Threshold on page 1876](#)

- [Configuring the Sample Type on page 1877](#)
- [Configuring the Startup Alarm on page 1878](#)
- [Configuring the System Log Tag on page 1878](#)
- [Configuring the Variable on page 1878](#)

---

### Configuring the Alarm Entry

An alarm entry monitors the value of a MIB variable. The **rising-event-index**, **rising-threshold**, **sample-type**, and **variable** statements are mandatory. All other statements are optional.

To configure the alarm entry, include the **alarm** statement and specify an index at the **[edit snmp rmon]** hierarchy level:

```
[edit snmp rmon]
alarm index {
  description description;
  falling-event-index index;
  falling-threshold integer;
  falling-threshold-interval seconds;
  interval seconds;
  rising-event-index index;
  rising-threshold integer;
  sample-type (absolute-value | delta-value);
  startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
  variable oid-variable;
}
```

**index** is an integer that identifies an alarm or event entry.

---

### Configuring the Description

The description is a text string that identifies the alarm entry.

To configure the description, include the **description** statement and a description of the alarm entry at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
description description;
```

---

### Configuring the Falling Event Index or Rising Event Index

The falling event index identifies the event entry that is triggered when a falling threshold is crossed. The rising event index identifies the event entry that is triggered when a rising threshold is crossed.

To configure the falling event index or rising event index, include the **falling-event-index** or **rising-event-index** statement and specify an index at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
falling-event-index index;
rising-event-index index;
```

**index** can be from 0 through 65,535. The default for both the falling and rising event index is 0.

---

### Configuring the Falling Threshold or Rising Threshold

The falling threshold is the lower threshold for the monitored variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold, and the associated startup alarm is equal to **falling-alarm** or **rising-or-falling-alarm**. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the rising threshold. You must specify the falling threshold as an integer. Its default is 20 percent less than the rising threshold.

By default, the rising threshold is 0. The rising threshold is the upper threshold for the monitored variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated **startup-alarm** is equal to **rising-alarm** or **rising-or-falling-alarm**. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. You must specify the rising threshold as an integer.

To configure the falling threshold or rising threshold, include the **falling-threshold** or **rising-threshold** statement at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
falling-threshold integer;
rising-threshold integer;
```

**integer** can be a value from -2,147,483,647 through 2,147,483,647.

### Configuring the Interval

The interval represents the period of time, in seconds, over which the monitored variable is sampled and compared with the rising and falling thresholds.

To configure the interval, include the **interval** statement and specify the number of seconds at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
interval seconds;
```

**seconds** can be a value from 1 through 2,147,483,647. The default is 60 seconds.

### Configuring the Falling Threshold Interval

The falling threshold interval represents the interval between samples when the rising threshold is crossed. Once the alarm crosses the falling threshold, the regular sampling interval is used.

**NOTE:** You cannot configure the falling threshold interval for alarms that have the request type set to **walk-request**.

To configure the falling threshold interval, include the **falling-threshold-interval** statement at the **[edit snmp rmon alarm index]** hierarchy level and specify the number of seconds:

```
[edit snmp rmon alarm index]
falling-threshold-interval seconds;
```

**seconds** can be a value from 1 through 2,147,483,647. The default is 60 seconds.

### Configuring the Request Type

By default an RMON alarm can monitor only one object instance (as specified in the configuration). You can configure a **request-type** statement to extend the scope of the RMON alarm to include all object instances belonging to a MIB branch or to include the next object instance after the instance specified in the configuration.

To configure the request type, include the **request-type** statement at the **[edit snmp rmon alarm index]** hierarchy level and specify **get-next-request**, **get-request**, or **walk-request**:

```
[edit snmp rmon alarm index]
request-type (get-next-request | get-request | walk-request);
```

**walk** extends the RMON alarm configuration to all object instances belonging to a MIB branch. **next** extends the RMON alarm configuration to include the next object instance after the instance specified in the configuration.

### Configuring the Sample Type

The sample type identifies the method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is **absolute-value**, the value of the selected variable is compared directly with the thresholds at the end of the sampling interval. If the value of this object is **delta-value**, the value of

the selected variable at the last sample is subtracted from the current value, and the difference is compared with the thresholds.

To configure the sample type, include the **sample-type** statement and specify the type of sample at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
sample-type (absolute-value | delta-value);
```

- **absolute-value**—Actual value of the selected variable is compared against the thresholds.
- **delta-value**—Difference between samples of the selected variable is compared against the thresholds.

---

### Configuring the Startup Alarm

The startup alarm identifies the type of alarm that can be sent when this entry is first activated. You can specify it as **falling-alarm**, **rising-alarm**, or **rising-or-falling-alarm**.

To configure the startup alarm, include the **startup-alarm** statement and specify the type of alarm at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
```

- **falling-alarm**—Generated if the first sample after the alarm entry becomes active is less than or equal to the falling threshold.
- **rising-alarm**—Generated if the first sample after the alarm entry becomes active is greater than or equal to the rising threshold.
- **rising-or-falling-alarm**—Generated if the first sample after the alarm entry becomes active satisfies either of the corresponding thresholds.

The default is **rising-or-falling-alarm**.

---

### Configuring the System Log Tag

The **syslog-subtag** statement specifies the tag to be added to the system log message. You can specify a string of not more than 80 uppercase characters as the system log tag.

To configure the system log tag, include the **syslog-subtag** statement at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
syslog-subtag syslog-subtag;
```

---

### Configuring the Variable

The variable identifies the MIB object that is being monitored.

To configure the variable, include the **variable** statement and specify the object identifier or object name at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
```

**variable** *oid-variable*;

**oid-variable** is a dotted decimal (for example, 1.3.6.1.2.1.2.1.2.2.1.10.1) or MIB object name (for example, `ifInOctets.1`).

## Configuring an Event Entry and Its Attributes

An event entry generates a notification for an alarm entry when its rising or falling threshold is crossed. You can configure the type of notification that is generated. To configure the event entry, include the **event** statement at the **[edit snmp rmon]** hierarchy level. All statements except the **event** statement are optional.

```
[edit snmp rmon]
event index {
  community community-name;
  description description;
  type type;
}
```

**index** identifies an entry event.

**community-name** is the trap group that is used when generating a trap. If that trap group has the **rmon-alarm** trap category configured, a trap is sent to all the targets configured for that trap group. The community string in the trap matches the name of the trap group. If nothing is configured, all the trap groups are examined, and traps are sent using each group with the **rmon-alarm** category set.

**description** is a text string that identifies the entry.

The **type** variable of an event entry specifies where the event is to be logged. You can specify the type as one of the following:

- **log**—Adds the event entry to the **logTable**.
- **log-and-trap**—Sends an SNMP trap and creates a log entry.
- **none**—Sends no notification.
- **snmptrap**—Sends an SNMP trap.

The default for the event entry type is **log-and-trap**.

- [Configuring an Alarm Entry and Its Attributes on page 1875](#)
- [Example: Configuring an RMON Alarm and Event Entry on page 1879](#)

## Example: Configuring an RMON Alarm and Event Entry

Configure an RMON alarm and event entry:

```
[edit snmp]
rmon {
```

```
alarm 100 {
  description "input traffic on fxp0";
  falling-event-index 100;
  falling-threshold 10000;
  interval 60;
  rising-event-index 100;
  rising-threshold 100000;
  sample-type delta-value;
  startup-alarm rising-or-falling-alarm;
  variable ifInOctets.1;
}
event 100 {
  community bedrock;
  description "emergency events";
  type log-and-trap;
}
}
```

- Related Documentation**
- [Understanding RMON Alarms and Events Configuration on page 1874](#)
  - [Configuring an Alarm Entry and Its Attributes on page 1875](#)
  - [Configuring an Event Entry and Its Attributes on page 1879](#)

## Example: Configuring Health Monitoring

Configure the health monitor:

```
[edit snmp]
health-monitor {
  falling-threshold 85;
  interval 600;
  rising-threshold 75;
}
```

In this example, the sampling interval is every **600** seconds (10 minutes), the falling threshold is **85** percent of the maximum possible value for each object instance monitored, and the rising threshold is **75** percent of the maximum possible value for each object instance monitored.

## Monitoring RMON Alarms and Events

---

- [Understanding RMON for Monitoring Service Quality on page 1880](#)
- [Understanding Measurement Points, Key Performance Indicators, and Baseline Values on page 1884](#)

### Understanding RMON for Monitoring Service Quality

Health and performance monitoring can benefit from the remote monitoring of SNMP variables by the local SNMP agents running on each router. The SNMP agents compare MIB values against predefined thresholds and generate exception alarms without the

need for polling by a central SNMP management platform. This is an effective mechanism for proactive management, as long as the thresholds have baselines determined and set correctly. For more information, see RFC 2819, *Remote Network Monitoring MIB*.

This topic includes the following sections:

- [Setting Thresholds on page 1881](#)
- [RMON Command-Line Interface on page 1882](#)
- [RMON Event Table on page 1882](#)
- [RMON Alarm Table on page 1883](#)
- [Troubleshooting RMON on page 1883](#)

### Setting Thresholds

By setting a rising and a falling threshold for a monitored variable, you can be alerted whenever the value of the variable falls outside of the allowable operational range. (See [Figure 33](#).)

**Figure 33: Setting Thresholds**

Events are only generated when the threshold is first crossed in any one direction rather than after each sample period. For example, if a rising threshold crossing event is raised, no more threshold crossing events will occur until a corresponding falling event. This considerably reduces the quantity of alarms that are produced by the system, making it easier for operations staff to react when alarms do occur.

To configure remote monitoring, specify the following pieces of information:

- The variable to be monitored (by its SNMP object identifier)
- The length of time between each inspection
- A rising threshold
- A falling threshold
- A rising event
- A falling event

Before you can successfully configure remote monitoring, you should identify what variables need to be monitored and their allowable operational range. This requires some period of baselining to determine the allowable operational ranges. An initial baseline period of at least three months is not unusual when first identifying the operational ranges and defining thresholds, but baseline monitoring should continue over the life span of each monitored variable.

### RMON Command-Line Interface

Junos OS provides two mechanisms you use to control the Remote Monitoring agent on the router: command-line interface (CLI) and SNMP. To configure an RMON entry using the CLI, include the following statements at the **[edit snmp]** hierarchy level:

```
rmon {
  alarm index {
    description;
    falling-event-index;
    falling-threshold;
    intervals;
    rising-event-index;
    rising-threshold;
    sample-type (absolute-value | delta-value);
    startup-alarm (falling | rising | rising-or-falling);
    variable;
  }
  event index {
    community;
    description;
    type (log | trap | log-and-trap | none);
  }
}
```

If you do not have CLI access, you can configure remote monitoring using the SNMP Manager or management application, assuming SNMP access has been granted. (See [Table 224.](#)) To configure RMON using SNMP, perform SNMP **Set** requests to the RMON event and alarm tables.

### RMON Event Table

Set up an event for each type that you want to generate. For example, you could have two generic events, *rising* and *falling*, or many different events for each variable that is being monitored (for example, *temperature rising* event, *temperature falling* event, *firewall hit* event, *interface utilization* event, and so on). Once the events have been configured, you do not need to update them.

**Table 224: RMON Event Table**

| Field                   | Description                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>eventDescription</b> | Text description of this event                                                                                            |
| <b>eventType</b>        | Type of event (for example, <b>log</b> , <b>trap</b> , or <b>log and trap</b> )                                           |
| <b>eventCommunity</b>   | Trap group to which to send this event (as defined in the Junos OS configuration, which is not the same as the community) |

Table 224: RMON Event Table (*continued*)

| Field              | Description                                                                                |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>eventOwner</b>  | Entity (for example, <b>manager</b> ) that created this event                              |
| <b>eventStatus</b> | Status of this row (for example, <b>valid</b> , <b>invalid</b> , or <b>createRequest</b> ) |

### RMON Alarm Table

The RMON alarm table stores the SNMP object identifiers (including their instances) of the variables that are being monitored, together with any rising and falling thresholds and their corresponding event indexes. To create an RMON request, specify the fields shown in [Table 225](#).

Table 225: RMON Alarm Table

| Field                         | Description                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------|
| <b>alarmStatus</b>            | Status of this row (for example, <b>valid</b> , <b>invalid</b> , or <b>createRequest</b> ) |
| <b>alarmInterval</b>          | Sampling period (in seconds) of the monitored variable                                     |
| <b>alarmVariable</b>          | OID (and instance) of the variable to be monitored                                         |
| <b>alarmValue</b>             | Actual value of the sampled variable                                                       |
| <b>alarmSampleType</b>        | Sample type ( <b>absolute</b> or <b>delta</b> changes)                                     |
| <b>alarmStartupAlarm</b>      | Initial alarm ( <b>rising</b> , <b>falling</b> , or <b>either</b> )                        |
| <b>alarmRisingThreshold</b>   | Rising threshold against which to compare the value                                        |
| <b>alarmFallingThreshold</b>  | Falling threshold against which to compare the value                                       |
| <b>alarmRisingEventIndex</b>  | Index (row) of the rising event in the event table                                         |
| <b>alarmFallingEventIndex</b> | Index (row) of the falling event in the event table                                        |

Both the **alarmStatus** and **eventStatus** fields are **entryStatus** primitives, as defined in RFC 2579, *Textual Conventions for SMIv2*.

### Troubleshooting RMON

You troubleshoot the RMON agent, **rmopd**, that runs on the router by inspecting the contents of the Juniper Networks enterprise RMON MIB, **jnxRmon**, which provides the extensions listed in [Table 226](#) to the RFC 2819 **alarmTable**.

Table 226: jnxRmon Alarm Extensions

| Field                                  | Description                                                             |
|----------------------------------------|-------------------------------------------------------------------------|
| <code>jnxRmonAlarmGetFailCnt</code>    | Number of times the internal <b>Get</b> request for the variable failed |
| <code>jnxRmonAlarmGetFailTime</code>   | Value of <b>sysUpTime</b> when the last failure occurred                |
| <code>jnxRmonAlarmGetFailReason</code> | Reason why the <b>Get</b> request failed                                |
| <code>jnxRmonAlarmGetOkTime</code>     | Value of <b>sysUpTime</b> when the variable moved out of failure state  |
| <code>jnxRmonAlarmState</code>         | Status of this alarm entry                                              |

Monitoring the extensions in this table provides clues as to why remote alarms may not behave as expected.

## Understanding Measurement Points, Key Performance Indicators, and Baseline Values

This chapter topic provides guidelines for monitoring the service quality of an IP network. It describes how service providers and network administrators can use information provided by Juniper Networks routers to monitor network performance and capacity. You should have a thorough understanding of the SNMP and the associated MIB supported by Junos OS.

**NOTE:** For a good introduction to the process of monitoring an IP network, see RFC 2330, *Framework for IP Performance Metrics*.

This topic contains the following sections:

- [Measurement Points on page 1884](#)
- [Basic Key Performance Indicators on page 1885](#)
- [Setting Baselines on page 1885](#)

### Measurement Points

Defining the measurement points where metrics are measured is equally as important as defining the metrics themselves. This section describes measurement points within the context of this chapter and helps identify where measurements can be taken from a service provider network. It is important to understand exactly where a measurement point is. Measurement points are vital to understanding the implication of what the actual measurement means.

