4. The selected DHCP local server sends an acknowledgement packet to the client that contains the client address lease and configuration parameters. The server and client installs the host route and ARP entry, and then monitors the lease state.

DHCP Local Server and Address-Assignment Pools

In a DHCP local server operation, the client address and configuration information reside in centralized address-assignment pools, that are managed independently from the DHCP local server and they can be shared by different client applications.

Configuring a DHCP environment that includes a DHCP local server requires two independent configuration operations, which you can complete in any order. In one operation, you configure the DHCP local server on the device and specify how the DHCP local server determines which address-assignment pool to use. In the other operation, you configure the address-assignment pools used by the DHCP local server. The address-assignment pools contain the IP addresses, named address ranges, and configuration information for DHCP clients.

NOTE: The DHCP local server and the address-assignment pools used by the server must be configured in the same routing instance.

DHCP Client

DHCP configuration consists of configuring DHCP clients and a DHCP local server. A client configuration determines how clients send a message requesting an IP address, while a server configuration enables the server to send an IP address back to the client.

For the device to operate as a DHCP client, you configure a logical interface on the device to obtain an IP address from the DHCP local server in the network. You set the vendor class ID, lease time, DHCP server address, retransmission attempts, and retry interval.

DHCP Relay Agent

You can configure DHCP relay options on the device and enable the device to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP local server.

To configure the DHCP relay agent on the router, include the **dhcp-relay** statement at the **[edit forwarding-options]** hierarchy level.

You can also include the **dhcp-relay** statement at the following hierarchy level:

[edit routing-instances routing-instance-name forwarding-options]

DHCP Client, DHCP Relay Agent, and DHCP Local Servers

In a typical branch network configuration, the DHCP client is on the subscriber's computer, and the DHCP relay agent is configured on the device between the DHCP client and one or more DHCP local servers.

The following steps describe, at a high level, how the DHCP client, DHCP relay agent, and DHCP local server interact in a configuration that includes two DHCP local servers.

1. The DHCP client sends a discover packet to find a DHCP local server in the network from which to obtain configuration parameters for the subscriber, including an IP address.
2. The DHCP relay agent receives the discover packet and forwards copies to each of the two DHCP local servers. The DHCP relay agent then creates an entry in its internal client table to keep track of the client's state.
3. In response to receiving the discover packet, each DHCP local server sends an offer packet to the client. The DHCP relay agent receives the offer packets and forwards them to the DHCP client.
4. On receipt of the offer packets, the DHCP client selects the DHCP local server from which to obtain configuration information. Typically, the client selects the server that offers the longest lease time on the IP address.
5. The DHCP client sends a request packet that specifies the DHCP local server from which to obtain configuration information.
6. The DHCP local server requested by the client sends an acknowledgement (ACK) packet that contains the client's configuration parameters.
7. The DHCP relay agent receives the ACK packet and forwards it to the client.
8. The DHCP client receives the ACK packet and stores the configuration information.
9. If configured to do so, the DHCP relay agent installs a host route and Address Resolution Protocol (ARP) entry for this client.
10. After establishing the initial lease on the IP address, the DHCP client and the DHCP local server use unicast transmission to negotiate lease renewal or release.

Considerations

The following considerations apply when you enable a DHCP local server, DHCP relay agent, or DHCP client in a routing instance:

- The DHCP local server, DHCP relay agent, and DHCP client can be configured in one routing instance, but the functionality is mutually exclusive on one interface. If the DHCP client is enabled on one interface, the DHCP local server or the DHCP relay agent cannot be enabled on that interface.
- The DHCP client, DHCP relay agent and DHCP local server services act independently in their respective routing instance. The following features can function simultaneously on a device:

- DHCP client and DHCP local server
- DHCP client and DHCP relay agent
- Multiple routing instances. Each instance can have a DHCP local server, DHCP relay agent, or DHCP client, or each routing instance can have a DHCP client and DHCP local server or a DHCP client and DHCP relay agent.

NOTE: Before you enable DHCP services in a routing instance, you must remove all the configuration related to DHCP services that does not include routing instance support. If you do not do this, the old default routing instance configuration will override the new routing instance configuration.

NOTE: On all SRX Series devices, logical systems and routing instances are not supported for a DHCP client in chassis cluster mode.

DHCP Server, Client, and Relay Agent Overview

A Dynamic Host Configuration Protocol (DHCP) server can automatically allocate IP addresses and also deliver configuration settings to client hosts on a subnet. DHCP lets network administrators centrally manage a pool of IP addresses among hosts and automate the assignment of IP addresses in a network. An IP address can be leased to a host for a limited period of time, allowing the DHCP server to share a limited number of IP addresses among a group of hosts that do not need permanent IP addresses.

The Juniper Networks device acts as the DHCP server, providing IP addresses and settings to hosts, such as PCs, that are connected to device interfaces. The DHCP server is compatible with the DHCP servers of other vendors on the network.

The device can also operate as a DHCP client and DHCP relay agent.

DHCP is based on BOOTP, a bootstrap protocol that allows a client to discover its own IP address, the IP address of a server host, and the name of a bootstrap file. DHCP servers can handle requests from BOOTP clients, but provide additional capabilities beyond BOOTP, such as the automatic allocation of reusable IP addresses and additional configuration options.

NOTE: Although a Juniper Networks device can act as a DHCP server, a DHCP client, or DHCP relay agent at the same time, you cannot configure more than one DHCP role on a single interface.

DHCP provides two primary functions:

- Allocate temporary or permanent IP addresses to clients.
- Store, manage, and provide client configuration parameters.

NOTE: On all SRX Series devices, DHCPv4 is supported only in Layer 3 mode; the DHCP server and DHCP client are not supported in Layer 2 transparent mode.

DHCP Settings and Restrictions Overview

This section contains the following topics:

- [Propagation of TCP/IP Settings for DHCP on page 1089](#)
- [DHCP Conflict Detection and Resolution on page 1089](#)
- [DHCP Interface Restrictions on page 1090](#)

Propagation of TCP/IP Settings for DHCP

The Juniper Networks device can operate simultaneously as a client of the DHCP server in the untrust zone and a DHCP server to the clients in the trust zone. The device takes the TCP/IP settings that it receives as a DHCP client and forwards them as a DHCP server to the clients in the trust zone. The device interface in the untrust zone operates as the DHCP client, receiving IP addresses dynamically from an Internet service provider (ISP) on the external network.

During the DHCP protocol exchange, the device receives TCP/IP settings from the external network on its DHCP client interface. Settings include the address of the ISP's DHCP name server and other server addresses. These settings are propagated to the DHCP server pools configured on the device to fulfill host requests for IP addresses on the device's internal network.

DHCP Conflict Detection and Resolution

A client that receives an IP address from the device operating as a DHCP server performs a series of Address Resolution Protocol (ARP) tests to verify that the address is available and no conflicts exist. If the client detects an address conflict, it informs the DHCP server about the conflict and can request another IP address from the DHCP server.

The device maintains a log of all client-detected conflicts and removes addresses with conflicts from the DHCP address pool. To display the conflicts list, you use the **show system services dhcp conflict** command. The addresses in the conflicts list remain excluded until you use the **clear system services dhcp conflict** command to manually clear the list.

DHCP Interface Restrictions

The device supports DHCP client requests received on any Ethernet interface. DHCP requests received from a relay agent are supported on all interface types.

DHCP is not supported on interfaces that are part of a virtual private network (VPN).

Understanding DHCP Server Operation

As a DHCP server, a Juniper Networks device can provide temporary IP addresses from an IP address pool to all clients on a specified subnet, a process known as dynamic binding. Juniper Networks devices can also perform static binding, assigning permanent IP addresses to specific clients based on their media access control (MAC) addresses. Static bindings take precedence over dynamic bindings.

This section contains the following topics:

- [DHCP Options on page 1091](#)
- [Compatibility with Autoinstallation on page 1092](#)
- [Chassis Cluster Support on page 1092](#)

DHCP Options

In addition to its primary DHCP server functions, you can also configure the device to send configuration settings like the following to clients through DHCP:

- IP address of the DHCP server (Juniper Networks device)
- List of Domain Name System (DNS) and NetBIOS servers
- List of gateway routers

- IP address of the boot server and the filename of the boot file to use
- DHCP options defined in RFC 2132, *DHCP Options and BOOTP Vendor Extensions*

Compatibility with Autoinstallation

The functions of a Juniper Networks device acting as a DHCP server are compatible with the autoinstallation feature. The DHCP server automatically checks any autoinstallation settings for conflicts and gives the autoinstallation settings priority over corresponding DHCP settings. For example, an IP address set by autoinstallation takes precedence over an IP address set by the DHCP server.

Chassis Cluster Support

DHCP server operations are supported on all SRX Series devices in chassis cluster mode.

DHCP Server Configuration Overview

A typical DHCP server configuration provides the following configuration settings for a particular subnet on a device interface:

- An IP address pool, with one address excluded from the pool.
- Default and maximum lease times.
- Domain search suffixes. These suffixes specify the domain search list used by a client when resolving hostnames with DNS.
- A DNS name server.
- Device solicitation address option (option 32). The IP address excluded from the IP address pool is reserved for this option.

In addition, the DHCP server might assign a static address to at least one client on the subnet. [Table 84](#) provides the settings and values for the sample DHCP server configuration.

Table 84: Sample DHCP Server Configuration Settings

Setting	Sample Value
DHCP Subnet Configuration	
Address pool subnet address	192.168.2.0/24
High address in the pool range	192.168.2.254
Low address in the pool range	192.168.2.2

Table 84: Sample DHCP Server Configuration Settings (*continued*)

Setting	Sample Value
Address pool default lease time, in seconds	1,209,600 (14 days)
Address pool maximum lease time, in seconds	2,419,200 (28 days)
Domain search suffixes	mycompany.net mylab.net
Address to exclude from the pool	192.168.2.33
DNS server address	192.168.10.2
Identifier code for router solicitation address option	32
Type choice for router solicitation address option	ip address
IP address for router solicitation address option	192.168.2.33
DHCP MAC Address Configuration	
Static binding MAC address	01:03:05:07:09:0B
Fixed address	192.168.2.50

Minimum DHCP Local Server Configuration

The following sample output shows the minimum configuration you must use to configure an SRX Series device as a DHCP local server. In this output, the server group is named `mobileusers`, and the DHCP local server is enabled on interface `ge-1/0/1.0` within the group.

```
[edit access]
address-assignment {
  pool acmenetwork family inet {
    network 192.168.1.0/24;
  }
}

edit system services
dhcp-local-server {
```

```
group mobileusers {  
  interface ge-1/0/1.0  
}  
}  
  
edit interfaces ge-1/0/1 unit 0  
family {  
  inet {  
    address 192.168.1.1/24  
  }  
}
```

NOTE: You can configure the DHCP local server in a routing instance by using the `dhcp-local server`, `interface`, and `address-assignment` statements in the `[edit routing-instances]` hierarchy level.

Related Documentation

- [Configuring Address-Assignment Pools on page 1094](#)

Configuring Address-Assignment Pools

The address-assignment pool feature enables you to create address pools that can be shared by different client applications.

To configure an address-assignment pool:

1. Configure the address-assignment pool name and specify the addresses for the pool.
See [“Configuring an Address-Assignment Pool Name and Addresses” on page 1095](#).
2. (Optional) Configure named ranges (subsets) of addresses.
See [“Configuring a Named Address Range for Dynamic Address Assignment” on page 1095](#).
3. (Optional; IPv4 only) Create static address bindings.
See [“Configuring Static Address Assignments” on page 1096](#).
4. (Optional) Configure attributes for DHCP clients.
See [“Configuring DHCP Client-Specific Attributes for Address-Assignment Pools” on page 1100](#).

Related Documentation

- [Configuring an Address-Assignment Pool Name and Addresses on page 1095](#)

Configuring an Address-Assignment Pool Name and Addresses

When configuring an address-assignment pool, you must specify the name of the pool and its addresses.

To configure an IPv4 address-assignment pool:

1. Configure the name of the pool and specify the IPv4 family.

```
[edit access]
user@host# edit address-assignment pool blr-pool family inet
```

2. Configure the network address and the prefix length of the addresses in the pool.

```
[edit access address-assignment pool blr-pool family inet]
user@host# set network 192.168.0.0/16
```

NOTE: You can configure an IPv4 address-assignment pool in a routing instance by configuring the address-assignment statements in the `[edit routing-instances]` hierarchy level.

Related Documentation

- [Configuring Address-Assignment Pools on page 1094](#)

Configuring a Named Address Range for Dynamic Address Assignment

You can optionally configure multiple named ranges, or subsets, of addresses within an address-assignment pool. During a dynamic address assignment, a client can be assigned an address from a specific named range. To create a named range, you specify a name for the range and define the address range.

To create a named range within an IPv4 address-assignment pool:

1. Specify the name of the address-assignment pool.

```
[edit access]
user@host# edit address-assignment pool blr-pool family inet
```

2. Configure the name of the range and the lower and upper boundaries of the addresses in the range.

```
[edit access address-assignment pool isp_] family inet]
user@host# set range southeast low 192.168.102.2 high 192.168.102.254
```

NOTE: To configure named address ranges in a routing instance, configure the address-assignment statements in the `[edit routing-instances]` hierarchy level.

Related Documentation • [Configuring Address-Assignment Pools on page 1094](#)

Configuring Static Address Assignments

You can optionally create a static IPv4 address binding by reserving a specific address for a particular client. The address is removed from the address-assignment pool so that it is not assigned to another client. When you reserve an address, you identify the client host and create a binding between the client MAC address and the assigned IP address.

To configure a static IPv4 address binding:

1. Specify the name of the IPv4 address-assignment pool containing the IP address you want to reserve for the client.

```
[edit access]
user@host# edit address-assignment pool blr-pool family inet
```

2. Specify the name of the client for the static binding, the client MAC address, and the IP address to reserve for the client. This configuration specifies that the client with MAC address 01:03:05:07:09:0b is always assigned IP address 192.168.10.2.

```
[edit access address-assignment pool blr-pool family inet]
user@host# set host svale6_boston_net hardware-address 01:03:05:07:09:0b
ip-address 192.168.10.2
```

NOTE: To configure static binding for an IPv4 address in a routing instance, configure the address-assignment statements in the [edit routing-instances] hierarchy.

Related Documentation • [Configuring Address-Assignment Pools on page 1094](#)

Enabling TCP/IP Propagation on a DHCP Local Server

This topic describes how to configure TCP/IP settings on a DHCP local server, which includes a DHCP client and a DHCP local server.

To enable TCP/IP setting propagation on a DHCP local server:

1. Configure the **update-server** option on the DHCP client.

```
[edit interfaces ge-0/0/1 unit 0 family inet]
dhcp-client {
  update-server;
}
```

2. Configure the address pool to specify the interface (where **update-server** is configured) from which TCP/IP settings can be propagated.

```
[edit access]
address-assignment {
```

```

pool sprint family inet {
  network 192.168.2.0/24;
  dhcp-attributes {
    propagate-settings ge-0/0/1.0;
  }
}

```

3. Configure the DHCP local server.

```

edit system services
dhcp-local-server {
  group bob {
    interface ge-1/0/1.0
  }
}

```

Verifying and Managing DHCP Local Server Configuration

Purpose View or clear information about client address bindings and statistics for the DHCP local server.

- Action**
- To display the address bindings in the client table on the DHCP local server:

```
user@host> show dhcp server binding
```

- To display DHCP local server statistics:

```
user@host> show dhcp server statistics
```

- To clear the binding state of a DHCP client from the client table on the DHCP local server:

```
user@host> clear dhcp server binding
```

- To clear all DHCP local server statistics:

```
user@host> clear dhcp server statistics
```

NOTE: To clear or view information about client bindings and statistics in a routing instance, run the following commands:

- `show dhcp server binding routing instance <routing-instance name>`
- `show dhcp server statistics routing instance <routing-instance name>`
- `clear dhcp server binding routing instance <routing-instance name>`
- `clear dhcp server statistics routing instance <routing-instance name>`

- [Configuring Optional DHCP Client Attributes on page 1101](#)
- [Verifying and Managing DHCP Client Configuration on page 1101](#)

Understanding DHCP Client Operation

A Juniper Networks device can act as a DHCP client, receiving its TCP/IP settings and the IP address for any physical interface in any security zone from an external DHCP server. The device can also act as a DHCP server, providing TCP/IP settings and IP addresses to clients in any zone. When the device operates as a DHCP client and a DHCP server simultaneously, it can transfer the TCP/IP settings learned through its DHCP client module to its default DHCP server module. For the device to operate as a DHCP client, you configure a logical interface on the device to obtain an IP address from the DHCP server in the network. You set the vendor class ID, lease time, DHCP server address, retransmission attempts, and retry interval. You can renew DHCP client releases.

DHCP client operations are supported on all SRX Series devices in chassis cluster mode.

Related Documentation

- [DHCP Server, Client, and Relay Agent Overview on page 1088](#)
- [Understanding DHCP Relay Agent Operation on page 1103](#)
- [DHCP Settings and Restrictions Overview on page 1089](#)

Minimum DHCP Client Configuration

The following sample output shows the minimum configuration you must use to configure an SRX Series device as a DHCP client. In this output, the interface is ge-0/0/0 and the logical unit is 0.

```
[edit interfaces]
ge-0/0/0 {
  unit 0 {
    family inet {
      dhcp-client
```

```

    }
  }
}

```

NOTE: To configure a DHCP client in a routing instance, add the interface in a routing instance using the [edit routing-instances] hierarchy.

Related Documentation

- [Configuring Optional DHCP Client Attributes on page 1101](#)

Configuring DHCP Client-Specific Attributes for Address-Assignment Pools

You use the address-assignment pool feature to include application-specific attributes when clients obtain an address. The client application, such as DHCP, uses the attributes to determine how addresses are assigned and to provide optional application-specific characteristics to the client. For example, the DHCP application might specify that a client that matches certain prerequisite information is dynamically assigned an address from a particular named range. Based on which named range is used, DHCP specifies additional DHCP attributes such as the boot file that the client uses, the DNS server, and the maximum lease time.

You use the **dhcp-attributes** statement to configure DHCP client-specific attributes for address-assignment pools.

To configure address-assignment pool attributes for DHCP clients:

1. Specify the name of the address-assignment pool.

```

[edit access]
user@host# edit address-assignment pool blr-pool family inet

```

2. Configure optional DHCP client attributes.

```

[edit access address-assignment pool blr-pool family inet]
user@host# set dhcp-attributes maximum-lease-time 2419200
user@host# set dhcp-attributes name-server 192.168.10.2
user@host# set dhcp-attributes boot-file boot-file.txt
user@host# set dhcp-attributes boot-file boot-server example.com

```

NOTE: To configure DHCP client-specific attributes in a routing instance, configure the **dhcp-attributes** statements in the [edit routing-instances] hierarchy.

Related Documentation

- [Configuring Address-Assignment Pools on page 1094](#)

Configuring Optional DHCP Client Attributes

For the device to operate as a DHCP client, you configure a logical interface on the device to obtain an IP address from the DHCP local server in the network. You can then set the client-identifier, options no-hostname, lease time, retransmission attempts, retry interval, preferred DHCP local server address, and vendor class ID.

To configure optional DHCP client attributes:

1. Configure the DHCP client identifier prefix as the routing instance name.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set client-identifier prefix host
```

2. Configure the DHCP options no-hostname if you do not want the client to send hostname (RFC option code 12) in the packets.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set options no-hostname
```

3. Set the DHCP lease time.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set lease-time 86400
```

4. Set the number of attempts allowed to retransmit a DHCP packet.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set retransmission-attempt 6
```

5. Set the interval (in seconds) allowed between retransmission attempts. The range is 4 through 64. The default is 4 seconds.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set retransmission-interval 5
```

6. Set the IPv4 address of the preferred DHCP local server.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set server-address 10.1.1.1
```

7. Set the vendor class ID for the DHCP client.

```
[edit interfaces ge-0/0/1 unit 0 family inet dhcp-client]
user@host# set vendor-id ether
```

NOTE: To configure the DHCP client in a routing instance, configure the interface in the [edit routing-instances] hierarchy.

CHAPTER 51

Configuring a DHCP Relay Agent

- [Understanding DHCP Relay Agent Operation on page 1103](#)
- [Minimum DHCP Relay Agent Configuration on page 1104](#)
- [Verifying and Managing DHCP Relay Configuration on page 1104](#)

Understanding DHCP Relay Agent Operation

A Juniper Networks device operating as a DHCP relay agent forwards incoming requests from BOOTP and DHCP clients to a specified BOOTP or DHCP server. Client requests can pass through virtual private network (VPN) tunnels.

You cannot configure a single device interface to operate as both a DHCP client and a DHCP relay.

NOTE: The DHCP requests received on an interface are associated to a DHCP pool that is in the same subnet as the primary IP address/subnet on an interface. If an interface is associated with multiple IP addresses/subnets, the device uses the lowest numerically assigned IP address as the primary IP address/subnet for the interface. To change the IP address/subnet that is listed as the primary address on an interface, use the `set interfaces < interface name > unit 0 family inet xxx.xxx.xxx.xxx/yy primary` command and commit the change.

Minimum DHCP Relay Agent Configuration

The following sample output shows the minimum configuration you must use to configure an SRX Series device as a DHCP relay agent. In this output, the active server group is named server-1 and its IP address is 203.0.113.1. The DHCP relay agent configuration is applied to a group named bob. Within this group, the DHCP relay agent is enabled on interface ge-1/0/1.0.

```
[edit forwarding-options]
dhcp-relay {
  server-group {
    server-1 {
      203.0.113.1;
    }
  }
  active-server-group server-1;
  group bob {
    interface ge-1/0/1.0;
  }
}
```

NOTE: To configure the DHCP relay agent in a routing instance, configure the `dhcp-relay` statements in the `[edit routing-instances]` hierarchy level.

Related Documentation

DHCPv6 Server Overview

A Dynamic Host Configuration Protocol version 6 (DHCPv6) server can automatically allocate IP addresses to IP version 6 (IPv6) clients and deliver configuration settings to client hosts on a subnet or to requesting devices that need an IPv6 prefix. A DHCPv6 server lets network administrators centrally manage a pool of IP addresses among hosts and automate the assignment of IP addresses in a network.

NOTE: SRX Series devices do not support DHCP client authentication. In a DHCPv6 deployment, security policies control access through the device for any DHCP client that has received an address and other attributes from the DHCPv6 server.

Some features include:

- Configuration for a specific interface or a group of interfaces
- Stateless address autoconfiguration (SLAAC)
- Prefix delegation, including access-internal route installation
- DHCPv6 server groups

The DHCPv6 server configuration usually consists of DHCPv6 options for clients, an IPv6 prefix, an address pool that contains IPv6 address ranges and options, and a security

policy to allow DHCPv6 traffic. In a typical setup the provider Juniper Networks device is configured as an IPv6 prefix delegation server that assigns addresses to the customer edge device. The customer's edge router then provides addresses to internal devices.

To configure DHCPv6 local server on a device, you include the DHCPv6 statement at the **[edit system services dhcp-local-server]** hierarchy level. You then create an address assignment pool for DHCPv6 that is configured in the **[edit access address-assignment pool]** hierarchy level using the **family inet6** statement.

You can also include the **dhcpv6** statement at the **[edit routing-instances routing-instance-name system services dhcp-local-server]** hierarchy.

NOTE: Existing DHCPv4 configurations in the **[edit system services dhcp]** hierarchy are not affected when you upgrade to Junos OS Release 10.4 from an earlier version or enable DHCPv6 server.

Related Documentation

- [Example: Configuring DHCPv6 Server Options on page 1109](#)
- [Example: Configuring an Address-Assignment Pool on page 1111](#)
- [Configuring a Named Address Range for Dynamic Address Assignment on page 1114](#)
- [Creating a Security Policy for DHCPv6 on page 1108](#)

Creating a Security Policy for DHCPv6

For the DHCPv6 server to allow DHCPv6 requests, you must create a security policy to enable DHCPv6 traffic. In this example, the zone **my-zone** allows DHCPv6 traffic from the zone **untrust**, and the **ge-0/0/3.0** interface is configured with the IPv6 address **2001:db8:3001::1**.

To create a security zone policy to allow DHCPv6:

1. Create the zone and add an interface to that zone.

```
[edit security zones]
user@host# edit security-zone my-zone interfaces ge-0/0/3.0
```

2. Configure host inbound traffic system services to allow DHCPv6.

```
[edit security zones security-zone my-zone interfaces ge-0/0/3.0]
user@host# set host-inbound-traffic system-services dhcpv6
```

3. If you are done configuring the device, enter **commit** from configuration mode.

Example: Configuring DHCPv6 Server Options

This example shows how to configure DHCPv6 server options.

- [Requirements on page 1109](#)
- [Overview on page 1109](#)
- [Configuration on page 1109](#)
- [Verification on page 1111](#)

Requirements

Before you begin:

- Determine the IPv6 address pool range.
- Determine the IPv6 prefix. See the *Understanding Address Books*.
- Determine the grace period, maximum lease time, or any custom options that should be applied to clients.
- List the IP addresses that are available for the devices on your network; for example, DNS and SIP servers.

Overview

In this example, you set a default client limit as 100 for all DHCPv6 groups. You then create a group called my-group that contains at least one interface. In this case, the interface is ge-0/0/3.0. You set a range of interfaces using the upto command and set a custom client limit as 200 for group my-group that overrides the default limit. Finally, you configure interface ge-0/0/3.0 with IPv6 address 2001:db8:3001::1/64 and set router advertisement for interface ge-0/0/3.0.

NOTE: A DHCPv6 group must contain at least one interface.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system services dhcp-local-server dhcpv6 overrides interface-client-limit 100
set system services dhcp-local-server dhcpv6 group my-group interface ge-0/0/3.0
set system services dhcp-local-server dhcpv6 group my-group interface ge-0/0/3.0 upto
  ge-0/0/6.0
set system services dhcp-local-server dhcpv6 group my-group overrides
  interface-client-limit 200
set interfaces ge-0/0/3 unit 0 family inet6 address 2001:db8:3000::1/64
set protocols router-advertisement interface ge-0/0/3.0 prefix 2001:db8:3000::/64
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure DHCPv6 server options:

1. Configure a DHCP local server.

```
[edit]  
user@host# edit system services dhcp-local-server dhcpv6
```
2. Set a default limit for all DHCPv6 groups.

```
[edit system services dhcp-local-server dhcpv6]  
user@host# set overrides interface-client-limit 100
```
3. Specify a group name and interface.

```
[edit system services dhcp-local-server dhcpv6]  
user@host# set group my-group interface ge-0/0/3.0
```
4. Set a range of interfaces.

```
[edit system services dhcp-local-server dhcpv6]  
user@host# set group my-group interface ge-0/0/3.0 upto ge-0/0/6.0
```
5. Set a custom client limit for the group.

```
[edit system services dhcp-local-server dhcpv6]  
user@host# set group my-group overrides interface-client-limit 200
```
6. Configure an interface with an IPv6 address.

```
[edit interfaces]  
user@host# set ge-0/0/3 unit 0 family inet6 address 2001:db8:3000::1/64
```
7. Set router advertisement for the interface.

```
[edit protocols]  
user@host# set router-advertisement interface ge-0/0/3.0 prefix  
2001:db8:3000::/64
```

Results From configuration mode, confirm your configuration by entering the **show system services dhcp-local-server**, **show interfaces ge-0/0/3**, and **show protocols** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]  
user@host# show system services dhcp-local-server  
dhcpv6 {  
  overrides {  
    interface-client-limit 100;  
  }  
  group my-group {  
    overrides {  
      interface-client-limit 200;  
    }  
    interface ge-0/0/3.0 {  
      upto ge-0/0/6.0;  
    }  
  }  
}
```

```

}
}
[edit]
user@host# show interfaces ge-0/0/3
unit 0 {
family inet6 {
address 2001:db8:3000::1/64;
}
}
[edit]
user@host# show protocols
router-advertisement {
interface ge-0/0/3.0 {
prefix 2001:db8:3000::1/64;
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying DHCPv6 Local Server Configuration

Purpose	Verify that the client address bindings and statistics for the DHCPv6 local server have been configured
Action	<p>From operational mode, enter these commands:</p> <ul style="list-style-type: none"> • show dhcpv6 server binding command to display the address bindings in the client table on the DHCPv6 local server. • show dhcpv6 server statistics command to display the DHCPv6 local server statistics. • clear dhcpv6 server bindings all command to clear all DHCPv6 local server bindings. You can clear all bindings or clear a specific interface, or routing instance. • clear dhcpv6 server statistics command to clear all DHCPv6 local server statistics.
Related Documentation	<ul style="list-style-type: none"> • DHCPv6 Server Overview on page 1107 • Example: Configuring an Address-Assignment Pool on page 1111 • Configuring a Named Address Range for Dynamic Address Assignment on page 1114 • Creating a Security Policy for DHCPv6 on page 1108

Example: Configuring an Address-Assignment Pool

This example shows how to configure an address-assignment pool.