An IP network consists of a collection of routers connected by physical links that are all running the Internet Protocol. You can view the network as a collection of routers with an ingress (entry) point and an egress (exit) point. See [Figure 34](#).

- Network-centric measurements are taken at measurement points that most closely map to the ingress and egress points for the network itself. For example, to measure delay across the provider network from Site A to Site B, the measurement points should be the ingress point to the provider network at Site A and the egress point at Site B.
- Router-centric measurements are taken directly from the routers themselves, but be careful to ensure that the correct router subcomponents have been identified in advance.

**Figure 34: Network Entry Points**

**NOTE:** Figure 34 does not show the client networks at customer premises, but they would be located on either side of the ingress and egress points. Although this chapter does not discuss how to measure network services as perceived by these client networks, you can use measurements taken for the service provider network as input into such calculations.

### Basic Key Performance Indicators

For example, you could monitor a service provider network for three basic key performance indicators (KPIs):

- *Availability* measures the “reachability” of one measurement point from another measurement point at the network layer (for example, using ICMP ping). The underlying routing and transport infrastructure of the provider network will support the availability measurements, with failures highlighted as unavailability.
- *Health* measures the number and type of errors that are occurring on the provider network, and can consist of both router-centric and network-centric measurements, such as hardware failures or packet loss.
- *Performance* of the provider network measures how well it can support IP services (for example, in terms of delay or utilization).

### Setting Baselines

How well is the provider network performing? We recommend an initial three-month period of monitoring to identify a network’s normal operational parameters. With this information, you can recognize exceptions and identify abnormal behavior. You should continue baseline monitoring for the lifetime of each measured metric. Over time, you must be able to recognize performance trends and growth patterns.

Within the context of this chapter, many of the metrics identified do not have an allowable operational range associated with them. In most cases, you cannot identify the allowable

operational range until you have determined a baseline for the actual variable on a specific network.

# Health Monitoring with SNMP

- [Configuring Health Monitoring on page 1887](#)

## Configuring Health Monitoring

---

- [Configuring Health Monitoring on Devices Running Junos OS on page 1887](#)

### Configuring Health Monitoring on Devices Running Junos OS

As the number of devices managed by a typical network management system (NMS) grows and the complexity of the devices themselves increases, it becomes increasingly impractical for the NMS to use polling to monitor the devices. A more scalable approach is to rely on network devices to notify the NMS when something requires attention.

On Juniper Networks routers, RMON alarms and events provide much of the infrastructure needed to reduce the polling overhead from the NMS. However, with this approach, you must set up the NMS to configure specific MIB objects into RMON alarms. This often requires device-specific expertise and customizing of the monitoring application. In addition, some MIB object instances that need monitoring are set only at initialization or change at runtime and cannot be configured in advance.

To address these issues, the health monitor extends the RMON alarm infrastructure to provide predefined monitoring for a selected set of object instances (for file system usage, CPU usage, and memory usage) and includes support for unknown or dynamic object instances (such as Junos OS processes).

Health monitoring is designed to minimize user configuration requirements. To configure health monitoring entries, include the **health-monitor** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
health-monitor {
  falling-threshold percentage;
  interval seconds;
  rising-threshold percentage;
}
```

You can use the **show snmp health-monitor** operational command to view information about health monitor alarms and logs.

This topic describes the minimum required configuration and discusses the following tasks for configuring the health monitor:

- [Monitored Objects on page 1888](#)
- [Minimum Health Monitoring Configuration on page 1889](#)
- [Configuring the Falling Threshold or Rising Threshold on page 1889](#)
- [Configuring the Interval on page 1889](#)
- [Log Entries and Traps on page 1890](#)

## Monitored Objects

When you configure the health monitor, monitoring information for certain object instances is available, as shown in [Table 227](#).

**Table 227: Monitored Object Instances**

| Object                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>jnxHrStoragePercentUsed.1</b>                                   | Monitors the following file system on the router or switch:<br><br><b>/dev/ad0s1a:</b><br><br>This is the root file system mounted on <b>/</b> .                                                                                                                                                                                                                                                                                                                                                                               |
| <b>jnxHrStoragePercentUsed.2</b>                                   | Monitors the following file system on the router or switch:<br><br><b>/dev/ad0s1e:</b><br><br>This is the configuration file system mounted on <b>/config</b> .                                                                                                                                                                                                                                                                                                                                                                |
| <b>jnxOperatingCPU (RE0)</b><br><b>jnxOperatingCPU (RE1)</b>       | Monitors CPU usage for Routing Engines ( <b>RE0</b> and <b>RE1</b> ). The index values assigned to Routing Engines depend on whether the Chassis MIB uses a zero-based or ones-based indexing scheme. Because the indexing scheme is configurable, the proper index is determined when the router or switch is initialized and when there is a configuration change. If the router or switch has only one Routing Engine, the alarm entry monitoring <b>RE1</b> is removed after five failed attempts to obtain the CPU value. |
| <b>jnxOperatingBuffer (RE0)</b><br><b>jnxOperatingBuffer (RE1)</b> | Monitors the amount of memory available on Routing Engines ( <b>RE0</b> and <b>RE1</b> ). Because the indexing of this object is identical to that used for <b>jnxOperatingCPU</b> , index values are adjusted depending on the indexing scheme used in the Chassis MIB. As with <b>jnxOperatingCPU</b> , the alarm entry monitoring <b>RE1</b> is removed if the router or switch has only one Routing Engine.                                                                                                                |
| <b>sysApplElmtRunCPU</b>                                           | Monitors the CPU usage for each Junos OS process (also called daemon). Multiple instances of the same process are monitored and indexed separately.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>sysApplElmtRunMemory</b>                                        | Monitors the memory usage for each Junos OS process. Multiple instances of the same process are monitored and indexed separately.                                                                                                                                                                                                                                                                                                                                                                                              |

### Minimum Health Monitoring Configuration

---

To enable health monitoring on the router or switch, include the **health-monitor** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]  
health-monitor;
```

### Configuring the Falling Threshold or Rising Threshold

---

The falling threshold is the lower threshold (expressed as a percentage of the maximum possible value) for the monitored variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the rising threshold. You must specify the falling threshold as a percentage of the maximum possible value. The default is **70** percent.

By default, the rising threshold is **80** percent of the maximum possible value for the monitored object instance. The rising threshold is the upper threshold for the monitored variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. You must specify the rising threshold as a percentage of the maximum possible value for the monitored variable.

To configure the falling threshold or rising threshold, include the **falling-threshold** or **rising-threshold** statement at the **[edit snmp health-monitor]** hierarchy level:

```
[edit snmp health-monitor]  
falling-threshold percentage;  
rising-threshold percentage;
```

*percentage* can be a value from 1 through 100.

The falling and rising thresholds apply to all object instances monitored by the health monitor.

### Configuring the Interval

---

The interval represents the period of time, in seconds, over which the object instance is sampled and compared with the rising and falling thresholds.

To configure the interval, include the **interval** statement and specify the number of seconds at the **[edit snmp health-monitor]** hierarchy level:

```
[edit snmp health-monitor]  
interval seconds;
```

*seconds* can be a value from 1 through 2147483647. The default is 300 seconds (5 minutes).

## Log Entries and Traps

---

The system log entries generated for any health monitor events (thresholds crossed, errors, and so on) have a corresponding **HEALTHMONITOR** tag rather than a generic **SNMPD\_RMON\_EVENTLOG** tag. However, the health monitor sends generic RMON **risingThreshold** and **fallingThreshold** traps.

## Configuration Statements at the `[edit snmp]` Hierarchy Level

This topic shows all possible configuration statements at the `[edit snmp]` hierarchy level and their level in the configuration hierarchy. When you are configuring Junos OS, your current hierarchy level is shown in the banner on the line preceding the `user@host#` prompt.

```
[edit]
snmp {
  client-list client-list-name {
    ip-addresses;
  }
  community community-name {
    authorization authorization;
    client-list-name client-list-name;
    clients {
      address <restrict>;
    }
    logical-system logical-system-name {
      routing-instance routing-instance-name;
      clients {
        address <restrict>;
      }
    }

## Complete SNMPv3 Configuration Statements

To configure SNMPv3, include the following statements at the **[edit snmp v3]** and **[edit snmp]** hierarchy levels:

```

[edit snmp]
engine-id {
  (local engine-id | use-mac-address | use-default-ip-address);
}
view view-name {
  oid object-identifier (include | exclude);
}
[edit snmp v3]
notify name {
  tag tag-name;
  type (trap | inform);
}
notify-filter profile-name {
  oid object-identifier (include | exclude);
}

```

```

snmp-community community-index {
  community-name community-name;
  security-name security-name;
  tag tag-name;
}
target-address target-address-name {
  address address;
  address-mask address-mask;
  logical-system logical-system;
  port port-number;
  retry-count number;
  routing-instance instance;
  tag-list tag-list;
  target-parameters target-parameters-name;
  timeout seconds;
}
target-parameters target-parameters-name {
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
usm {
  (local-engine | remote-engine engine-id) {
    user username {
      authentication-md5 {
        authentication-password authentication-password;
      }
      authentication-none;
      authentication-sha {
        authentication-password authentication-password;
      }
      privacy-3des {
        privacy-password privacy-password;
      }
      privacy-aes128 {
        privacy-password privacy-password;
      }
      privacy-des {
        privacy-password privacy-password;
      }
      privacy-none;
    }
  }
}
vacm {
  access {
    group group-name {
      (default-context-prefix | context-prefix context-prefix){
        security-model (any | usm | v1 | v2c) {
          security-level (authentication | none | privacy) {

## alarm (SNMP RMON)

---

**Syntax**    `alarm index {  
              description description;  
              falling-event-index index;  
              falling-threshold integer;  
              falling-threshold-interval seconds;  
              interval seconds;  
              request-type (get-next-request | get-request | walk-request);  
              rising-event-index index;  
              rising-threshold integer;  
              sample-type (absolute-value | delta-value);  
              startup-alarm (falling-alarm | rising-alarm | rising-or-falling alarm);  
              syslog-subtag syslog-subtag;  
              variable oid-variable;  
          }`

**Hierarchy Level**    [edit snmp rmon]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description**    Configure RMON alarm entries.

**Options**    *index*—Identifies this alarm entry as an integer.  
  
The remaining statements are explained separately.

**Required Privilege Level**    snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | The trap group that is used when generating a trap (if <b>eventType</b> is configured to send traps). If that trap group has the <b>rmon-alarm</b> trap category configured, a trap is sent to all the targets configured for that trap group. The community string in the trap matches the name of the trap group (and hence, the value of <b>eventCommunity</b> ). If nothing is configured, traps are sent to each group with the <b>rmon-alarm</b> category set. |
| <b>Options</b>                  | <b><i>community-name</i></b> —Identifies the trap group that is used when generating a trap if the event is configured to send traps.                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | The local engine ID is defined as the administratively unique identifier of an SNMPv3 engine, and is used for identification, not for addressing. There are two parts of an engine ID: prefix and suffix. The prefix is formatted according to the specifications defined in RFC 3411, <i>An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks</i> . You can configure the suffix here. |
| <div>  <p><b>NOTE:</b> SNMPv3 authentication and encryption keys are generated based on the associated passwords and the engine ID. If you configure or change the engine ID, you must commit the new engine ID before you configure SNMPv3 users. Otherwise the keys generated from the configured passwords are based on the previous engine ID.</p> <p>For the engine ID, we recommend using the MAC address of the management port.</p> </div> |                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Release Information      | Statement introduced in Junos OS Release 10.0                                                                                                                                                                                                                                                                                                                                                                                            |
| Description              | Add the <b>snmpTrapEnterprise</b> object, which shows the association between an enterprise-specific trap and the organization that defined the trap, to standard SNMP traps. By default, the <b>snmpTrapEnterprise</b> object is added only to the enterprise-specific traps. When the <b>enterprise-oid</b> statement is included in the configuration, <b>snmpTrapEnterprise</b> is added to all the traps generated from the device. |

| <b>Description</b>              | The lower threshold is expressed as a percentage of the maximum possible value for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the <b>rising-threshold</b> . |
| <b>Options</b>                  | <b><i>percentage</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> 1 through 100<br><b>Default:</b> 70 percent of the maximum possible value                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b>              | The lower threshold for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold, and the associated startup-alarm value is equal to falling-alarm value or rising-or-falling-alarm value. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the <b>rising-threshold</b> . |
| <b>Options</b>                  | <b><i>integer</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> -2,147,483,648 through 2,147,483,647<br><b>Default:</b> 20 percent less than <b>rising-threshold</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## group (Configuring Group Name)

```
Syntax  group group-name {
        (default-context-prefix | context-prefix context-prefix){
            security-model (any | usm | v1 | v2c) {
                security-level (authentication | none | privacy) {
                    notify-view view-name;
                    read-view view-name;
                    write-view view-name;
                }
            }
        }
    }
```

**Hierarchy Level** [edit snmp v3 vacm access]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Assign the security name to a group, and specify the SNMPv3 context applicable to the group. The **default-context-prefix** statement, when included, adds all the contexts configured on the device to the group, whereas the **context-prefix context-prefix** statement enables you to specify a context and to add that particular context to the group.

(Not applicable to the QFX Series and OCX Series.) When the context prefix is specified as default (for example, **context-prefix default**), the context associated with the master routing instance is added to the group. To specify a routing instance that is part of a logical system, specify it as **logical system/routing instance**. For example, to specify routing instance ri1 in logical system ls1, include **context-prefix ls1/ri1**.

The remaining statements under this hierarchy are explained separately.

**Options** *group-name*—SNMPv3 group name created for the SNMPv3 group.

**Required Privilege Level** snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Description</b>         | Configure vital log data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | <p><b>add&lt;oid&gt;</b>—Specify the OID to be used to collect the raw data.</p> <ul style="list-style-type: none"> <li><b>comment</b>—Specify the comment for the raw OID.</li> </ul> <p><b>file-size</b>—Specify the size of the current dump file.</p> <p><b>Range:</b> 1 MB to 100 MB.</p> <p><b>Default:</b> 5 MB for branch SRX Series devices and 10 MB for high-end SRX Series devices.</p> <p><b>files</b>—Specify the lifetime (number of days) for the dump file to be stored. The dump file is stored at <code>/var/log/vital/</code>.</p> <p><b>Range:</b> 1 to 30 days.</p> <p><b>Default:</b> 3 days.</p> <p><b>group</b>—Specify the pre-defined OID group to be used. Each group contains multiple OIDs within the same area. Once a group enabled, all OIDs in the group will be periodically collected and dumped.</p> <ul style="list-style-type: none"> <li><b>operating</b>—This group includes state, temperature, current CPU utilization percentage, buffer utilization percentage, heap-utilization percentage, up time, average-load in the last 1 minute, 5 minutes, or 15 minutes, and buffer-pool utilization percentage in the control plane of each operating component in the system.</li> <li><b>idp</b>—This group includes IDP data plane memory usage, IDP session usage and policies loaded number.</li> </ul> |

- **storage**—This group includes storage utilization of directory `/var/log`.
- **cluster-counter**—This group includes current total session number, total CPS, IPv4 CPS, IPv6 CPS, current total IPv4 session number, and current total IPv6 session number of both node 0 and node 1.
- **screen**—This group includes screen statistics of a specified zone.
- **spu**—This group includes CPU usage, memory usage, current flow session number, current CP session number, IPv4 session number, IPv6 session number, CP IPv4 session number, and CP IPv6 session number of the SPU.

**interval**—Specify the collection interval in minutes. The configuration takes effect immediately with new interval value.

**Range:** 1 to 1440 minutes.

**Default:** 10 minutes.

**storage-limit**—Specify the storage usage limit in percentage. If the current storage usage of the directory `/var/log/` is above the upper limit, collection is canceled but is tried next time.

**Range:** 1 to 100 percent.

**Default:** 80 percent.

| <b>Description</b>              | Upper threshold for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated startup alarm value is equal to the falling alarm or rising or falling alarm value. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. |
| <b>Options</b>                  | <i>integer</i> —The lower threshold for the alarm entry.<br><b>Range:</b> -2,147,483,648 through 2,147,483,647                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.0.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | The upper threshold is expressed as a percentage of the maximum possible value for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the <b>falling-threshold</b> . |
| <b>Options</b>                  | <b><i>percentage</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> 1 through 100<br><b>Default:</b> 80 percent of the maximum possible value                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## routing-engine (SNMP Resource Level)

**Syntax**    routing-engine {  
               resource <cpu | memory | open-files-count | process-count | storage | temperature> ;  
               {  
                   interval <interval in secs>;  
                   moderate-threshold <percentage level>;  
                   high-threshold <percentage level>;  
                   critical-threshold <percentage level>;  
                   action <monitor | prevent | recover>;  
               }  
           }

**Hierarchy Level**    [edit snmp health-monitor routing-engine]

**Release Information**    Statement introduced in Junos OS Release 12.1X44-D10. Statement modified in Junos OS Release 15.1X49-D10.

**Description**    Override the global configuration for a resource.

- Options**
- **interval**—Monitoring interval in seconds.  
       Default: 300 seconds
  - **moderate-threshold**—Percentage of moderate threshold level resource utilization.  
       Default: 70 percent.
  - **high-threshold** —Percentage of high-threshold level resource utilization.  
       Default: 80 percent.
  - **critical-threshold** —Percentage of critical threshold level resource utilization.  
       Default: 90 percent.
  - **action**—Enable action for all resources.  
       Default: If action is not enabled, the default action is prevent.

**WARNING:** If the system health management action for an affected resource is configured to recover, then certain intrusive operations necessary for preventing system breakdown are taken. Intrusive operations can include restarting or terminating processes, deleting files, and so on. Such action information is logged in the system health management history and system log.

**Required Privilege Level**    security—To view this statement in the configuration.  
                                   security-control—To add this statement to the configuration.

## routing-engine (SNMP Global Level)

**Syntax** routing-engine

```
{
  interval <interval in secs>;
  moderate-threshold <percentage level>;
  high-threshold <percentage level>;
  critical-threshold <percentage level>;
  traceoptions;
  action <monitor | prevent | recover>;
}
```

**Hierarchy Level** [edit snmp health-monitor routing-engine]

**Release Information** Statement introduced in Junos OS Release 12.1X44-D10. Statement modified in Junos OS Release 12.1X45-D10.

**Description** Enable the system health management feature to use the specified parameters.

- Options**
- **interval**—Monitoring interval in seconds.  
Default: 300 seconds
  - **moderate-threshold**—Percentage of moderate threshold level resource utilization.  
Default: 70 percent.
  - **high-threshold** —Percentage of high-threshold level resource utilization.  
Default: 80 percent.
  - **critical-threshold** —Percentage of critical threshold level resource utilization.  
Default: 90 percent.
  - **traceoptions**—Enable tracing of system health monitoring daemon.
  - **action**—Enable action for all resources.  
Default: If action is not enabled, the default is prevent.

**WARNING:** If the system health management action for an affected resource is configured to recover, then certain intrusive operations necessary for preventing system breakdown are taken. Intrusive operations can include restarting or terminating processes, deleting files, and so on. Such action information is logged in the system health management history and system log.

| <b>Description</b>              | Configure the address of an SNMP management application and the parameters to be used in sending notifications.                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>                  | <p><b><i>target-address-name</i></b>—String that identifies the target address.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                 |
| <b>Required Privilege Level</b> | snmp—To view this statement in the configuration.<br>snmp-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                 |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"><li>• <a href="#">Configuring the Trap Target Address on page 1821</a></li></ul>                                                                                                                                                                                                                                                                                                            |

## target-parameters

**Syntax** At the `[edit snmp v3]` hierarchy level:

```
target-parameters target-parameters-name {
  profile-name;
  parameters {
    message-processing-model (v1 | v2c | V3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
```

At the `[edit snmp v3 target-address target-address-name]` hierarchy level:

```
target-parameters target-parameters-name;
```

**Hierarchy Level** `[edit snmp v3]`  
`[edit snmp v3 target-address target-address-name]`

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure the message processing and security parameters for sending notifications to a particular management target. The target parameters are configured at the `[edit snmp v3]` hierarchy level. The remaining statements at this level are explained separately.

Then apply the target parameters configured at the `[edit snmp v3 target-parameters target-parameters-name]` hierarchy level to the target address configuration at the `[edit snmp v3]` hierarchy level.

**Required Privilege Level** snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Description</b>         | <p>The output of the tracing operations is placed into log files in the <b>/var/log</b> directory. Each log file is named after the SNMP agent that generates it. Currently, the following logs are created in the <b>/var/log</b> directory when the <b>traceoptions</b> statement is used:</p> <ul style="list-style-type: none"> <li>• chassisd</li> <li>• craftd</li> <li>• ilmids</li> <li>• mib2d</li> <li>• rmopd</li> <li>• serviced</li> <li>• snmpd</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—By default, the name of the log file that records trace output is the name of the process being traced (for example, <b>mib2d</b> or <b>snmpd</b>). Use this option to specify another name.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files per SNMP subagent. When a trace file (for example, <b>snmpd</b>) reaches its maximum size, it is archived by being renamed to <b>snmpd.0</b>. The previous <b>snmpd.1</b> is renamed to <b>snmpd.2</b>, and so on. The oldest archived file is deleted.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 10 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—Log all SNMP events.</li> <li>• <b>general</b>—Log general events.</li> </ul> |

- **interface-stats**—Log physical and logical interface statistics.
- **nonvolatile-sets**—Log nonvolatile SNMP set request handling.
- **pdu**—Log SNMP request and response packets.
- **protocol-timeouts**—Log SNMP response timeouts.
- **routing-socket**—Log routing socket calls.
- **subagent**—Log subagent restarts.
- **timer**—Log internally generated events.
- **varbind-error**—Log variable binding errors.

**match *regular-expression***—(Optional) Refine the output to include lines that contain the regular expression.

**size *size***—(Optional) Maximum size, in kilobytes (KB), of each trace file before it is closed and archived.

**Range:** 10 KB through 1 GB

**Default:** 1000 KB

**world-readable | no-world-readable**—(Optional) By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

Hierarchy Level [edit snmp v3]

Release Information Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Configure user-based security model (USM) information.

The remaining statements are explained separately.

**Required Privilege** snmp—To view this statement in the configuration.  
**Level** snmp-control—To add this statement to the configuration.

**Related** • [Creating SNMPv3 Users on page 1800](#)  
**Documentation** • [Configuring the Remote Engine and Remote User on page 1833](#)

| <b>Description</b>              | <p>Define a MIB view. A MIB view identifies a group of MIB objects. Each MIB object in a view has a common OID prefix. Each object identifier represents a subtree of the MIB object hierarchy. The <b>view</b> statement uses a view to specify a group of MIB objects on which to define access. To enable a view, you must associate the view with a community by including the <b>view</b> statement at the <b>[edit snmp community community-name]</b> hierarchy level.</p> |
|                                 | <div>  <p><b>NOTE:</b> To remove an OID completely, use the <b>delete view all oid oid-number</b> command but omit the <b>include</b> parameter.</p> </div>                                                                                                                                                                                                                                     |
| <b>Options</b>                  | <p><b>view-name</b>—Name of the view.</p> <p>The remaining statement is explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                |

| Field Name           | Field Description                                                           |
|----------------------|-----------------------------------------------------------------------------|
| Alarm Index          | Alarm identifier.                                                           |
| Variable description | Description of the health monitor object instance being monitored.          |
| Variable name        | Name of the health monitor object instance being monitored.                 |
| Value                | Current value of the monitored variable in the most recent sample interval. |

Table 228: show snmp health-monitor Output Fields (*continued*)

| Field Name           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>         | <p>State of the alarm or event entry:</p> <ul style="list-style-type: none"> <li>Alarms: <ul style="list-style-type: none"> <li><b>moderate-threshold</b>—Percentage of moderate threshold level resource utilization.</li> <li><b>high-threshold</b>—Percentage of high-threshold level resource utilization.</li> <li><b>critical-threshold</b>—Percentage of critical threshold level resource utilization.</li> <li><b>active</b>—Entry is fully configured and activated.</li> <li><b>falling threshold crossed</b>—Value of the variable has crossed the lower threshold limit.</li> <li><b>rising threshold crossed</b>—Value of the variable has crossed the upper threshold limit.</li> <li><b>under creation</b>—Entry is being configured and is not yet activated.</li> <li><b>startup</b>—Alarm is waiting for the first sample of the monitored variable.</li> <li><b>object not available</b>—Monitored variable of that type is not available to the health monitor agent.</li> <li><b>instance not available</b>—Monitored variable's instance is not available to the health monitor agent.</li> <li><b>object type invalid</b>—Monitored variable is not a numeric value.</li> <li><b>object processing errored</b>—An error occurred when the monitored variable was processed.</li> <li><b>unknown</b>—State is not one of the above.</li> </ul> </li> </ul> |
| <b>Variable OID</b>  | Object ID to which the variable name is resolved. The format is x.x.x.x.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Sample type</b>   | Method of sampling the monitored variable and calculating the value to compare against the upper and lower thresholds. It can have the value of <b>absolute value</b> or <b>delta value</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Startup alarm</b> | <p>Alarm that might be sent when this entry is first activated, depending on the following criteria:</p> <ul style="list-style-type: none"> <li>Alarm is sent when one of the following situations exists: <ul style="list-style-type: none"> <li>Value of the alarm is above or equal to the rising threshold and the startup type is either <b>rising alarm</b> or <b>rising or falling alarm</b>.</li> <li>Value of the alarm is below or equal to the falling threshold and the startup type is either <b>falling alarm</b> or <b>rising or falling alarm</b>.</li> </ul> </li> <li>Alarm is <i>not</i> sent when one of the following situations exists: <ul style="list-style-type: none"> <li>Value of the alarm is above or equal to the rising threshold and the startup type is <b>falling alarm</b>.</li> <li>Value of the alarm is below or equal to the falling threshold and the startup type is <b>rising alarm</b>.</li> <li>Value of the alarm is between the thresholds.</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Owner</b>         | Name of the entry configured by the user. If the entry was created through the CLI, the owner has <b>monitor</b> prepended to it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Creator</b>       | Mechanism by which the entry was configured ( <b>Health Monitor</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Table 228: show snmp health-monitor Output Fields (*continued*)

| Field Name          | Field Description                                                          |
|---------------------|----------------------------------------------------------------------------|
| Sample interval     | Time period between samples (in seconds).                                  |
| Rising threshold    | Upper limit threshold value as a percentage of the maximum possible value. |
| Falling threshold   | Lower limit threshold value as a percentage of the maximum possible value. |
| Rising event index  | Event triggered when the rising threshold is crossed.                      |
| Falling event index | Event triggered when the falling threshold is crossed.                     |

## Sample Output

### show snmp health-monitor

```
user@host> show snmp health-monitor
```

```

| <b>Output Fields</b>            | Table 230 describes the output fields for the <b>show snmp health-monitor routing-engine status</b> command. Output fields are listed in the approximate order in which they appear. |

**Table 230: show snmp health-monitor routing engine status Output Fields**

| Field Name    | Field Description                                                            |
|---------------|------------------------------------------------------------------------------|
| Alarm Index   | Alarm identifier.                                                            |
| Resource name | Name of the resource.                                                        |
| Current State | Current state of the monitored variable.                                     |
| Config Action | Displays the configured action.                                              |
| Threshold     | Displays the threshold value for medium, high, and critical as a percentage. |
| Interval      | Displays the time taken in seconds.                                          |

## Sample Output

### show snmp health-monitor routing-engine status