- [Requirements on page 1112](#)
- [Overview on page 1112](#)

- [Configuration on page 1112](#)
- [Verification on page 1113](#)

Requirements

Before you begin:

- Specify the name of the address-assignment pool and configure addresses for the pool.
- Set DHCPv6 attributes for the address-assignment pool.

Overview

In this example, you configure an address-pool called `my-pool` and specify the IPv6 family as `inet6`. You configure the IPv6 prefix as `2001:db8:3000:1::/64`, the range name as `range1`, and the IPv6 range for DHCPv6 clients from a low of `2001:db8:3000:1::/64` to a high of `2001:db8:3000:200::/64`. You can define the range based on the lower and upper boundaries of the prefixes in the range or based on the length of the prefixes in the range. Finally, you specify the DHCPv6 attribute for the DNS server as `2001:db8:3001::1`, the grace period as `3600`, and the maximum lease time as `120`.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set access address-assignment pool my-pool family inet6 prefix 2001:db8:3000:1::/64
set access address-assignment pool my-pool family inet6 range range1 low
  32001:db8:3000:1::/64 high 2001:db8:3000:200::/64
set access address-assignment pool my-pool family inet6 dhcp-attributes dns-server
  2001:db8:3001::1
set access address-assignment pool my-pool family inet6 dhcp-attributes grace-period
  3600
set access address-assignment pool my-pool family inet6 dhcp-attributes
  maximum-lease-time 120
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure an IPv6 address-assignment pool:

1. Configure an address-pool and specify the IPv6 family.

```
[edit access]
user@host# edit address-assignment pool my-pool family inet6
```
2. Configure the IPv6 prefix, the range name, and IPv6 range for DHCPv6 clients.

```
[edit access address-assignment pool my-pool family inet6]
user@host# set prefix 2001:db8:3000:1::/64
```

```
user@host# set range range1 low 2001:db8:3000:1::/64 high
2001:db8:3000:200::/64
```

3. Configure the DHCPv6 attribute for the DNS server for the address pool.

```
[edit access address-assignment pool my-pool family inet6]
user@host# set dhcp-attributes dns-server 2001:db8:3001::1
```

4. Configure the DHCPv6 attribute for the grace period.

```
[edit access address-assignment pool my-pool family inet6]
user@host# set dhcp-attributes grace-period 3600
```

5. Configure the DHCPv6 attribute for the maximum lease time.

```
[edit access address-assignment pool my-pool family inet6]
user@host# set dhcp-attributes maximum-lease-time 120
```

Results From configuration mode, confirm your configuration by entering the **show access address-assignment** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show access address-assignment
pool my-pool {
  family inet6 {
    prefix 2001:db8:3000:1::/64;
    range range1 {
      low 2001:db8:3000:1::/64 ;
      high 2001:db8:3000:200::/64;
    }
    dhcp-attributes {
      maximum-lease-time 120;
      grace-period 3600;
      dns-server {
        2001:db8:3001::1;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Configuration

Purpose Verify that the address-assignment pool has been configured.

Action From operational mode, enter the **show access address-assignment** command.

Configuring a Named Address Range for Dynamic Address Assignment

You can optionally configure multiple named ranges, or subsets of addresses, within an address-assignment pool. During dynamic address assignment, a client can be assigned an address from a specific named range. To create a named range, you specify a name for the range and define the address range and DHCPv6 attributes.

To configure a named address range for dynamic address assignment:

1. Specify the name of the address-assignment pool and the IPv6 family.

```
[edit access]
user@host# edit address-assignment pool my-pool2 family inet6
```

2. Configure the IPv6 prefix and then define the range name and IPv6 range for DHCPv6 clients. You can define the range based on the lower and upper boundaries of the prefixes in the range, or based on the length of the prefixes in the range.

```
[edit access address-assignment pool my-pool2 family inet6]
user@host# set prefix 2001:db8:3000:5::/64
user@host# set range range2 low 2001:db8:3000:2::/64 high 2001:db8:3000:300::/64
```

3. Configure DHCPv6 attributes for the address pool.

```
[edit access address-assignment pool my-pool2 family inet6]
user@host# set dhcp-attributes dns-server 2001:db8:18:: grace-period 3600
maximum-lease-time 120
```

4. If you are done configuring the device, enter **commit** from configuration mode.

Related Documentation

- [Configuring Address-Assignment Pool Linking on page 1114](#)

Configuring Address-Assignment Pool Linking

Address-assignment pool linking enables you to specify a secondary address pool for the device to use when the primary address-assignment pool is fully allocated. When the primary pool has no available addresses remaining, the device automatically switches over to the linked secondary pool and begins allocating addresses from that pool. The device uses a secondary pool only when the primary address-assignment pool is fully allocated.

You can create a chain of multiple linked pools. For example, you can link pool A to pool B, and link pool B to pool C. When pool A has no available addresses, the device switches to pool B for addresses. When pool B is exhausted, the device switches to pool C. There is no limit to the number of linked pools in a chain. However, you cannot create multiple links to or from the same pool—a pool can be linked to only one secondary pool, and a secondary pool can be linked from only one primary pool.

To link a primary address-assignment pool named `pool1` to a secondary pool named `pool2`:

```
[edit access address-assignment]
user@host# set pool pool1 link pool2
```

**Related
Documentation**

- [Configuring a Named Address Range for Dynamic Address Assignment on page 1095](#)

Configuring DHCP Client-Specific Attributes

You use the address-assignment pool feature to include application-specific attributes when clients obtain an address. A client application, such as DHCPv6, uses the attributes to determine how addresses are assigned and to provide optional application-specific characteristics to the client. For example, the DHCPv6 application might specify that a client that matches certain prerequisite information is dynamically assigned an address from a particular named range. Based on which named range is used, DHCPv6 specifies additional DHCPv6 attributes such as the DNS server or the maximum lease time for clients.

You use the **dhcp-attributes** statement to configure DHCPv6 client-specific attributes for address-assignment pools at the **[edit access address-assignment pool *pool-name* family inet6]** hierarchy.

[Table 85](#) describes the DHCPv6 client attributes for configuring IPv6 address-assignment pools.

Table 85: DHCPv6 Attributes

Attribute	Description	DHCPv6 Option
dns-server	IPv6 address of DNS server to which clients can send DNS queries	23
grace-period	Grace period offered with the lease	—
maximum-lease-time	Maximum lease time allowed by the DHCPv6 server	—
option	User-defined options	—
sip-server-address	IPv6 address of SIP outbound proxy server	22
sip-server-domain-name	Domain name of the SIP outbound proxy server	21

Documentation**

- [Configuring a Named Address Range for Dynamic Address Assignment on page 1114](#)

Configuring an Address-Assignment Pool for Router Advertisement

You can create an address-assignment pool that is explicitly used for router advertisement address assignment. You populate the address-assignment pool using the standard procedure, but you additionally specify that the pool is used for router advertisement.

To configure an address-assignment pool that is used for router advertisement:

1. Create the IPv6 address-assignment pool.
2. Specify that the address-assignment pool is used for router advertisement.

```
[edit access address-assignment]
user@host# set neighbor-discovery-router-advertisement router1
```

3. If you are done configuring the device, enter **commit** from configuration mode.

Related Documentation

- [Configuring a Named Address Range for Dynamic Address Assignment on page 1114](#)

Understanding DHCPv6 Client and Server Identification

Each DHCPv6 client and server is identified by a DHCP unique identifier (DUID). The DUID is unique across all DHCPv6 clients and servers, and it is stable for any specific client or server. DHCPv6 clients use DUIDs to identify a server in messages where a server needs to be identified. DHCPv6 servers use DUIDs to determine the configuration parameters to be used for clients and in the association of addresses with clients.

The DUID is a 2-octet type code represented in network byte order, followed by a variable number of octets that make up the actual identifier; for example, 00:02:00:01:02:03:04:05:07:a0. A DUID can be up to 128 octets in length (excluding the type code). The following types are currently defined for the DUID parameter:

- Type 1—Link Layer address plus time (duid-llt)
- Type 2—Vendor-assigned unique ID based on enterprise number (vendor)
- Type 3—Link Layer address (duid-ll)

The duid-llt DUID consists of a 2-octet type field that contains the value 1, a 2-octet hardware type code, 4 octets that signify a time value, followed by the Link Layer address of any one network interface that is connected to the DHCP device at the time that the DUID is generated.

The vendor DUID is assigned by the vendor to the device and contains the vendor's registered private enterprise number as maintained by the identity association for nontemporary addresses (IA_NA) assignment, followed by a unique identifier assigned by the vendor.

The duid-ll DUID contains a 2-octet type field that stores the value 3, and a 2-octet network hardware type code, followed by the Link Layer address of any one network interface that is permanently connected to the client or server device.

DHCPv6 Client Overview

A Juniper Networks device can act as a Dynamic Host Configuration Protocol version 6 (DHCPv6) client, receiving its TCP/IP settings and the IPv6 address for any physical interface in any security zone from an external DHCPv6 server. When the device operates as a DHCPv6 client and a DHCPv6 server simultaneously, it can transfer the TCP/IP settings learned through its DHCPv6 client module to its default DHCPv6 server module. For the device to operate as a DHCPv6 client, you configure a logical interface on the device to obtain an IPv6 address from the DHCPv6 server in the network.

DHCPv6 client support for Juniper Networks devices includes the following features:

- Identity association for nontemporary addresses (IA_NA)
- Identity association for prefix delegation (IA_PD)
- Rapid commit
- TCP/IP propagation
- Auto-prefix delegation
- Autoconfig mode (stateful and stateless)

To configure the DHCPv6 client on the device, include the **dhcpv6-client** statement at the **[edit interfaces]** hierarchy level.

NOTE: To configure a DHCPv6 client in a routing instance, add the interface in a routing instance using the **[edit routing-instances]** hierarchy.

NOTE: On all SRX Series devices, DHCPv6 client authentication is not supported.

NOTE: On all branch SRX Series devices, DHCPv6 client does not support:

- Temporary addresses
- Reconfigure messages
- Multiple identity association for nontemporary addresses (IA_NA)
- Multiple prefixes in a single identity association for prefix delegation (IA_PD)
- Multiple prefixes in a single router advertisement

Related Documentation

- [Minimum DHCPv6 Client Configuration on page 1121](#)

Minimum DHCPv6 Client Configuration

This topic describes the minimum configuration you must use to configure an SRX Series device as a DHCPv6 client.

To configure the device as a DHCPv6 client:

1. Specify the DHCPv6 client interface.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client
```

2. Configure the DHCPv6 client type. The client type can be **autoconfig** or **statefull**.

- To enable DHCPv6 auto configuration mode, configure the client type as **autoconfig**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-type autoconfig
```

- For stateful address assignment, configure the client type as **statefull**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-type statefull
```

3. Specify the identity association type.

- To configure identity association for nontemporary address (IA_NA) assignment, specify the **client-ia type** as **ia-na**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-na
```

- To configure identity association for prefix delegation (IA_PD), specify the **client-ia-type** as **ia-pd**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-pd
```

4. Configure the DHCPv6 client identifier by specifying the DHCP unique identifier (DUID) type. The following DUID types are supported:

- Link Layer address (duid-ll)
- Link Layer address plus time (duid-llt)
- Vendor-assigned unique ID based on enterprise number (vendor)

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-identifier duid-type duid-ll
```

NOTE: To configure a DHCPv6 client in a routing instance, add the interface to a routing instance using the `[edit routing-instances]` hierarchy.

Related Documentation

- [DHCPv6 Client Overview on page 1120](#)

Configuring Optional DHCPv6 Client Attributes

To enable a device to operate as a DHCPv6 client, you configure a logical interface on the device to obtain an IPv6 address from the DHCPv6 local server in the network. You can then specify the retransmission attempts, client requested configuration options, interface used to delegate prefixes, rapid commit, and update server options.

To configure optional DHCPv6 client attributes:

1. Specify one of the following DHCPv6 client requested configuration options:

- dns-server
- domain
- ntp-server
- sip-domain
- sip-server

For example, to specify the DHCPv6 client requested option as **dns-server**:

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set req-option dns-server
```

2. Set the number of attempts allowed to retransmit a DHCPv6 client protocol packet.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set retransmission-attempt 6
```

3. Configure the **update-server** option on the DHCPv6 client.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set update-server
```

4. Specify the interface used to delegate prefixes.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set update-router-advertisement interface ge-0/0/0
```

5. Configure the two-message (rapid commit) exchange option for address assignment.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set rapid-commit
```

NOTE: To configure a DHCPv6 client in a routing instance, add the interface to a routing instance using the [edit routing-instances] hierarchy.

NOTE: On all SRX Series devices, DHCPv6 client authentication is not supported.

NOTE: On all branch SRX Series devices, DHCPv6 client does not support:

- Temporary addresses
- Reconfigure messages
- Multiple identity association for nontemporary addresses (IA_NA)
- Multiple prefixes in a single identity association for prefix delegation (IA_PD)
- Multiple prefixes in a single router advertisement

Related Documentation • [Minimum DHCPv6 Client Configuration on page 1121](#)

Configuring Nontemporary Address Assignment

Nontemporary address assignment is also known as stateful address assignment. In the stateful address assignment mode, the DHCPv6 client requests global addresses from the DHCPv6 server. Based on the DHCPv6 server's response, the DHCPv6 client assigns the global addresses to interfaces and sets a lease time for all valid responses. When the lease time expires, the DHCPv6 client renews the lease from the DHCPv6 server.

To configure nontemporary (stateful) address assignment:

1. Specify the DHCPv6 client interface.

[edit]

```
user@host# set interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client
```

2. Configure the client type as **statefull**.

[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]

```
user@host# set client-type statefull
```

3. Specify the IA_NA assignment.

[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]

```
user@host# set client-ia-type ia-na
```

Related Documentation • [Minimum DHCPv6 Client Configuration on page 1121](#)

Configuring Identity Associations for Nontemporary Addresses and Prefix Delegation

The DHCPv6 client requests IPv6 addresses and prefixes from the DHCPv6 server. Based on the DHCPv6 server's response, the DHCPv6 client assigns the IPv6 addresses to interfaces and sets a lease time for all valid responses. When the lease time expires, the DHCPv6 client renews the lease from the DHCPv6 server.

To configure identity association for nontemporary addresses (IA_NA) and identity association for prefix delegation (IA_PD):

1. Specify the DHCPv6 client interface.

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client
```

2. Configure the client type as **statefull**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-type statefull
```

3. Specify the IA_NA.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-na
```

4. Specify the IA_PD.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-pd
```

Related Documentation

- [Minimum DHCPv6 Client Configuration on page 1121](#)

Configuring Auto-Prefix Delegation

You can use DHCPv6 client prefix delegation to automate the delegation of IPv6 prefixes to the customer premises equipment (CPE). With prefix delegation, a delegating router delegates IPv6 prefixes to a requesting router. The requesting router then uses the prefixes to assign global IPv6 addresses to the devices on the subscriber LAN. The requesting router can also assign subnet addresses to subnets on the LAN.

To configure auto-prefix delegation:

1. Configure the DHCPv6 client type as **statefull**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-type statefull
```

2. Specify the identity association type as **ia-na** for nontemporary addresses.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-na
```

3. Specify the identity association type as **ia-pd** for prefix delegation.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-pd
```

4. Configure the DHCPv6 client identifier by specifying the DUID type.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]  
user@host# set client-identifier duid-type duid-ll
```

5. Specify the interface used to delegate prefixes.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]  
user@host# set update-router-advertisement interface ge-0/0/0
```

- [Configuring Optional DHCPv6 Client Attributes on page 1122](#)

Configuring the DHCPv6 Client Rapid Commit Option

The DHCPv6 client can obtain configuration parameters from a DHCPv6 server through a rapid two-message exchange (solicit and reply). When the rapid commit option is enabled by both the DHCPv6 client and the DHCPv6 server, the two-message exchange is used, rather than the default four-method exchange (solicit, advertise, request, and reply). The two-message exchange provides faster client configuration and is beneficial in environments in which networks are under a heavy load.

To configure the DHCPv6 client to support the DHCPv6 rapid commit option:

1. Specify the DHCPv6 client interface.

```
[edit]  
user@host# set interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client
```

2. Configure the two-message exchange option for address assignment.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]  
user@host# set rapid-commit
```

**Related
Documentation**

- [DHCPv6 Client Overview on page 1120](#)

Configuring a DHCPv6 Client in Autoconfig Mode

A DHCPv6 client configured in autoconfig mode acts as a stateful client, a stateless client (DHCPv6 server is required for TCP/IP configuration), and stateless–no DHCP client, based on the managed (M) and other configuration (O) bits in the received router advertisement messages.

If the managed bit is 1 and the other configuration bit is 0, the DHCPv6 client acts as a stateful client. In stateful mode, the client receives IPv6 addresses from the DHCPv6 server, based on the identity association for nontemporary addresses (IA_NA) assignment.

If the managed bit is 0 and the other configuration bit is 1, the DHCPv6 client acts as a stateless client. In stateless mode, the addresses are automatically configured, based on the prefixes in the router advertisement messages received from the router. The stateless client receives configuration parameters from the DHCPv6 server.

If the managed bit is 0 and the other configuration bit is also 0, the DHCPv6 client acts as a stateless–no DHCP client. In the stateless–no DHCP mode, the client receives IPv6 addresses from the router advertisement messages.

To configure DHCPv6 client in autoconfig mode:

1. Configure the DHCPv6 client type as **autoconfig**.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-type autoconfig
```

2. Specify the identity association type as **ia-na** for nontemporary addresses.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
user@host# set client-ia-type ia-na
```

3. Specify the interface on which to configure router advertisement.

```
[edit protocols router-advertisement]
user@host# set interface ge-0/0/1.0
```

Configuring TCP/IP Propagation on a DHCPv6 Client

You can enable or disable the propagation of TCP/IP settings received on the device acting as a DHCPv6 client. The settings can be propagated to the server pool running on the device. This topic describes how to configure TCP/IP settings on a DHCPv6 client, where both the DHCPv6 client and DHCPv6 server are on the same device.

To configure TCP/IP setting propagation on a DHCPv6 client:

1. Configure the **update-server** option on the DHCPv6 client.

```
[edit interfaces ge-0/0/0 unit 0 family inet6 dhcpv6-client]
```

```
user@host# set update-server
```

2. Configure the address pool to specify the interface (where **update-server** is configured) from which TCP/IP settings can be propagated.

```
[edit access]
```

```
user@host# set address-assignment pool 2 family inet6 dhcp-attributes  
propagate-settings ge-0/0/0
```

File Management Overview

You can use the J-Web user interface and the CLI to perform routine file management operations such as archiving log files and deleting unused log files, cleaning up temporary files and crash files, and downloading log files from the routing platform to your computer. You can also encrypt the configuration files with the CLI to prevent unauthorized users from viewing sensitive configuration information.

Before you perform any file management tasks, you must perform the initial device configuration described in the Getting Started Guide for your device.

Decrypting Configuration Files

To disable the encryption of configuration files on a device and make them readable to all:

1. Enter operational mode in the CLI.
2. Verify your permission to decrypt configuration files on this device by entering the encryption key for the device.

```
user@host> request system set-encryption-key
Enter EEPROM stored encryption key:
Verifying EEPROM stored encryption key:
```

3. At the second prompt, reenter the encryption key.
4. Enter configuration mode in the CLI.
5. Enable configuration file decryption.

```
[edit]
user@host# edit system
user@host# set no-encrypt-configuration-files
```

6. Begin the decryption process by committing the configuration.

```
[edit]
user@host# commit
commit complete
```

- [Encrypting Configuration Files on page 1132](#)

Encrypting Configuration Files

To configure an encryption key in EEPROM and determine the encryption process, enter one of the **request system set-encryption-key** commands in operational mode described in [Table 86](#).

NOTE: The **request system set-encryption-key** command is not supported on high-end SRX Series devices; therefore, this task does not apply to such devices.

Table 86: request system set-encryption-key Commands

CLI Command	Description
request system set-encryption-key	Sets the encryption key and enables default configuration file encryption: <ul style="list-style-type: none"> • AES encryption for the Canada and U.S. version of Junos OS • DES encryption for the international version of Junos OS

Table 86: request system set-encryption-key Commands (*continued*)

CLI Command	Description
request system set-encryption-key algorithm des	Sets the encryption key and specifies configuration file encryption by DES.
request system set-encryption-key unique	<p>Sets the encryption key and enables default configuration file encryption with a unique encryption key that includes the chassis serial number of the device.</p> <p>Configuration files encrypted with the unique key can be decrypted only on the current device. You cannot copy such configuration files to another device and decrypt them.</p>
request system set-encryption-key des unique	Sets the encryption key and specifies configuration file encryption by DES with a unique encryption key.

To encrypt configuration files on a device:

1. Enter operational mode in the CLI.
2. Configure an encryption key in EEPROM and determine the encryption process; for example, enter the **request system set-encryption-key** command.

```
user@host> request system set-encryption-key
Enter EEPROM stored encryption key:
```

3. At the prompt, enter the encryption key. The encryption key must have at least six characters.

```
Enter EEPROM stored encryption key:juniper1
Verifying EEPROM stored encryption key:
```

4. At the second prompt, reenter the encryption key.
5. Enter configuration mode in the CLI.
6. Enable configuration file encryption to take place.

```
[edit]
user@host# edit system
user@host# set encrypt-configuration-files
```

7. Begin the encryption process by committing the configuration.

```
[edit]
user@host# commit
commit complete
```

- [Decrypting Configuration Files on page 1132](#)

Modifying the Encryption Key

When you modify the encryption key, the configuration files are decrypted and then reencrypted with the new encryption key.

To modify the encryption key:

1. Enter operational mode in the CLI.
2. Configure a new encryption key in EEPROM and determine the encryption process; for example, enter the **request system set-encryption-key** command.

```
user@host> request system set-encryption-key
Enter EEPROM stored encryption key:
```

3. At the prompt, enter the new encryption key. The encryption key must have at least six characters.

```
Enter EEPROM stored encryption key:juniperone
Verifying EEPROM stored encryption key:
```

4. At the second prompt, reenter the new encryption key.

Cleaning Up Files in J-Web

You can use the J-Web user interface to rotate log files and delete unnecessary files on the device. If you are running low on storage space, the file cleanup procedure quickly identifies files that can be deleted.

The file cleanup procedure performs the following tasks:

- Rotates log files—Archives all information in the current log files and creates fresh log files.
- Deletes log files in **/var/log**—Deletes any files that are not currently being written to.
- Deletes temporary files in **/var/tmp**—Deletes any files that have not been accessed within two days.
- Deletes all crash files in **/var/crash**—Deletes any core files that the device has written during an error.
- Deletes all software images (*.tgz files) in **/var/sw/pkg**—Deletes any software images copied to this directory during software upgrades.

To rotate log files and delete unnecessary files with the J-Web user interface:

1. In the J-Web user interface, select **Maintain>Files**.

2. In the Clean Up Files section, click **Clean Up Files**. The device rotates log files and identifies the files that can be safely deleted.

The J-Web user interface displays the files that you can delete and the amount of space that will be freed on the file system.

3. Click one of the following buttons on the confirmation page:
 - To delete the files and return to the Files page, click **OK**.
 - To cancel your entries and return to the list of files in the directory, click **Cancel**.

Related Documentation

- [Managing Accounting Files on page 1141](#)
- [Encrypting Configuration Files on page 1132](#)
- [Decrypting Configuration Files on page 1132](#)
- [Cleaning Up Files with the CLI on page 1135](#)

Cleaning Up Files with the CLI

You can use the CLI **request system storage cleanup** command to rotate log files and delete unnecessary files on the device. If you are running low on storage space, the file cleanup procedure quickly identifies files that can be deleted.

The file cleanup procedure performs the following tasks:

- Rotates log files—Archives all information in the current log files, deletes old archives, and creates fresh log files.
- Deletes log files in **/var/log**—Deletes any files that are not currently being written to.
- Deletes temporary files in **/var/tmp**—Deletes any files that have not been accessed within two days.
- Deletes all crash files in **/var/crash**—Deletes any core files that the device has written during an error.
- Deletes all software images (***.tgz** files) in **/var/sw/pkg**—Deletes any software images copied to this directory during software upgrades.

To rotate log files and delete unnecessary files with the CLI:

1. Enter operational mode in the CLI.
2. Rotate log files and identify the files that can be safely deleted.

```
user@host> request system storage cleanup
```

The device rotates log files and displays the files that you can delete.

3. Enter **yes** at the prompt to delete the files.

NOTE: You can issue the `request system storage cleanup dry-run` command to review the list of files that can be deleted with the `request system storage cleanup` command, without actually deleting the files.

NOTE:

On SRX Series devices, the `/var` hierarchy is hosted in a separate partition (instead of the root partition). If Junos OS installation fails as a result of insufficient space:

- Use the `request system storage cleanup` command to delete temporary files.
- Delete any user-created files in both the root partition and under the `/var` hierarchy.

Related Documentation

- [Cleaning Up Files in J-Web on page 1134](#)
- [Managing Accounting Files on page 1141](#)
- [Encrypting Configuration Files on page 1132](#)

Deleting Files

You can use the J-Web user interface to delete an individual file from the device. When you delete the file, it is permanently removed from the file system.

CAUTION: If you are unsure whether to delete a file from the device, we recommend using the **Cleanup Files** tool. This tool determines which files can be safely deleted from the file system.

To delete files with the J-Web user interface:

1. In the J-Web user interface, select **Maintain>Files**.
2. In the Download and Delete Files section, click one of the following file types:
 - **Log Files**—Lists the log files located in the `/var/log` directory on the device.
 - **Temporary Files**—Lists the temporary files located in the `/var/tmp` directory on the device.
 - **Old Junos OS**—Lists the software images in the (`*.tgz` files) in the `/var/sw/pkg` directory on the device.
 - **Crash (Core) Files**—Lists the core files located in the `/var/crash` directory on the device.

The J-Web user interface displays the files located in the directory.

3. Check the box next to each file you plan to delete.
4. Click **Delete**.

The J-Web user interface displays the files you can delete and the amount of space that will be freed on the file system.

5. Click one of the following buttons on the confirmation page:
 - To delete the files and return to the Files page, click **OK**.
 - To cancel your entries and return to the list of files in the directory, click **Cancel**.

Related Documentation

- [Managing Accounting Files on page 1141](#)

Deleting the Backup Software Image

Junos OS keeps a backup image of the software that was previously installed so that you can downgrade to that version of the software if necessary. You can use the J-Web user interface to delete this backup image. If you delete this image, you cannot downgrade to this particular version of the software.

To delete the backup software image:

1. In the J-Web user interface, select **Maintain>Files**.
2. Review the backup image information listed in the Delete Backup Junos Package section.
3. Click the **Delete backup Junos package** link to delete the backup image.
4. Click one of the following buttons on the confirmation page:
 - To delete the backup image and return to the Files page, click **OK**.
 - To cancel the deletion of the backup image and return to the Files page, click **Cancel**.

Related Documentation

- [Deleting Files on page 1136](#)

Downloading Files

You can use the J-Web user interface to download a copy of an individual file from the device. When you download a file, it is not deleted from the file system.

To download files with the J-Web user interface:

1. In the J-Web user interface, select **Maintain>Files**.
2. In the Download and Delete Files section, click one of the following file types:
 - **Log Files**—Lists the log files located in the **/var/log** directory on the device.
 - **Temporary Files**—Lists the temporary files located in the **/var/tmp** directory on the device.

- **Old Junos OS**—Lists the software images located in the (***.tgz** files) in the **/var/sw/pkg** directory on the device.
- **Crash (Core) Files**—Lists the core files located in the **/var/crash** directory on the device.

The J-Web user interface displays the files located in the directory.

3. Click **Download** to download an individual file.
4. Choose a location for the browser to save the file.

The file is downloaded.

Documentation**

- [Managing Accounting Files on page 1141](#)

Configuring RADIUS System Accounting

With RADIUS accounting enabled, Juniper Networks routers or switches, acting as RADIUS clients, can notify the RADIUS server about user activities such as software logins, configuration changes, and interactive commands. The framework for RADIUS accounting is described in RFC 2866.

Tasks for configuring RADIUS system accounting are:

1. [Configuring Auditing of User Events on a RADIUS Server on page 1138](#)
2. [Specifying RADIUS Server Accounting and Auditing Events on page 1139](#)
3. [Configuring RADIUS Server Accounting on page 1139](#)

Configuring Auditing of User Events on a RADIUS Server

To audit user events, include the following statements at the **[edit system accounting]** hierarchy level:

```
[edit system accounting]
destination {
  radius {
    server {
      server-address {
        accounting-port port-number;
        max-outstanding-requests value;
        port port-number;
        retry value;
        secret password;
        source-address address;
        timeout seconds;
      }
    }
  }
}
```

Specifying RADIUS Server Accounting and Auditing Events

To specify the events you want to audit when using a RADIUS server for authentication, include the **events** statement at the **[edit system accounting]** hierarchy level:

```
[edit system accounting]
events [ events ];
```

events is one or more of the following:

- **login**—Audit logins
- **change-log**—Audit configuration changes
- **interactive-commands**—Audit interactive commands (any command-line input)

Configuring RADIUS Server Accounting

To configure RADIUS server accounting, include the **server** statement at the **[edit system accounting destination radius]** hierarchy level:

```
server {
  server-address {
    accounting-port port-number;
    max-outstanding-requests value;
    port port-number;
    retry value;
    secret password;
    source-address address;
    timeout seconds;
  }
}
```

server-address specifies the address of the RADIUS server. To configure multiple RADIUS servers, include multiple **server** statements.

NOTE: If no RADIUS servers are configured at the **[edit system accounting destination radius]** statement hierarchy level, the Junos OS uses the RADIUS servers configured at the **[edit system radius-server]** hierarchy level.

accounting-port *port-number* specifies the RADIUS server accounting port number.

The default port number is 1813.

NOTE: If you enable RADIUS accounting at the **[edit access profile *profile-name* accounting-order]** hierarchy level, accounting is triggered on the default port of 1813 even if you do not specify a value for the **accounting-port** statement.

You must specify a secret (password) that the local router or switch passes to the RADIUS client by including the **secret** statement. If the password contains spaces, enclose the entire password in quotation marks (" ").

In the **source-address** statement, specify a source address for the RADIUS server. Each RADIUS request sent to a RADIUS server uses the specified source address. The source address is a valid IPv4 address (in case if radius-server address is IPv4) or IPv6 address (in case if radius-server address is IPv6) configured on one of the router or switch interfaces.

Optionally, you can specify the number of times that the router or switch attempts to contact a RADIUS authentication server by including the **retry** statement. By default, the router or switch retries three times. You can configure the router or switch to retry from 1 through 10 times.

Optionally, you can specify the length of time that the local router or switch waits to receive a response from a RADIUS server by including the **timeout** statement. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 90 seconds.

If you use the **enhanced-accounting** statement at the **[edit system radius-options]** hierarchy level, the RADIUS attributes such as access method, remote port, and access privileges can be audited. You can limit the number of attribute values to be displayed for auditing by using the **enhanced-avs-max <number>** statement at the **[edit system accounting]** hierarchy level.

```
[edit system radius-options]
enhanced-accounting;

[edit system accounting]
enhanced-avs-max <number>;
```

When a Juniper Networks router or switch is configured with RADIUS accounting, it sends **Accounting-Start** and **Accounting-Stop** messages to the RADIUS server. These messages contain information about user activities such as software logins, configuration changes, and interactive commands. This information is typically used for monitoring a network, collecting usage statistics, and ensuring that users are billed properly.

The following example shows three servers (10.5.5.5, 10.6.6.6, and 10.7.7.7) configured for RADIUS accounting:

```
system {
  accounting {
    events [ login change-log interactive-commands ];
    destination {
      radius {
        server {
          10.5.5.5 {
            accounting-port 3333;
            secret $ABC123;
            source-address 10.1.1.1;
            retry 3;
            timeout 3;
          }
          10.6.6.6 secret $ABC123;
          10.7.7.7 secret $ABC123;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

Managing Accounting Files

If you configure your system to capture accounting data in log files, set the location for your accounting files to the DRAM.

The default location for accounting files is the **cfs/var/log** directory on the CompactFlash (CF) card. The **nonpersistent** option minimizes the read/write traffic to your CF card. We recommend that you use the **nonpersistent** option for all accounting files configured on your system.

To store accounting log files in DRAM instead of the CF card:

1. Enter configuration mode in the CLI.
2. Create an accounting data log file in DRAM and replace *filename* with the name of the file.

[edit]

user@host# **edit accounting-options file *filename***

3. Store accounting log files in the DRAM file.

[edit]

user@host# **set file *filename* nonpersistent**

CAUTION: If log files for accounting data are stored on DRAM, these files are lost when the device reboots. Therefore, we recommend that you back up these files periodically.

Junos OS Feature License Keys

This section contains the following topics:

- [License Key Components on page 1145](#)
- [License Management Fields Summary on page 1146](#)

License Key Components

A license key consists of two parts:

- **License ID**—Alphanumeric string that uniquely identifies the license key. When a license is generated, it is given a license ID.
- **License data**—Block of binary data that defines and stores all license key objects.

For example, in the following typical license key, the string **XXXXXXXXXX** is the license ID, and the trailing block of data is the license data:

```
XXXXXXXXXX xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx  
          xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx  
          xxxxxx xxxxxx xxx
```

The license data defines the device ID for which the license is valid and the version of the license.

License Management Fields Summary

The Licenses page displays a summary of licensed features that are configured on the device and a list of licenses that are installed on the device. The information on the license management page is summarized in [Table 87](#).

Table 87: Summary of License Management Fields

Field Name	Definition
Feature Summary	
Feature	Name of the licensed feature: <ul style="list-style-type: none"> • Features—Software feature licenses. • All features—All-inclusive licenses
Licenses Used	Number of licenses currently being used on the device. Usage is determined by the configuration on the device. If a feature license exists and that feature is configured, the license is considered used.
Licenses Installed	Number of licenses installed on the device for the particular feature.
Licenses Needed	Number of licenses required for legal use of the feature. Usage is determined by the configuration on the device: If a feature is configured and the license for that feature is not installed, a single license is needed.
Installed Licenses	
ID	Unique alphanumeric ID of the license.
State	Valid —The installed license key is valid. Invalid —The installed license key is not valid.
Version	Numeric version number of the license key.
Group	If the license defines a group license, this field displays the group definition. If the license requires a group license, this field displays the required group definition. NOTE: Because group licenses are currently unsupported, this field is always blank.
Enabled Features	Name of the feature that is enabled with the particular license.
Expiry	Verify that the expiration information for the license is correct. For Junos OS, only permanent licenses are supported. If a license has expired, it is shown as invalid.

Displaying License Keys in J-Web

To display license keys installed on the device:

1. In the J-Web interface, select **Maintain>Licenses**.
2. Under Installed Licenses, click **Display Keys** to display all the license keys installed on the device.

A screen displaying the license keys in text format appears. Multiple licenses are separated by a blank line.

- [Downloading License Keys on page 1152](#)

Downloading License Keys

To download license keys installed on the device:

1. In the J-Web interface, select **Maintain>Licenses**.
2. Under Installed Licenses, click **Download Keys** to download all the license keys installed on the device to a single file.
3. Select **Save it to disk** and specify the file to which the license keys are to be written.

Related Documentation

Generating a License Key

To generate a license key:

1. Gather the authorization code that you received when you purchased your license as well as your device serial number.
2. Go to the Juniper Networks licensing page at:

<https://www.juniper.net/lcrs/generateLicense.do>

3. Enter the device serial number and authorization code in the webpage and click **Generate**. Depending on the type of license you purchased, you will receive one of the following responses:

- License key—If you purchased a perpetual license, you will receive a license key from the licensing management system. You can enter this key directly into the system to activate the feature on your device.
- License key entitlement—If you purchased a subscription-based license, you will receive a license key entitlement from the licensing management system. You can use this entitlement to validate your license on the Juniper Networks licensing server and download the feature license from the server to your device.

Saving License Keys

To save license keys installed on the device:

1. From operational mode, save the installed license keys to a file or URL.

```
user@host>request system license save filename | url
```

For example, the following command saves the installed license keys to a file named **license.config**:

```
request system license save ftp://user@host/license.conf
```

Updating License Keys

To update a license key from the device:

1. From operational mode, do one of the following tasks:

- Update the license keys automatically.

```
user@host> request system license update
```

NOTE: The `request system license update` command will always use the default Juniper license server <https://ae1.juniper.net>

You can only use this command to update subscription-based licenses (such as UTM).

- Update the trial license keys automatically.

```
user@host> request system license update trial
```

Example: Adding a New License Key

This example shows how to add a new license key.

- [Requirements on page 1154](#)
- [Overview on page 1154](#)
- [Configuration on page 1155](#)
- [Verification on page 1156](#)

Requirements

Before you begin, confirm that your Junos OS feature requires you to purchase, install, and manage a separate software license.

Overview

You can add a license key from a file or URL, from a terminal, or from the J-Web user interface. Use the ***filename*** option to activate a perpetual license directly on the device. (Most feature licenses are perpetual.) Use the ***url*** to send a subscription-based license key entitlement (such as UTM) to the Juniper Networks licensing server for authorization. If authorized, the server downloads the license to the device and activates it.

In this example, the file name is `bgp-reflection`.

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, you can add a license key in either way:

- From a file or URL:

```
user@hostname> request system license add bgp-reflection
```
- From the terminal:

```
user@hostname> request system license add terminal
```

GUI Step-by-Step Procedure To add a new license key:

1. In the J-Web user interface, select **Maintain>Licenses**.
2. Under Installed Licenses, click **Add** to add a new license key.
3. Do one of the following, using a blank line to separate multiple license keys:
 - In the **License File URL** box, type the full URL to the destination file containing the license key to be added.
 - In the **License Key Text** box, paste the license key text, in plain-text format, for the license to be added.
4. Click **OK** to add the license key.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure To add a new license key:

1. From operational mode, add a license key in either way:
 - From a file or URL:

```
user@host> request system license add bgp-reflection
```
 - From the terminal:

```
user@host>request system license add terminal
```
2. When prompted, enter the license key, separating multiple license keys with a blank line. If the license key you enter is invalid, an error is generated when you press Ctrl-D to exit license entry mode.

Results From operational mode, confirm your configuration by entering the **show system license** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@hostname> show system license
```

License usage:

Feature name	Licenses used	Licenses installed	Licenses needed	Expiry
bgp-reflection	0	1	0	permanent

Licenses installed:

License identifier: G0300000xxxx

License version: 2

Valid for device: JN001875AB

Features:

bgp-reflection - Border Gateway Protocol route reflection
permanent

License identifier: G0300000xxxx

License version: 2

Valid for device: JN001875AB

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Installed Licenses

Purpose Verify that the expected licenses have been installed and are active on the device.

Action From operational mode, enter the **show system license** command.

The output shows a list of the licenses used and a list of the licenses installed on the device and when they expire.

Verifying License Usage

Purpose Verify that the licenses fully cover the feature configuration on the device.

Action From operational mode, enter the **show system license usage** command.

```
user@hostname> show system license usage
```

Feature name	Licenses used	Licenses installed	Licenses needed	Expiry
bgp-reflection	1	1	0	permanent

The output shows a list of the licenses installed on the device and how they are used.

Verifying Installed License Keys

Purpose Verify that the license keys were installed on the device.

Action From operational mode, enter the **show system license keys** command.

```
user@hostname> show system license keys
```

```
XXXXXXXXXX xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx
          xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx
          xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx
          xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx xxxxxx
```

The output shows a list of the license keys installed on the device. Verify that each expected license key is present.

Example: Deleting a License Key

This example shows how to delete a license key.

- [Requirements on page 1157](#)
- [Overview on page 1157](#)
- [Configuration on page 1157](#)
- [Verification on page 1158](#)

Requirements

Before you delete a license key, confirm that it is no longer needed.

Overview

You can delete a license key from the CLI or J-Web user interface. In this example, the license ID is G0300000xxxx.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
user@host> request system license delete G0300000xxxx
```

GUI Step-by-Step Procedure

To delete a license key:

1. In the J-Web user interface, select **Maintain>Licenses**.
2. Select the check box of the license or licenses you want to delete.

3. Click **Delete**.
4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

To delete a license key:

1. From operational mode, for each license, enter the following command and specify the license ID. You can delete only one license at a time.

```
user@host> request system license delete G0300000xxxx
```

Results

From configuration mode, confirm your deletion by entering the **show system license** command. The license key you deleted will be removed. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying Installed Licenses on page 1158](#)

Verifying Installed Licenses

Purpose

Verify that the expected licenses have been removed from the device.

Action

From operational mode, enter the **show system license** command.

Hierarchy Level [edit access]

Release Information Statement introduced in Junos OS Release 10.4.

Description The address-assignment pool feature enables you to create IPv4 and IPv6 address pools that different client applications can share. For example, multiple client applications, such as DHCPv4 or DHCPv6, can use an address-assignment pool to provide addresses for their particular clients.

Required Privilege Level access—To view this statement in the configuration.
access-control—To add this statement to the configuration.

address-pool (Access)

Syntax	<pre> address-pool <i>pool-name</i> { address <i>address or address prefix</i>; address-range { high <i>upper-limit</i>; low <i>lower-limit</i>; mask <i>network-mask</i>; } primary-dns <i>IP address</i>; primary-wins <i>IP address</i>; secondary-dns <i>IP address</i>; secondary-wins <i>IP address</i>; } </pre>
Hierarchy Level	[edit access]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Create an address-pool for L2TP clients.
Options	<ul style="list-style-type: none"> • pool-name—Name assigned to the address-pool. • address—Configure subnet information for the address-pool. • address-range—Defines the address range available for clients. • primary-dns—Specify the primary-dns IP address. • secondary-dns—Specify the secondary-dns IP address. • primary-wins—Specify the primary-wins IP address. • secondary-wins—Specify the secondary-wins IP address.
Required Privilege Level	access—To view this statement in the configuration. access-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • access-control on page 842

allow-configuration

Syntax	<code>allow-configuration "regular-expression";</code>
Hierarchy Level	[edit system login class <i>class-name</i>]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 11.2 for SRX Series devices.
Description	Explicitly allow configuration access to the specified levels in the hierarchy even if the permissions set with the permissions statement do not grant such access by default.
Default	If you omit this statement and the deny-configuration statement, users can edit only those commands for which they have access privileges through the permissions statement.
Options	<i>regular-expression</i> —Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks.
Required Privilege Level	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.

allow-configuration-regexps

Syntax	<code>allow-configuration-regexps "regular expression 1" "regular expression 2";</code>
Hierarchy Level	[edit system login class <i>class-name</i>]
Release Information	Statement introduced in Junos OS Release 11.2.
Description	Explicitly allow configuration access to specified hierarchies using regular expressions even if the permissions set with the permissions statement allow that access. The statement deny-configuration-regexps takes precedence if it is used in the same login class definition.
Default	If you do not configure this statement or the deny-configuration-regexps statement, users can edit only those commands for which they have access privileges set with the permissions statement.
Options	<i>regular expression</i> —Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

authentication-key

Syntax	<code>authentication-key <i>key-number</i> type <i>md5</i> value <<i>password</i>>;</code>
Hierarchy Level	[edit system <i>ntp</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>Configure Network Time Protocol (NTP) authentication keys so that the SRX Series device can send authenticated packets. If you configure the SRX Series device to operate in authenticated mode, you must configure a key.</p> <p>Both the keys and the authentication scheme (MD5) must be identical between a set of peers sharing the same key number.</p>
Options	<p><i>key-number</i>—Positive integer that identifies the key.</p> <p><i>type md5</i>—Authentication type. It can only be <i>md5</i>.</p> <p><i>value password</i>—The key itself, which can be from 1 through 8 ASCII characters. If the key contains spaces, enclose it in quotation marks.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • ntp on page 1248

authentication-order

Syntax	<code>authentication-order [<i>authentication-methods</i>];</code>
Hierarchy Level	<code>[edit system]</code>
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Configure the order in which the software tries different user authentication methods when attempting to authenticate a user. For each login attempt, the software tries the authentication methods in order, starting with the first one, until the password matches.
Default	If you do not include the authentication-order statement, users are verified based on their configured passwords.
Options	<i>authentication-methods</i> —One or more authentication methods, listed in the order in which they should be tried. The method can be one or more of the following: <ul style="list-style-type: none">• password—Use the password configured for the user with the authentication statement at the <code>[edit system login user]</code> hierarchy level.• radius—Use RADIUS authentication services.• tacplus—Use TACACS+ authentication services.
Required Privilege Level	<code>system</code> —To view this statement in the configuration. <code>system-control</code> —To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Understanding User Authentication Methods on page 804

boot-server (NTP)

Syntax	<code>boot-server (address hostname);</code>
Hierarchy Level	[edit system <i>ntp</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>Configure the server that NTP queries when the SRX Series device boots to determine the local date and time.</p> <p>When you boot the SRX Series device, it issues an ntpdate request, which polls a network server to determine the local date and time. You need to configure a server that the SRX Series device uses to determine the time when the SRX Series device boots. You can configure either an IP address or a hostname for the boot server. If you configure a hostname instead of an IP address, the ntpdate request resolves the hostname to an IP address when the SRX Series device boots up.</p> <p>If you configure an NTP boot server, then when the SRX Series device boots, it immediately synchronizes with the boot server even if the NTP process is explicitly disabled or if the time difference between the client and the boot server exceeds the threshold value of 1000 seconds.</p>
Options	<ul style="list-style-type: none">• address—The IP address of an NTP boot server.• hostname—The hostname of an NTP boot server.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• ntp on page 1248

broadcast

Syntax	<code>broadcast address <key key-number> <routing-instance-name routing-instance-name> <ttl value> <version value>;</code>
Hierarchy Level	[edit system <i>ntp</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure the SRX Series device to operate in broadcast mode with the remote system at the specified address. In this mode, the SRX Series device sends periodic broadcast messages to a client population at the specified broadcast or multicast address. Normally, you include this statement only when the SRX Series device is operating as a transmitter.
Options	<p>address—The broadcast address on one of the local networks or a multicast address assigned to NTP. You must specify an address, not a hostname. If the multicast address is used, it must be 224.0.1.1.</p> <p>key key-number—(Optional) All packets sent to the address include authentication fields that are encrypted using the specified key number.</p> <p>Range: Any unsigned 32-bit integer</p> <p>routing-instance-name routing-instance-name—(Optional) The routing instance name in which the interface has an address in the broadcast subnet.</p> <p>Default: The default routing instance is used to broadcast packets.</p> <p>ttl value—(Optional) Time-to-live (TTL) value to use.</p> <p>Range: 1 through 255</p> <p>Default: 1</p> <p>version value—(Optional) Specify the version number to be used in outgoing NTP packets.</p> <p>Range: 1 through 4</p> <p>Default: 4</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• ntp on page 1248

broadcast-client

Syntax	<code>broadcast-client;</code>
Hierarchy Level	<code>[edit system <i>ntp</i>]</code>
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure the SRX Series device to listen for broadcast messages on the local network to discover other servers on the same subnet.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• ntp on page 1248

ciphers

Syntax	<code>ciphers [cipher-1 cipher-2 cipher-3 ...]</code>
Hierarchy Level	<code>[edit system services ssh]</code>
Release Information	Statement introduced in Junos OS Release 11.2.
Description	Specify the set of ciphers the SSH server can use to perform encryption and decryption functions.
Options	<ul style="list-style-type: none"> • 3des-cbc—Triple Data Encryption Standard (DES) in Cipher Block Chaining (CBC) mode. • aes128-cbc—128-bit Advanced Encryption Standard (AES) in CBC mode. • aes256-cbc—256-bit AES in CBC mode. • aes128-ctr—128-bit AES in CBC mode. • aes192-ctr—192-bit AES in counter mode. • aes256-ctr—256-bit AES in counter mode. • aes128-gcm@openssh.com—128-bit AES in Galois/Counter Mode. • aes256-gcm@openssh.com—256-bit AES in Galois/Counter Mode. • arcfour128—128-bit RC4-stream cipher in CBC mode. • arcfour256—256-bit RC4-stream cipher in CBC mode. • blowfish128-cbc—128-bit blowfish-symmetric block cipher in CBC mode. • cast128-cbc—128-bit cast in CBC mode.
<div>  <p>NOTE: Ciphers represent a set. To configure SSH ciphers:</p> <pre>user@host#set system services ssh ciphers [aes256-cbc aes192-cbc]</pre> </div>	
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • <i>Configuring SSH Service for Remote Access to the Router or Switch</i>

connection-limit

Syntax	connection-limit <i>limit</i> ;
Hierarchy Level	[edit system services finger] [edit system services ftp] [edit system services netconf ssh] [edit system services ssh] [edit system services telnet] [edit system services xnm-clear-text] [edit system services xnm-ssl]
Release Information	Statement introduced in Junos OS Release 11.4.
Description	Configure the maximum number of connection sessions for each type of system services (finger, ftp, ssh, telnet, xnm-clear-text, or xnm-ssl) per protocol (either IPv6 or IPv4).
Options	<p>limit—Maximum number of established connections per protocol (either IPv6 or IPv4).</p> <p>On all high-end SRX Series devices, the range and default value are as follows: Range: 1 through 250 Default: 75</p> <p>On all branch SRX Series devices, the range is as follows: Range: 1 through 5</p>
<div>  <p>NOTE: The actual number of maximum connections depends on the availability of system resources, and might be fewer than the configured connection-limit value if the system resources are limited.</p> </div>	
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

client-ia-type

Syntax	client-ia-type (ia-na ia-pd);
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcpv6-client]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Configure the DHCPv6 client identity association type.
Options	ia-na — Identity association for nontemporary address ia-pd —Identity association for prefix delegation
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• DHCPv6 Client Overview on page 1120

client-identifier (dhcp-client)

Syntax	client-identifier { user-id {ascii <i>ascii</i> hexadecimal <i>hexadecimal</i> ; use-interface-description {logical device}; prefix [host-name routing-instance-name]; }
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	The DHCP server identifies a client by a client-identifier value.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• DHCPv6 Client Overview on page 1120

client-identifier (dhcpv6-client)

Syntax	client-identifier duid-type (duid-ll duid-llt vendor);
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcpv6-client]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	The DHCPv6 server identifies a client by a client-identifier value.
Options	<p>duid-type—The DHCPv6 client is identified by a DHCP unique identifier (DUID).</p> <p>duid-ll—Link Layer address.</p> <p>duid-llt—Link Layer address plus time.</p> <p>vendor—Vendor-assigned unique ID based on the enterprise number.</p>
Required Privilege Level	<p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>

client-list-name (SNMP)

Syntax	client-list-name <i>client-list-name</i> ;
Hierarchy Level	[edit snmp community <i>community-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the name of the list of SNMP network management system (NSM) clients that are authorized to collect information about network operations. You cannot use an SNMP client list and individually configured SNMP clients in the same configuration.
Options	client-list-name — Name of the client list. Client list is the list of IP address prefixes defined with the prefix-list statement in the policy-options hierarchy.
Required Privilege Level	<p>snmp—To view this statement in the configuration.</p> <p>snmp-control—To add this statement to the configuration.</p>

deny-configuration

Syntax	deny-configuration " <i>regular-expression</i> ";
Hierarchy Level	[edit system login class]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 11.2 for SRX Series devices.
Description	Explicitly deny configuration access to the specified levels in the hierarchy even if the permissions set with the permissions statement grant such access by default.
Default	If you omit this statement and the allow-configuration statement, users can edit those levels in the configuration hierarchy for which they have access privileges through the permissions statement.
Options	<i>regular-expression</i> —Extended (modern) regular expression as defined in POSIX 1003.2. If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks.
Required Privilege Level	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.

deny-configuration-regexps

Syntax	<code>deny-configuration-regexps "regular expression 1" "regular expression 2";</code>
Hierarchy Level	[edit system login class <i>class-name</i>]
Release Information	Statement introduced in Junos OS Release 11.2. Statement introduced in Junos OS Release 11.2 for SRX Series devices.
Description	<p>Explicitly deny configuration access to specified hierarchies using regular expressions even if the permissions set with the permissions statement allow that access.</p> <p>Expressions configured with this statement take precedence over allow-configuration-regexps if the two statements are used in the same login class definition.</p>
Default	If you do not configure this statement or the deny-configuration-regexps statement, users can edit only those commands for which they have access privileges set with the permissions statement.
Options	<p><i>regular expression</i>—Extended (modern) regular expression as defined in POSIX 1003.2.</p> <p>If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

destination (Accounting)

```
Syntax  destination {  
        radius {  
            server {  
                server-address {  
                    accounting-port port-number;  
                    max-outstanding-requests value;  
                    port port-number;  
                    retry value;  
                    secret password;  
                    source-address source-address;  
                    timeout seconds;  
                }  
            }  
        }  
        tacplus {  
            server {  
                server-address {  
                    port port-number;  
                    secret password;  
                    single-connection;  
                    timeout seconds;  
                }  
            }  
        }  
    }
```

Hierarchy Level [edit system accounting]

Release Information Statement introduced before Junos OS Release 7.4.
radius statement added in Junos OS Release 7.4. Support for IPv6 source address added in Junos OS Release 12.1X47-D15.

Description Configure the authentication server.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

dhcp-attributes (Access IPv4 Address Pools)

```
Syntax  dhcp-attributes {
    boot-file boot-file-name;
    boot-server boot-server-name;
    domain-name domain-name;
    grace-period seconds;
    maximum-lease-time (seconds | infinite);

        ip-address ipv4-address;
        name sip-server-name;
    }
    tftp-server server-name;
    wins-server ipv4-address;
}
```

Hierarchy Level [edit access address-assignment pool *pool-name* family inet]

Release Information	Statement introduced in Junos OS Release 10.4.
Description	Configure attributes for IPv4 address pools that can be used by different clients. The DHCP attributes for this statement uses standard IPv4 DHCP options.
Required Privilege Level	access—To view this statement in the configuration. access-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• DHCP Server, Client, and Relay Agent Overview on page 1088

dhcp-attributes (Access IPv6 Address Pools)

Syntax

```
dhcp-attributes {
  dns-server ipv6-address;
  grace-period seconds;
  maximum-lease-time (seconds | infinite);
  option dhcp-option-identifier-code {
    array {
      byte [8-bit-value];
      flag [ false | off | on | true];
      integer [32-bit-numeric-values];
      ip-address [ip-address];
      short [signed-16-bit-numeric-value];
      string [character string value];
      unsigned-integer [unsigned-32-bit-numeric-value];
      unsigned-short [16-bit-numeric-value];
    }
    byte 8-bit-value;
    flag ( false | off | on | true);
    integer 32-bit-numeric-values;
    ip-address ip-address;
    short signed-16-bit-numeric-value;
    string character string value;
    unsigned-integer unsigned-32-bit-numeric-value;
    unsigned-short 16-bit-numeric-value;
  }
  propagate-ppp-settings [interface-name];
  sip-server-address ipv6-address;
  sip-server-domain-name domain-name;
}
```

Hierarchy Level [edit access address-assignment pool *pool-name* family inet6]

Release Information Statement introduced in Junos OS Release 10.4.

Description Configure attributes for address pools that can be used by different clients.

- Options**
- **dns-server *IPv6-address***—Specify a DNS server to which clients can send DNS queries.
 - **grace-period *seconds***—Specify the grace period offered with the lease.

Range: 0 through 4,294,967,295 seconds

Default: 0 (no grace period)

- **maximum-lease-time *seconds***—Specify the maximum length of time in seconds for which a client can request and hold a lease on a DHCP server.