```
user@host> show snmp health-monitor routing-engine status
```

```
Health monitor status
```

| Alarm Index | Resource Name        | Current State | Config Action | Threshold (M/H/C)% | Interval (sec) |
|-------------|----------------------|---------------|---------------|--------------------|----------------|
| 32770       | MD3:/jail/mfs        | Active(47)    | Monitor       | 70/80/90           | 1              |

| <b>Syntax</b>                   | <code>show snmp mib (get   get-next   walk) (ascii   decimal) <i>object-id</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Release Information</b>      | Command introduced in Junos OS Release 9.4. Support for IPv4 and IPv6 systemwide policy statistics added in Junos OS Release 12.1X46-D10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Display local SNMP MIB object values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <p><b>get</b>—Retrieve and display one or more SNMP object values.</p> <p><b>get-next</b>—Retrieve and display the next SNMP object values.</p> <p><b>walk</b>—Retrieve and display the SNMP object values that are associated with the requested object identifier (OID). When you use this option, the Junos OS displays the objects below the subtree that you specify.</p> <p><b>ascii</b>—Display the SNMP object's string indices as an ASCII-key representation.</p> <p><b>decimal</b>—Display the SNMP object values in the decimal (default) format. The <b>decimal</b> option is the default option for this command. Therefore, issuing the <b>show snmp mib (get   get-next   walk) decimal object-id</b> and the <b>show snmp mib (get   get-next   walk) object-id</b> commands display the same output.</p> <p><b>object-id</b>—The object can be represented by a sequence of dotted integers (such as 1.3.6.1.2.1.2) or by its subtree name (such as <b>interfaces</b>). When entering multiple objects, enclose the objects in quotation marks.</p> |
|                                 | <p> <b>NOTE:</b> On all high-end SRX Series devices, the <b>show snmp mib</b> command will not display the output for security related MIBs. We recommend that you use an SNMP client and prefix <b>logical-system-name@</b> to the community name. For example, if the community is <b>public</b>, use <b>default@public</b> for default root logical system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Required Privilege Level</b> | <b>snmp</b> —To view this statement in the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 232: show system log-vital Output fields**

| Field Name | Field Description                                    |
|------------|------------------------------------------------------|
| Node       | Identification number of the node. It can be 0 or 1. |
| SPU        | Identification of Services Processing Unit.          |
| CPU        | CPU usage of SPU in percentage.                      |
| Mem        | Memory usage of SPU in percentage.                   |
| Flow-Sess  | Number of flow sessions.                             |
| CP-Sess    | Number of central point sessions.                    |
| IPv4-Sess  | Number of IPv4 sessions.                             |
| IPv6-Sess  | Number of IPv6 sessions.                             |
| CP-IPv4    | Number of central point IPv4 sessions.               |
| CP-IPv6    | Number of central point IPv6 sessions.               |

Table 232: show system log-vital Output fields (*continued*)

| Field Name               | Field Description                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| OID list                 | OIDs that are being monitored.                                                                                    |
| OID number               | Number of OIDs that are being monitored.                                                                          |
| Group SPU list           | SPUs that are being monitored.                                                                                    |
| Group SPU number         | Number of SPU's that are being monitored.                                                                         |
| Group screen list        | Security zones whose screen stats are being monitored.                                                            |
| Group screen number      | Number of security zones whose screen stats are being monitored.                                                  |
| Group                    | A set of OIDs. Once a group is enabled, all OIDs in the group are monitored.                                      |
| interval                 | Number of minutes used for the data collection interval.                                                          |
| file-days                | Number of days for the dump file to be stored.                                                                    |
| storage-limit            | Storage usage limit in percentage.                                                                                |
| file-size                | Size of the current dump file.                                                                                    |
| state                    | Number that indicates which state the current collection is in. It could indicate <b>IDLE</b> or <b>ONGOING</b> . |
| snmp mgmt-sock op number | Stat number of the querying MIB.                                                                                  |
| current timer counter    | Number that indicates the collection timer.                                                                       |

## Accessing Standards Documents on the Internet

---

The following information about the location of standards on the Internet is accurate as of February 2011. It is subject to change and is provided only as a courtesy to the reader.

Information about accessing MIBs is provided in the entry for each MIB.

- ANSI standards are published by the American National Standards Institute. You can search for specific standards at <http://webstore.ansi.org>.
- FRF (Frame Relay Forum) standards are published by the Broadband Forum. They can be accessed at <http://www.broadband-forum.org>.
- GR (Generic Requirements) standards are published by Telcordia. Information about them can be accessed by clicking the “Document Center” link at <http://telecom-info.telcordia.com/site-cgi/ido/>.
- IEEE standards are published by the Institute of Electrical and Electronics Engineers. They can be accessed at <http://standards.ieee.org/getieee802/index.html>.
- ISO/IEC standards are published by the International Organization for Standardization/International Electrotechnical Commission. They can be accessed at [http://www.iso.org/iso/iso\\_catalogue/catalogue\\_tc/](http://www.iso.org/iso/iso_catalogue/catalogue_tc/).
- INCITS standards are published by the InterNational Committee for Information Technology Standards. They can be accessed at <https://standards.incits.org/>.
- Internet drafts are published by the Internet Engineering Task Force (IETF). They can be accessed at <http://tools.ietf.org/id/>.
- ITU–T Recommendations are published by the International Telecommunication Union. They can be accessed at <http://www.itu.int/rec/T-REC>.
- RFCs are published by the IETF. They can be accessed at <http://www.ietf.org/rfc.html>.

## Supported BOOTP and DHCP Standards

---

The Junos OS substantially supports the following RFCs, which define standards for bootstrap protocol (BOOTP) and Dynamic Host Control Protocol (DHCP):

- RFC 951, *BOOTSTRAP PROTOCOL (BOOTP)*
- RFC 1001, *PROTOCOL STANDARD FOR A NetBIOS SERVICE ON A TCP/UDP TRANSPORT: CONCEPTS AND METHODS*
- RFC 1002, *PROTOCOL STANDARD FOR A NetBIOS SERVICE ON A TCP/UDP TRANSPORT: DETAILED SPECIFICATIONS*
- RFC 1035, *DOMAIN NAMES - IMPLEMENTATION AND SPECIFICATION*
- RFC 1534, *Interoperation Between DHCP and BOOTP*
- RFC 1700, *ASSIGNED NUMBERS*
- RFC 2131, *Dynamic Host Configuration Protocol*
- DHCP over virtual LAN (VLAN)-tagged interfaces is not supported.
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 3046, *DHCP Relay Agent Information Option*
- RFC 3118, *Authentication for DHCP Messages*

Only Section 4, "Configuration token," is supported.

- RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*
- Address assignment is supported with IP version 4 (IPv4) but not IP version 6 (IPv6).
- RFC 3397, *Dynamic Host Configuration Protocol (DHCP) Domain Search Option*

- RFC 3633, *IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6*
- RFC 3925, *Vendor-Identifying Vendor Options for Dynamic Host Configuration Protocol version 4 (DHCPv4)*
- RFC 4649, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6) Relay Agent Remote-ID Option*

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported Mobile IP Standards

The Junos OS supports only static configuration of home agent addresses and IP tunnels; dynamic configuration is not supported. The Junos OS does not support the Mobile IP foreign agent, accounting, QoS, policy, data path, or logical interfaces per mobile node (for a mobile subscriber).

The Junos OS substantially supports the following RFCs, which define standards for Mobile IP:

- RFC 2794, *Mobile IP Network Access Identifier Extension for IPv4*
- RFC 3024, *Reverse Tunneling for Mobile IP, revised*
- RFC 3344, *IP Mobility Support for IPv4*

Only the Mobile IP home agent is supported.

- RFC 3543, *Registration Revocation in Mobile IPv4*
- RFC 4433, *Mobile IPv4 Dynamic Home Agent (HA) Assignment*

The following RFC does not define a standard, but provides information about Mobile IP. The IETF classifies it as “Informational.”

- RFC 2977, *Mobile IP Authentication, Authorization, and Accounting Requirements*  
Accounting is not supported.

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Network Management Standards

The Junos OS supports the majority of network management features defined in the following standards documents:

- Extended Security Options (ESO) Consortium, *ESO Consortium MIB*.

As of February 2011, the text of this MIB is accessible at

<http://www.snmp.com/eso/esoConsortiumMIB.txt>.

- Institute of Electrical and Electronics Engineers (IEEE) Standard 802.3ad, *Aggregation of Multiple Link Segments* (published as Clause 43 in Section 3 of the 802.3 specification)

Only the following MIB objects are supported:

- dot3adAggPortDebugActorChangeCount**
- dot3adAggPortDebugActorSyncTransitionCount**
- dot3adAggPortDebugMuxState**
- dot3adAggPortDebugPartnerChangeCount**
- dot3adAggPortDebugPartnerSyncTransitionCount**
- dot3adAggPortDebugRxState**
- dot3adAggPortListTable**
- dot3adAggPortStatsTable**
- dot3adAggPortTable**
- dot3adAggTable**
- dot3adTablesLastChanged**
- Integrated Local Management Interface (ILMI) MIB in the *Integrated Local Management Interface (ILMI) Specification, Version 4.0*.

As of February 2011, this document is accessible at

<http://www.broadband-forum.org/ftp/pub/approved-specs/af-ilmi-0065.000.pdf>.

Only the **atmfMYIPNmAddress** and **atmfPortMyIfname** objects are supported.

- Internet Assigned Numbers Authority (IANA), *IANAiftype Textual Convention MIB* (referenced by RFC 2863, *The Interfaces Group MIB*)

As of February 2011, the text of this MIB is accessible at

<http://www.iana.org/assignments/ianaiftype-mib>.

- RFC 1122, *Requirements for Internet Hosts -- Communication Layers*
- RFC 1155, *Structure and Identification of Management Information for TCP/IP-based Internets*
- RFC 1156, *Management Information Base for Network Management of TCP/IP-based internets*

- RFC 1157, *A Simple Network Management Protocol (SNMP)*
- RFC 1195, *Use of OSI IS-IS for Routing in TCP/IP and Dual Environments*

Only the following MIB objects are supported:

- **isisAdjIPAddr**
  - **isisAreaAddr**
  - **isisCirc**
  - **isisCircLevel**
  - **isisIPRA**
  - **isisISAdj**
  - **isisISAdjAreaAddr**
  - **isisISAdjProtSupp**
  - **isisMANAreaAddr**
  - **isisPacketCount**
  - **isisRa**
  - **isisSysProtSupp**
  - **isisSummAddr**
  - **isisSystem**
- RFC 1212, *Concise MIB Definitions*
  - RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II*

Only the following features are supported:

- Junos-specific secured access list
  - Master configuration keywords
  - MIB II and its SNMP version 2 derivatives, including the following:
    - Interface management
    - IP (except for the **ipRouteTable** object which has been replaced by **ipCidrRouteTable** [RFC 2096, *IP Forwarding Table MIB*])
    - SNMP management
    - Statistics counters
  - Reconfigurations upon receipt of the SIGHUP signal
  - SNMP version 1 **Get** and **GetNext** requests and version 2 **GetBulk** requests
- RFC 1215, *A Convention for Defining Traps for use with the SNMP*

Only MIB II SNMP version 1 traps and version 2 notifications are supported.

- RFC 1406, *Definitions of Managed Objects for the DS1 and E1 Interface Types* (obsoleted by RFC 2495)

The T1 MIB is supported.

- RFC 1407, *Definitions of Managed Objects for the DS3/E3 Interface Type* (obsoleted by RFC 2496)

The T3 MIB is supported.

- RFC 1472, *The Definitions of Managed Objects for the Security Protocols of the Point-to-Point Protocol*
- RFC 1473, *The Definitions of Managed Objects for the IP Network Control Protocol of the Point-to-Point Protocol*
- RFC 1657, *Definitions of Managed Objects for the Fourth Version of the Border Gateway Protocol (BGP-4) using SMIv2*

The **bgpBackwardTransition** and **bgpEstablished** notifications are not supported.

- RFC 1695, *Definitions of Managed Objects for ATM Management Version 8.0 Using SMIv2* (obsoleted by RFC 2515)
- RFC 1724, *RIP Version 2 MIB Extension*
- RFC 1850, *OSPF Version 2 Management Information Base*

The following features are not supported:

- Host Table
- **ospfLsdbApproachingOverflow** trap
- **ospfLsdbOverflow** trap
- **ospfOriginateLSA** trap
- **ospfOriginateNewLsas** MIB object
- **ospfRxNewLsas** MIB object
- RFC 1905, *Protocol Operations for Version 2 of the Simple Network Management Protocol (SNMPv2)* (obsoleted by RFC 3416)
- RFC 1907, *Management Information Base for Version 2 of the Simple Network Management Protocol (SNMPv2)* (obsoleted by RFC 3418)
- RFC 2011, *SNMPv2 Management Information Base for the Internet Protocol using SMIv2*
- RFC 2012, *SNMPv2 Management Information Base for the Transmission Control Protocol using SMIv2*
- RFC 2013, *SNMPv2 Management Information Base for the User Datagram Protocol using SMIv2*
- RFC 2068, *Hypertext Transfer Protocol -- HTTP/1.1*

- RFC 2096, *IP Forwarding Table MIB*

The **ipCidrRouteTable** object is extended to include the tunnel name when the next hop is through an RSVP-signaled label-switched path (LSP).

- RFC 2115, *Management Information Base for Frame Relay DTEs Using SMIv2*

Only the **frDlcmiTable** object is supported.

- RFC 2233, *The Interfaces Group MIB using SMIv2* (obsoleted by RFC 2863)
- RFC 2287, *Definitions of System-Level Managed Objects for Applications*

Only the following MIB objects are supported:

- **sysApplElmtRunTable**
- **sysApplInstallElmtTable**
- **sysApplInstallPkgTable**
- **sysApplMapTable**

- RFC 2465, *Management Information Base for IP Version 6: Textual Conventions and General Group*

IP version 6 (IPv6) and Internet Control Message Protocol version 6 (ICMPv6) statistics are not supported.

- RFC 2466, *Management Information Base for IP Version 6: ICMPv6 Group*
- RFC 2495, *Definitions of Managed Objects for the DS1, E1, DS2 and E2 Interface Types*

The following MIB objects are not supported:

- **dsx1FarEndConfigTable**
- **dsx1FarEndCurrentTable**
- **dsx1FarEndIntervalTable**
- **dsx1FarEndTotalTable**
- **dsx1FracTable**

- RFC 2496, *Definitions of Managed Objects for the DS3/E3 Interface Type*

The following MIB objects are not supported:

- **dsx3FarEndConfigTable**
- **dsx3FarEndCurrentTable**
- **dsx3FarEndIntervalTable**
- **dsx3FarEndTotalTable**
- **dsx3FracTable**

- RFC 2515, *Definitions of Managed Objects for ATM Management*

The following MIB objects are not supported:

- **aal5VccTable**
- **atmVcCrossConnectTable**
- **atmVpCrossConnectTable**
- RFC 2558, *Definitions of Managed Objects for the SONET/SDH Interface Type* (obsoleted by RFC 3592)
- RFC 2571, *An Architecture for Describing SNMP Management Frameworks*  
Only read-only access is supported.
- RFC 2572, *Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)* (obsoleted by RFC 3412)  
Only read-only access is supported.
- RFC 2578, *Structure of Management Information Version 2 (SMIv2)*
- RFC 2579, *Textual Conventions for SMIv2*
- RFC 2580, *Conformance Statements for SMIv2*
- RFC 2665, *Definitions of Managed Objects for the Ethernet-like Interface Types*
- RFC 2667, *IP Tunnel MIB*
- RFC 2787, *Definitions of Managed Objects for the Virtual Router Redundancy Protocol*

The following features are not supported:

- Row creation
- **Set** operation
- **vrrpStatsPacketLengthErrors** MIB object
- RFC 2790, *Host Resources MIB*

Only the following MIB objects are supported:

- **hrStorageTable** object. The file systems **/**, **/config**, **/var**, and **/tmp** always return the same index number. When SNMP restarts, the index numbers for the remaining file systems might change.
- Objects in the **hrSystem** group.
- Objects in the **hrSWInstalled** group.
- RFC 2819, *Remote Network Monitoring Management Information Base*

Only the following MIB objects are supported:

- **alarmTable**
- **etherStatsTable** object for Ethernet interfaces

- **eventTable**
- **logTable**
- RFC 2863, *The Interfaces Group MIB*
- RFC 2864, *The Inverted Stack Table Extension to the Interfaces Group MIB*
- RFC 2925, *Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations*

Only the following MIB objects are supported:

- **pingCtlTable**
- **pingMaxConcurrentRequests**
- **pingProbeHistoryTable**
- **pingResultsTable**
- **traceRouteCtlTable**
- **traceRouteHopsTable**
- **traceRouteProbeHistoryTable**
- **traceRouteResultsTable**
- RFC 2932, *IPv4 Multicast Routing MIB*
- RFC 2933, *Internet Group Management Protocol MIB*
- RFC 2981, *Event MIB*
- RFC 3014, *Notification Log MIB*
- RFC 3019, *IP Version 6 Management Information Base for The Multicast Listener Discovery Protocol*
- RFC 3411, *An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks*
- RFC 3412, *Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)*
- RFC 3413, *Simple Network Management Protocol (SNMP) Applications*

The proxy MIB is not supported.

- RFC 3414, *User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)*
- RFC 3415, *View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)*
- RFC 3416, *Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)*
- RFC 3417, *Transport Mappings for the Simple Network Management Protocol (SNMP)*

- RFC 3418, *Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)*
- RFC 3498, *Definitions of Managed Objects for Synchronous Optical Network (SONET) Linear Automatic Protection Switching (APS) Architectures*

Support is implemented under the Juniper Networks enterprise branch.

- RFC 3592, *Definitions of Managed Objects for the Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH) Interface Type*
- RFC 3811, *Definitions of Textual Conventions (TCs) for Multiprotocol Label Switching (MPLS) Management*
- RFC 3812, *Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Management Information Base (MIB)*

Only read-only access is supported, and the following features and MIB objects are not supported:

- MPLS tunnels as interfaces
- `mplsTunnelCRLDPResTable` object
- `mplsTunnelPerfTable` object
- The following objects in the `TunnelResource` table:
  - `mplsTunnelResourceExBurstSize`
  - `mplsTunnelResourceMaxBurstSize`
  - `mplsTunnelResourceMeanBurstSize`
  - `mplsTunnelResourceMeanRate`
  - `mplsTunnelResourceWeight`

The `mplsTunnelCHopTable` object is supported on ingress routers only.

**NOTE:** The branch used by the proprietary LDP MIB (`ldpmib.mib`) conflicts with RFC 3812. `ldpmib.mib` has been deprecated and replaced by `jnx-mpls-ldp.mib`.

- RFC 3813, *Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)*

Only read-only access is supported, and the following MIB objects are not supported:

- `mplsInSegmentMapTable`
- `mplsInSegmentPerfTable`
- `mplsInterfacePerfTable`
- `mplsOutSegmentPerfTable`

- **mplsXCDown**
- **mplsXCUp**
- RFC 3815, *Definitions of Managed Objects for the Multiprotocol Label Switching (MPLS), Label Distribution Protocol (LDP)*

Only the following MIB objects are supported:

- **mplsLdpLsrID**
- **mplsLdpSesPeerAddrTable**
- RFC 3826, *The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model*
- RFC 4188, *Definitions of Managed Objects for Bridges*
- Internet draft draft-ietf-bfd-mib-02.txt, *Bidirectional Forwarding Detection Management Information Base*

Only read-only access is supported, and the **bfdSessDown** and **bfdSessUp** traps are supported. Objects in the **bfdSessMapTable** and **bfdSessPerfTable** tables are not supported. The MIB that supports this draft is **mib-jnx-bfd-exp.txt** under the Juniper Networks Enterprise **jnxExperiment** branch.

- Internet draft draft-ietf-idr-bgp4-mibv2-04.txt, *Definitions of Managed Objects for the Fourth Version of Border Gateway Protocol (BGP-4), Second Version*

Only the following MIB objects are supported:

- **jnxBgpM2PrefixInPrefixes**
- **jnxBgpM2PrefixInPrefixesAccepted**
- **jnxBgpM2PrefixInPrefixesRejected**
- Internet draft draft-ietf-isis-wg-mib-07.txt, *Management Information Base for IS-IS*

Only the following tables are supported:

- **isisISAdjAreaAddrTable**
- **isisISAdjIPAddrTable**
- **isisISAdjProtSuppTable**
- **isisISAdjTable**
- Internet draft draft-ietf-msdp-mib-08.txt, *Multicast Source Discovery protocol MIB*

The following MIB objects are not supported:

- **msdpBackwardTransition**
- **msdpEstablished**
- **msdpRequestsTable**

- Internet draft draft-ietf-ospf-ospfv3-mib-11.txt, *Management Information Base for OSPFv3*

Only read-only access is supported, and only for the **ospfv3NbrTable** table. The MIB that supports this draft is **mib-jnx-ospfv3mib.txt** under the Juniper Networks Enterprise **jnxExperiment** branch; MIB object names are prefixed with **jnx** (for example, **jnxOspfv3NbrAddressType**).

- Internet draft draft-reeder-snmpv3-usm-3desede-00.txt, *Extension to the User-Based Security Model (USM) to Support Triple-DES EDE in “Outside” CBC Mode*

The following RFCs do not define standards, but provide information about network management. The IETF classifies them variously as “Best Current Practice,” “Experimental” or “Informational.”

- RFC 1901, *Introduction to Community-based SNMPv2*
- RFC 2330, *Framework for IP Performance Metrics*
- RFC 2934, *Protocol Independent Multicast MIB for IPv4*
- RFC 3410, *Introduction and Applicability Statements for Internet Standard Management Framework*
- RFC 3584, *Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework*

#### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported RADIUS and TACACS+ Standards for User Authentication

For validation of the identity of users who attempt to access a router, the Junos OS supports RADIUS authentication, TACACS+ authentication, and authentication by means of Junos user accounts configured on the router. The Junos OS supports the configuration of Juniper Networks-specific RADIUS and TACACS+ attributes, and the creation of template accounts.

All users who can log in to the router must already be assigned to a Junos login class. A *login class* defines its members' access privileges during a login session, the commands they can and cannot issue, the configuration statements they can and cannot view or change, and the idle time before a member's login session is terminated.

The Junos OS substantially supports the following RFCs, which define standards for RADIUS and TACACS+:

- RFC 1492, *An Access Control Protocol, Sometimes Called TACACS*
- RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
- RFC 3162, *RADIUS and IPv6*
- RFC 4818, *RADIUS Delegated-IPv6-Prefix Attribute*

The following Internet drafts do not define standards, but provide information about RADIUS. The IETF classifies them as “Informational.”

- RFC 2866, *RADIUS Accounting*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
- RFC 2869, *RADIUS Extensions*
- RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*
- RFC 5176, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*

- Related Documentation**

---

## Supported System Access Standards

The Junos OS substantially supports the following protocols and applications for remote access to routers: telnet, FTP, rlogin, and finger. In addition, the Canada and U.S. version of the Junos OS substantially supports SSH as an access protocol.

The Junos OS substantially supports RFC 1994, *PPP Challenge Handshake Authentication Protocol (CHAP)*.

The Canada and U.S. version of the Junos OS substantially supports the following RFCs, which define standards for technologies used with Secure Sockets Layer (SSL):

- RFC 1319, *The MD2 Message-Digest Algorithm*
- RFC 1321, *The MD5 Message-Digest Algorithm*
- RFC 2246, *The TLS Protocol Version 1.0*
- RFC 3280, *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*

The following RFCs provide information about TFTP, which Junos OS supports as a remote access protocol. The IETF does not include the RFCs in its Standards track, instead assigning them status “Unknown (Legacy Stream)”.

- RFC 783, *THE TFTP PROTOCOL (REVISION 2)*.
- RFC 906, *Bootstrap Loading using TFTP*.

- Related Documentation**
- [Supported RADIUS and TACACS+ Standards for User Authentication on page 2017](#)
  - [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Time Synchronization Standard

---

The Junos OS substantially supports RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*.

RFC 2030, *Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI*, does not define a standard, but provides information about time synchronization technology. The IETF classifies it as “Informational.”

In CLI operational mode, you can set the current date and time on the router manually or from an NTP server.

- [Supported Serial Interface Standards on page 2026](#)
- [Supported T3 Interface Standard on page 2026](#)

### Supported ATM Interface Standards

---

The Junos OS substantially supports the following standards for Asynchronous Transfer Mode (ATM) interfaces:

- International Telecommunication Union–Telecommunication Standardization (ITU–T) Recommendation I.432.3, *B-ISDN user-network interface - Physical layer specification: 1544 kbit/s and 2048 kbit/s operation*
- RFC 1483, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*  
Only routed protocol data units (PDUs) are supported.
- RFC 2225, *Classical IP and ARP over ATM*  
Only responses are supported.
- RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*  
Only routed PDUs and Ethernet bridged PDUs are supported.

#### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Ethernet Interface Standards

---

The Junos OS substantially supports the following standards for Ethernet interfaces:

- Institute of Electrical and Electronics Engineers (IEEE) Standard 802.1ag, *IEEE Standard for Local and metropolitan area networks—Virtual Bridged Local Area Networks, Amendment 5: Connectivity Fault Management*
- IEEE Standard 802.1ah, *IEEE Standard for Local and metropolitan area networks—Virtual Bridged Local Area Networks, Amendment 7: Provider Backbone Bridges*
- IEEE Standard 802.1Q, *IEEE Standard for Local and metropolitan area networks—Virtual Bridged Local Area Networks*
- IEEE Standard 802.1Qbb, *IEEE Standard for Local and Metropolitan Area Networks---Virtual Bridged Local Area Networks - Amendment: Enhanced Transmission Selection*
- IEEE Standard 802.1Qbb, *IEEE Standard for Local and Metropolitan Area Networks---Virtual Bridged Local Area Networks - Amendment: Priority-based Flow Control*
- IEEE Standard 802.1s, *IEEE Standard for Multiple Instances of Spanning Tree Protocol (MSTP)---Virtual Bridged Local Area Networks*
- IEEE Standard 802.3, *IEEE Standard for Information technology—Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements, Part 3: Carrier sense multiple access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications*
- IEEE Standard 802.3ab, *1000BASE-T* (published as Clause 40 in Section 3 of the 802.3 specification)
- IEEE Standard 802.3ad, *Aggregation of Multiple Link Segments* (published as Clause 43 in Section 3 of the 802.3 specification)
- IEEE Standard 802.3ae, *10-Gigabit Ethernet* (published as Clauses 44-53 in Section 4 of the 802.3 specification)
- IEEE Standard 802.3ah, *Operations, Administration, and Maintenance (OAM)* (published as Clause 57 in Section 5 of the 802.3 specification)
- IEEE Standard 802.3z, *1000BASE-X* (published as Clauses 34-39, 41-42 in Section 3 of the 802.3 specification)
- InterNational Committee for Information Technology Standards (INCITS) T11, *Fibre Channel Interfaces*
- International Telecommunication Union—Telecommunication Standardization (ITU-T) Recommendation Y.1731, *OAM functions and mechanisms for Ethernet based networks*

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Frame Relay Interface Standards

The Junos OS substantially supports the following standards for Frame Relay interfaces:

- American National Standards Institute (ANSI), *Annex D, Additional Procedures for Permanent Virtual Connections (PVCs) Using Unnumbered Information Frames* to T1.617-1991, *Integrated Services Digital Network (ISDN)—Signaling Specification for Frame Relay Bearer Service for Digital Subscriber Signaling System Number 1 (DSS1)*
- Broadband Forum standard FRF.12, *Frame Relay Fragmentation Implementation Agreement*
- FRF.15, *End-to-End Multilink Frame Relay Implementation Agreement*
- FRF.16.1, *Multilink Frame Relay UNI/NNI Implementation Agreement*
- International Telecommunication Union–Telecommunication Standardization (ITU–T), *Annex A, Additional procedures for Permanent Virtual Connection (PVC) status management (using Unnumbered Information frames)* to Recommendation Q.933, *ISDN Digital Subscriber Signalling System No. 1 (DSS1) - Signalling specifications for frame mode switched and permanent virtual connection control and status monitoring*
- RFC 1973, *PPP in Frame Relay*
- RFC 2390, *Inverse Address Resolution Protocol*
- RFC 2427, *Multiprotocol Interconnect over Frame Relay* (obsoletes RFC 1490)
- RFC 2590, *Transmission of IPv6 Packets over Frame Relay Networks Specification*
- Internet draft draft-martini-frame-encap-mpls-01.txt, *Frame Relay Encapsulation over Pseudo-Wires* (expires December 2002)

Translation of the command/response bit and sequence numbers and padding are not supported.

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported GRE and IP-IP Interface Standards

The Junos OS substantially supports the following RFCs, which define standards for generic routing encapsulation (GRE) and IP-IP interfaces:

- RFC 2003, *IP Encapsulation within IP*
- RFC 2784, *Generic Routing Encapsulation (GRE)*
- RFC 2890, *Key and Sequence Number Extensions to GRE*

The key field is supported, but the sequence number field is not.

The following RFCs do not define standards, but provide information about GRE, IP-IP, and related technologies. The IETF classifies them as “Informational.”

- RFC 1701, *Generic Routing Encapsulation (GRE)*

- RFC 1702, *Generic Routing Encapsulation over IPv4 networks*
- RFC 2547, *BGP/MPLS VPNs* (over GRE tunnels)

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported PPP Interface Standards

The Junos OS substantially supports the following RFCs, which define standards for Point-to-Point Protocol (PPP) interfaces:

- RFC 1332, *The PPP Internet Protocol Control Protocol (IPCP)*
- RFC 1334, *PPP Authentication Protocols*
- RFC 1661, *The Point-to-Point Protocol (PPP)*
- RFC 1662, *PPP in HDLC-like Framing*
- RFC 1989, *PPP Link Quality Monitoring*
- RFC 1990, *The PPP Multilink Protocol (MP)*
- RFC 2364, *PPP Over AAL5*
- RFC 2615, *PPP over SONET/SDH*
- RFC 2686, *The Multi-Class Extension to Multi-Link PPP*

The following features are not supported:

- Negotiation of address field compression and protocol field compression PPP NCP options; instead, a full 4-byte PPP header is always sent
- Prefix elision
- RFC 3021, *Using 31-Bit Prefixes on IPv4 Point-to-Point Links*