Range: 30 through 4,294,967,295 seconds

Default: 86,400 seconds (24 hours)

- **option *dhcp-option-identifier-code***—Specify the DHCP option identifier code.
- **propagate-ppp-settings [*interface-name*]**—Specify PPP interface name for propagating DNS or WINS settings.

- **sip-server-address** *IPv6-address*—Specify the IPv6 address of the SIP outbound proxy server.
- **sip-server-domain-name** *domain-name*—Specify the domain name of the SIP outbound proxy server.

Required Privilege Level access—To view this statement in the configuration.
 access-control—To add this statement to the configuration.

Hierarchy Level [edit system syslog]

Release Information Statement introduced before Junos OS Release 12.1X47 for SRX Series.

Description Specify the file in which to log data.

- Options**
- *filename*—Specify the name of the file in which to log data.
 - *allow-duplicates*—Do not suppress the repeated messages.
 - *any*—Specify all facilities information.
 - *alert*—Specify the conditions that should be corrected immediately.
 - *critical*—Specify the critical conditions.
 - *emergency*—Specify the conditions that cause security functions to stop.
 - *error*—Specify the general error conditions.

- *info*—Specify the information about normal security operations.
- *none*—Do not specify any messages.
- *notice*—Specify the conditions that should be handled specifically.
- *warning*—Specify the general warning conditions.
- *archive*—Specify the archive file information.
 - *archive-sites*—Specify a list of destination URLs for the archived log files.
 - *url*—Specify the primary and failover URLs to receive archive files.
 - *binary-data*—Mark file such that it contains binary data.
 - *no-binary-data*—Do not mark the file such that it contains binary data.
 - *files*—Specify the number of files to be archived. Range: 1 through 1000 files.
 - *size*—Specify the size of files to be archived. Range: 65,536 through 1,073,741,824 bytes.
 - *world-readable*—Allow any user to read the log file.
 - *no-world-readable*—Do not allow any user to read the log file.
 - *start-time*—Specify the start time for file transmission. Enter the start time in the yyyy-mm-dd.hh:mm format.
 - *transfer-interval*—Specify the frequency at which to transfer the files to archive sites.
- *authorization*—Specify the authorization system.
- *change-log*—Specify the configuration change log.
- *conflict-log*—Specify the configuration conflict log.
- *daemon*—Specify the various system processes.
- *dfc*—Specify the dynamic flow capture.
- *explicit-priority*—Include the priority and facility in messages.
- *external*—Specify the local external applications.
- *firewall*—Specify the firewall filtering system.
- *ftp*—Specify the FTP process.
- *interactive-commands*—Specify the commands executed by the UI.
- *kernel*—Specify the kernel information.
- *match*—Specify the regular expression for lines to be logged.
- *ntp*—Specify the NTP process.
- *pfe*—Specify the Packet Forwarding Engine.
- *security*—Specify the security-related information.

- *structured-data*—Log the messages in structured log format.
 - *brief*—Omit English language text from the end of the logged message.
- *user*—Specify the user processes.
 - *info*—Specify the informational messages.

Required Privilege	system—To view this statement in the configuration.
Level	system-control—To add this statement to the configuration.

forwarding-options (Security)

Syntax

```
forwarding-options {
  family {
    inet6 {
      mode (drop | flow-based | packet-based);
    }
    iso {
      mode packet-based;
    }
    mpls {
      mode packet-based;
    }
  }
}
```

Hierarchy Level [edit security]

Release Information Statement introduced in Junos OS Release 8.5.

Description Determine how the **inet6**, **iso**, and **mpls** protocol families manage security forwarding options.

NOTE:

- Packet-based processing is not supported on the following SRX Series devices: SRX5400, SRX5600, and SRX5800.
- On SRX Series devices, the default mode for processing traffic is flow mode. To configure an SRX Series device as a border router, you must change the mode from flow-based processing to packet-based processing. Use the `set security forwarding-options family mpls mode packet-based` statement to configure the SRX device to packet mode. You must reboot the device for the configuration to take effect.

Options The remaining statements are explained separately. See [CLI Explorer](#).

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

interfaces (Security Zones)

Syntax	<pre>interfaces <i>interface-name</i> { host-inbound-traffic { protocols <i>protocol-name</i> { except; } } system-services <i>service-name</i> { except; } }</pre>
Hierarchy Level	[edit security zones functional-zone management], [edit security zones security-zone <i>zone-name</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the set of interfaces that are part of the zone.
Options	<i>interface-name</i> —Name of the interface. The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	security—To view this statement in the configuration. security-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Understanding Security Zones</i>

interface-traceoptions (System Services DHCP)

Syntax	<pre> interface-traceoptions { file { filename ; files number; match regular-expression; size maximum-file-size; (world-readable no-world-readable); } flag flag; level (all error info notice verbose warning); no-remote-trace; } </pre>
Hierarchy Level	[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server], [edit system services dhcp-local-server]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Configure extended DHCP local server tracing operations that can be enabled on a specific interface or group of interfaces. You use the interface <i>interface-name</i> trace statement at the [edit system services group <i>group-name</i>] hierarchy level to enable the tracing operation on the specific interfaces.
Options	<p>file-name—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks (" "). All files are placed in a file named jdhcpd in the directory /var/log. If you include the file statement, you must specify a filename.</p> <p>files number—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the size option.</p> <p>Range: 2 through 1000</p> <p>Default: 3 files</p> <p>flag flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> • all—Trace all events • dhcpv6-packet—Trace DHCPv6 packet decoding operations. • dhcpv6-packet-option—Trace DHCPv6 option decoding operations. • dhcpv6-state—Trace changes in state for DHCPv6 operations. • packet—Trace packet decoding operations • packet-option—Trace DHCP option decoding operations • state—Trace changes in state

match *regular-expression*—(Optional) Refine the output to include lines that contain the regular expression.

no-remote-trace—Disable remote tracing.

no-world-readable—(Optional) Disable unrestricted file access.

size *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

Syntax: **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

world-readable—(Optional) Enable unrestricted file access.

Required Privilege Level	interface—To view this statement in the configuration.
	interface-control—To add this statement to the configuration.

internet-options

Syntax

```
internet-options {
    icmpv4-rate-limit {
        bucket size seconds;
        packet-rate packet-rate;
    }
    icmpv6-rate-limit {
        bucket size seconds;
        packet-rate packet-rate;
    }
    ipv6-duplicate-addr-detection-transmits number;
    no-path-mtu-discovery;
    no-source-quench;
    no-tcp-reset;
    no-tcp-rfc1323;
    no-tcp-rfc1323-paws;
    path-mtu-discovery;
    source-port {
        upper-limit range;
    }
    source-quench;
    tcp-drop-synfin-set;
}
```

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 11.1.

Description Configure tunable options for Internet operations.

- Options**
- **icmpv4-rate-limit**—Configure rate-limiting parameters for Internet Control Message Protocol version 4 (ICMPv4) messages.
 - **bucket-size *seconds***—Set ICMP rate-limiting maximum bucket size in seconds.
 - **packet-rate *packet-rate***— Set ICMP rate-limiting packets earned per second.
 - **icmpv6-rate-limit**—Configure rate-limiting parameters for Internet Control Message Protocol version 6 (ICMPv6) messages.
 - **bucket-size *seconds***—Set ICMP rate-limiting maximum bucket size in seconds.
 - **packet-rate *packet-rate***— Set ICMP rate-limiting packets earned per second.
 - **ipv6-duplicate-addr-detection-transmits *number***—Control the number of attempts for IPv6 duplicate address detection.
 - **no-path-mtu-discovery**—Do not enable path maximum transmission unit (MTU) discovery on TCP connections.
 - **no-source-quench**—Do not react to incoming ICMP source quench messages.
 - **no-tcp-reset**—Do not send RST TCP packets for packets sent to non-listening ports.
 - **no-tcp-rfc1323**—Disable RFC 1323 TCP extensions.

- **no-tcp-rfc1323-paws**—Disable RFC 1323 Protection Against Wrapped Sequence Number extension.
- **path-mtu-discovery**—Enable path MTU discovery on TCP connections.
- **source-port**—Configure source port selection parameters.
 - **upper-limit *range***—Specify upper limit of source port selection range.
- **source-quench**—React to incoming ICMP source quench messages.
- **tcp-drop-synfin-set**—Drop TCP packets that have both SYN and FIN flags.

Required Privilege system—To view this statement in the configuration.
Level system-control—To add this statement to the configuration.

kernel-replication (System)

Syntax kernel-replication;

Hierarchy Level [edit system]

Release Information Statement introduced in Junos OS Release 11.1.

Description Configure kernel replication.

Required Privilege system—To view this statement in the configuration.
Level system-control—To add this statement to the configuration.

lease-time (dhcp-client)

Syntax lease-time *seconds*;

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family *family* dhcp-client]

Release Information Statement introduced in Junos OS Release 12.1X44-D10.

Description Specify the time to negotiate and exchange Dynamic Host Configuration Protocol (DHCP) information.

Options **seconds**— Request time to negotiate and exchange information.

Required Privilege interface—To view this statement in the configuration.
Level interface-control—To add this statement to the configuration.

location

Syntax	<pre>location { altitude <i>feet</i>; building <i>name</i>; country -code <i>code</i>; floor <i>number</i>; hcoord <i>horizontal-coordinate</i>; lata <i>service-area</i>; latitude <i>degrees</i>; longitude <i>degrees</i>; npa-nxx <i>number</i>; postal-code <i>postal-code</i>; rack <i>number</i>; vcoord <i>vertical-coordinate</i>; }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the physical location of the device.
Options	<ul style="list-style-type: none"> • altitude <i>feet</i>—Number of feet above sea level. • building <i>name</i>—Name of building. The name of the building can be 1 to 28 characters in length. If the string contains spaces, enclose it in quotation marks (" "). • country-code <i>code</i>—Two-letter country code. • floor <i>number</i>—Floor number in the building. • hcoord <i>horizontal-coordinate</i>—Bellcore Horizontal Coordinate. • lata <i>service-area</i>—Long-distance service area. • latitude <i>degrees</i>—Latitude in degree format. • longitude <i>degrees</i>—Longitude in degree format. • npa-nxx <i>number</i>—First six digits of the phone number (area code and exchange). • postal-code <i>postal-code</i>—Zip code or Postal code. • rack <i>number</i>—Rack number. • vcoord <i>vertical-coordinate</i>—Bellcore Vertical Coordinate.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

lockout-period

Syntax	lockout-period <i>minutes</i> ;
Hierarchy Level	[edit system login retry-options]
Release Information	Statement introduced in Junos OS Release 11.2.
Description	Configure the amount of time before the user can attempt to log in to the router after being locked out due to the number of failed login attempts specified in the tries-before-disconnect statement.
Options	<i>minutes</i> —Amount of time before the user can attempt to log in after being locked out. Default: Off Range: 1 through 43200
Required Privilege Level	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• <i>Limiting the Number of User Login Attempts for SSH and Telnet Sessions</i>• Handling Authorization Failure on page 822• Example: Configuring System Retry Options on page 823• <i>retry-options</i>• clear system login lockout on page 291• show system login lockout on page 409

macs

Syntax	<code>macs [algorithm]</code>
Hierarchy Level	<code>[edit system services ssh]</code>
Release Information	Statement introduced in Junos OS Release 11.2. SHA-2 options introduced in Junos OS Release 12.1.
Description	Specify the set of message authentication code (MAC) algorithms that the SSH server can use to authenticate messages.
Options	<ul style="list-style-type: none"> • <code>hmac-md5</code>—Hash-based MAC using Message-Digest 5 (MD5). • <code>hmac-md5-96</code>—96-bits of Hash-based MAC using MD5. • <code>hmac-ripemd160</code>—Hash-based MAC using RIPEMD. • <code>hmac-sha1</code>—Hash-based MAC using Secure Hash Algorithm (SHA-1). • <code>hmac-sha1-96</code>—96-bits of Hash-based MAC using SHA-1. • <code>hmac-sha2-256</code>—256-bits of Hash-based MAC using SHA-2. • <code>hmac-sha2-256-96</code>—first 96-bits of hmac-sha2-256. • <code>hmac-sha2-512</code>—96-bits of Hash-based MAC using SHA-1. • <code>umac-64</code>—Message Authentication Code using Universal Hashing.
<div>  <p>NOTE: The <i>macs</i> configuration statement represents a set. Therefore, it should be configured as in the following.</p> <pre>user@host#set system services ssh macs [hmac-md5 hmac-sha1]</pre> </div>	
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

max-pre-authentication-packets

Syntax	<code>max-pre-authentication-packets <i>value</i>;</code>
Hierarchy Level	[edit system services ssh]
Release Information	Statement introduced in Junos OS Release 12.3X48-D10.
Description	Define the number of pre-authentication SSH packets that the SSH server will accept prior to user authentication.
Options	<i>value</i> —Maximum number of pre-authentication SSH packets that the server will accept. Range: 20 through 2147483647. Default: 128
Required Privilege Level	admin-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• The ssh Command on page 1063

multicast-client

Syntax	<code>multicast-client <<i>address</i>>;</code>
Hierarchy Level	[edit system ntp]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For NTP, configure the SRX Series device to listen for multicast messages on the local network to discover other servers on the same subnet.
Options	<i>address</i> —(Optional) One or more IP addresses. If you specify addresses, the SRX Series device joins those multicast groups. Default: 224.0.1.1.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• ntp on page 1248

name-server (Access)

Syntax	<code>name-server address</code>
Hierarchy Level	[edit access address-assignment pool <name> family (inet inet6) xauth-attributes]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Specify the DNS server IP address for an address-assignment pool.
Required Privilege Level	access—To view this statement in the configuration. access-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • address-assignment (Access) on page 1196 • <i>Access Configuration Statement Hierarchy</i>

neighbor-discovery-router-advertisement (Access)

Syntax	<code>neighbor-discovery-router-advertisement <i>ndra-pool-name</i>;</code>
Hierarchy Level	[edit access address-assignment]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Configure the name of the address-assignment pool used to assign the router advertisement prefix.
Options	<i>ndra-pool-name</i> —Name of the address assignment pool.
Required Privilege Level	access—To view this statement in the configuration. access-control—To add this statement to the configuration.

Hierarchy Level [edit system]

Release Information Statement introduced before Junos OS Release 7.4.

Description Configure Network Time Protocol (NTP) on the SRX Series device.

The remaining statements are explained separately.

Required Privilege Level system—To view this statement in the configuration.
 system-control—To add this statement to the configuration.

outbound-ssh

Syntax

```

outbound-ssh {
  client client-id {
    address address {
      port port-number;
      retry number;
      timeout seconds;
    }
    device-id device-id;
    keep-alive {
      retry number;
      timeout seconds;
    }
    reconnect-strategy (in-order | sticky);
    secret password;
    services netconf;
  }
  traceoptions {
    file filename <files number> <match regex> <size size> <world-readable |
      no-world-readable>;
    flag flag;
    no-remote-trace;
  }
}

```

Hierarchy Level [edit system services]

Release Information Statement introduced in Junos OS Release 10.4.
Support for IPv6 address added in Junos OS Release 12.1X47-D15.

Description Initiate outbound SSH connections.

Options **client *client-id***—Defines a device-initiated connection. This value serves to uniquely identify the outbound-ssh configuration stanza. Each outbound-ssh stanza represents a single outbound SSH connection. Thus, the administrator is free to assign the client-id any meaningful unique value.

address *address*—Specifies the IPv4 or IPv6 address or hostname of the client.

port *port-number*—Specifies the port at which a server listens for outbound SSH connection requests.

retry *number*—Specifies the maximum number of connection attempts a device can make to the specified IP address. The default is three attempts.

timeout *seconds*—Specifies how long the application waits between attempts to reconnect to the specified IP address, in seconds. The default is 15 seconds.

device *device-id*—Identifies the device to the management client. Each time the device establishes an outbound SSH connection, it first sends an initiation sequence (device-id) to the management client.

keep-alive—Enables the device to send SSH protocol keepalive messages to the client application. The **timeout** statement specifies how long the device waits to receive data before sending a request for acknowledgment from the application. The default is 15 seconds. The **retry** statement specifies how many keepalive messages the router sends without receiving a response from the client. When that number is exceeded, the device disconnects from the application, ending the outbound SSH connection. The default is three retries.

reconnect-strategy (in-order|sticky)—Specifies how the device reconnects to the server after a connection is dropped.

in-order—Configures the device to reconnect to the first configured server. If this server is unavailable, the device tries to connect to the next configured server. This process repeats until a connection is completed.

sticky—Configures the device to reconnect to the server from which it disconnected.

secret password—Sends the device's public SSH host key when the device connects to the client.

services netconf—Configures the application to accept NETCONF as an available service.

Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

overrides (System Services DHCP)

Syntax	<pre>overrides { interface-client-limit <i>number</i>; }</pre>
Hierarchy Level	<pre>[edit system services dhcp-local-server dhcpv6] [edit system services dhcp-local-server dhcpv6 group <i>group-name</i>] [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> interface <i>interface-name</i>]</pre>
Release Information	Statement introduced in Junos OS Release 10.4.
Description	<p>Override the default configuration settings for the extended DHCP local server. Specifying the overrides statement with no subordinate statements removes all DHCP local server overrides at that hierarchy level.</p> <ul style="list-style-type: none"> To override global DHCP local server configuration options, include the overrides statement and its subordinate statements at the [edit system services dhcp-local-server] hierarchy level. To override configuration options for a named group of interfaces, include the statements at the [edit system services dhcp-local-server dhcpv6 group <i>group-name</i>] hierarchy level. To override configuration options for a specific interface within a named group of interfaces, include the statements at the [edit system services dhcp-local-server dhcpv6 group <i>group-name</i> interface <i>interface-name</i>] hierarchy level. Use the DHCPv6 hierarchy levels to override DHCPv6 configuration options.
Options	<p>interface-client-limit <i>number</i>—Sets the maximum number of DHCP clients per interface allowed for a specific group or for all groups. A group specification takes precedence over a global specification for the members of that group.</p> <p>Range: 1 through 500,000</p> <p>Default: No limit</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> DHCP Server, Client, and Relay Agent Overview on page 1088

peer (NTP)

Syntax	<code>peer address <key key-number> <version value> <prefer>;</code>
Hierarchy Level	[edit system ntp]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For NTP, configure the SRX Series device to operate in symmetric active mode with the remote system at the specified address. In this mode, the SRX Series device and the remote system can synchronize with each other. This configuration is useful in a network in which either the SRX Series device or the remote system might be a better source of time.
Options	<p>address—Address of the remote system. You must specify an address, not a hostname.</p> <p>key key-number—(Optional) All packets sent to the address include authentication fields that are encrypted using the specified key number.</p> <p>Range: Any unsigned 32-bit integer</p> <p>prefer—(Optional) Mark the remote system as the preferred host, which means that if all other factors are equal, this remote system is chosen for synchronization among a set of correctly operating systems.</p> <p>version value—(Optional) Specify the NTP version number to be used in outgoing NTP packets.</p> <p>Range: 1 through 4</p> <p>Default: 4</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none">• ntp on page 1248

prefix

Syntax	<pre>prefix { host-name; logical-system-name; routing-instance-name; }</pre>
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client client-identifier]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify a prefix as a client identifier.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

profiller

Syntax	<pre>profiller { command <i>binary-file-path</i>; disable; failover (alternate-media other-routing-engine); }</pre>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the profiler process.
Options	<ul style="list-style-type: none"> • command <i>binary-file-path</i>—Path to binary for process. • disable—Disable the profiler process. • failover—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot. <ul style="list-style-type: none"> • alternate-media—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly. • other-routing-engine—Instruct the secondary Routing Engine to take mastership if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

proxy

Syntax	<pre>proxy { password <i>password</i>; port <i>port-number</i>; server <i>url</i>; username <i>user-name</i>; }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the proxy information for the router.
Options	<ul style="list-style-type: none">• password <i>password</i>—Password configured in the proxy server.• port <i>port number</i>—Proxy server port number. Range: 0 through 65,535• server <i>url</i>—URL or IP address of the proxy server host.• username <i>username</i>—Username configured in the proxy server.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

radius-options

Syntax	<pre>radius-options { attributes { nas-ip-address <i>nas-ip-address</i>; } password-protocol mschap-v2; }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5. Support for network access server (NAS) IPv6 address added in Junos OS Release 12.1X47-D15.
Description	Configure RADIUS options for the NAS-IP address for outgoing RADIUS packets and password protocol used in RADIUS packets.
Options	<ul style="list-style-type: none"> • attributes—Configure RADIUS attributes. <ul style="list-style-type: none"> • nas-ip-address <i>nas-ip-address</i>—Valid IPv4 or IPv6 address of the NAS requesting user authentication. • password-protocol mschap-v2—Protocol MS-CHAPv2, used for password authentication and password changing.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

radius-server

Syntax	<pre>radius-server server-address { accounting-port <i>port-number</i>; max-outstanding-requests <i>value</i>; port <i>port-number</i>; retry <i>value</i>; secret <i>password</i>; source-address <i>source-address</i>; timeout <i>seconds</i>; }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5. Support for IPv6 source address added in Junos OS Release 12.1X47-D15.
Description	<p>Configure RADIUS server address for subscriber access management, Layer 2 Tunnelling Protocol (L2TP), or (Point-to-Point Protocol (PPP).</p> <p>To configure multiple RADIUS servers, include multiple radius-server statements. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers or until all the configured retry limits are reached.</p>
Options	<ul style="list-style-type: none">• server-address—Address of the RADIUS server.• accounting-port <i>port-number</i>—RADIUS server accounting port number. Range: 1 through 65,335 files Default: 1813• port <i>port-number</i>—RADIUS server authentication port number. Range: 1 through 65,335 files Default: 1812• retry <i>value</i>—Number of times that the router is allowed to attempt to contact a RADIUS server. Range: 1 through 10 Default: 3• secret <i>password</i>—Password to use; it can include spaces if the character string is enclosed in quotation marks.• max-outstanding-requests <i>value</i>—Maximum number of outstanding requests in flight to server. Range: 1 through 65,335 files• source-address <i>source-address</i>—Valid IPv4 or IPv6 address configured on one of the router or switch interfaces.• timeout <i>seconds</i>—Amount of time to wait.

Range: 1 through 90 seconds

Default: 3 seconds

Required Privilege Level system—To view this statement in the configuration.
 system-control—To add this statement to the configuration.

rapid-commit

Syntax rapid-commit;

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family *family* dhcpv6-client]

Release Information Statement introduced in Junos OS Release 12.1X45-D10.

Description Used to signal the use of the two-message exchange for address assignment.

Required Privilege Level interface—To view this statement in the configuration.
 interface-control—To add this statement to the configuration.

reconfigure (System Services DHCP)

Syntax	<pre>reconfigure { attempts <i>number</i>; clear-on-abort; strict; timeout <i>number</i>; token <i>token-name</i>; trigger { radius-disconnect; } }</pre>
Hierarchy Level	<pre>[edit system services dhcp-local-server dhcpv6] [edit system services dhcp-local-server group <i>group-name</i>] [edit system services dhcp-local-server dhcpv6 group <i>group-name</i>]</pre>
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Enable dynamic reconfiguration triggered by the DHCP local server of all DHCP clients or only the DHCP clients serviced by the specified group of interfaces. A group configuration takes precedence over a DHCP local server configuration.
Options	<p>attempts <i>number</i>—Configure maximum number of attempts to reconfigure all DHCP clients or only the DHCP clients serviced by the specified group of interfaces before reconfiguration is considered to have failed. A group configuration takes precedence over a DHCP local server configuration.</p> <p>Range: 1 through 10 attempts</p> <p>Default: 8 attempts</p> <p>clear-on-abort—Delete all DHCP clients or only the DHCP clients serviced by the specified group of interfaces when reconfiguration fails; that is, when the maximum number of retry attempts have been made without success. A group configuration takes precedence over a DHCP local server configuration.</p> <p>strict—Configure the system to only allow packets that contain the reconfigure accept option.</p> <p>timeout <i>seconds</i>—Configure the initial value in seconds between attempts to reconfigure all DHCP clients or only the DHCP clients serviced by the specified group of interfaces. Each successive attempts doubles the interval between attempts. For example, if the first value is 2, the first retry is attempted 2 seconds after the first attempt fails. The second retry is attempted 4 seconds after the first retry fails. The third retry is attempted 8 seconds after the second retry fails, and so on. A group configuration takes precedence over a DHCP local server configuration.</p> <p>Range: 1 through 10 seconds</p> <p>Default: 2 seconds</p> <p>token <i>token-name</i>—Configure a plain-text token for all DHCP clients or only the clients specified by the specified group of interfaces. The default is null (empty string).</p>

trigger — Specify DHCP reconfigure trigger.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

req-option

Syntax req-option (dns-server | domain | fqdn | nis-domain | nis-server | ntp-server | sip-domain | sip-server | time-zone | vendor-spec);

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family *family* dhcpv6-client]

Release Information Statement introduced in Junos OS Release 12.1X45-D10.

Description The configuration options requested by the DHCPv6 client.

Options

dns-server—Specify a DNS server.

domain—Specify a domain name.

fqdn—Specify a fully qualified domain name.

nis-domain—Specify a Network Information Service (NIS) domain.

nis-server—Specify a Network Information Service (NIS) server.

ntp-server—Specify a Network Time Protocol (NTP) server.

sip-domain—Specify a Session Initiation Protocol (SIP) domain.

sip-server—Specify a Session Initiation Protocol (SIP) server.

time-zone—Specify a time zone.

vendor-spec—Specify vendor specification.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

retransmission-attempt (dhcp-client)

Syntax	retransmission-attempts <i>number</i> ;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the number of times the device attempts to retransmit a Dynamic Host Control Protocol (DHCP) packet fallback.
Options	number —Number of attempts to retransmit the packet. Range: 0 through 6
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

retransmission-attempt (dhcpv6-client)

Syntax	retransmission-attempt <i>number</i> ;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcpv6-client]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Specify the number of times the device retransmits a DHCPv6 client packet if a DHCPv6 server fails to respond. After the specified number of attempts, no further attempts at reaching a server are made.
Options	number —Number of retransmit attempts
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

retransmission-interval (dhcp-client)

Syntax	retransmission-interval <i>seconds</i> ;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify the time between successive retransmission attempts.
Options	seconds —Number of seconds between successive retransmission attempts. Range: 4 through 64 seconds
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.

root-authentication

Syntax	<pre>root-authentication { encrypted-password <i>password</i>; load-key-file <i>URL</i>; plain-text-password; ssh-dsa <i>public-key</i> { <from <i>pattern-list</i>>; } ssh-rsa <i>public-key</i> { <from <i>pattern-list</i>>; } }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify authentication information for the root login.
Options	<ul style="list-style-type: none">• encrypted-password <i>password</i>—Specify the encrypted authentication password. You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.• plain-text-password—The CLI prompts you for a password encrypts it, and stores the encrypted version in its user database.• load-key-file <i>URL</i>—File URL containing one or more SSH keys.• ssh-dsa <i>public-key</i>—SSH DSA public key string.<ul style="list-style-type: none">• from <i>pattern-list</i>—Pattern list of allowed hosts.• ssh-rsa <i>public-key</i>—SSH RSA public key string.<ul style="list-style-type: none">• from <i>pattern-list</i>—Pattern list of allowed hosts.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

single-connection

Syntax	single-connection;
Hierarchy Level	[edit system accounting destination tacplus server <i>server-address</i>] [edit system tacplus-server <i>server-address</i>]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Optimize the attempt to connect to a TACACS+ server. Junos OS maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

server (NTP)

Syntax	<code>server address <key key-number> <version value> <prefer>;</code>
Hierarchy Level	[edit system ntp]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>For NTP, configure the SRX Series device to operate in client mode with the remote system at the specified address. In this mode, the SRX Series device can be synchronized with the remote system, but the remote system can never be synchronized with the SRX Series device.</p> <p>If the NTP client time drifts so that the difference in time from the NTP server exceeds 128 milliseconds, the client is automatically stepped back into synchronization. If the offset between the NTP client and server exceeds the 1000-second threshold, the client still synchronizes with the server, but it also generates a system log message noting that the threshold was exceeded.</p>
Options	<p>address—Address of the remote system. You must specify an address, not a hostname.</p> <p>key key-number—(Optional) Use the specified key number to encrypt authentication fields in all packets sent to the specified address.</p> <p>Range: Any unsigned 32-bit integer</p> <p>prefer—(Optional) Mark the remote system as the preferred host, which means that if all other things are equal, this remote system is chosen for synchronization among a set of correctly operating systems.</p> <p>version value—(Optional) Specify the version number to be used in outgoing NTP packets.</p> <p>Range: 1 through 4</p> <p>Default: 4</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

static-subscribers

Syntax	<code>static-subscribers { disable; }</code>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Associate subscribers with statically configured interfaces, and provide dynamic service activation for these subscribers.
Options	disable —Disable the static subscribers process.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

statistics-service

Syntax	<code>statistics-service { command <i>binary-file-path</i>; disable; }</code>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the Packet Forwarding Engine (PFE) statistics service management process.
Options	<ul style="list-style-type: none"> • command <i>binary-file-path</i>—Path to the binary process. • disable—Disable the Packet Forwarding Engine (PFE) statistics service management process.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

subscriber-management

Syntax	subscriber-management { command <i>binary-file-path</i> ; disable; }
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the subscriber management process.
Options	<ul style="list-style-type: none">• command <i>binary-file-path</i>—Path to the binary process.• disable—Disable the subscriber management process.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

subscriber-management-helper

Syntax	subscriber-management-helper { command <i>binary-file-path</i> ; disable; failover (alternate-media other-routing-engine); }
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the subscriber management helper process.
Options	<ul style="list-style-type: none">• command <i>binary-file-path</i>—Path to the binary process.• disable—Disable the subscriber management helper process.• failover—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot.<ul style="list-style-type: none">• alternate-media—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly.• other-routing-engine—Instruct the secondary Routing Engine to take mastership if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

system master password

Syntax	<pre>set system master-password plain-text-password Master password: *** Repeat master password: ***</pre>
Hierarchy Level	system
Release Information	Statement introduced in Junos OS Release 15.1X49-D50.
Description	Use to set a master password in a hidden configuration within the Junos OS configuration database.
Options	<p>set system master-password iteration-count—(Optional) The number of iterations to use for the PBKDF2 hash function. The range is 10 through 10000. Default value is 100. High iteration counts can impact system performance on systems with many secrets.</p> <p>set system master-password pseudorandom-function (hmac-sha1 hmac-sha2-256 hmac-sha2-512); default hmac-sha2-256—(Optional) Hash (prf) algorithm to be used for the PBKDF2 key derivation.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> request system decrypt password

tacplus

Syntax	<pre>tacplus { server <i>server-address</i> { port <i>port-number</i>; secret <i>password</i>; single-connection; source-address <i>source-address</i>; timeout <i>seconds</i>; } }</pre>
Hierarchy Level	[edit system accounting destination]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure the TACACS+ accounting server.
Options	<ul style="list-style-type: none">• <i>server-address</i>—Specify the address of the TACACS+ authentication server.• <i>port number</i>—Configure the port number on which to contact the TACACS+ server.• <i>single-connection</i>—Optimize attempts to connect to a TACACS+ server. The software maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.• <i>source-address address</i>—Configure a source address for each configured TACACS+ server.• <i>timeout seconds</i>—Configure the amount of time that the local device waits to receive a response from a TACACS+ server.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring a TACACS+ Server for System Authentication on page 1019

tacplus-options

Syntax	<pre> tacplus-options { (exclude-cmd-attribute no-cmd-attribute-value); enhanced-accounting; service-name <i>service-name</i>; timestamp-and-timezone; } </pre>
Hierarchy Level	[edit system]
Release Information	<p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>no-cmd-attribute-value and exclude-cmd-attribute options introduced in Junos OS Release 9.3.</p> <p>Statement introduced in Junos OS Release 11.1 for QFX Series.</p> <p>timestamp-and-timezone option introduced in Junos OS Release 12.2.</p> <p>enhanced-accounting option introduced in Junos OS Release 14.1.</p> <p>Statement introduced in Junos OS Release 14.1X53-D20 for OCX Series switches.</p>
Description	Configure TACACS+ options for authentication and accounting.
Options	<p>enhanced-accounting—View the attribute values of a logged in user.</p> <p>exclude-cmd-attribute—Exclude the cmd attribute value completely from start and stop accounting records to enable logging of accounting records in the correct log file on a TACACS+ server.</p> <p>no-cmd-attribute-value—Set the cmd attribute value to an empty string in the TACACS+ accounting start and stop requests to enable logging of accounting records in the correct log file on a TACACS+ server.</p> <p>service-name <i>service-name</i>—Name of the authentication service used when you configure multiple TACACS+ servers to use the same authentication service.</p> <p>Default: junos-exec</p> <p>timestamp-and-timezone—Include this statement if you want start time, stop time, and timezone attributes included in start/stop accounting records.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring the Same Authentication Service for Multiple TACACS+ Servers on page 1018 • <i>Configuring TACACS+ System Accounting</i> • <i>Junos OS Authentication Order for RADIUS, TACACS+, and Password Authentication</i> • <i>enhanced-accounting</i>

tacplus-server

Syntax	<code>tacplus-server server-address { port <i>port-number</i>; secret <i>password</i>; single-connection; source-address <i>source-address</i>; timeoutseconds; }</code>
Hierarchy Level	[edit system]
Release Information	Statement introduced before Junos OS Release 7.4. Statement introduced in Junos OS Release 9.0 for EX Series switches.
Description	Configure the TACACS+ server.

- Options**
- **server-address**—Address of the TACACS+ authentication server.

NOTE: Wildcard characters cannot be used in the TACACS server address or source address. This is because the TACACS server and source can accept both IPv4 and IPv6 addresses and, if you use wildcard characters for these addresses, Junos OS cannot validate mismatching server and source address families.

- **port**—Port number of TACACS+ authentication server.
- **secret**—Password to use with the RADIUS or TACACS+ server. The secret password used by the local router or switch must match that used by the server. Password to use; can include spaces included in quotation marks.
- **single-connection**—Optimize attempts to connect to a TACACS+ server. The software maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.
- **source-address**—Source address for each configured TACACS+ server, RADIUS server, NTP server, or the source address to record in system log messages that are directed to a remote machine. Configure a valid IP address on one of the device interfaces. For system logging, the address is recorded as the message source in messages sent to the remote machines specified in all **host *hostname*** statements at the **[edit system syslog]** hierarchy level.
- **timeout**—The amount of time that the local device waits to receive a response from a RADIUS or TACACS+ server. The timeout range is 1 through 90 seconds. The default is 3 seconds.

Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

traceoptions (Outbound SSH)

Syntax	<pre> traceoptions { file { filename ; files <i>number</i>; match <i>regular-expression</i>; size <i>maximum-file-size</i>; (world-readable no-world-readable); } flag <i>flag</i>; no-remote-trace; } </pre>
Hierarchy Level	[edit system services outbound-ssh]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Set the trace options.
Options	<ul style="list-style-type: none"> file—Configure the trace file information. <ul style="list-style-type: none"> filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. By default, the name of the file is the name of the process being traced. files <i>number</i>—Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed to trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> match <i>regular-expression</i>—Refine the output to include lines that contain the regular expression. size <i>maximum-file-size</i>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When trace-file again reaches its maximum size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p> <p>Range: 10 KB through 1 GB</p>

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Specify the tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags.
 - **all**—Trace all events.
 - **configuration**—Trace configuration events.
 - **connectivity**—Trace TCP connection handling.
- **no-remote-trace**—Disable remote tracing.

Required Privilege	trace—To view this statement in the configuration.
Level	trace-control—To add this statement to the configuration.

traceoptions (System Services DHCP)

Syntax	<pre> traceoptions { file { filename; files number; size maximum-file-size; (world-readable no-world-readable); } flag flag; no-remote-trace; } </pre>
Hierarchy Level	[edit routing-instances <i>routing-instance-name</i> system services dhcp-local-server], [edit system services dhcp-local-server] [edit system processes dhcp-service]
Release Information	Statement introduced in Junos OS Release 10.4.
Description	Configure extended DHCP local server tracing operations for DHCP processes.
Options	<ul style="list-style-type: none"> • file-name—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks (" "). All files are placed in a file named jdhcpd in the directory /var/log. If you include the file statement, you must specify a filename. • files number—(Optional) Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the size option. <p>Range: 2 through 1000 Default: 3 files</p> <ul style="list-style-type: none"> • match regular-expression—(Optional) Refine the output to include lines that contain the regular expression. • size maximum-file-size—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). If you specify a maximum file size, you also must specify a maximum number of trace files with the files option. <p>Syntax: xk to specify KB, xm to specify MB, or xg to specify GB Range: 10 KB through 1 GB Default: 128 KB</p> <ul style="list-style-type: none"> • world-readable—(Optional) Enable unrestricted file access. • no-world-readable—(Optional) Disable unrestricted file access. • flag flag—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags: <ul style="list-style-type: none"> • all—Trace all events.

- **database**—Trace database operations.
- **dhcpv6-general**—Trace operations for DHCPv6.
- **dhcpv6-io**—Trace input/output operations for DHCPv6.
- **dhcpv6-packet**—Trace DHCPv6 packet decoding operations.
- **dhcpv6-packet-option**—Trace DHCPv6 option decoding operations.
- **dhcpv6-rpd**—Trace routing protocol process operations.
- **dhcpv6-session-db**—Trace session database operations for DHCPv6.
- **dhcpv6-state**—Trace changes in state for DHCPv6 operations.
- **fwd**—Trace firewall process operations.
- **general**—Trace miscellaneous general operations.
- **ha**—Trace high-availability related operations.
- **interface**—Trace interface operations.
- **io**—Trace input/output operations.
- **packet**—Trace packet decoding operations.
- **packet- option**—Trace DHCP option decoding operations.
- **performance**—Trace DHCP performance measurement operations.
- **profile**—Trace DHCP profile operations.
- **rpd**—Trace routing protocol process operations.
- **rtsock**—Trace routing socket operations.
- **session-db**—Trace session database operations.
- **state**—Trace changes in state.
- **statistics**—Trace changes in statistics.
- **ui**—Trace changes in user interface operations.
- **no remote-trace**—Disable remote tracing.

Required Privilege Level trace—To view this statement in the configuration.
 trace-control—To add this statement to the configuration.

Related Documentation • [System Configuration Statement Hierarchy on page 1165](#)

trusted-key

Syntax	<code>trusted-key [<i>key-numbers</i>];</code>
Hierarchy Level	[edit system <i>ntp</i>]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	For NTP, configure the keys you are allowed to use when you configure the SRX Series device to synchronize its time with other systems on the network.
Options	key-numbers —One or more key numbers. Each key can be any 32-bit unsigned integer except 0.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

update-router-advertisement

Syntax	update-router-advertisement (interface <i>interface-name</i>);
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcpv6-client]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Specify the interface used to delegate prefixes.
Options	interface <i>interface-name</i> —Interface on which to delegate prefixes
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

update-server (dhcp-client)

Syntax	update-server;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Propagate DHCP options to a local DHCP server.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

update-server (dhcpv6-client)

Syntax	update-server;
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcpv6-client]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Propagate TCP/IP settings to the DHCPv6 server.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

usb-control

Syntax	usb-control { command <i>binary-file-path</i> ; disable; }
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the universal serial bus (USB) supervise process.
Options	<ul style="list-style-type: none"> • command <i>binary-file-path</i>—Path to the binary process. • disable—Disable the universal serial bus (USB) supervise process.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

use-interface

Syntax	use-interface-description {logical device};
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client client-identifier]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	The description configured at the physical or logical interface level is used for client identification.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

user-id

Syntax	<code>user-id {ascii <i>ascii</i> hexadecimal <i>hexadecimal</i>};</code>
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client client-identifier]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Specify an ASCII or hexadecimal user ID for the Dynamic Host Configuration Protocol (DHCP) client.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

vendor-id

Syntax	<code>vendor-id <i>vendor-id</i>;</code>
Hierarchy Level	[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i> dhcp-client]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Configure a vendor class ID for the Dynamic Host Configuration Protocol (DHCP) client.
Options	vendor-id —Vendor class ID.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	

vpn (Forwarding Options)

Syntax	<code>vpn;</code>
Hierarchy Level	[edit forwarding-options helpers bootp]
Release Information	Statement introduced in Junos OS Release 9.0.
Description	For Dynamic Host Configuration Protocol (DHCP) or BOOTP client request forwarding, enable virtual private network (VPN) encryption for a client request to pass through a VPN tunnel.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • DHCP Server, Client, and Relay Agent Overview on page 1088

watchdog

Syntax	<pre>watchdog { disable; enable; timeout <i>value</i>; }</pre>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Enable or disable the watchdog timer when Junos OS encounters a problem.
Options	<ul style="list-style-type: none"> • disable—Disable the watchdog timer. • enable—Enable the watchdog timer. • timeout <i>value</i>—Specify amount of time to wait in seconds. Range: 1 through 3600 seconds.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

web-management

Syntax	<pre>web-management { disable; failover (alternate-media other-routing-engine); }</pre>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the Web management process.
Options	<ul style="list-style-type: none">• disable—Disable the Web management process.• failover—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot.<ul style="list-style-type: none">• alternate-media—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly.• other-routing-engine—Instruct the secondary Routing Engine to take mastership if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>

web-management (System Services)

```
Syntax  web-management {
        http {
            interfaces interface-names ;
            port port;
        }
        https {
            interfaces interface-names;
            local-certificate name;
            pki-local-certificate name;
            system-generated-certificate name;
            port port;
        }
        management url management url;
        session {
            idle-timeout minutes;
            session-limit number;
        }
        traceoptions {
            file {
                filename;
                files number;
                match regular-expression;
                size maximum-file-size;
                (no-world-readable | world-readable);
            }
            flag flag;
            level level;
            no-remote-trace;
        }
    }
```

Hierarchy Level [edit system services]

Release Information Statement introduced in Junos OS Release 9.0.
Support for **https** introduced for high-end SRX Series Services Gateways starting from Junos OS Release 12.1X44-D10 and on vSRX, SRX300, SRX320, SRX340, SRX345, SRX550M, and SRX1500 Services Gateways starting from Junos OS Release 15.1X49-D40.

Description Configure settings for HTTP or HTTPS access. HTTP access allows management of the device using the J-Web interface. HTTPS access allows secure management of the device using the J-Web interface. With HTTPS access, communication is encrypted between your browser and the webserver for your device.

Options **control**—Disable the SBC process.

- **max-threads**—Maximum simultaneous threads to handle requests.
Range: 0 through 16

http—Configure HTTP.

- **interface [value]**—Interface value that accepts HTTP access.

- **port *number***—TCP port for incoming HTTP connections.

Range: 1 through 65,535

https—Configure HTTPS.

- **interface [*value*]**—Interface value that accept HTTP access.
- **port *number***—TCP port for incoming HTTP connections.

Range: 1 through 65,535

- **local-certificate**—X.509 certificate to use from the configuration.
- **pki-local-certificate**—X.509 certificate to use from the PKI local store.
- **system-generated-certificate**—X.509 certificate generated automatically by the system.

management url *management url*—URL path for Web management access.

session—Configure the Web-management session.

- **idle-timout *minutes***—Default timeout of Web-management sessions in minutes.
- **session-limit *number***—Maximum number of Web-management sessions to allow.

traceoptions—Set the trace options.

- **file**—Configure the trace file information.
 - *filename*—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. All files are placed in the directory **/var/log**. By default, the name of the file is the name of the process being traced.
 - **files number**—Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size maximum file-size** option.

Range: 2 through 1000 files

Default: 10 files

- **match regular-expression**—Refine the output to include lines that contain the regular expression.
- **size maximum-file-size**—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

Range: 10 KB through 1 GB

Default: 128 KB

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files number** option.

- **(world-readable | no-world-readable)**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag flag**—Specify which tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. You can include the following flags.
 - **all**—Trace all areas.
 - **configuration**—Trace configuration.
 - **dynamic-vpn**—Trace dynamic VPN events.
 - **init**—Trace the daemon init process.
 - **mgd**—Trace MGD requests.
 - **webauth**—Trace Web authentication requests.
- **level level**—Specify the level of debugging output.
 - **all**—Match all levels.
 - **error**—Match error conditions.

- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.
- **no-remote-trace**—Disable remote tracing.

Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

clear dhcp client binding

Syntax	clear dhcp client binding [all interface <interface-name>] [routing-instance <routing-instance-name>]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Clear the binding state of a Dynamic Host Configuration Protocol (DHCP) client from the DHCP client table.
Options	<p>all—(Optional) Clear the binding state for all DHCP clients.</p> <p>interface <interface-name>—(Optional) Clear the binding state for DHCP clients on the specified interface.</p> <p>routing-instance <routing-instance-name>—(Optional) Clear the binding state for DHCP clients on the specified routing instance. If you do not specify a routing instance, binding state is cleared for DHCP clients on the default routing instance.</p>
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show dhcp client binding on page 1346
Output Fields	This command produces no output.

clear dhcp client statistics

Syntax	clear dhcp client statistics <all> <interface> <routing-instance>
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Clear all Dynamic Host Configuration Protocol (DHCP) client statistics.
Options	<p>all—(Optional) Clear all the DHCP client statistics.</p> <p>interface—(Optional) Clear the statistics for DHCP clients on the specified interface.</p> <p>routing-instance —(Optional) Clear the statistics for DHCP clients on the specified routing instance. If you do not specify a routing instance, statistics are cleared for the default routing instance.</p>
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• show dhcp client statistics on page 1349
Output Fields	This command produces no output.

clear dhcp relay binding

Syntax	clear dhcp relay binding <all ip-address mac-address> <interface interface-name> <routing-instance routing-instance-name>
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Clear the binding state of a Dynamic Host Configuration Protocol (DHCP) client from the client table.
Options	<p>all—(Optional) Clear the binding state for all DHCP clients.</p> <p>ip-address— (Optional) Clear the binding state for the DHCP client, using the specified IP address.</p> <p>mac-address—(Optional) Clear the binding state for the DHCP client, using the specified MAC address.</p> <p>interface interface-name—(Optional) Clear the binding state for DHCP clients on the specified interface</p> <p>routing-instance routing-instance-name—(Optional) Clear the binding state for DHCP clients on the specified routing instance. file archive

Syntax	<code>file archive destination <i>destination</i> source <i>source</i> <compress></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Archive, and optionally compress, one or multiple local system files as a single file, locally or at a remote location.
Options	<p>destination <i>destination</i>—Name of the created archive. Specify the destination as a URL or filename.</p> <p>source <i>source</i>— Path of directory to archive.</p> <p>compress—(Optional) Compress the archived file with the GNU zip (gzip) compression utility. The compressed files have the suffix .tgz.</p>
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • <i>Administration Guide for Security Devices</i>
List of Sample Output	file archive (Multiple Files) on page 1302 file archive (Single File) on page 1302 file archive (with Compression) on page 1302
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

file archive (Multiple Files)

The following sample command archives all message files in the local directory `/var/log/messages` as the single file `messages-archive.tar`.

```
user@host> file archive source /var/log/messages* destination /var/log/messages-archive.tar
/usr/bin/tar: Removing leading / from absolute path names in the archive.
```

file archive (Single File)

The following sample command archives one message file in the local directory `/var/log/messages` as the single file `messages-archive.tar`.

```
user@host> file archive source /var/log/messages destination /var/log/messages-archive.tar
/usr/bin/tar: Removing leading / from absolute path names in the archive.
user@host
```

file archive (with Compression)

The following sample command archives and compresses all message files in the local directory `/var/log/messages` as the single file `messages-archive.tar`.

```
user@host> file archive compress source /var/log/messages* destination  
/var/log/messages-archive.tgz  
/usr/bin/tar: Removing leading / from absolute path names in the archive.
```

file checksum md5

Syntax	<code>file checksum md5 <i>path</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Calculate the Message Digest 5 (MD5) checksum of a file.
Options	<i>path</i> —(Optional) Path to a filename.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• <i>Administration Guide for Security Devices</i>• file checksum sha1 on page 1305• file checksum sha-256 on page 1306

user@host> file checksum sha-256 /var/db/scripts/commitscript.slax

SHA256 (/var/db/scripts/commitscript.slax) =
94c2b061fb55399e15babd2529453815601a602b5c98e5c12ed929c9d343dd71
```

file compare

Syntax	<code>file compare (files <i>from-file to-file</i>) <context unified> <ignore-white-space></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Compare two local files and describe the differences between them in default, context, or unified output styles:</p> <ul style="list-style-type: none"> • default—In the first line of output, c means lines were changed between the two files, d means lines were deleted between the two files, and a means lines were added between the two files. The numbers preceding this alphabetical marker represent the first file, and the lines after the alphabetical marker represent the second file. A left angle bracket (<) in front of output lines refers to the first file. A right angle bracket (>) in front of output lines refers to the second file. • context—The display is divided into two parts. The first part is the first file; the second part is the second file. Output lines preceded by an exclamation point (!) have changed. Additions are marked with a plus sign (+), and deletions are marked with a minus sign (-). • unified—The display is preceded by the line number from the first and the second file (xx,xxx,x). Before the line number, additions to the file are marked with a plus sign (+), and deletions to the file are marked with a minus sign (-). The body of the output contains the affected lines. Changes are viewed as additions plus deletions.
Options	<p>files <i>from-file</i>—Names of files to compare.</p> <p>files <i>to-file</i>—Names of files to compare against.</p> <p>context—(Optional) Display output in context format.</p> <p>ignore-white-space—(Optional) Ignore changes in the amount of white space.</p> <p>unified—(Optional) Display output in unified format.</p>
Required Privilege Level	none

file copy

Syntax `file copy source destination`
`<source-address source- address>`

Release Information Command introduced before Junos OS Release 7.4.

Description Copy files from one location to another location on the local device or to a location on a remote device that is reachable by the local device.

WARNING: The `sslv3-support` option is not available for configuration with the `set system services xnm-ssl` and `file copy` commands. SSLv3 is no longer supported or available.

You can use the `set system services xnm-ssl sslv3-support` command to enable SSLv3 for a Junos XML protocol client application to use as the protocol to connect to the Junos XML protocol server on a device, and you can use the `file copy source destination sslv3-support` command to enable the copying of files from an SSLv3 URL.

Using SSLv3 presents a potential security vulnerability, and we recommend that you not use SSLv3. For more details about this security vulnerability, go to <http://kb.juniper.net/InfoCenter/index?page=content&id=JSA10656>.

Required Privilege Level maintenance

List of Sample Output

- [Copy a File from the Local Device to a Personal Computer on page 1310](#)
- [Copy a Configuration File Between Routing Engines on page 1311](#)
- [Copy a Log File Between Routing Engines on page 1311](#)
- [Copy a File Using FTP on page 1311](#)
- [Copy a File Using FTP and Requiring a Password on page 1311](#)
- [Copy a File Using Secure Copy on page 1311](#)

Sample Output

The following are examples of a variety of file copy scenarios.

Copy a File from the Local Device to a Personal Computer

```
user@host> file copy /var/tmp/rpd.core.4 mypc:/c/junipero/tmp
```

```
...transferring.file..... | 0 KB | 0.3 kB/s | ETA: 00:00:00 | 100%
```

Copy a Configuration File Between Routing Engines

The following sample command copies a configuration file from Routing Engine 0 to Routing Engine 1:

```
user@host> file copy /config/juniper.conf re1:/var/tmp/copied-juniper.conf
```

Copy a Log File Between Routing Engines

The following sample command copies a log file from Routing Engine 0 to Routing Engine 1:

```
user@host> file copy lcc0-re0:/var/log/chassisd lcc0-re1:/var/tmp
```

Copy a File Using FTP

To use anonymous FTP to copy a local file to a remote system:

```
user@host> file copy filename ftp://hostname/filename
```

In the following example, `/config/juniper.conf` is the local file and `hostname` is the FTP server:

```
user@host> file copy /config/juniper.conf ftp://hostname/juniper.conf
Receiving ftp: //hostname/juniper.conf (2198 bytes): 100%
2198 bytes transferred in 0.0 seconds (2.69 MBps)
```

Copy a File Using FTP and Requiring a Password

To use FTP where you require more privacy and are prompted for a password:

```
root@host> file copy filename ftp://user@hostname/filename
```

In the following example, `/config/juniper.conf` is the local file and `hostname` is the FTP server:

```
root@host> file copy /config/juniper.conf ftp://user@hostname/juniper.conf
Password for user@hostname: *****
Receiving ftp: //user@hostname/juniper.conf (2198 bytes): 100%
2198 bytes transferred in 0.0 seconds (2.69 MBps)
```

Copy a File Using Secure Copy

To use scp to copy a local file to a remote system:

```
root@host> file copy filename scp://user@hostname/path/filename
```

In the following example, `/config/juniper.conf` is the local file, `user` is the username, and `ssh-host` is the scp server:

```
root@host> file copy /config/juniper.conf scp://user@ssh-host/tmp/juniper.conf
user@ssh-host's password: *****
juniper.conf          100%
| ***** |
2198          00:00
```

file delete

Syntax	<code>file delete path</code> <code><purge></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Delete a path on the device.
Options	path —Name of the path to delete. purge —(Optional) Overwrite regular files before deleting them.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• <i>Administration Guide for Security Devices</i>
List of Sample Output	file delete on page 1312
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

file delete

```
user@host> file list /var/tmp
dcd.core
rpd.core
snmpd.core

user@host> file delete /var/tmp/snmpd.core
user@host> file list /var/tmp
dcd.core
rpd.core
```

file list

Syntax	<code>file list path</code> <detail recursive>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Display a list of paths on the device.
Options	<p>path—(Optional) Display a list of paths.</p> <p>detail recursive—(Optional) Display detailed output or descend recursively through the directory hierarchy, respectively.</p>
Additional Information	The default directory is the home directory of the user logged in to the device. To view available directories, enter a space and then a slash (/) after the file list command. To view files within a specific directory, include a slash followed by the directory and, optionally, subdirectory name after the file list command.

file rename

Syntax	<code>file rename <i>source destination</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Rename a file on the device.
Options	<i>destination</i> —New name for the file. <i>source</i> —Original name of the file.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• <i>Administration Guide for Security Devices</i>
List of Sample Output	file rename on page 1314
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

file rename

The following example lists the files in `/var/tmp`, renames one of the files, and then displays the list of files again to reveal the newly named file.