The following RFCs do not define standards, but provide information about PPP. The IETF classifies them as “Informational.”

- RFC 1877, *PPP Internet Protocol Control Protocol Extensions for Name Server Addresses*
- RFC 2153, *PPP Vendor Extensions*

**Related  
Documentation**

---

## Supported SDH and SONET Interface Standards

---

The Junos OS substantially supports the following standards for SDH and SONET interfaces:

- American National Standards Institute (ANSI) standard T1.105-2001, *Synchronous Optical Network (SONET) – Basic Description including Multiplex Structure, Rates, and Formats*
- ANSI standard T1.105.02-2001, *Synchronous Optical Network (SONET) – Payload Mappings*
- ANSI standard T1.105.06-2002, *Synchronous Optical Network (SONET): Physical Layer Specifications*
- GR-253-CORE (Telcordia Generic Requirements standard), *Synchronous Optical Network (SONET) Transport Systems: Common Generic Criteria* (replaces GR-1377-CORE, SONET OC-192 Transport System Generic Criteria)
- GR-499-CORE, *Transport Systems Generic Requirements (TSGR): Common Requirements*
- International Telecommunication Union–Telecommunication Standardization (ITU–T) Recommendation G.691, *Optical interfaces for single channel STM-64 and other SDH systems with optical amplifiers*
- ITU–T Recommendation G.707 (1996), *Network node interface for the synchronous digital hierarchy (SDH)*
- ITU–T Recommendation G.783 (1994), *Characteristics of synchronous digital hierarchy (SDH) equipment functional blocks*
- ITU–T Recommendation G.813 (1996), *Timing characteristics of SDH equipment slave clocks (SEC)*
- ITU–T Recommendation G.825 (1993), *The control of jitter and wander within digital networks which are based on the synchronous digital hierarchy (SDH)*
- ITU–T Recommendation G.826 (1999), *Error performance parameters and objectives for international, constant bit-rate digital paths at or above the primary rate*
- ITU–T Recommendation G.831 (1993), *Management capabilities of transport networks based on the synchronous digital hierarchy (SDH)*
- ITU–T Recommendation G.957 (1995), *Optical interfaces for equipments and systems relating to the synchronous digital hierarchy*
- ITU–T Recommendation G.958 (1994), *Digital line systems based on the synchronous digital hierarchy for use on optical fibre cables*
- ITU–T Recommendation I.432 (1993), *B-ISDN user-network interface – Physical layer specification*
- RFC 1619, *PPP over SONET/SDH*

- Related Documentation**
- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Serial Interface Standards

---

The Junos OS substantially supports the following standards for serial interfaces:

- International Telecommunication Union–Telecommunication Standardization (ITU–T) Recommendation V.35, *Data transmission at 48 kilobits per second using 60-108 kHz group band circuits*
- ITU–T Recommendation X.21 (1992), *Interface between Data Terminal Equipment and Data Circuit-terminating Equipment for synchronous operation on public data networks*

- Related Documentation**
- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported T3 Interface Standard

---

The Junos OS substantially supports International Telecommunication Union–Telecommunication Standardization (ITU–T) Recommendation G.703, *Physical/electrical characteristics of hierarchical digital interfaces*.

- Related Documentation**
- [Accessing Standards Documents on the Internet on page 2003](#)

# Layer 2 Standards

- [Supported Layer 2 Networking Standards on page 2027](#)
- [Supported L2TP Standards on page 2028](#)
- [Supported Layer 2 Circuit Standards on page 2028](#)
- [Supported Layer 2 VPN Standard on page 2029](#)

## Supported Layer 2 Networking Standards

---

The Junos OS substantially supports the following standards for Layer 2 networking:

- Institute of Electrical and Electronics Engineers (IEEE) Standard 802.1ab, *IEEE Standard for Local and metropolitan area networks—Station and Media Access Control Connectivity Discovery*
- IEEE Standard 802.1D, *IEEE Standard for Local and Metropolitan Area Networks: Media Access Control (MAC) Bridges*

This document includes the standard for Rapid Spanning Tree Protocol (RSTP), which is often referred to as 802.1w. It also discusses Quality of Service (QoS) at the MAC level, often referred to as 802.1p.

### Related Documentation

- [Supported L2TP Standards on page 2028](#)
- [Supported Layer 2 Circuit Standards on page 2028](#)
- [Supported Layer 2 VPN Standard on page 2029](#)
- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported L2TP Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports the following RFC, which defines the standard for Layer 2 Tunneling Protocol (L2TP):

- RFC 2661, *Layer Two Tunneling Protocol "L2TP"*

The following RFC does not define a standard, but provides information about technology related to L2TP. The IETF classifies it as "Informational."

- RFC 2866, *RADIUS Accounting*

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Layer 2 Circuit Standards

---

The Junos OS substantially supports the following RFCs, which define standards for Layer 2 circuits:

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*

The Junos OS does not support Section 5.3, "The Generalized Pwid FEC Element."

- RFC 4448, *Encapsulation Methods for Transport of Ethernet over MPLS Networks*

The following Internet drafts do not define standards, but provide information about Layer 2 technologies. The IETF classifies them as "Historic."

- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

The Junos OS differs from the Internet draft in the following ways:

- A packet with a sequence number of 0 (zero) is treated as out of sequence.
- Any packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*

### Related Documentation

- [Supported LDP Standards on page 2032](#)
- [Supported MPLS Standards on page 2033](#)
- [Supported RSVP Standards on page 2035](#)

## Supported GMPLS Standards

---

The Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Generalized MPLS (GMPLS):

- RFC 3471, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description*

Only the following features are supported:

- Bidirectional LSPs (upstream label only)
  - Control channel separation
  - Generalized label (suggested label only)
  - Generalized label request (bandwidth encoding only)
- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*  
Only Section 9, "Fault Handling," is supported.
  - RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*
  - Internet draft draft-ietf-ccamp-gmpls-routing-09.txt, *Routing Extensions in Support of Generalized Multi-Protocol Label Switching*  
Only interface switching is supported.
  - Internet draft draft-ietf-ccamp-gmpls-rsvp-te-ason-02.txt, *Generalized MPLS (GMPLS) RSVP-TE Signalling in support of Automatically Switched Optical Network (ASON)* (expires January 2005)
  - Internet draft draft-ietf-ccamp-gmpls-sonet-sdh-08.txt, *Generalized Multi-Protocol Label Switching Extensions for SONET and SDH Control*

Only S,U,K,L,M-format labels and SONET traffic parameters are supported.

- Internet draft draft-ietf-ccamp-lmp-10.txt, *Link Management Protocol (LMP)*
- Internet draft draft-ietf-ccamp-ospf-gmpls-extensions-12.txt, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching*

The following sub-TLV types for the Link type, link, value (TLV) are not supported:

- Link Local/Remote Identifiers (type 11)
- Link Protection Type (type 14)
- Shared Risk Link Group (SRLG) (type 16)

The features described in Section 2 of the draft, “Implications on Graceful Restart,” are also not supported.

The Interface Switching Capability Descriptor (type 15) sub-TLV type is implemented, but only for packet switching.

- Internet draft draft-ietf-mpls-bundle-04.txt, *Link Bundling in MPLS Traffic Engineering*

#### Related Documentation

---

## Supported LDP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for LDP:

- RFC 3212, *Constraint-Based LSP Setup using LDP*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- Internet draft draft-napierala-mpls-targeted-mldp-01.txt, *Using LDP Multipoint Extensions on Targeted LDP Sessions*

The following RFCs do not define standards, but provide information about LDP. The IETF classifies them as “Informational.”

- RFC 3215, *LDP State Machine*
- RFC 5036, *LDP Specification*

For the following features described in the indicated sections of the RFC, Junos OS supports one of the possible modes but not the others:

- Label distribution control (section 2.6.1): Ordered mode is supported, but not Independent mode.

- Label retention (section 2.6.2): Liberal mode is supported, but not Conservative mode.
- Label advertisement (section 2.6.3): Downstream Unsolicited mode is supported, but not Downstream on Demand mode.
- RFC 5443, *LDP IGP Synchronization*

**Related  
Documentation**

---

## Supported MPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for MPLS and traffic engineering:

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3032, *MPLS Label Stack Encoding*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*  
Only E-LSPs are supported.
- RFC 3443, *Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS) Networks*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*  
Node protection in facility backup is not supported.
- RFC 4124, *Protocol Extensions for Support of Diffserv-aware MPLS Traffic Engineering*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*
- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 4950, *ICMP Extensions for Multiprotocol Label Switching*
- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*  
Only Point-to-Multipoint LSPs are supported.
- Internet draft draft-ietf-bfd-mpls-02.txt, *BFD for MPLS LSPs*

- Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*
- Internet draft draft-ietf-mpls-soft-preemption-02.txt, *MPLS Traffic Engineering Soft preemption*

The following RFCs and Internet drafts do not define standards, but provide information about MPLS, traffic engineering, and related technologies. The IETF classifies them variously as “Experimental,” “Historic,” or “Informational.”

- RFC 2547, *BGP/MPLS VPNs*
- RFC 2702, *Requirements for Traffic Engineering Over MPLS*
- RFC 2917, *A Core MPLS IP VPN Architecture*
- RFC 3063, *MPLS Loop Prevention Mechanism*
- RFC 3208, *PGM Reliable Transport Protocol Specification*

Only the network element is supported.

- RFC 3469, *Framework for Multi-Protocol Label Switching (MPLS)-based Recovery*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

Junos OS differs from the Internet draft in the following ways:

- A packet with a sequence number of 0 is treated as out of sequence.
- Any packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*
- Internet draft draft-raggarwa-mpls-p2mp-te-02.txt, *Establishing Point to Multipoint MPLS TE LSPs*

The features discussed in the indicated sections of the draft are not supported:

- Nonadjacent signaling for branch LSPs (section 7.1)
- Make-before-break and fast reroute (section 9)
- LSP hierarchy using point-to-point LSPs (section 10)

- Related Documentation**

## Supported RSVP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for RSVP:

- RFC 2205, *Resource ReSerVation Protocol (RSVP)—Version 1 Functional Specification*
- RFC 2210, *The Use of RSVP with IETF Integrated Services*
- RFC 2211, *Specification of the Controlled-Load Network Element Service*
- RFC 2212, *Specification of Guaranteed Quality of Service*
- RFC 2215, *General Characterization Parameters for Integrated Service Network Elements*
- RFC 2745, *RSVP Diagnostic Messages*
- RFC 2747, *RSVP Cryptographic Authentication* (updated by RFC 3097)
- RFC 2961, *RSVP Refresh Overhead Reduction Extensions*
- RFC 3097, *RSVP Cryptographic Authentication—Updated Message Type Value*
- RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*

The Null Service Object for maximum transmission unit (MTU) signaling in RSVP is not supported.

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReSerVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

Only Section 9, “Fault Handling,” is supported.

- RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*
- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*

(OSPF extensions can carry traffic engineering information over unnumbered links.)

- RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*
- RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*

The RRO node ID subobject is for use in inter-AS link and node protection configurations.

- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*

The following RFCs do not define standards, but provide information about RSVP and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 2209, *Resource ReSerVation Protocol (RSVP)—Version 1 Message Processing Rules*
- RFC 2216, *Network Element Service Specification Template*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

## CHAPTER 76

# Packet Processing Standards

- [Supported CoS Standards on page 2037](#)
- [Supported Packet Filtering Standards on page 2038](#)
- [Supported Policing Standard on page 2038](#)

### Supported CoS Standards

---

The Junos OS substantially supports the following standards for class of service (CoS):

- IEEE Standard 802.1D, *IEEE Standard for Local and Metropolitan Area Networks: Media Access Control (MAC) Bridges*

This document discusses Quality of Service (QoS) at the MAC level, often referred to as 802.1p.

- RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 2598, *An Expedited Forwarding PHB*

The following RFCs do not define standards, but provide information about CoS and related technologies. The IETF classifies them as “Informational.”

- RFC 2475, *An Architecture for Differentiated Services*
- RFC 2697, *A Single Rate Three Color Marker*
- RFC 2698, *A Two Rate Three Color Marker*
- RFC 2983, *Differentiated Services and Tunnels*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3246, *An Expedited Forwarding PHB (Per-Hop Behavior)*
- RFC 3260, *New Terminology and Clarifications for Diffserv*

## Supported Packet Filtering Standards

---

The Junos OS provides a packet-filtering language that enables you to control the flow of packets being forwarded to a network destination, as well as packets destined for and sent by the router. It substantially supports the following RFCs, which define standards for packet filtering:

- RFC 792, *INTERNET CONTROL MESSAGE PROTOCOL - DARPA INTERNET PROGRAM PROTOCOL SPECIFICATION*
- RFC 2460, *Internet Protocol, Version 6 (IPv6) Specification*
- RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- RFC 2597, *Assured Forwarding PHB Group*
- RFC 2598, *An Expedited Forwarding PHB*
- RFC 3246, *An Expedited Forwarding PHB (Per-Hop Behavior)*
- RFC 4291, *IP Version 6 Addressing Architecture*
- RFC 4443, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*

The following RFCs do not define standards, but provide information about packet filtering and related technologies. The IETF classifies them as “Informational.”

- RFC 2267, *Network Ingress Filtering: Defeating Denial of Service Attacks which employ IP Source Address Spoofing*
- RFC 2475, *An Architecture for Differentiated Services*
- RFC 2983, *Differentiated Services and Tunnels*
- RFC 3260, *New Terminology and Clarifications for Diffserv*

## Supported Policing Standard

---

The Junos OS supports policing, or rate limiting, to limit the amount of traffic that passes through an interface. For information about rate limiting, see RFC 2698, *A Two Rate Three Color Marker*.

The Junos implementation of policing uses a token-bucket algorithm and supports the following features:

- Adaptive shaping for Frame Relay traffic
- Virtual channels

## Supported BGP Standards

---

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for IP version 4 (IPv4) BGP:

For a list of supported IP version 6 (IPv6) BGP standards, see [“Supported IPv6 Standards” on page 2047](#).

Junos OS BGP supports authentication for protocol exchanges (MD5 authentication).

- RFC 1745, *BGP4/IDRP for IP—OSPF Interaction*
- RFC 1772, *Application of the Border Gateway Protocol in the Internet*
- RFC 1997, *BGP Communities Attribute*
- RFC 2283, *Multiprotocol Extensions for BGP-4*
- RFC 2385, *Protection of BGP Sessions via the TCP MD5 Signature Option*