```
user@host> file list /var/tmp
dcd.core
rpd.core
snmpd.core

user@host> file rename /var/tmp/dcd.core /var/tmp/dcd.core.990413
user@host> file list /var/tmp
dcd.core.990413
rpd.core
snmpd.core
```

file show

Syntax	<code>file show <i>filename</i></code> <code><encoding (base64 raw)></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Display the contents of a file.
Options	<p><i>filename</i>—Name of a file.</p> <p>encoding (base64 raw)—(Optional) Encode file contents with base64 encoding or show raw text.</p>
Required Privilege Level	maintenance

`request system autorecovery state clear`

```
user@host> request system autorecovery state clear
Clearing config recovery information
Clearing license recovery information
Clearing bsdlablel recovery information
```

request system decrypt password

Syntax	request system decrypt password
Release Information	Statement introduced in Junos OS Release 15.1X49-D50.
Description	Use to display plain text versions of obfuscated (\$9) or encrypted (\$8) passwords. If the password was encrypted using the new \$8\$ method, you are prompted for the master password.
Options	<ul style="list-style-type: none">decrypt—Decrypt a \$8\$-encrypted or \$9\$-encrypted password.
Required Privilege Level	system
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

```
// Decrypting a $9 password
user@host> request system decrypt password $9$ABC123
Plaintext password: mysecret
```

Sample Output

```
// Decrypting a $8 password
user@host> request system decrypt password $8$ABC123
Master password:
Plaintext password: mysecret
(Simple passwords like "mysecret" are discouraged. This is an example only.)
```

request system download abort

Syntax	request system download abort <download-id>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Abort a download. The download instance is stopped and cannot be resumed. Any partially downloaded file is automatically deleted to free disk space. Information regarding the download is retained and can be displayed with the show system download command until a request system download clear operation is performed.
<div>  NOTE: Only downloads in the active, paused, and error states can be aborted. </div>	
Options	download-id —(Required) The ID number of the download to be aborted.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • request system download start on page 298 • request system download pause on page 296 • request system download resume on page 297 • request system download clear on page 295

Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system download pause

```
user@host> request system download pause 1
Paused download #1
```

request system download resume

Syntax	<code>request system download resume <i>download-id</i> <max-rate></code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Resume a download that has been paused. Download instances that are not in progress because of an error or that have been explicitly paused by the user can be resumed by the user. The file will continue downloading from the point where it paused. By default, the download resumes with the same bandwidth specified with the request system download start command. The user can optionally specify a new (maximum) bandwidth with the request system download resume command.
<div>  NOTE: Only downloads in the paused and error states can be resumed. </div>	
Options	download-id —(Required) The ID number of the download to be resumed. max-rate —(Optional) The maximum bandwidth for the download.
Required Privilege Level	maintenance

Sample Output

request system download resume

```
user@host> request system download resume 1
Resumed download #1
```

request system download start

Syntax	<code>request system download start (url max-rate save as login delay)</code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Creates a new download instance and identifies it with a unique integer called the download ID.
Options	<p>url—(Required) The FTP or HTTP URL location of the file to be downloaded.</p> <p>max-rate—(Optional) The maximum average bandwidth for the download. Numbers with the suffix k or K, m or M, and g or G are interpreted as kbps, mbps, or gbps, respectively.</p> <p>save-as—(Optional) The filename to be used for saving the file in the <code>/var/tmp</code> location.</p> <p>login—(Optional) The username and password for the server in the format <code>username:password</code>.</p> <p>delay—(Optional) The number of hours after which the download should start.</p>
Required Privilege Level	maintenance

request system services dhcp

Syntax	request system services dhcp (release <i>interface-name</i> renew <i>interface-name</i>)
Release Information	Command introduced in Junos OS Release 8.5.
Description	<p>Release or renew the acquired IP address for a specific interface.</p> <p>To view the status of the Dynamic Host Configuration Protocol (DHCP) clients on the specified interfaces, enter the show system services dhcp client <i>interface-name</i> command.</p>
Options	<ul style="list-style-type: none">• release <i>interface-name</i> —Clears other resources received earlier from the server, and reinitializes the client state to INIT for the particular interface.• renew <i>interface-name</i> —Reacquires an IP address from the server for the interface. When you use this option, the command sends a discover message if the client state is INIT and a renew request message if the client state is BOUND. For all other states it performs no action.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• <i>dhcp</i>• show system services dhcp client on page 1380
Output Fields	This command produces no output.

request system snapshot (SRX Series)

Syntax request system snapshot
 <factory>
 <media (compact-flash | hard-disk | internal | usb)>
 <node (all | local | node-id | primary)>
 <partition>
 <slice (alternate) >

Release Information Command introduced in Junos OS Release 10.2.

Description Back up the currently running and active file system partitions on the device.

- Options**
- media— (Optional) Specifies the media to be included in the snapshot:
 - compact-flash— Copies the snapshot to the CompactFlash card.
 - hard-disk— Copies the snapshot to the hard disk.
 - usb— Copies the snapshot to the USB storage device.
 - node— (Optional) Specifies the archive data and executable areas of a specific node.
 - node-id— Specifies for node(0, 1).
 - all— Specifies for all nodes.
 - local— Specifies for local nodes.
 - primary— Specifies for primary nodes.
 - partition - (Default) Specifies that the target media should be repartitioned before the backup is saved to it.

NOTE: The target media is partitioned whether or not it is specified in the command, because this is a mandatory option.

Example: **request system snapshot media usb partition**

Example: **request system snapshot media usb partition factory**

- slice— (Optional) Takes a snapshot of the root partition the system has currently booted from to another slice in the same media.
- alternate— (Optional) Stores the snapshot on the other root partition in the system.

NOTE: The slice option cannot be used along with the other **request system snapshot** options, because the options are mutually exclusive. If you use the factory, media, or partition option, you cannot use the slice option; if you use the slice option, you cannot use any of the other options.

Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • Example: Installing Junos OS on SRX Series Devices Using the Partition Option on page 110
List of Sample Output	request system snapshot media hard-disk on page 1331 request system snapshot media usb (when usb device is missing on page 1331 request system snapshot media compact-flash on page 1331 request system snapshot partition on page 1331
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

[request system snapshot media hard-disk](#)

```
user@host> request system snapshot media hard-disk
Verifying compatibility of destination media partitions...
Running newfs (880MB) on hard-disk media / partition (ad2s1a)...

```

request system software abort in-service-upgrade (ICU)

Syntax	request system software abort in-service-upgrade
Release Information	Command introduced in Junos OS Release 11.2.
Description	Abort an in-band cluster upgrade (ICU). This command must be issued from a router session other than the one on which you issued the request system in-service-upgrade command that launched the ICU. If an ICU is in progress, this command aborts it. If the node is being upgraded, this command will cancel the upgrade. The command is also helpful in recovering the node in case of a failed ICU.
Options	This command has no options.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>request system software in-service-upgrade (Maintenance)</i>
List of Sample Output	request system software abort in-service-upgrade on page 1332
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system software abort in-service-upgrade

```
user@host> request system software abort in-service-upgrade
In-Service-Upgrade aborted
```

request system software add (Maintenance)

Syntax	<code>request system software add <i>package-name</i></code>
Release Information	Partition option introduced in the command in Junos OS Release 10.1.
Description	Install the new software package on the device. For example: request system software add junos-srxsme-10.0R2-domestic.tgz no-copy no-validate partition reboot.
Options	<ul style="list-style-type: none">• <code>delay-restart</code> — Installs the software package but does not restart the software process• <code>best-effort-load</code> — Activate a partial load and treat parsing errors as warnings instead of errors• <code>no-copy</code> — Installs the software package but does not saves the copies of package files• <code>no-validate</code> — Does not check the compatibility with current configuration before installation starts• <code>partition</code> — Formats and re-partitions the media before installation• <code>reboot</code> — Reboots the device after installation is completed• <code>unlink</code> — Removes the software package after successful installation• <code>validate</code> — Checks the compatibility with current configuration before installation starts
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• request system reboot on page 1334

request system reboot

Syntax `request system reboot <at time> <in minutes> <media> <message 'text'>`

Release Information Command introduced in Junos OS Release 10.1.
 Command **hypervisor** option introduced in Junos OS Release 15.1X49-D10 for vSRX.
 Command introduced in Junos OS Release 15.1X49-D50 for SRX1500 devices.

Description Reboot the software.

- Options**
- **at time**— Specifies the time at which to reboot the device . You can specify time in one of the following ways:
 - **now**— Reboots the device immediately. This is the default.
 - **+minutes**— Reboots the device in the number of minutes from now that you specify.
 - **yymmddhhmm**— Reboots the device at the absolute time on the date you specify. Enter the year, month, day, hour (in 24-hour format), and minute.
 - **hh:mm**— Reboots the device at the absolute time you specify, on the current day. Enter the time in 24-hour format, using a colon (:) to separate hours from minutes.
 - **in minutes**— Specifies the number of minutes from now to reboot the device. This option is a synonym for the **at +minutes** option
 - **media type**— Specifies the boot device to boot the device from:
 - **disk/internal**— Reboots from the internal media. This is the default.
 - **usb**— Reboots from the USB storage device.
 - **compact flash**— Reboots from the external CompactFlash card.

NOTE: The **media** command option is not available on vSRX.

- **message text**— Provides a message to display to all system users before the device reboots.

Example: **request system reboot at 5 in 50 media internal message stop**

Required Privilege Level maintenance

Related Documentation • [request system software rollback \(SRX Series\) on page 356](#)

request system software rollback (SRX Series)

Syntax	request system software rollback <node-id>
Release Information	Command introduced in Junos OS Release 10.1. Command introduced in Junos OS Release 15.1X49-D50 for SRX1500 devices.
Description	Revert to the software that was loaded at the last successful request system software add command. Example: request system software rollback .
Options	<i>node-id</i> —Identification number of the chassis cluster node. It can be 0 or 1.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• request system reboot on page 1334

request system zeroize

Syntax `request system zeroize <media>`

Description Erases all configuration information and resets all key values. The command removes all data files, including customized configuration and log files, by unlinking the files from their directories.

The command removes all user-created files from the system including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as root and start the Junos OS command-line interface (CLI) by typing `cli` at the prompt.

Options **media**—(Optional) In addition to removing all configuration and log files, the media option causes memory and the media to be scrubbed, removing all traces of any user-created files. Every storage device attached to the system is scrubbed, including disks, flash drives, removable USBs, and the like. The duration of the scrubbing process is dependent on the size of the media being erased. As a result, the request system zeroize media operation can take considerably more time than the request system zeroize operation. However, the critical security parameters are all removed at the beginning of the process.

NOTE: The media option is not supported on SRX5000 line devices.

Required Privilege Level Not applicable.

Release Information Command introduced before Junos OS Release 9.2

Description Restart a Junos OS process.

CAUTION: Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router to drop calls and interrupt transmission, resulting in possible loss of data.

- Options**
- application-identification—(Optional) Restart the process that identifies an application using intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports.
 - application-security—(Optional) Restart the application security process.
 - audit-process—(Optional) Restart the RADIUS accounting process that gathers statistical data that can be used for general network monitoring, for analyzing and tracking usage patterns, and for billing a user based upon the amount of time used or the type of services accessed.
 - chassis-control—(Optional) Restart the chassis management process.
 - class-of-service—(Optional) Restart the class-of-service (CoS) process, which controls the router's or switch's CoS configuration.
 - commitd-service—(Optional) Restart the committed services.
 - database-replication—(Optional) Restart the database replication process.
 - datapath-trace-service—(Optional) Restart the Restart the packet path tracing process.
 - ddns—(Optional) Restart the dynamic domain name system, which dynamically updates IP addresses for registered domain names.

- `dhcp`—(Optional) Restart the software process for a Dynamic Host Configuration Protocol (DHCP) server. A DHCP server allocates network IP addresses and delivers configuration settings to client hosts without user intervention.
- `dhcp-service`—(Optional) Restart the Dynamic Host Configuration Protocol process.
- `disk-monitoring`—(Optional) Restart disk monitoring, which checks the health of the hard disk drive on the Routing Engine.
- `dynamic-flow-capture`—(Optional) Restart the dynamic flow capture (DFC) process, which controls DFC configurations on PIC3 monitoring services cards.
- `ethernet-connectivity-fault-management`—(Optional) Restart the process that provides IEEE 802.1ag Operation, Administration, and Maintenance (OAM) connectivity fault management (CFM) database information for CFM maintenance association end points (MEPs) in a CFM session.
- `ethernet-link-fault-management`—(Optional) Restart the process that provides the OAM link fault management (LFM) information for Ethernet interfaces.
- `event-processing`—(Optional) Restart the event process (`eventd`).
- `extensible-subscriber-services`—(Optional) Restart the extensible subscriber services process.
- `fipsd`—(Optional) Restart the `fipsd` services.
- `firewall`—(Optional) Restart the firewall management process, which manages the firewall configuration and accepts or rejects packets that are transiting an interface on a router or switch.
- `firewall-authentication-service`—(Optional) Restart the firewall authentication service process.
- `general-authentication-service`—(Optional) Restart the general authentication process.
- `gprs-process`—(Optional) Restart the General Packet Radio Service (GPRS) process.
- `gracefully`—(Optional) Restart the software process.
- `idp-policy`—(Optional) Restart the intrusion detection and prevention (IDP) protocol process.
- `immediately`—(Optional) Immediately restart the software process.
- `interface-control`—(Optional) Restart the interface process, which controls the router's or switch's physical interface devices and logical interfaces.
- `ipmi`—(Optional) Restart the intelligent platform management interface process.
- `ipsec-key-management`—(Optional) Restart the IPsec key management process.
- `jflow-service`—(Optional) Restart `jflow` service process.
- `jnu-management`—(Optional) Restart `jnu` management process.
- `jnx-wmicd-service`—(Optional) Restart `jnx wmicd` service process.
- `jsrp-service`—(Optional) Restart the Juniper Services Redundancy Protocol (`jsrdp`) process, which controls chassis clustering.

- **kernel-replication**—(Optional) Restart the kernel replication process, which replicates the state of the backup Routing Engine when graceful Routing Engine switchover (GRES) is configured.
- **lACP**—(Optional) Restart the Link Aggregation Control Protocol (LACP) process. LACP provides a standardized means for exchanging information between partner systems on a link. The LACP process allows link aggregation control instances to reach agreement on the identity of the LAG to which a link belongs, moves the link to that LAG, and enables the transmission and reception processes for the link to function in an orderly manner.
- **l2cpd-service**—(High-end SRX Series only) (Optional) Restart the Layer 2 Control Protocol (L2CP) process, which enables features such as L2 protocol tunneling and nonstop bridging.
- **l2-learning**—(Optional) Restart the Layer 2 (L2) address flooding and learning process.
- **license-service**—(Optional) Restart the feature license management process.
- **logical-system-service**—(Optional) Restart the logical system service process.
- **mib-process**—(Optional) Restart the MIB version II process, which provides the router's MIB II agent.
- **mountd-service**—(Optional) Restart the service for Network File System (NFS) mount requests.
- **named-service**—(Optional) Restart the DNS Server process, which is used by a router or a switch to resolve hostnames into addresses.
- **network-security**—(Optional) Restart the network security process.
- **network-security-trace**—(Optional) Restart the network security trace process.
- **nfsd-service**—(Optional) Restart the remote NFS server process, which provides remote file access for applications that need NFS-based transport.
- **ntpd-service**—(Optional) Restart the Network Time Protocol (NTP) process.
- **pgm**—(Optional) Restart the process that implements the Pragmatic General Multicast (PGM) protocol for assisting in the reliable delivery of multicast packets.
- **pic-services-logging**—(Optional) Restart the logging process for some PICs. With this process, also known as fsad (the file system access daemon), PICs send special logging information to the Routing Engine for archiving on the hard disk.
- **pki-service**—(Optional) Restart the public key infrastructure (PKI) service process.
- **profillerd**—(Optional) Restart the profiler process.
- **remote-operations**—(Optional) Restart the remote operations process, which provides the ping and traceroute MIBs.
- **rest-api**—(Optional) Restart the rest api process.
- **routing**—(Optional) Restart the routing protocol process (rpd).
- **sampling**—(Optional) Restart the sampling process, which performs packet sampling based on particular input interfaces and various fields in the packet header.

- `sampling-route-record`—(Optional) Restart the sampling route record process.
- `scc-chassisd`—(Optional) Restart the scc chassisd process.
- `secure-neighbor-discovery`—(Optional) Restart the secure Neighbor Discovery Protocol (NDP) process, which provides support for protecting NDP messages.
- `security-intelligence`—(Optional) Restart security intelligence process.
- `security-log`—(Optional) Restart the security log process.
- `service-deployment`—(Optional) Restart the service deployment process, which enables Junos OS to work with the Session and Resource Control (SRC) software.
- `services`—(Optional) Restart a service.
- `simple-mail-client-service`—(Optional) Restart the simple mail client service process.
- `snmp`—(Optional) Restart the SNMP process, which enables the monitoring of network devices from a central location and provides the router's or switch's SNMP master agent.
- `static-routed`—(Optional) Restart the static routed process.
- `soft`—(Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.
- `statistics-service`—(Optional) Restart the process that manages the Packet Forwarding Engine statistics.
- `subscriber-management`—(Optional) Restart the subscriber management process.
- `subscriber-management-helper`—(Optional) Restart the subscriber management helper process.
- `system-log-vital`—(Optional) Restart system log vital process.
- `tunnel-oamd`—(Optional) Restart the tunnel OAM process for L2 tunneled networks.
- `uac-service`—(Optional) Restart the Unified Access Control (UAC) process.
- `user-ad-authentication`—(Optional) Restart User ad Authentication process
- `vrrp`—(Optional) Restart the Virtual Router Redundancy Protocol (VRRP) process, which enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts.
- `web-management`—(Optional) Restart the Web management process.

Required Privilege Level reset

show chassis routing-engine (View)

Syntax	show chassis routing-engine
Release Information	Command introduced in Junos OS Release 9.5.
Description	Display the Routing Engine status of the chassis cluster.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • cluster (Chassis) on page 1998 • request system snapshot (SRX Series) on page 331
List of Sample Output	show chassis routing-engine (Sample 1 - SRX550M) on page 1344 show chassis routing-engine (Sample 2- vSRX) on page 1344
Output Fields	Table 90 lists the output fields for the show chassis routing-engine command. Output fields are listed in the approximate order in which they appear.

Table 90: show chassis routing-engine Output Fields

Field Name	Field Description
Temperature	Routing Engine temperature. (Not available for vSRX deployments.)
CPU temperature	CPU temperature. (Not available for vSRX deployments.)
Total memory	Total memory available on the system.
Control plane memory	Memory available for the control plane.
Data plane memory	Memory reserved for data plane processing.
CPU utilization	Current CPU utilization statistics on the control plane core.
User	Current CPU utilization in user mode on the control plane core.
Background	Current CPU utilization in nice mode on the control plane core.
Kernel	Current CPU utilization in kernel mode on the control plane core.
Interrupt	Current CPU utilization in interrupt mode on the control plane core.
Idle	Current CPU utilization in idle mode on the control plane core.
Model	Routing Engine model.
Start time	Routing Engine start time.

Table 90: show chassis routing-engine Output Fields (*continued*)

Field Name	Field Description
Uptime	Length of time the Routing Engine has been up (running) since the last start.
Last reboot reason	Reason for the last reboot of the Routing Engine.
Load averages	The average number of threads waiting in the run queue or currently executing over 1-, 5-, and 15-minute periods.

Sample Output

show chassis routing-engine (Sample 1 - SRX550M)

```

user@host> show chassis routing-engine
Routing Engine status:
  Temperature          38 degrees C / 100 degrees F
  CPU temperature      36 degrees C / 96 degrees F
  Total memory         512 MB Max  435 MB used ( 85 percent)
    Control plane memory 344 MB Max  296 MB used ( 86 percent)
    Data plane memory   168 MB Max  138 MB used ( 82 percent)
  CPU utilization:
    User                8 percent
    Background          0 percent
    Kernel              4 percent
    Interrupt           0 percent
    Idle                88 percent
  Model                RE-SRX5500-LOWMEM
  Serial ID            AAP8652
  Start time           2009-09-21 00:04:54 PDT
  Uptime               52 minutes, 47 seconds
  Last reboot reason    0x200:chassis control reset
  Load averages:       1 minute   5 minute   15 minute
                       0.12       0.15       0.10

```

Sample Output

show chassis routing-engine (Sample 2- vSRX)

```

user@host> show chassis routing-engine
Routing Engine status:
  Total memory         1024 MB Max  358 MB used ( 35 percent)
  Control plane memory 1024 MB Max  358 MB used ( 35 percent)
  5 sec CPU utilization:
    User                2 percent
    Background          0 percent
    Kernel              4 percent
    Interrupt           6 percent
    Idle                88 percent
  Model                VSRX RE
  Start time           2015-03-03 07:04:18 UTC
  Uptime               2 days, 11 hours, 51 minutes, 11 seconds
  Last reboot reason    Router rebooted after a normal shutdown.
  Load averages:       1 minute   5 minute   15 minute
                       0.07       0.04       0.06

```

show cli authorization

Syntax show cli authorization

Release Information Command introduced before Junos OS Release 7.4.

Description Display the permissions for the current user.

```
user@host> show cli authorization
Current user: 'root' login: 'boojum' class '(root)'
Permissions:
Permissions:
  admin          -- Can view user accounts
  admin-control-- Can modify user accounts
  clear          -- Can clear learned network info
  configure      -- Can enter configuration mode
  control        -- Can modify any config
  edit          -- Can edit full files
  field          -- Can use field debug commands
  floppy         -- Can read and write the floppy
  interface      -- Can view interface configuration
  interface-control-- Can modify interface configuration
  network        -- Can access the network
  reset          -- Can reset/restart interfaces and daemons
  routing        -- Can view routing configuration
  routing-control-- Can modify routing configuration
  shell          -- Can start a local shell
  snmp           -- Can view SNMP configuration
  snmp-control-- Can modify SNMP configuration
  system         -- Can view system configuration
  system-control-- Can modify system configuration
  trace          -- Can view trace file settings
  trace-control-- Can modify trace file settings
  view           -- Can view current values and statistics
  maintenance    -- Can become the super-user
  firewall       -- Can view firewall configuration
  firewall-control-- Can modify firewall configuration
  secret         -- Can view secret statements
  secret-control-- Can modify secret statements
  rollback       -- Can rollback to previous configurations
  security       -- Can view security configuration

show dhcp client binding

Syntax	show dhcp client binding [<address> interface <interface-name>] routing-instance <routing-instance name> [brief detail summary]
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Display the address bindings in the Dynamic Host Configuration Protocol (DHCP) client table.
Options	<p>address—(Optional) Display DHCP binding information for a specific client identified by one of the following entries:</p> <ul style="list-style-type: none"> ip-address—The specified IP address. mac-address—The specified MAC address. <p>routing-instance <routing-instance name>—(Optional) Display DHCP binding information for DHCP clients on the specified routing instance.</p> <p>interface <interface-name>—(Optional) Perform this operation on the specified interface.</p> <p>brief—(Optional) Display brief information about the active client bindings.</p> <p>detail—(Optional) Display detailed client binding information.</p> <p>summary—(Optional) Display a summary of DHCP client information.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> clear dhcp client binding on page 1291
List of Sample Output	show dhcp client binding on page 1347
Output Fields	Table 91 lists the output fields for the show dhcp client binding command. Output fields are listed in the approximate order in which they appear.

Table 91: show dhcp client binding Output Fields

Field Name	Field Description
IP address	IP address of the DHCP client.
Hardware address	Hardware address of the DHCP client.
Server	IP address of the DHCP server.
Expires	Number of seconds in which the lease expires.

Table 91: show dhcp client binding Output Fields (*continued*)

Field Name	Field Description
State	State of the address binding table on the DHCP local server.
Interface	Interface on which the request was received.
Lease Expires	Date and time at which the client's IP address lease expires.
Lease Expires in	Number of seconds in which the lease expires.
Lease Start	Date and time at which the client's IP address lease started.
Vendor Identifier	Vendor identifier.
Server Identifier	IP address of the DHCP server.
Client IP Address	IP address of the DHCP client.

Sample Output

show dhcp client binding

```

user@host> show dhcp client binding
2 clients, (2 bound, 0 init, 0 discover, 0 renew, 0 rebind)

Type	Type of DHCP packet processing performed on the device.

Table 95: show dhcp server binding Output Fields (*continued*)

Field Name	Field Description
Obtained at	Date and time at which the client's IP address lease started.
Expires at	Date and time at which the client's IP address lease expires.
State	State of the address binding table on the DHCP local server.

Sample Output

show dhcp server binding

```
user@host> show dhcp server binding 100.20.32.1 detail
Active binding information:
    IP address          100.20.32.1
    Hardware address    90:00:00:01:00:01
    Request received on fe-0/0/2.0, relayed by 100.20.32.2

Lease information:
    Type                DHCP
    Obtained at         2007-01-17 11:28:47 PST
    Expires at          2007-01-17 11:38:47 PST
    State               rebind
```

show dhcp server statistics

Syntax	show dhcp server statistics <routing-instance>
Release Information	Statement introduced in Junos OS Release 12.1X44-D10.
Description	Display Dynamic Host Configuration Protocol (DHCP) local server statistics.
Options	routing-instance —(Optional) Display information about DHCP local server statistics on the specified routing instance. If you do not specify a routing instance, statistics are displayed for the default routing instance.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • clear dhcp server statistics on page 1296
List of Sample Output	show dhcp server statistics on page 1358
Output Fields	Table 96 lists the output fields for the show dhcp server statistics command. Output fields are listed in the approximate order in which they appear.

Table 96: show dhcp server statistics

Field Name	Field Description
Packets dropped	Number of packets discarded by the DHCP local server because of errors. Only nonzero statistics appear in the Packets dropped output. When all of the Packets dropped statistics are 0 (zero), only the Total field appears.
Messages received	Number of DHCP messages sent. <ul style="list-style-type: none"> • BOOTREQUEST—Number of BOOTP protocol data units (PDUs) received • DHCPDECLINE—Number of DHCP PDUs of type DECLINE received • DHCPDISCOVER—Number of DHCP PDUs of type DISCOVER received • DHCPREQUEST—Number of DHCP PDUs of type REQUEST received • DHCPINFORM—Number of DHCP PDUs of type INFORM received • DHCPRELEASE—Number of DHCP PDUs of type RELEASE received
Messages sent	Number of DHCP messages received. <ul style="list-style-type: none"> • BOOTREPLY—Number of BOOTP PDUs transmitted • DHCPOFFER—Number of DHCP PDUs of type OFFER transmitted • DHCPACK—Number of DHCP PDUs of type ACK transmitted • DHCPNACK—Number of DHCP PDUs of type NACK transmitted • DHCPFORCERENEW—Number of DHCP PDUs of type FORCERENEW transmitted

Sample Output

show dhcp server statistics

```
user@host> show dhcp server statistics
Packets dropped:
  Total                                0

Messages received:
  BOOTREQUEST                         0
  DHCPDECLINE                         0
  DHCPDISCOVER                        0
  DHCPINFORM                          0

  DHCPOFFER                           0
  DHCPACK                             0
  DHCPNAK                             0
  DHCPFORCERENEW                      0
```

show dhcpv6 client binding

Syntax	show dhcpv6 client binding interface <i>interface-name</i> routing-instance < <i>routing-instance-name</i> > [brief detail summary]
Release Information	Statement introduced in Junos OS Release 12.1X45-D10.
Description	Display the address bindings in the Dynamic Host Configuration Protocol version 6 (DHCPv6) client table.
Options	<p>interface <i>interface-name</i>—(Optional) Perform this operation on the specified interface.</p> <p>routing-instance <i>routing-instance-name</i>—(Optional) Display DHCPv6 binding information for DHCPv6 clients on the specified routing instance.</p> <p>brief—(Optional) Display brief information about the active client bindings.</p> <p>detail—(Optional) Display detailed client binding information.</p> <p>summary—(Optional) Display a summary of DHCPv6 client information.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> clear dhcpv6 client binding on page 1297
List of Sample Output	show dhcpv6 client binding on page 1360
Output Fields	Table 97 lists the output fields for the show dhcpv6 client binding command. Output fields are listed in the approximate order in which they appear.

Table 97: show dhcpv6 client binding Output Fields

Field Name	Field Description
Hardware Address	Hardware address of the DHCPv6 client.
State	State of the address-binding table on the DHCPv6 local server.
Lease Expires	Date and time at which the client's IP address lease expires.
Lease Expires in	Number of seconds until the lease expires.
Lease Start	Date and time at which the client's IP address lease started.
Client DUID	The DHCPv6 client's unique identifier.
Bind type	The bind type.

Table 97: show dhcpv6 client binding Output Fields (*continued*)

Field Name	Field Description
Client Type	The type of DHCPv6 client. The client type can be autoconfig or stateful.
Rapid Commit	Two-message exchange option for address assignment.
Server IP Address	IP address of the DHCPv6 server.
Client IP Address	IP address of the DHCPv6 client.

Sample Output

show firewall (View)

Syntax	<pre>show firewall <filter <i>filter-name</i>> <counter <i>counter-name</i>> <log> <prefix-action-stats> <terse></pre>
Release Information	Command introduced before Junos OS Release 10.0 .
Description	Display statistics about configured firewall filters.
Options	<p>none—Display statistics about configured firewall filters.</p> <p>filter <i>filter-name</i>—Name of a configured filter.</p> <p>counter <i>counter-name</i>—Name of a filter counter.</p> <p>log—Display log entries for firewall filters.</p> <p>prefix-action-stats—Display prefix action statistics for firewall filters.</p> <p>terse—Display firewall filter names only.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> firewall on page 896
List of Sample Output	show firewall on page 1371
Output Fields	Table 101 lists the output fields for the show firewall command. Output fields are listed in the approximate order in which they appear.

Table 101: show firewall Output Fields

Field Name	Field Description
Filter	<p>Name of a filter that has been configured with the filter statement at the [edit firewall] hierarchy level.</p> <p>When an interface-specific filter is displayed, the name of the filter is followed by the full interface name and by either -i for an input filter or -o for an output filter.</p> <p>When dynamic filters are displayed, the name of the filter is followed by the full interface name and by either -in for an input filter or -out for an output filter. When a logical system-specific filter is displayed, the name of the filter is prefixed with two underscore (__) characters and the name of the logical system (for example, __ls1/filter1).</p>

Table 101: show firewall Output Fields (*continued*)

Field Name	Field Description
Counters	Display filter counter information: <ul style="list-style-type: none"> • Name—Name of a filter counter that has been configured with the counter firewall filter action. • Bytes—Number of bytes that match the filter term under which the counter action is specified. • Packets—Number of packets that matched the filter term under which the counter action is specified.
Policers	Display policer information: <ul style="list-style-type: none"> • Name—Name of policer. • Bytes—Number of bytes that match the filter term under which the policer action is specified. This is only the number out-of-specification (out-of-spec) byte counts, not all the bytes in all packets policed by the policer. • Packets—Number of packets that matched the filter term under which the policer action is specified. This is only the number of out-of-specification (out-of-spec) packet counts, not all packets policed by the policer.

Sample Output

show firewall

```

user@host> show firewall
Filter: ef_path
Counters:
Name          Bytes          Packets
def-count     0              0
video-count   0              0
voice-count    0              0

Filter: __default_bpdu_filter__

Filter: deep
Counters:
Name          Bytes          Packets
deep2         302076         5031

Filter: deep-flood
Counters:
Name          Bytes          Packets
deep_flood_def 302136         5032
deep1         0              0
Policers:
Name          Packets
deep-pol-op-first 0

```

show system autorecovery state

Syntax	show system autorecovery state
Release Information	Command introduced in Junos OS Release 11.2.
Description	Perform checks and show status of all autorecovered items.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • request system autorecovery state on page 292 • Understanding Integrity Check and Autorecovery of Configuration, Licenses, and Disk Information on SRX Series Devices on page 169
List of Sample Output	show system autorecovery state on page 1372
Output Fields	Table 48 lists the output fields for the show system autorecovery state command. Output fields are listed in the approximate order in which they appear.

Table 102: show system autorecovery state Output Fields

Field Name	Field Description
File	The name of the file on which autorecovery checks are performed.
Slice	The disk partition on which autorecovery checks are performed.
Recovery Information	Indicates whether autorecovery information for the file or slice has been saved.
Integrity Check	Displays the status of the file's integrity check (passed or failed).
Action / Status	Displays the status of the item, or the action required to be taken for that item.

Sample Output

show system autorecovery state

```
user@host> show system autorecovery state
```

```
Configuration:
File          Recovery Information  Integrity Check  Action / Status
rescue.conf.gz Saved                Passed           None
Licenses:
File          Recovery Information  Integrity Check  Action / Status
JUNOS282736.lic Saved                Passed           None
JUNOS282737.lic Not Saved           Not checked     Requires save
BSD Labels:
Slice         Recovery Information  Integrity Check  Action / Status
s1            Saved                Passed           None
s2            Saved                Passed           None

show system download

Syntax	<code>show system download <download-id></code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Display a brief summary of all the download instances along with their current state and extent of progress. If a download-id is provided, the command displays a detailed report of the particular download instance.
Options	<ul style="list-style-type: none"> download-id—(Optional) The ID number of the download instance.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> request system download start on page 298 Understanding Download Manager for SRX Series Devices on page 51 Understanding Download Manager for EX Series Devices
List of Sample Output	show system download on page 1374 show system download 1 on page 1375
Output Fields	Table 50 lists the output fields for the show system download command. Output fields are listed in the approximate order in which they appear.