- RFC 2439, *BGP Route Flap Damping*
- RFC 2545, *Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing*
- RFC 2796, *BGP Route Reflection – An Alternative to Full Mesh IBGP*
- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 2918, *Route Refresh Capability for BGP-4*

- RFC 3065, *Autonomous System Confederations for BGP*
- RFC 3107, *Carrying Label Information in BGP-4*
- RFC 3345, *Border Gateway Protocol (BGP) Persistent Route Oscillation Condition*
- RFC 3392, *Capabilities Advertisement with BGP-4*
- RFC 4271, *A Border Gateway Protocol 4 (BGP-4)*
- RFC 4273, *Definitions of Managed Objects for BGP-4*
- RFC 4360, *BGP Extended Communities Attribute*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4456, *BGP Route Reflection: An Alternative to Full Mesh Internal BGP (IBGP)*
- RFC 4486, *Subcodes for BGP Cease Notification Message*
- RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*
- RFC 4632, *Classless Inter-domain Routing (CIDR): The Internet Address Assignment and Aggregation Plan*
- RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*
- RFC 4724, *Graceful Restart Mechanism for BGP*
- RFC 4760, *Multiprotocol Extensions for BGP-4*
- RFC 4781, *Graceful Restart Mechanism for BGP with MPLS*
- RFC 4798, *Connecting IPv6 Islands over IPv4 MPLS Using IPv6 Provider Edge Routers (6PE)*

Option 4b (eBGP redistribution of labeled IPv6 routes from AS to neighboring AS) is not supported.

- RFC 4893, *BGP Support for Four-octet AS Number Space*
- RFC 5004, *Avoid BGP Best Path Transitions from One External to Another*
- RFC 5065, *Autonomous System Confederations for BGP*
- RFC 5082, *The Generalized TTL Security Mechanism (GTSM)*
- RFC 5291, *Outbound Route Filtering Capability for BGP-4 (partial support)*
- RFC 5292, *Address-Prefix-Based Outbound Route Filter for BGP-4 (partial support)*

Devices running Junos OS can receive prefix-based ORF messages.

- RFC 5396, *Textual Representation of Autonomous System (AS) Numbers*
- RFC 5492, *Capabilities Advertisement with BGP-4*
- RFC 5575, *Dissemination of flow specification rules*
- RFC 5668, *4-Octet AS Specific BGP Extended Community*
- RFC 6368, *Internal BGP as the Provider/Customer Edge Protocol for BGP/MPLS IP Virtual Private Networks (VPNs)*

- RFC 6810, *The Resource Public Key Infrastructure (RPKI) to Router Protocol*
  - RFC 6811, *BGP Prefix Origin Validation*
  - RFC 7311, *The Accumulated IGP Metric Attribute for BGP*
  - Internet draft draft-ietf-idr-add-paths-04.txt, *Advertisement of Multiple Paths in BGP* (expires February 2011)
  - Internet draft draft-ietf-idr-flow-spec-00.txt, *Dissemination of flow specification rules*
  - Internet draft draft-ietf-idr-as0-06, *Codification of AS 0 processing* (expires February 2013)
  - Internet draft draft-ietf-idr-link-bandwidth-01.txt, *BGP Link Bandwidth Extended Community* (expires August 2010)
  - Internet draft draft-ietf-sidr-origin-validation-signaling-00, *BGP Prefix Origin Validation State Extended Community (partial support)* (expires May 2011)
- The extended community (origin validation state) is supported in Junos OS routing policy. The specified change in the route selection procedure is not supported.
- Internet draft draft-kato-bgp-ipv6-link-local-00.txt, *BGP4+ Peering Using IPv6 Link-local Address*

The following RFCs and Internet draft do not define standards, but provide information about BGP and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 1965, *Autonomous System Confederations for BGP*
- RFC 1966, *BGP Route Reflection—An alternative to full mesh IBGP*
- RFC 2270, *Using a Dedicated AS for Sites Homed to a Single Provider*
- Internet draft draft-ietf-ngtrans-bgp-tunnel-04.txt, *Connecting IPv6 Islands across IPv4 Clouds with BGP* (expires July 2002)

## Supported ES-IS Standards

The Junos OS substantially supports the following standards for End System-to-Intermediate System (ES-IS):

- International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) standard 8473, *Information technology — Protocol for providing the connectionless-mode network service*
- ISO/IEC standard 9542, *Information processing systems — Telecommunications and information exchange between systems — End system to Intermediate system routing exchange protocol for use in conjunction with the Protocol for providing the connectionless-mode network service (ISO 8473)*

- Related Documentation**
- [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported ICMP and Neighbor Discovery Standards

The Junos OS substantially supports the following RFCs, which define standards for Internet Control Message Protocol (ICMP, for IP version 4 [IPv4]) and neighbor discovery (for IP version 6 [IPv6]):

- RFC 1256, *ICMP Router Discovery Messages*
- RFC 4861, *Neighbor Discovery for IP Version 6 (IPv6)*
- RFC 2462, *IPv6 Stateless Address Autoconfiguration*
- RFC 4862, *IPv6 Stateless Address Autoconfiguration*
- RFC 4443, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*
- RFC 4861, *IPv6 Stateless Address Autoconfiguration*
- RFC 4862, *Neighbor Discovery for IP version 6 (IPv6)*
- RFC 6106, *IPv6 Router Advertisement Options for DNS Configuration*

---

## Supported IP Multicast Protocol Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for IP multicast protocols, including the Distance Vector Multicast Routing Protocol (DVMRP), Internet Group Management Protocol (IGMP), Multicast Listener Discovery (MLD), Multicast Source Discovery Protocol (MSDP), Pragmatic General Multicast (PGM), Protocol Independent Multicast (PIM), Session Announcement Protocol (SAP), and Session Description Protocol (SDP):

- RFC 1112, *Host Extensions for IP Multicasting* (defines IGMP Version 1)
- RFC 2236, *Internet Group Management Protocol, Version 2*
- RFC 2327, *SDP: Session Description Protocol*
- RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*
- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3376, *Internet Group Management Protocol, Version 3*
- RFC 3590, *Source Address Selection for the Multicast Listener Discovery (MLD) Protocol*

- RFC 4601, *Protocol Independent Multicast – Sparse Mode (PIM-SM): Protocol Specification (Revised)*
- RFC 4607, *Source-Specific Multicast for IP*
- RFC 5015, *Bidirectional Protocol Independent Multicast (BIDIR-PIM)*
- *Using IGMPv3 and MLDv2 for Source-Specific Multicast*
- RFC 6513, *Multicast in MPLS/BGP IP VPNs*
- Internet draft draft-ietf-l3vpn-2547bis-mcast-bgp-08.txt, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*
- Internet draft draft-ietf-pim-sm-bsr-05.txt, *Bootstrap Router (BSR) Mechanism for PIM*

The scoping mechanism is not supported.

- Internet draft draft-raggarwa-l3vpn-2547-mvpn-00.txt, *Base Specification for Multicast in BGP/MPLS VPNs* (expires December 2004)

The following RFCs and Internet drafts do not define standards, but provide information about multicast protocols and related technologies. The IETF classifies them variously as “Best Current Practice,” “Experimental,” or “Informational.”

- RFC 1075, *Distance Vector Multicast Routing Protocol*
- RFC 2362, *Protocol Independent Multicast-Sparse Mode (PIM-SM): Protocol Specification*
- RFC 2365, *Administratively Scoped IP Multicast*
- RFC 2547, *BGP/MPLS VPNs*
- RFC 2974, *Session Announcement Protocol*
- RFC 3208, *PGM Reliable Transport Protocol Specification*
- RFC 3446, *Anycast Rendezvous Point (RP) mechanism using Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP)*
- RFC 3569, *An Overview of Source-Specific Multicast (SSM)*
- RFC 3618, *Multicast Source Discovery Protocol (MSDP)*
- RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*
- RFC 3973, *Protocol Independent Multicast – Dense Mode (PIM-DM): Protocol Specification (Revised)*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- Internet draft draft-ietf-idmr-dvmrp-v3-11.txt, *Distance Vector Multicast Routing Protocol*
- Internet draft draft-ietf-mboned-ssm232-08.txt, *Source-Specific Protocol Independent Multicast in 232/8*
- Internet draft draft-ietf-mmusic-sap-00.txt, *SAP: Session Announcement Protocol*
- Internet draft draft-rosen-vpn-mcast-07.txt, *Multicast in MPLS/BGP VPNs*

Only section 7, “Data MDT: Optimizing flooding,” is supported.

**Related Documentation** • [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported IPv4, TCP, and UDP Standards

The Junos OS substantially supports the following RFCs, which define standards for Internet Protocol version 4 (IPv4), Transmission Control Protocol (TCP), and User Datagram Protocol (UDP):

- RFC 768, *User Datagram Protocol*
- RFC 791, *INTERNET PROTOCOL - DARPA INTERNET PROGRAM PROTOCOL SPECIFICATION*
- RFC 792, *INTERNET CONTROL MESSAGE PROTOCOL - DARPA INTERNET PROGRAM PROTOCOL SPECIFICATION*
- RFC 793, *TRANSMISSION CONTROL PROTOCOL - DARPA INTERNET PROGRAM PROTOCOL SPECIFICATION*
- RFC 826, *Ethernet Address Resolution Protocol—or—Converting Network Protocol Addresses to 48.bit Ethernet Address for Transmission on Ethernet Hardware*
- RFC 854, *TELNET PROTOCOL SPECIFICATION*
- RFC 862, *Echo Protocol*
- RFC 863, *Discard Protocol*
- RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*
- RFC 896, *Congestion Control in IP/TCP Internetworks*
- RFC 903, *A Reverse Address Resolution Protocol*
- RFC 919, *BROADCASTING INTERNET DATAGRAMS*
- RFC 922, *BROADCASTING INTERNET DATAGRAMS IN THE PRESENCE OF SUBNETS*
- RFC 950, *Internet Standard Subnetting Procedure*
- RFC 959, *FILE TRANSFER PROTOCOL (FTP)*
- RFC 1027, *Using ARP to Implement Transparent Subnet Gateways*
- RFC 1042, *A Standard for the Transmission of IP Datagrams over IEEE 802 Networks*
- RFC 1157, *A Simple Network Management Protocol (SNMP)*
- RFC 1166, *INTERNET NUMBERS*
- RFC 1195, *Use of OSI IS-IS for Routing in TCP/IP and Dual Environments*
- RFC 1256, *ICMP Router Discovery Messages*
- RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*
- RFC 1519, *Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy*
- RFC 1812, *Requirements for IP Version 4 Routers*

- RFC 2338, *Virtual Router Redundancy Protocol* (obsoleted by RFC 3768 in April 2004)
- RFC 2873, *TCP Processing of the IPv4 Precedence Field*
- RFC 3021, *Using 31-Bit Prefixes on IPv4 Point-to-Point Links*
- RFC 3246, *An Expedited Forwarding PHB (Per-Hop Behavior)*
- RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*
- RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6*
- RFC 6527, *Definitions of Managed Objects for the Virtual Router Redundancy Protocol Version 3 (VRRPv3)*

The following features are not supported:

- Row creation
- **Set** operation
- **vrrpv3StatisticsRowDiscontinuityTime** MIB object
- **vrrpv3StatisticsPacketLengthErrors** MIB object

The following RFCs do not define standards but provide information about IP, TCP, UDP, and related technologies. The IETF classifies them as “Informational.”

- RFC 1878, *Variable Length Subnet Table For IPv4*
- RFC 1948, *Defending Against Sequence Number Attacks*

**Related  
Documentation**

---

## Supported IPv6 Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Internet Protocol version 6 (IPv6):

- RFC 1157, *A Simple Network Management Protocol (SNMP)*
- RFC 1195, *Use of OSI IS-IS for Routing in TCP/IP and Dual Environments*
- RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II*

Only the following features are supported:

- Junos OS-specific secured access list
- Master configuration keywords

- MIB II and its SNMP version 2 derivatives, including the following:
  - Interface management
  - IP (except for the **ipRouteTable** object, which has been replaced by **inetCidrRouteTable** [RFC 4292, *IP Forwarding Table MIB*])

**NOTE:** RFC 2096 has been replaced by RFC 4292. However, Junos OS currently supports both RFC 2096 and RFC 4292.

- SNMP management
- Statistics counters
- Reconfigurations upon receipt of the SIGHUP signal
- SNMP version 1 **Get** and **GetNext** requests and version 2 **GetBulk** requests
- RFC 1215, *A Convention for Defining Traps for use with the SNMP*  
Only MIB II SNMP version 1 traps and version 2 notifications are supported.
- RFC 1771, *A Border Gateway Protocol 4 (BGP-4)*
- RFC 1772, *Application of the Border Gateway Protocol in the Internet*
- RFC 1902, *Structure of Management Information for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1905, *Protocol Operations for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1981, *Path MTU Discovery for IP version 6*
- RFC 2080, *RIPng for IPv6*
- RFC 2081, *RIPng Protocol Applicability Statement*
- RFC 2283, *Multiprotocol Extensions for BGP-4*
- RFC 2373, *IP Version 6 Addressing Architecture*
- RFC 2375, *Multicast Address Assignments*
- RFC 2460, *Internet Protocol, Version 6 (IPv6) Specification*
- RFC 2464, *Transmission of IPv6 Packets over Ethernet Networks*
- RFC 2465, *Management Information Base for IP Version 6: Textual Conventions and General Group*  
Internet Protocol version 6 (IPv6) and Internet Control Message Protocol version 6 (ICMPv6) statistics are not supported.
- RFC 2472, *IP Version 6 over PPP*
- RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- RFC 2491, *IPv6 Over Non-Broadcast Multiple Access (NBMA) networks*

- RFC 2492, *IPv6 over ATM Networks*
- RFC 2526, *Reserved IPv6 Subnet Anycast Addresses*
- RFC 2545, *Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing*
- RFC 2578, *Structure of Management Information Version 2 (SMIv2)*
- RFC 2675, *IPv6 Jumbograms*
- RFC 2711, *IPv6 Router Alert Option*
- RFC 2740, *OSPF for IPv6* (partial support for RFC 5340)

Junos OS does not support the following components of RFC 5340:

- Multiple interfaces on the same link
  - Deprecation of Multicast Extensions to OSPF (MOSPF) for IPv6
  - Not-so-stubby area (NSSA) specification
  - Link LSA suppression
  - LSA options and prefix options updates
  - IPv6 site-local addresses
- RFC 2784, *Generic Routing Encapsulation*
  - RFC 2878, *PPP Bridging Control Protocol (BCP)*
  - RFC 2893, *Transition Mechanisms for IPv6 Hosts and Routers*
  - RFC 3306, *Unicast-Prefix-based IPv6 Multicast Addresses*
  - RFC 3307, *Allocation Guidelines for IPv6 Multicast Addresses*
  - RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*

Address assignment is supported with Internet Protocol version 4 (IPv4) but not Internet Protocol version 6 (IPv6).

- RFC 3484, *Default Address Selection for Internet Protocol version 6 (IPv6)*
- RFC 3513, *Internet Protocol Version 6 (IPv6) Addressing Architecture*
- RFC 3515, *The Session Initiation Protocol (SIP) Refer Method*
- RFC 3590, *Source Address Selection for the Multicast Listener D* (Supported for SSM include mode only)
- RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*
- RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*
- RFC 3971, *Secure Neighbor Discovery for IPv6* (No support for certification paths, anchored on trusted parties)
- RFC 3972, *Cryptographically Generated Addresses*
- RFC 4087, *IP Tunnel MIB*
- RFC 4291, *IP Version 6 Addressing Architecture*

- RFC 4292, *IP Forwarding Table MIB*
- RFC 4294, *IPv6 Node Requirements* (Partial support)
- RFC 4443, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*
- RFC 4552, *Authentication/Confidentiality for OSPFv3*
- RFC 4604, *Using Internet Group Management Protocol Version 3 (IGMPv3)*
- RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*
- RFC 4798, *Connecting IPv6 Islands over IPv4 MPLS Using IPv6 Provider Edge Routers (6PE)*

Option 4b (eBGP redistribution of labeled IPv6 routes from AS to neighboring AS) is not supported.

- RFC 4861 *Neighbor Discovery for IP Version 6 (IPv6)*
- RFC 4862, *IPv6 Stateless Address Autoconfiguration*
- RFC 4890, *Recommendations for Filtering ICMPv6 Messages in Firewalls*
- RFC 4942, *IPv6 Transition/Coexistence Security Considerations*
- RFC 5072, *IP Version 6 over PPP*
- RFC 5095, *Deprecation of Type 0 Routing Headers in IPv6*
- RFC 5308, *Routing IPv6 with IS-IS*
- RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6*
- RFC 5905, *Network Time Protocol Version 4 (for IPv6)*
- RFC 6164, *Using 127-Bit IPv6 Prefixes on Inter-Router Links*
- RFC 6527, *Definitions of Managed Objects for the Virtual Router Redundancy Protocol Version 3 (VRRPv3)*

The following features are not supported:

- Row creation