Table 103: show system download Output Fields

Field Name	Field Description
ID	Displays the download identification number.
Status	Displays the state of a particular download.
Start Time	Displays the start time of a particular download.
Progress	Displays the percentage of a download that has been completed.
URL	Displays the URL from which the file was downloaded.

Sample Output

show system download

```

user@host> show system download
Download Status Information:
ID  Status  Start Time      Progress  URL
1   Active   May 4 06:28:36  5%        ftp://ftp-server//tftpboot/1m_file
2   Active   May 4 06:29:07  3%        ftp://ftp-server//tftpboot/5m_file
3   Error    May 4 06:29:22  Unknown   ftp://ftp-server//tftpboot/badfile

```

4 Completed May 4 06:29:40 100% ftp://ftp-server//tftpboot/smallfile

show system download 1

```
user@host> show system download 1
```

```
Download ID      : 1
Status           : Active
Progress         : 6%
URL              : ftp://ftp-server//tftpboot/1m_file
Local Path       : /var/tmp/1m_file
Maximum Rate     : 1k
Creation Time    : May 4 06:28:36
Scheduled Time   : May 4 06:28:36
Start Time       : May 4 06:28:37
Error Count      : 0
```

show system license (View)

Syntax	show system license <installed keys status usage>
Release Information	Command introduced in Junos OS Release 9.5. Logical system status option added in Junos OS Release 11.2.
Description	Display licenses and information about how licenses are used.
Options	<p>none—Display all license information.</p> <p>installed—(Optional) Display installed licenses only.</p> <p>keys—(Optional) Display a list of license keys. Use this information to verify that each expected license key is present.</p> <p>status—(Optional) Display license status for a specified logical system or for all logical systems.</p> <p>usage—(Optional) Display the state of licensed features.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> <i>Working with License Keys for SRX Series Devices</i>
List of Sample Output	<p>show system license on page 1377</p> <p>show system license installed on page 1377</p> <p>show system license keys on page 1378</p> <p>show system license usage on page 1378</p> <p>show system license status logical-system all on page 1378</p>
Output Fields	Table 52 lists the output fields for the show system license command. Output fields are listed in the approximate order in which they appear.

Table 104: show system license Output Fields

Field Name	Field Description
Feature name	Name assigned to the configured feature. You use this information to verify that all the features for which you installed licenses are present.
Licenses used	Number of licenses used by the device. You use this information to verify that the number of licenses used matches the number configured. If a licensed feature is configured, the feature is considered used.

Table 104: show system license Output Fields (*continued*)

Field Name	Field Description
Licenses installed	Information about the installed license key: <ul style="list-style-type: none"> • License identifier—Identifier associated with a license key. • License version—Version of a license. The version indicates how the license is validated, the type of signature, and the signer of the license key. • Valid for device—Device that can use a license key. • Features—Feature associated with a license.
Licenses needed	Number of licenses required for features being used but not yet properly licensed.
Expiry	Time remaining in the grace period before a license is required for a feature being used.
Logical system license status	Displays whether a license is enabled for a logical system.

Sample Output

show system license

```
user@host> show system license
```

```
License usage:
```

Feature name	Licenses used	Licenses installed	Licenses needed	Expiry
av_key_kaspersky_engine 01:00:00 IST	1	1	0	2012-03-30
wf_key_surfcontrol_cpa 01:00:00 IST	0	1	0	2012-03-30
dynamic-vpn	0	1	0	permanent
ax411-wlan-ap	0	2	0	permanent

```
Licenses installed:
```

```
License identifier: JUNOS301998
```

```
License version: 2
```

```
Valid for device: AG4909AA0080
```

```
Features:
```

```
av_key_kaspersky_engine - Kaspersky AV
```

```
date-based, 2011-03-30 01:00:00 IST - 2012-03-30 01:00:00 IST

show system license status logical-system all

```
user@host> show system license status logical-system all
Logical system license status:
```

logical system name	license status
root-logical-system	enabled
LSYS0	enabled
LSYS1	enabled
LSYS2	enabled

show system login logout

Syntax	show system login logout
Release Information	Command introduced in Junos OS Release 11.2.
Description	Display the usernames locked after unsuccessful login attempts.
Required Privilege Level	view and system
Related Documentation	<ul style="list-style-type: none"> • lockout-period on page 1244 • clear system login logout on page 291
List of Sample Output	show system login logout on page 1379
Output Fields	Table 53 lists the output fields for the show system login logout command. Output fields are listed in the approximate order in which they appear.

Table 105: show system login logout

Field Name	Field Description	Level of Output
User	Username	All levels
Lockout start	Date and time the username was locked	All levels
Lockout end	Date and time the username was unlocked	All levels

Sample Output

show system login logout

```
user@host> show system login logout
```

```
User          Lockout start      Lockout end
root          2011-05-11 09:11:15 UTC 2011-05-11 09:13:15 UTC
```

show system services dhcp client

Syntax	<code>show system services dhcp client</code> <code>< interface-name ></code> <code><statistics></code>
Release Information	Command introduced in Junos OS Release 8.5. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Display information about DHCP clients.
Options	<ul style="list-style-type: none"> • <code>none</code>—Display DHCP information for all interfaces. • <code>interface-name</code>—(Optional) Display DHCP information for the specified interface. • <code>statistics</code>—(Optional) Display DHCP client statistics.
Required Privilege Level	view and system
Related Documentation	<ul style="list-style-type: none"> • <i>dhcp (Interfaces)</i> • request system services dhcp on page 1329 • <i>Administration Guide for Security Devices</i>
List of Sample Output	show system services dhcp client on page 1381 show system services dhcp client ge-0/0/34.0 on page 1382 show system services dhcp client statistics on page 1382
Output Fields	<p>Table 106 lists the output fields for the <code>show system services dhcp client</code> command. Output fields are listed in the approximate order in which they appear.</p>

Table 106: show system services dhcp client Output Fields

Field Name	Field Description
Logical Interface Name	Name of the logical interface.
Client Status	State of the client binding.
Vendor Identifier	Vendor ID.
Server Address	IP address of the DHCP server.
Address obtained	IP address obtained from the DHCP server.
Lease Obtained at	Date and time the lease was obtained.
Lease Expires in	(EX Series switches only) Time the current lease expires in (seconds).
<i>Reviewer: Madhavi, does this field exist in SRX platform as well?</i>	

Table 106: show system services dhcp client Output Fields (*continued*)

Field Name	Field Description
Lease Expires at	Date and time the lease expires.
DHCP Options	<ul style="list-style-type: none"> • Name: server-identifier, Value: IP address of the name server. • Name: device, Value: IP address of the name device. • Name: domain-name, Value: Name of the domain.
Packets dropped	Total packets dropped.
Messages received	<p>Number of the following DHCP messages received:</p> <ul style="list-style-type: none"> • DHCPOFFER—First packet received on a logical interface when DHCP is enabled. • DHCPACK—When received from the server, the client sends an ARP request for that address and adds a (ARP response) timer for 4 seconds and stops the earlier timer added for DHCPACK. • DHCPNAK—When a DHCPNAK is received instead of DHCPACK, the logical interface sends a DHCPDISCOVER packet.
Messages sent	<p>Number of the following DHCP messages sent:</p> <ul style="list-style-type: none"> • DHCPDECLINE—Packet sent when ARP response is received and there is a conflict. The logical interface sends a new DHCPDISCOVER packet. • DHCPDISCOVER—Packet sent on the interface for which the DHCP client is enabled. • DHCPREQUEST—Packet sent to the DHCP server after accepting the DHCPOFFER. After sending the DHCPREQUEST, the device adds a retransmission-interval timer. • DHCPINFORM—Packet sent to the DHCP server for local configuration parameters. • DHCPRELEASE—Packet sent to the DHCP server to relinquish network address and cancel remaining lease. • DHCPRENEW—Packet sent to the DHCP server to renew the address. The next message to be sent will be a DHCPREQUEST message, which will be unicast directly to the server. • DHCPREBIND—Packet sent to any server to renew the address. The next message to be sent will be a DHCPREQUEST message, which will be broadcast.

Sample Output

show system services dhcp client

```

user@host> show system services dhcp client
Logical Interface name      ge-0/0/34.0
Hardware address           00:1f:12:38:5f:e5
Client status              bound
Address obtained           10.0.0.2
Update server              disabled
Lease obtained at          2013-12-23 08:11:40 UTC
Lease expires in           93
Lease expires at           2013-12-23 08:13:20 UTC

DHCP options:
  Name: server-identifier, Value: 10.0.0.1
  Code: 1, Type: ip-address, Value: 255.255.255.0

```

Sample Output

show system services dhcp client ge-0/0/34.0

```
user@host> show system services dhcp client ge-0/0/34.0
Logical Interface name      ge-0/0/34.0
Hardware address           00:1f:12:38:5f:e5
Client status               bound
Address obtained            10.0.0.2
Update server               disabled
Lease obtained at           2013-12-23 08:11:40 UTC
Lease expires in            87
Lease expires at            2013-12-23 08:13:20 UTC

DHCP options:
Name: server-identifier, Value: 10.0.0.1
Code: 1, Type: ip-address, Value: 255.255.255.0
```

Sample Output

show system services dhcp client statistics

```
user@host> show system services dhcp client statistics
Packets dropped:
  Total                      0
Messages received:
  DHCPPOFFER                  0
  DHCPACK                     8
  DHCPNAK                     0
Messages sent:
  DHCPDECLINE                  0
  DHCPDISCOVER                 0
  DHCPREQUEST                  1
  DHCPINFORM                   0
  DHCPRELEASE                  0
  DHCPRENEW                     7
  DHCPREBIND                   0
```

show system services dhcp relay-statistics

Syntax	<code>show system services dhcp relay-statistics</code>
Release Information	Command introduced in Junos OS Release 8.5 .
Description	Display information about the DHCP relay.
Required Privilege Level	view and system
Related Documentation	<ul style="list-style-type: none"> <i>dhcp</i>
List of Sample Output	show system services dhcp relay-statistics on page 1383
Output Fields	Table 107 lists the output fields for the <code>show system services dhcp relay-statistics</code> command. Output fields are listed in the approximate order in which they appear.

Table 107: show system services dhcp relay-statistics Output Fields

Field Name	Field Description
Received packets	Total DHCP packets received.
Forwarded packets	Total DHCP packet forwarded.
Dropped packets	<p>Total DHCP packets dropped for the following reasons:</p> <ul style="list-style-type: none"> • Due to a missing interface in the relay database—Number of packets discarded because they did not belong to a configured interface. • Due to a missing matching routing instance—Number of packets discarded because they did not belong to a configured routing instance. • Due to an error during packet read—Number of packets discarded because of a system read error. • Due to an error during packet send—Number of packets that the DHCP relay application could not send. • Due to an invalid server address—Number of packets discarded because an invalid server address was specified. • Due to a missing valid local address—Number of packets discarded because there was no valid local address. • Due to a missing route to the server or client—Number of packets discarded because there were no addresses available for assignment.

Sample Output

show system services dhcp relay-statistics

```

user@host> show system services dhcp relay-statistics
Received packets: 4
Forwarded packets: 4
Dropped packets: 4
  Due to missing interface in relay database: 4
  Due to missing matching routing instance: 0

```

Due to an error during packet read: 0
Due to an error during packet send: 0
Due to invalid server address: 0
Due to missing valid local address: 0
Due to missing route to server/client: 0

show system snapshot media

Syntax	<code>show system snapshot media <i>media-type</i></code>
Release Information	Command introduced in Junos OS Release 10.2 .
Description	Display the snapshot information for both root partitions on SRX Series devices
Options	<ul style="list-style-type: none"> • <code>internal</code>— Show snapshot information from internal media. • <code>usb</code>— Show snapshot information from device connected to USB port. • <code>external</code>— Show snapshot information from the external CompactFlash card.
Required Privilege Level	View
Related Documentation	<ul style="list-style-type: none"> • Example: Creating a Snapshot and Using It to Boot an SRX Series Device on page 166

Network Management Administration Guide for Routing Devices

PART 16

Overview

- [Network Management Overview on page 1393](#)
- [Introduction to Network Monitoring on page 1397](#)

Network Management Overview

- [Understanding Device Management Functions in Junos OS on page 1393](#)
- [Understanding the Integrated Local Management Interface on page 1396](#)

Understanding Device Management Functions in Junos OS

After you have installed a device into your network, you need to manage the device within your network. Device management can be divided into five tasks:

- Fault management—Monitor the device; detect and fix faults.
- Configuration management—Configure device attributes.
- Accounting management—Collect statistics for accounting purposes.
- Performance management—Monitor and adjust device performance.
- Security management—Control device access and authenticate users.

The Junos[®] operating system (Junos OS) network management features work in conjunction with an operations support system (OSS) to manage the devices within the network. Junos OS can assist you in performing these management tasks, as described in [Table 108](#).

Table 108: Device Management Features in Junos OS

Task	Junos OS Feature
Fault management	<p>Monitor and see faults using:</p> <ul style="list-style-type: none"> Operational mode commands—For more information about operational mode commands, see the CLI Explorer, CLI Explorer, and CLI Explorer. SNMP MIBs—For more information about SNMP MIBs supported by Junos OS, see ““Standard SNMP MIBs Supported by Junos OS” on page 1409” and ““Enterprise-Specific SNMP MIBs Supported by Junos OS” on page 1427” in the <i>SNMP MIBs and Traps Reference</i> . Standard SNMP traps—For more information about standard SNMP traps, see the ““Standard SNMP Traps Supported on Devices Running Junos OS” on page 1456” in the <i>SNMP MIBs and Traps Reference</i> . Enterprise-specific SNMP traps—For more information about enterprise-specific traps, see ““Juniper Networks Enterprise-Specific SNMP Traps” on page 1456” in the <i>SNMP MIBs and Traps Reference</i> . Understanding the Integrated Local Management Interface

The Integrated Local Management Interface (ILMI) provides a mechanism for Asynchronous Transfer Mode (ATM)-attached devices, such as hosts, routers, and ATM switches, to transfer management information. ILMI provides bidirectional exchange of management information between two ATM interfaces across a physical connection. ILMI information is exchanged over a direct encapsulation of SNMP version 1 (RFC 1157, *A Simple Network Management Protocol*) over ATM Adaptation Layer 5 (AAL5) using a virtual path identifier/virtual channel identifier (VPI/VCI) value (VPI=0, VCI=16).

Junos OS supports only two ILMI MIB variables: **atmfMYIPNmAddress** and **atmfPortMyIfname**. For ATM1 and ATM2 intelligent queuing (IQ) interfaces, you can configure ILMI to communicate directly with an attached ATM switch to enable querying of the switch's IP address and port number.

For more information about the ILMI MIB, see the ATM Forum at <http://www.atmforum.com/>.

Introduction to Network Monitoring

- [Monitoring Overview on page 1397](#)
- [Diagnostic Tools Overview on page 1398](#)

Monitoring Overview

Junos OS supports a suite of J-Web tools and CLI operational mode commands for monitoring the system health and performance of your device. Monitoring tools and commands display the current state of the device. To use the J-Web user interface and CLI operational tools, you must have the appropriate access privileges.

You can use the J-Web Monitor option to monitor a device. J-Web results appear in the browser.

You can also monitor the device with CLI operational mode commands. CLI command output appears on the screen of your console or management device, or you can filter the output to a file. For operational commands that display output, such as the **show** commands, you can redirect the output into a filter or a file. When you display help about these commands, one of the options listed is **|**, called a *pipe*, which allows you to filter the command output.

For example, if you enter the **show configuration** command, the complete device configuration appears on the screen. To limit the display to only those lines of the configuration that contain **address**, enter the **show configuration** command using a pipe into the **match** filter:

```
user@host> show configuration | match address
address-range low 192.168.3.2 high 192.168.3.254;
address-range low 192.168.71.71 high 192.168.71.254;
address 192.168.71.70/21;
address 192.168.2.1/24;
address 127.0.0.1/32;
```

For a complete list of the filters, type a command, followed by the pipe, followed by a question mark (?):

```
user@host> show configuration | ?
Possible completions:
compare          Compare configuration changes with prior version
count           Count occurrences
display         Show additional kinds of information
except          Show only text that does not match a pattern
```

find	Search for first occurrence of pattern
hold	Hold text without exiting the prompt
last	Display end of output only
match	Show only text that matches a pattern
no-more	Don't paginate output
request	Make system-level requests
resolve	Resolve IP addresses
save	Save output text to file
trim	Trim specified number of columns from start of line

You can specify complex expressions as an option for the **match** and **except** filters.

NOTE: To filter the output of configuration mode commands, use the filter commands provided for the operational mode commands. In configuration mode, an additional filter is supported.

Diagnostic Tools Overview

Juniper Networks devices support a suite of J-Web tools and CLI operational mode commands for evaluating system health and performance. Diagnostic tools and commands test the connectivity and reachability of hosts in the network.

- Use the J-Web Diagnose options to diagnose a device. J-Web results appear in the browser.
- Use CLI operational mode commands to diagnose a device. CLI command output appears on the screen of your console or management device, or you can filter the output to a file.

To use the J-Web user interface and CLI operational tools, you must have the appropriate access privileges.

This section contains the following topics:

- [J-Web Diagnostic Tools on page 1398](#)
- [CLI Diagnostic Commands on page 1399](#)

J-Web Diagnostic Tools

The J-Web diagnostic tools consist of the options that appear when you select **Troubleshoot** and **Maintain** in the task bar. [Table 109](#) describes the functions of the Troubleshoot options.

Table 109: J-Web Interface Troubleshoot Options

Option	Function
Troubleshoot Options	

Table 109: J-Web Interface Troubleshoot Options (*continued*)

Option	Function
Ping Host	Allows you to ping a remote host. You can configure advanced options for the ping operation.
Ping MPLS	Allows you to ping an MPLS endpoint using various options.
Traceroute	Allows you to trace a route between the device and a remote host. You can configure advanced options for the traceroute operation.
Packet Capture	Allows you to capture and analyze router control traffic.
Maintain Options	
Files	Allows you to manage log, temporary, and core files on the device.
Upgrade	Allows you to upgrade and manage Junos OS packages.
Licenses	Displays a summary of the licenses needed and used for each feature that requires a license. Allows you to add licenses.
Reboot	Allows you to reboot the device at a specified time.

CLI Diagnostic Commands

The CLI commands available in operational mode allow you to perform the same monitoring, troubleshooting, and management tasks you can perform with the J-Web user interface. Instead of invoking the tools through a graphical interface, you use operational mode commands to perform the tasks.

You can perform certain tasks only through the CLI. For example, you can use the **mtrace** command to display trace information about a multicast path from a source to a receiver, which is a feature available only through the CLI.

To view a list of top-level operational mode commands, type a question mark (?) at the command-line prompt.

At the top level of operational mode are the broad groups of CLI diagnostic commands listed in [Table 110](#).

Table 110: CLI Diagnostic Command Summary

Command	Function
Controlling the CLI Environment	
set option	Configures the CLI display.
Diagnosis and Troubleshooting	
clear	Clears statistics and protocol database information.
mtrace	Traces information about multicast paths from source to receiver.

Table 110: CLI Diagnostic Command Summary (*continued*)

Command	Function
monitor	Performs real-time debugging of various Junos OS components, including the routing protocols and interfaces.
ping	Determines the reachability of a remote network host.
ping mpls	Determines the reachability of an MPLS endpoint using various options.
test	Tests the configuration and application of policy filters and AS path regular expressions.
traceroute	Traces the route to a remote network host.
Connecting to Other Network Systems	
ssh	Opens secure shell connections.
telnet	Opens Telnet sessions to other hosts on the network.
Management	
copy	Copies files from one location on the device to another, from the device to a remote system, or from a remote system to the device.
restart option	Restarts the various system processes, including the routing protocol, interface, and SNMP processes.
request	Performs system-level operations, including stopping and rebooting the device and loading Junos OS images.
start	Exits the CLI and starts a UNIX shell.
configuration	Enters configuration mode.
quit	Exits the CLI and returns to the UNIX shell.

SNMP Overview

- [Understanding SNMP Implementation in Junos OS on page 1403](#)
- [SNMPv3 Overview on page 1406](#)

Understanding SNMP Implementation in Junos OS

Do you use a central network management system (NMS)? Most NMS's use a version of Simple Network Management Protocol (SNMP) that can monitor the status of Junos OS devices that send unsolicited messages called traps. You can configure the IP address of your NMS so that Junos OS can send its traps.

SNMP uses a very basic form of authentication called community strings to control access between a manager and remote agents. Community strings are administrative names used to group collections of devices (and the agents running on them) into common management domains. If a manager and an agent share the same community, they can talk to one another.

Many people associate SNMP community strings with passwords and keys because the jobs they do are similar. As a result, SNMP communities are traditionally referred to as strings. The community string is the first level of management authentication implemented by the SNMP agent in Junos OS.

You might also want to configure remote logging on your device. Junos OS uses a system log (syslog) mechanism similar to many Unix devices to forward log messages to a specified log host address. This allows each of your devices to forward their messages to one central host, making it easier to monitor the network as a whole. Syslog is a very flexible and rich way of logging messages and is used by many device vendors to supplement the information provided by SNMP traps.

A typical SNMP implementation includes three components:

- Managed device
- SNMP agent
- Network management system (NMS)

A managed device is any device on a network, also known as a network element, that is managed by the network management system. Routers and switches are common examples of managed devices. The SNMP agent is the SNMP process that resides on

the managed device and communicates with the network management system. The NMS is a combination of hardware and software that is used to monitor and administer a network.

The SNMP data is stored in a highly-structured, hierarchical format known as a management information base (MIB). The MIB structure is based on a tree structure, which defines a grouping of objects into related sets. Each object in the MIB is associated with an object identifier (OID), which names the object. The “leaf” in the tree structure is the actual managed object instance, which represents a resource, event, or activity that occurs in your network device.

The SNMP agent exchanges network management information with SNMP manager software running on an NMS, or host. The agent responds to requests for information and actions from the manager. The agent also controls access to the agent's MIB, the collection of objects that can be viewed or changed by the SNMP manager.

The SNMP manager collects information about network connectivity, activity, and events by polling managed devices.

Communication between the agent and the manager occurs in one of the following forms:

- **Get, GetBulk, and GetNext** requests—The manager requests information from the agent. The agent returns the information in a **Get** response message.
- **Set** requests—The manager changes the value of a MIB object controlled by the agent. The agent indicates status in a **Set** response message.
- **Traps** notification—The agent sends traps to notify the manager of significant events that occur on the network device.

The SNMP implementation in Junos OS contains:

- A master SNMP agent (known as the SNMP process or `snmpd`) that resides on the managed device and is managed by the NMS or host.
- Various subagents that reside on different modules of Junos OS, such as the Routing Engine, and are managed by the master SNMP agent (`snmpd`).

NOTE: By default, SNMP is not enabled on devices running Junos OS. For information about enabling SNMP on a device running the Junos OS, see [“Configuring SNMP on Devices Running Junos OS” on page 1471](#).

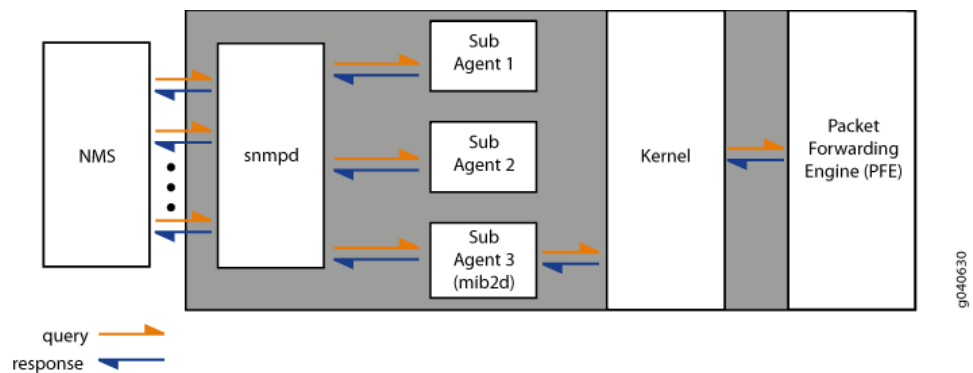

The SNMP implementation in Junos OS uses both standard (developed by the IETF and documented in RFCs) and enterprise-specific (developed and supported by specific vendors) MIBs.

In Junos OS, the management data is maintained by the `snmpd` at one level (for example, `snmpVacmMIB` and `snmpUsmMIB`), and the subagents at the next level (for example, routing MIBs and RMON MIBs). However, there is another level of data that is maintained neither by the master agent nor by the subagents. In such cases, the data is maintained

by the Junos OS processes that share the data with the subagents when polled for SNMP data. Interface-related MIBs and Firewall MIBs are good examples of data maintained by Junos OS processes.

When a network management system polls the master agent for data, the master agent immediately shares the data with the network management system if the requested data is available with the master agent or one of the subagents. However, if the requested data does not belong to those categories that are maintained by the master agent or the subagents, the subagent polls the Junos OS kernel or the process that maintains that data. On receiving the required data, the subagent passes the response back to the master agent, which in turn passes it to the NMS.

The following illustration shows the communication flow among the NMS, SNMP process (snmpd), SNMP subagents, and the Junos OS processes.

When a significant event, most often an error or a failure, occurs on a network device, the SNMP agent sends notifications to the SNMP manager. The SNMP implementation in Junos OS supports two types of notifications: traps and informs. *Traps* are unconfirmed notifications, whereas *informs* are confirmed notifications. Informs are supported only on devices that support SNMP version 3 (SNMPv3) configuration.

Junos OS supports trap queuing to ensure that traps are not lost because of temporary unavailability of routes. Two types of queues, *destination queues* and a *throttle queue*, are formed to ensure delivery of traps and to control the trap traffic.

Junos OS forms a destination queue when a trap to a particular destination is returned because the host is not reachable, and adds the subsequent traps to the same destination to the queue. Junos OS checks for availability of routes every 30 seconds and sends the traps from the destination queue in a round-robin fashion.

If the trap delivery fails, the trap is added back to the queue, and the delivery attempt counter and the next delivery attempt timer for the queue are reset. Subsequent attempts occur at progressive intervals of 1 minute, 2 minutes, 4 minutes, and 8 minutes. The maximum delay between the attempts is 8 minutes, and the maximum number of attempts is 10. After 10 unsuccessful attempts, the destination queue and all the traps in the queue are deleted.

Junos OS also has a throttle mechanism to control the number of traps (throttle threshold; default value of 500 traps) sent during a particular time period (throttle interval; default

of 5 seconds) and to ensure consistency in trap traffic, especially when large number of traps are generated because of interface status changes. The throttle interval period begins when the first trap arrives at the throttle. All traps within the trap threshold are processed, and the traps beyond the threshold limit are queued.

The maximum size of trap queues—that is, throttle queue and destination queue put together—is 40,000. However, on EX Series Ethernet Switches, the maximum size of the trap queue is 1,000. The maximum size of any one queue is 20,000 for devices other than EX Series Switches. On EX Series Switches, the maximum size of one queue is 500. When a trap is added to the throttle queue, or if the throttle queue has exceeded the maximum size, the trap is added back on top of the destination queue, and all subsequent attempts from the destination queue are stopped for a 30-second period, after which the destination queue restarts sending the traps.

SNMPv3 Overview

In contrast to SNMP version 1 (SNMPv1) and SNMP version 2 (SNMPv2), SNMP version 3 (SNMPv3) supports authentication and encryption. SNMPv3 uses the user-based security model (USM) for message security and the view-based access control model (VACM) for access control. USM specifies authentication and encryption. VACM specifies access-control rules.

USM uses the concept of a user for which security parameters (levels of security, authentication, privacy protocols, and keys) are configured for both the agent and the manager. Messages sent using USM are better protected than messages sent with community strings, where passwords are sent in the clear. With USM, messages exchanged between the manager and the agent can have data integrity checking and data origin authentication. USM protects against message delays and message replays by using time indicators and request IDs. Encryption is also available.

To complement the USM, SNMPv3 uses the VACM, a highly granular access-control model for SNMPv3 applications. Based on the concept of applying security policies to the name of the groups querying the agent, the agent decides whether the group is allowed to view or change specific MIB objects. VACM defines collections of data (called views), groups of data users, and access statements that define which views a particular group of users can use for reading, writing, or receiving traps.

Trap entries in SNMPv3 are created by configuring the notify, notify filter, target address, and target parameters. The **notify** statement specifies the type of notification (trap) and contains a single tag. The tag defines a set of target addresses to receive a trap. The notify filter defines access to a collection of trap object identifiers (OIDs). The target address defines a management application's address and other attributes to be used in sending notifications. Target parameters define the message processing and security parameters to be used in sending notifications to a particular management target.

To configure SNMPv3, perform the following tasks:

Enterprise-Specific SNMP MIBs Supported by Junos OS

Junos OS supports the following enterprise-specific MIBs:

- **AAA Objects MIB**—Provides support for monitoring user authentication, authorization, and accounting through the RADIUS, LDAP, SecurID, and local authentication servers. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-user-aaa.txt. For more information, see *AAA Objects MIB*.
- **Access Authentication Objects MIB**—Provides support for monitoring firewall authentication, including data about the users trying to access firewall-protected resources and the firewall authentication service itself. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-auth.txt.

For more information, see *Access Authentication Objects MIB*.

- Alarm MIB—Provides support for alarms from the router. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-chassis-alarm.txt

For more information, see *Alarm MIB*.

- Analyzer MIB—Contains analyzer and remote analyzer data related to port mirroring on the EX Series Ethernet Switches. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-analyzer.txt

For more information, see *Analyzer MIB*.

- Antivirus Objects MIB—Provides information about the antivirus engine, antivirus scans, and antivirus scan-related traps. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-utm-av.txt

For more information, see *Antivirus Objects MIB*.

- ATM Class-of-Service MIB—Provides support for monitoring Asynchronous Transfer Mode, version 2 (ATM2) virtual circuit (VC) class-of-service (CoS) configurations. It also provides CoS queue statistics for all VCs that have CoS configured. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-atm-cos.txt

For more information, see *ATM Class-of-Service MIB*.

- ATM MIB—Provides support for ATM interfaces and virtual connections. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-atm.txt.

For more information, see *ATM MIB*.

- BGP4 V2 MIB—Contains objects used to monitor BGP peer-received prefix counters. It is based upon similar objects in the MIB documented in Internet draft draft-ietf-idr-bgp4-mibv2-03.txt, *Definitions of Managed Objects for the Fourth Version of BGP (BGP-4), Second Version*. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-bgpmib2.txt

For more information, see *BGP4 V2 MIB*.

- Bidirectional Forwarding Detection MIB—Provides support for monitoring Bidirectional Forwarding Detection (BFD) sessions. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-bfd.txt

For more information, see *Bidirectional Forwarding Detection MIB*.

- Chassis Definitions for Router Model MIB—Contains the object identifiers (OIDs) that are used by the Chassis MIB to identify platform and chassis components. The Chassis MIB provides information that changes often, whereas the Chassis Definitions for Router Model MIB provides information that changes less often. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-chas-defines.txt

For more information, see *Chassis MIBs*.

- Chassis MIB—Provides support for environmental monitoring (power supply state, board voltages, fans, temperatures, and air flow) and inventory support for the chassis, System Control Board (SCB), System and Switch Board (SSB), Switching and Forwarding Module (SFM), Flexible PIC Concentrators (FPCs), and PICs. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-chassis.txt

For more information, see *Chassis MIBs*.

- Chassis Cluster MIB—Provides information about objects that are used whenever the state of the control link interfaces or fabric link interfaces changes (up to down or down to up) in a chassis cluster deployment. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-jsrpd.txt

For more information, see *Chassis Cluster MIB*.

- Class-of-Service MIB—Provides support for monitoring interface output queue statistics per interface and per forwarding class. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-cos.txt

For more information, see *Class-of-Service MIB*.

- Configuration Management MIB—Provides notification for configuration changes as SNMP traps. Each trap contains the time at which the configuration change was committed, the name of the user who made the change, and the method by which the change was made. A history of the last 32 configuration changes is kept in `jnxCmChgEventTable`. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-cfgmgmt.txt

For more information, see *Configuration Management MIB*.

- Destination Class Usage MIB—Provides support for monitoring packet counts based on the ingress and egress points for traffic transiting your networks. Ingress points are identified by the input interface. Egress points are identified by destination prefixes grouped into one or more sets, known as destination classes. One counter is managed per interface per destination class, up to a maximum of 16 counters per interface. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-dcu.txt

For more information, see *Destination Class Usage MIB*.

- DHCP Objects MIB— Provides SNMP support (get and trap) for DHCP local server and relay configurations. It also provides support for bindings and leases tables, and for statistics. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-jdhcp.txt

For more information, see *DHCP MIB*.

- DHCPv6 MIB—Provides SNMP support (get and trap) for DHCPv6 local server and relay configurations. It also provides support for bindings and leases tables, and for statistics. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-jdhcpv6.txt

For more information, see *DHCPv6 MIB*.

- Digital Optical Monitoring MIB—Provides support for the **SNMP Get** request for statistics and **SNMP Trap** notifications for alarms. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-dom.txt
For more information, see *Digital Optical Monitoring MIB*.
- DNS Objects MIB—Provides support for monitoring DNS proxy queries, requests, responses, and failures. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-dns.txt
For more information, see *DNS Objects MIB*.
- Dynamic Flow Capture MIB—Provides support for monitoring the operational status of dynamic flow capture (DFC) PICs. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-dfc.txt
For more information, see *Dynamic Flow Capture MIB*.
- Ethernet MAC MIB—Monitors media access control (MAC) statistics on Gigabit Ethernet intelligent queuing (IQ) interfaces. It collects MAC statistics; for example, **inoctets**, **inframes**, **outoctets**, and **outframes** on each source MAC address and virtual LAN (VLAN) ID for each Ethernet port. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-mac.txt
For more information, see *Ethernet MAC MIB*.
- Event MIB—Defines a generic trap that can be generated using an op script or event policy. This MIB provides the ability to specify a system log string and raise a trap if that system log string is found. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-event.txt
For more information, see *Event MIB*.
- Experimental MIB—Contains object identifiers for experimental MIBs. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-exp.txt
For more information, see *jnxExperiment MIB*.
- Firewall MIB—Provides support for monitoring firewall filter counters. Routers must have the Internet Processor II ASIC to perform firewall monitoring. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-firewall.txt
For more information, see *Firewall MIB*.
- Flow Collection Services MIB—Provides statistics on files, records, memory, FTP, and error states of a monitoring services interface. It also provides SNMP traps for unavailable destinations, unsuccessful file transfers, flow overloading, and memory overloading. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-coll.txt
For more information, see *Flow Collection Services MIB*.
- Host Resources MIB—Extends the **hrStorageTable** object, providing a measure of the usage of each file system on the router in percentage format. Previously, the objects

in the **hrStorageTable** measured the usage in allocation units—**hrStorageUsed** and **hrStorageAllocationUnits**—only. Using the percentage measurement, you can more easily monitor and apply thresholds on usage. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-hostresources.txt

For more information, see *Host Resources MIB*.

- IDP Objects MIB—Provides support for monitoring SNMP IDP queries, requests, responses, and failures. This MIB defines the key monitoring and threshold crossing trap support, IDP database update status and trap support, attack-related monitoring and trap support for SRX100, SRX210, SRX220, SRX240, SRX550, and SRX650 Services Gateways. This MIB models IDP attributes specific to the appropriate Juniper Networks implementation. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-idp.txt

For more information, see *IDP MIB*.

- Interface MIB—Extends the standard **ifTable** (RFC 2863) with additional statistics and Juniper Networks enterprise-specific chassis information. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-if-extensions.txt

For more information, see *Interface MIB*.

- Interface Accounting Forwarding Class MIB—Extends the Juniper Enterprise Interface MIB and provides support for monitoring statistics data for interface accounting and IETF standardization. This MIB is currently supported by Junos OS for M Series and MX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-if-accounting.txt

For more information, see *Interface Accounting Forwarding Class MIB*.

- IP Forward MIB—Extends the standard IP Forwarding Table MIB (RFC 4292) to include CIDR forwarding information. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ipforward.txt

For more information, see *IP Forwarding MIB*.

- IPsec Generic Flow Monitoring Object MIB—Based on **jnx-ipsec-monitor-mib**, this MIB provides support for monitoring IPsec and IPsec VPN management objects. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ipsec-flow-mon.txt

For more information, see *IPsec Generic Flow Monitoring Object MIB*.

- IPsec Monitoring MIB—Provides operational and statistical information related to the IPsec and IKE tunnels on Juniper Networks routers. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ipsec-monitor-asp.txt

For more information, see *IPSec Monitoring MIB*.

- **IPsec VPN Objects MIB**—Provides support for monitoring IPsec and IPsec VPN management objects for Juniper security product lines. This MIB is an extension of **jnx-ipsec-flow-mon.mib**. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-ipsec-vpn.txt
For more information, see *IPsec VPN Objects MIB*.
- **IPv4 MIB**—Provides additional Internet Protocol version 4 (IPv4) address information, supporting the assignment of identical IPv4 addresses to separate interfaces. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ipv4.txt
For more information, see *IPv4 MIB*.
- **IPv6 and ICMPv6 MIB**—Provides IPv6 and Internet Control Message Protocol version 6 (ICMPv6) statistics. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ipv6.txt
For more information, see *IPv6 MIB*.
- **L2ALD MIB**—Contains information about the Layer 2 Address Learning Daemon (L2ALD) and related traps, such as the routing instance MAC limit trap and the interface MAC limit trap. This MIB also provides VLAN information in the **jnxL2aldVlanTable** table for Enhanced Layer 2 Software (ELS) EX Series and QFX Series switches.

NOTE: Non-ELS EX Series switches use the VLAN MIB (**jnxExVlanTable**) for VLAN information instead of this MIB. For details, see *VLAN MIB*.

For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-l2ald.txt

For more information, see *L2ALD MIB*.

- **L2CP MIB**—Provides information about Layer 2 Control Protocols (L2CP) based features on MX Series 3D Universal Edge Routers. Currently, Junos OS supports only the **jnxDot1dStpPortRootProtectEnabled**, **jnxDot1dStpPortRootProtectState**, and **jnxPortRootProtectStateChangeTrap** objects. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-l2cp-features.txt
For more information, see *L2CP MIB*.
- **L2TP MIB**—Provides information about Layer 2 Transport Protocol (L2TP) tunnels and sessions. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-l2tp.txt
For more information, see *L2TP MIB*.
- **LDP MIB**—Provides LDP statistics and defines LDP label-switched path (LSP) notifications. LDP traps support only IPv4 standards. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ldp.txt

For more information, see *LDP MIB*.

- License MIB—Extends SNMP support to licensing information, and introduces SNMP traps that alert users when the licenses are about to expire, expire, or when the total number of users exceeds the number specified in the license. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-license.txt

For more information, see *License MIB*.

- Logical Systems MIBs—Extend SNMP support to logical systems security profile through various MIBs defined under **jnxLsysSecurityProfile**. For downloadable versions of the MIBs, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-lsys-securityprofile.txt

For more information, see *Logical Systems MIB*.

- MIMSTP MIB—Provides information about MSTP instances (that is, routing instances of type Virtual Switch/Layer 2 control, also known as virtual contexts), MSTIs within the MSTP instance, and VLANs associated with the MSTI. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-mimstp.txt

For more information, see *MIMSTP MIB*.

- MPLS MIB—Provides MPLS information and defines MPLS notifications. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-mpls.txt

NOTE: To collect information about MPLS statistics on transit routers, use the enterprise-specific RSVP MIB (**mib-jnx-rsvp.txt**) instead of the enterprise-specific MPLS MIB (**mib-jnx-mpls.txt**).

For more information, see *MPLS MIB*.

- MPLS LDP MIB—Contains object definitions as described in RFC 3815, *Definitions of Managed Objects for the Multiprotocol Label Switching (MPLS), Label Distribution Protocol (LDP)*. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-mpls-ldp.txt

NOTE: Objects in the MPLS LDP MIB were supported in earlier releases of Junos OS as a proprietary LDP MIB (**mib-ldpmib.txt**). Because the branch used by the proprietary LDP (**mib-ldpmib.txt**) conflicts with RFC 3812, the proprietary LDP MIB (**mib-ldpmib.txt**) has been deprecated and replaced by the enterprise-specific MPLS LDP MIB (**mib-jnx-mpls-ldp.txt**).

For more information, see *MPLS LDP MIB*.

- MVPN MIB—Contains objects that enable SNMP manager to monitor MVPN connections on the provider edge routers. The enterprise-specific MVPN MIB is the Juniper Networks extension of the IETF standard MIBs defined in Internet draft

draft-ietf-l3vpn-mvpn-mib-03.txt, *MPLS/BGP Layer 3 VPN Multicast Management Information Base*. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-mvpn.txt.

For a downloadable version of the table in the Juniper Networks enterprise-specific L2L3-VPN-MCAST MIB that is supported in the MVPN MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-l2l3vpn-mcast.txt.

For more information, see *MVPN MIB*.

- NAT Objects MIB—Provides support for monitoring network address translation (NAT). This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-nat.txt

For more information, see *NAT Objects MIB*.

- NAT Resources-Monitoring MIB—Provides support for monitoring NAT pools usage and NAT rules. Notifications of usage of NAT resources are also provided by this MIB. This MIB is currently supported on the Multiservices PIC and Multiservices DPC on M Series and MX Series routers only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-sp-nat.txt

For more information, see *Network Address Translation Resources—Monitoring MIB*.

- OTN Interface Management MIB—Defines objects for managing Optical Transport Network (OTN) interfaces on devices running Junos OS. For a downloadable version of the MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-otn.txt

For more information, see *OTN Interface Management MIB*.

- Packet Forwarding Engine MIB—Provides notification statistics for Packet Forwarding Engines. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pfe.txt

For more information, see *Packet Forwarding Engine MIB*.

- Packet Mirror MIB—Enables you to capture and view packet mirroring-related information. This MIB is currently supported by Junos OS for MX Series routers only. Packet mirroring traps are an extension of the standard SNMP implementation and are only available to SNMPv3 users. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-packet-mirror.txt

For more information, see *Packet Mirror MIB Overview*.

- PAE Extension MIB—Extends the standard IEEE802.1x PAE Extension MIB, and contains information for Static MAC Authentication. The enterprise-specific PAE Extension MIB is supported only on EX Series Ethernet Switches. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pae-extension.txt

For more information, see *PAE Extension MIB*.

- Passive Monitoring MIB—Performs traffic flow monitoring and lawful interception of packets transiting between two routers. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pmon.txt

For more information, see *Passive Monitoring MIB*.

- Ping MIB—Extends the standard Ping MIB control table (RFC 2925). Items in this MIB are created when entries are created in **pingCtlTable** of the Ping MIB. Each item is indexed exactly as it is in the Ping MIB. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ping.txt

For more information, see *PING MIB*.

- Policy Objects MIB—Provides support for monitoring the security policies that control the flow of traffic from one zone to another. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-policy.txt

For more information, see *Policy Objects MIB*.

- Power Supply Unit MIB—Enables monitoring and managing of the power supply on a device running Junos OS. This MIB is currently supported only on EX Series Ethernet Switches. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-power-supply-unit.txt

For more information, see *Power Supply Unit MIB*.

- PPP MIB—Provides SNMP support for PPP-related information such as the type of authentication used, interface characteristics, status, and statistics. This MIB is supported on Common Edge PPP process, jpppd. This MIB is currently supported only on M Series and MX Series routers. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ppp.txt

For more information, see *PPP MIB*.

- PPPoE MIB—Provides SNMP support for PPPoE-related information such as the type of authentication used, interface characteristics, status, and statistics. This MIB is supported on Common Edge PPPoE process, jpppoed. This MIB is currently supported only on M Series and MX Series routers. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pppoe.txt

For more information, see *PPPoE MIB*.

- Pseudowire TDM MIB—Extends the standard Pseudowire MIB, and contains information about configuration and statistics for specific pseudowire types. The enterprise-specific Pseudowire TDM MIB is the Juniper Networks implementation of the standard Managed Objects for TDM over Packet Switched Network MIB (draft-ietf-pwe3-tdm-mib-08.txt). For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pwtdm.txt

For more information, see *Pseudowire TDM MIB*.

- Pseudowire ATM MIB—Extends the standard Pseudowire MIB, and defines objects used for managing the ATM pseudowires in Juniper products. The enterprise-specific Pseudowire ATM MIB is the Juniper Networks implementation of RFC 5605, *Managed Objects for ATM over Packet Switched Networks (PSNs)*. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-pwatm.txt

For more information, see *Pseudowire ATM MIB*.

- PTP MIB—Monitors the operation of PTP clocks within the network. This MIB is currently supported by Junos OS for MX Series routers only. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-timing-notifications.txt

For more information, see *PTP MIB*.

- Real-Time Performance Monitoring MIB—Provides real-time performance-related data and enables you to access jitter measurements and calculations using SNMP. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-rpm.txt

For more information, see *Real-Time Performance Monitoring MIB*.

- Reverse-Path-Forwarding MIB—Monitors statistics for traffic that is rejected because of reverse-path-forwarding (RPF) processing. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-rpf.txt

NOTE: The enterprise-specific RPF MIB is not supported on EX Series Ethernet Switches.

For more information, see *Reverse Path Forwarding MIB*.

- RMON Events and Alarms MIB—Supports the Junos OS extensions to the standard Remote Monitoring (RMON) Events and Alarms MIB (RFC 2819). The extension augments **alarmTable** with additional information about each alarm. Two new traps are also defined to indicate when problems are encountered with an alarm. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-rmon.txt

For more information, see *RMON Events and Alarms MIB*.

- RSVP MIB—Provides information about RSVP-traffic engineering sessions that correspond to MPLS LSPs on transit routers in the service provider core network. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-rsvp.txt

NOTE: To collect information about MPLS statistics on transit routers, use the enterprise-specific RSVP MIB (**mib-jnx-rsvp.txt**) instead of the enterprise-specific MPLS MIB (**mib-jnx-mpls.txt**).

For more information, see *RSVP MIB*.

- Security Interface Extension Objects MIB—Provides support for the security management of interfaces. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-if-ext.txt

For more information, see *Security Interface Extension Objects MIB*.

- Security Screening Objects MIB—Defines the MIB for the Juniper Networks Enterprise Firewall screen functionality. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-screening.txt
For more information, see *Security Screening Objects MIB*.
- Services PIC MIB—Provides statistics for Adaptive Services (AS) PICs and defines notifications for AS PICs. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-sp.txt
For more information, see *Services PIC MIB*.
- SONET APS MIB—Monitors any SONET interface that participates in Automatic Protection Switching (APS). For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-sonetaps.txt
For more information, see *SONET APS MIB*.
- SONET/SDH Interface Management MIB—Monitors the current alarm for each SONET/SDH interface. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-sonet.txt
For more information, see *SONET/SDH Interface Management MIB*.
- Source Class Usage MIB—Counts packets sent to customers by performing a lookup on the IP source address and the IP destination address. The Source Class Usage (SCU) MIB makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-scu.txt
For more information, see *Source Class Usage MIB*.
- SPU Monitoring MIB—Provides support for monitoring SPUs on SRX5600 and SRX5800 devices. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-spu-monitoring.txt
For more information, see *SPU Monitoring Objects MIB*.
- Structure of Management Information MIB—Explains how the Juniper Networks enterprise-specific MIBs are structured. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-smi.txt
For more information, see *Structure of Management Information MIB*.
- Structure of Management Information MIB for EX Series Ethernet Switches—Defines a MIB branch for switching-related MIB definitions for the EX Series Ethernet Switches. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-ex-smi.txt
For more information, see *EX Series SMI MIB*.
- Structure of Management Information MIB for SRX Series —Contains object identifiers (OIDs) for the security branch of the MIBs used in Junos OS for SRX Series devices, services, and traps. This MIB is currently supported by Junos OS for SRX Series devices

only. For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-smi.txt

For more information, see *Structure of Management Information MIB*.

- Subscriber MIB—Provides SNMP support for subscriber-related information. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-subscriber.txt

For more information, see *Subscriber MIB*.

- System Log MIB—Enables notification of an SNMP trap-based application when an important system log message occurs. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-syslog.txt

For more information, see *System Log MIB*.

- Traceroute MIB—Supports the Junos OS extensions of traceroute and remote operations. Items in this MIB are created when entries are created in the **traceRouteCtlTable** of the Traceroute MIB. Each item is indexed exactly the same way as it is in the Traceroute MIB. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-traceroute.txt

For more information, see *Traceroute MIB*.

- Utility MIB—Provides SNMP support for exposing the Junos OS data and has tables that contain information about each type of data, such as integer and string. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-util.txt

For more information, see *Utility MIB*.

- Virtual Chassis MIB—Contains information about the virtual chassis on the EX Series Ethernet Switches and the MX Series. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-virtualchassis.txt

For more information, see *Virtual Chassis MIBs*.

- VLAN MIB—Contains information about prestandard IEEE 802.10 VLANs and their association with LAN emulation clients. The enterprise-specific VLAN MIB is supported only on EX Series Ethernet Switches.

NOTE: For ELS EX Series switches and QFX Series switches, VLAN information is available in the L2ALD MIB in the **jnxL2aldVlanTable** table instead of in the VLAN MIB. See *L2ALD MIB* for details. For non-ELS EX Series switches, VLAN information is provided in the VLAN MIB in the **jnxExVlanTable** table.

For a downloadable version of this MIB, see

http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-vlan.txt

For more information, see *VLAN MIB*.

- VPLS MIBs—Provides information about generic, BGP-based, and LDP-based VPLS and pseudowires associated with the VPLS networks. The enterprise-specific VPLS

MIBs are Juniper Networks extensions of the following IETF standard MIBs defined in Internet draft draft-ietf-l2vpn-vpls-mib-05.txt, and are implemented as part of the `jnxExperiment` branch:

- **VPLS-Generic-Draft-01-MIB** implemented as `mib-jnx-vpls-generic.txt`
- **VPLS-BGP-Draft-01-MIB** implemented as `mib-jnx-vpls-bgp.txt`
- **VPLS-LDP-Draft-01-MIB** implemented as `mib-jnx-vpls-ldp.txt`

For downloadable versions of these MIBs, see:

- http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-vpls-generic.txt
- http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-vpls-bgp.txt
- http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-vpls-ldp.txt

For more information, see *Interpreting the Enterprise-Specific VPLS MIBs*.

- **VPN Certificate Objects MIB**—Provides support for monitoring the local and CA certificates loaded on the router. This MIB is currently supported by Junos OS for SRX Series devices only. For a downloadable version of this MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-js-cert.txt

For more information, see *VPN Certificate Objects MIB*.

- **VPN MIB**—Provides monitoring for Layer 3 VPNs, Layer 2 VPNs, and virtual private LAN service (VPLS) (read access only). For a downloadable version of the MIB, see http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-vpn.txt

For more information, see *VPN MIB*.

Enterprise-Specific MIBs and Supported Devices

Table 112 lists the enterprise-specific MIBs that are supported on various devices running the Junos OS.

NOTE: In this table, a value of 1 in any of the platform columns (ACX, M, MX, T, EX, PTX, and SRX) denotes that the corresponding MIB is supported on that particular platform. A value of 0 denotes that the MIB is not supported on the platform.

NOTE: This topic uses the following classification for SRX Series devices: Low-End (SRX300, SRX320, and SRX340), Mid-Range (SRX550M), and High-End (SRX1500, SRX5400, SRX5600, and SRX5800).

Table 112: Enterprise-Specific MIBs and Supported Devices

Enterprise-Specific MIB	Platforms								
	ACX	M	T	MX	EX	PTX	SRX		
							Low-End	Mid-Range	High-End
AAA Objects MIB http://www.juniper.net/techpubs/en_US/junos15.1/topics/reference/mibs/mib-jnx-user-aaa.txt	0	1	1	0	0	0	0	1	1

SNMP MIB Objects Supported by Junos OS for the SNMP Set Operation

The following table lists the SNMP MIB objects that are supported for the **snmp set** operation by Junos OS.

Object Name	Object Identifier
RFC 1907	
sysContact	1.3.6.1.2.1.1.4
sysName	1.3.6.1.2.1.1.5

Loading MIB Files to a Network Management System

- Loading MIB Files to a Network Management System on page 1459

Loading MIB Files to a Network Management System

For your network management system (NMS) to identify and understand the MIB objects used by the Junos OS, you must first load the MIB files to your NMS using a MIB compiler. A MIB compiler is a utility that parses the MIB information such as the MIB object name, IDs, and data type for the NMS.

You can download the Junos MIB package from the Junos OS Enterprise MIBs index at http://www.juniper.net/techpubs/en_US/release-independent/junos/mibs/mibs.html. The Junos MIB package is available in **.zip** and **.tar** packages. You can download the appropriate format based on your requirements.

The Junos MIB package contains two folders: **StandardMibs** and **JuniperMibs**. The **StandardMibs** folder contains the standard MIBs and RFCs that are supported on devices running the Junos OS, whereas the **JuniperMibs** folder contains the Juniper Networks enterprise-specific MIBs.

To load MIB files that are required for managing and monitoring devices running the Junos OS:

1. Go to the