- **Set** operation
- **vrpv3StatisticsPacketLengthErrors** MIB object
- **vrpv3StatisticsRowDiscontinuityTime** MIB object
- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN*
- Internet draft draft-ietf-idr-flow-spec-00.txt, *Dissemination of flow specification rules*
- Internet draft draft-ietf-software-dual-stack-lite-04.txt, *Dual-Stack Lite Broadband Deployments Following IPv4 Exhaustion*
- Internet draft draft-kato-bgp-ipv6-link-local-00.txt, *BGP4+ Peering Using IPv6 Link-local Address*

The following RFCs and Internet draft do not define standards, but provide information about IPv6 and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 1901, *Introduction to Community-based SNMPv2*
- RFC 2767, *Dual Stack Hosts using the "Bump-In-the-Stack" Technique (BIS)*
- RFC 3587, *IPv6 Global Unicast Address Format*
- Internet draft draft-ietf-ngtrans-bgp-tunnel-04.txt, *Connecting IPv6 Islands across IPv4 Clouds with BGP*

Only the MP-BGP over Internet Protocol version 4 (IPv4) approach is supported.

## Supported IS-IS Standards

Junos OS substantially supports the following standards for IS-IS:

- International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 8473, *Information technology — Protocol for providing the connectionless-mode network service*
- ISO 9542, *End System to Intermediate System Routing Exchange Protocol for Use in Conjunction with the Protocol for the Provision of the Connectionless-mode Network Service*
- ISO/IEC 10589, *Information technology — Telecommunications and information exchange between systems — Intermediate System to Intermediate System intra-domain routing information exchange protocol for use in conjunction with the protocol for providing the connectionless-mode network service (ISO 8473)*
- RFC 1195, *Use of OSI IS-IS for Routing in TCP/IP and Dual Environments*
- RFC 3719, *Recommendations for Interoperable Networks using Intermediate System to Intermediate System (IS-IS)*
- RFC 3847, *Restart Signaling for Intermediate System to Intermediate System (IS-IS)*
- RFC 5120, *M-ISIS: Multi Topology (MT) Routing in Intermediate System to Intermediate Systems (IS-ISs)*
- RFC 5130, *A Policy Control Mechanism in IS-IS Using Administrative Tags*
- RFC 5286, *Basic Specification for IP Fast Reroute: Loop-Free Alternates*
- RFC 5301, *Dynamic Hostname Exchange Mechanism for IS-IS*
- RFC 5302, *Domain-wide Prefix Distribution with Two-Level IS-IS*
- RFC 5303, *Three-Way Handshake for IS-IS Point-to-Point Adjacencies*
- RFC 5304, *IS-IS Cryptographic Authentication*

- RFC 5305, *IS-IS Extensions for Traffic Engineering*
- RFC 5306, *Restart Signaling for IS-IS*
- RFC 5307, *IS-IS Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*
- RFC 5308, *Routing IPv6 with IS-IS*
- Internet draft draft-ietf-bfd-base-09.txt, *Bidirectional Forwarding Detection*  
Transmission of echo packets is not supported.
- Internet draft draft-ietf-isis-restart-02.txt, *Restart signaling for IS-IS*

The following RFCs do not define standards, but provide information about IS-IS and related technologies. The IETF classifies them as “Informational.”

- RFC 2973, *IS-IS Mesh Groups*
- RFC 3358, *Optional Checksums in Intermediate System to Intermediate System (ISIS)*
- RFC 3359, *Reserved Type, Length and Value (TLV) Codepoints in Intermediate System to Intermediate System*
- RFC 3373, *Three-Way Handshake for Intermediate System to Intermediate System (IS-IS) Point-to-Point Adjacencies*
- RFC 3567, *Intermediate System to Intermediate System (IS-IS) Cryptographic Authentication*
- RFC 3787, *Recommendations for Interoperable IP Networks using Intermediate System to Intermediate System (IS-IS)*
- RFC 5309, *Point-to-Point Operation over LAN in Link State Routing Protocols*
- Internet draft draft-ietf-bfd-base-09.txt, *Bidirectional Forwarding Detection* (except for the transmission of echo packets)
- Internet draft draft-ietf-isis-wg-255adj-02.txt, *Maintaining more than 255 circuits in IS-IS*

**Related  
Documentation**

- [Supported ES-IS Standards on page 2043](#)

---

## Supported OSPF and OSPFv3 Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for OSPF and OSPF version 3 (OSPFv3):

- RFC 1583, *OSPF Version 2*
- RFC 1765, *OSPF Database Overflow*
- RFC 1793, *Extending OSPF to Support Demand Circuits*
- RFC 2154, *OSPF with Digital Signatures*

- RFC 2328, *OSPF Version 2*
- RFC 2370, *The OSPF Opaque LSA Option*

Support is provided by the **update-threshold** configuration statement at the **[edit protocols rsvp interface *interface-name* ]** hierarchy level.

- RFC 2740, *OSPF for IPv6* (partial support for RFC 5340)

Junos OS does not support the following components of RFC 5340:

- Multiple interfaces on the same link
  - Deprecation of Multicast Extensions to OSPF (MOSPF) for IPv6
  - Not-so-stubby area (NSSA) specification
  - Link LSA suppression
  - LSA options and prefix options updates
  - IPv6 site-local addresses
- RFC 3101, *The OSPF Not-So-Stubby Area (NSSA) Option*
  - RFC 3623, *Graceful OSPF Restart*
  - RFC 3630, *Traffic Engineering (TE) Extensions to OSPF Version 2*
  - RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*

Only interface switching is supported.

- RFC 4552, *Authentication/Confidentiality for OSPFv3*
- RFC 4576, *Using a Link State Advertisement (LSA) Options Bit to Prevent Looping in BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4577, *OSPF as the Provider/Customer Edge Protocol for BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4811, *OSPF Out-of-Band Link State Database (LSDB) Resynchronization*
- RFC 4812, *OSPF Restart Signaling*
- RFC 4813, *OSPF Link-Local Signaling*
- RFC 4915, *Multi-Topology (MT) Routing in OSPF*
- RFC 5185, *OSPF Multi-Area Adjacency*
- RFC 5187, *OSPFv3 Graceful Restart*
- RFC 5286, *Basic Specification for IP Fast Reroute: Loop-Free Alternates*
- RFC 5838, *Support of Address Families in OSPFv3*
- Internet draft draft-ietf-ospf-af-alt-10.txt, *Support of address families in OSPFv3*
- Internet draft draft-katz-ward-bfd-02.txt, *Bidirectional Forwarding Detection*

Transmission of echo packets is not supported.

The following RFCs do not define standards, but provide information about OSPF and related technologies. The IETF classifies them as “Informational.”

- RFC 3137, *OSPF Stub Router Advertisement*
- RFC 3509, *Alternative Implementations of OSPF Area Border Routers*
- RFC 5309, *Point-to-Point Operation over LAN in Link State Routing Protocols*

---

## Supported RIP and RIPng Standards

Junos OS substantially supports the following RFCs, which define standards for RIP (for IP version 4 [IPv4]) and RIP next generation (RIPng, for IP version 6 [IPv6]):

Junos OS supports authentication for all RIP protocol exchanges (MD5 or simple authentication).

- RFC 1058, *Routing Information Protocol*
- RFC 2080, *RIPng for IPv6*
- RFC 2082, *RIP-2 MD5 Authentication*

Multiple keys using distinct key IDs are not supported.

- RFC 2453, *RIP Version 2*

The following RFC does not define a standard, but provides information about RIPng. The IETF classifies it as “Informational.”

- RFC 2081, *RIPng Protocol Applicability Statement*

**Related  
Documentation**

## CHAPTER 78

# Services PIC and DPC Standards

- Supported DTCP Standard on page 2055
- Supported Flow Monitoring and Discard Accounting Standards on page 2055
- Supported IPsec and IKE Standards on page 2056
- Supported L2TP Standards on page 2057
- Supported Link Services Standards on page 2057
- Supported NAT and SIP Standards on page 2057
- Supported RPM Standard on page 2058
- Supported Voice Services Standards on page 2058

### Supported DTCP Standard

---

The Junos OS substantially supports Internet draft draft-cavuto-dtcp-03.txt, *DTCP: Dynamic Tasking Control Protocol*.

#### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

### Supported Flow Monitoring and Discard Accounting Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions), Monitoring Services PICs, or Multiservices PICs or DPCs, the Junos OS substantially supports the standards for cflowd version 5 and version 8 formats that are maintained by CAIDA and accessible at <http://www.caida.org>.

The following RFC does not define a standard, but provides information about flow monitoring. The IETF classifies it as “Informational.”

- RFC 3954, *Cisco Systems NetFlow Services Export Version 9*

#### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported IPsec and IKE Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Canada and U.S. version of the Junos OS substantially supports the following RFCs, which define standards for IP Security (IPsec) and Internet Key Exchange (IKE):

- RFC 2085, *HMAC-MD5 IP Authentication with Replay Prevention*
- RFC 2401, *Security Architecture for the Internet Protocol*
- RFC 2402, *IP Authentication Header*

This RFC is not supported on the ES PIC.

- RFC 2403, *The Use of HMAC-MD5-96 within ESP and AH*
- RFC 2404, *The Use of HMAC-SHA-1-96 within ESP and AH*
- RFC 2405, *The ESP DES-CBC Cipher Algorithm With Explicit IV*
- RFC 2406, *IP Encapsulating Security Payload (ESP)*
- RFC 2407, *The Internet IP Security Domain of Interpretation for ISAKMP*
- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 2409, *The Internet Key Exchange (IKE)*
- RFC 2410, *The NULL Encryption Algorithm and Its Use With IPsec*
- RFC 3602, *The AES-CBC Cipher Algorithm and Its Use with IPsec*
- RFC 3948, *UDP Encapsulation of IPsec ESP Packets*
- RFC 4301, *Security Architecture for the Internet Protocol*
- RFC 4302, *IP Authentication Header*

This RFC is not supported on the ES PIC.

- RFC 4303, *IP Encapsulating Security Payload (ESP)*

The following RFCs and Internet draft do not define standards, but provide information about IPsec, IKE, and related technologies. The IETF classifies them as "Informational."

- RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- RFC 3706, *A Traffic-Based Method of Detecting Dead Internet Key Exchange (IKE) Peers*
- Internet draft draft-eastlake-sha2-02.txt, *US Secure Hash Algorithms (SHA and HMAC-SHA)* (expires July 2006)

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported L2TP Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports the following RFC, which defines the standard for Layer 2 Tunneling Protocol (L2TP):

- RFC 2661, *Layer Two Tunneling Protocol "L2TP"*

The following RFC does not define a standard, but provides information about technology related to L2TP. The IETF classifies it as "Informational."

- RFC 2866, *RADIUS Accounting*

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported Link Services Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports the following RFCs, which define standards for link services:

- RFC 1990, *The PPP Multilink Protocol (MP)*
- RFC 2364, *PPP Over AAL5*
- RFC 2686, *The Multi-Class Extension to Multi-Link PPP*

The following features are not supported:

- Negotiation of address field compression and protocol field compression PPP NCP options; instead, a full 4-byte PPP header is always sent
- Prefix elision

### Related Documentation

- [Accessing Standards Documents on the Internet on page 2003](#)

## Supported NAT and SIP Standards

---

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports the following Network Address Translation (NAT) and Session Initiation Protocol (SIP) standards. NAT supports SIP dialogs and UDP/IP version 4 (IPv4) transport of SIP messages.

The Junos OS substantially supports the following RFC and Internet draft:

- RFC 3261, *SIP: Session Initiation Protocol*
- Internet draft draft-mrw-behave-nat66-01.txt, *IPv6-to-IPv6 Network Address Translation (NAT66)*

The following RFCs do not define standards, but provide information about NAT. The IETF classifies them variously as “Best Current Practice,” “Historic” or “Informational.”

- RFC 1631, *The IP Network Address Translator (NAT)*
- RFC 2663, *IP Network Address Translator (NAT) Terminology and Considerations*
- RFC 2766, *Network Address Translation - Protocol Translation (NAT-PT)*
- RFC 2993, *Architectural Implications of NAT*
- RFC 3022, *Traditional IP Network Address Translator (Traditional NAT)*
- RFC 4787, *Network Address Translation (NAT) Behavioral Requirements for Unicast UDP*
- RFC 5382, *NAT Behavioral Requirements for TCP*
- RFC 5508, *NAT Behavioral Requirements for ICMP*

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported RPM Standard

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports real-time performance monitoring (RPM), and provides MIB support with extensions in substantial support of RFC 2925, *Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations*.

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

---

## Supported Voice Services Standards

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Junos OS substantially supports the following following RFCs, which define standards for technologies used with voice services:

- RFC 2508, *Compressing IP/UDP/RTP Headers for Low-Speed Serial Links*
- RFC 2509, *IP Header Compression over PPP*

**Related  
Documentation**

- [Accessing Standards Documents on the Internet on page 2003](#)

## CHAPTER 79

# VPLS and VPN Standards

- [Supported Carrier-of-Carriers and Interprovider VPN Standards on page 2059](#)
- [Supported Layer 2 VPN Standard on page 2059](#)
- [Supported Layer 3 VPN Standards on page 2060](#)

- [Supported VPLS Standards on page 2061](#)

### Supported Carrier-of-Carriers and Interprovider VPN Standards

---

The Junos OS substantially supports the following RFCs and Internet draft, which define standards for carrier-of-carriers and interprovider virtual private networks (VPNs):

- RFC 3107, *Carrying Label Information in BGP-4*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- Internet draft draft-marques-ppvnp-ibgp-00.txt, *RFC2547bis networks using internal BGP as PE-CE protocol*

#### Related Documentation

---

## Supported Layer 3 VPN Standards

The Junos OS substantially supports the following RFCs, which define standards for Layer 3 virtual private networks (VPNs):

- RFC 2283, *Multiprotocol Extensions for BGP-4*
- RFC 2685, *Virtual Private Networks Identifier*
- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*

The traceroute functionality is supported only on transit routers.

- RFC 4576, *Using a Link State Advertisement (LSA) Options Bit to Prevent Looping in BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4577, *OSPF as the Provider/Customer Edge Protocol for BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*
- RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*

The following RFC does not define a standard, but provides information about technology related to Layer 3 VPNs. The IETF classifies it as a “Best Current Practice.”

- RFC 1918, *Address Allocation for Private Internets*

### Related Documentation

- [Supported VPLS Standards on page 2061](#)
- [Supported MPLS Standards on page 2033](#)
- [Supported BGP Standards on page 2041](#)

## Supported Multicast VPN Standards

Junos OS substantially supports the following RFC and Internet draft, which define standards for multicast virtual private networks (VPNs):

- RFC 6513, *Multicast in MPLS/BGP IP VPNs*
- Internet draft draft-ietf-l3vpn-2547bis-mcast-bgp-08.txt, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*
- RFC 6515, *IPv4 and IPv6 Infrastructure Addresses in BGP Updates for Multicast VPN*
- RFC 6625, *Wildcards in Multicast VPN Auto-Discovery Routes*
- Internet draft draft-morin-l3vpn-mvpn-fast-failover-06.txt, *Multicast VPN Fast Upstream Failover*
- Internet draft draft-raggarwa-l3vpn-bgp-mvpn-extranet-08.txt, *Extranet in BGP Multicast VPN (MVPN)*

### Related Documentation

- [Supported VPLS Standards on page 2061](#)
- [Supported MPLS Standards on page 2033](#)
- [Supported BGP Standards on page 2041](#)

## Supported VPLS Standards

The Junos OS substantially supports the following following RFCs, which define standards for virtual private LAN service (VPLS):

- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*
- RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*

FEC 128, FEC 129, control bit 0, the Ethernet pseudowire type 0x0005, and the Ethernet tagged mode pseudowire type 0x0004 are supported.
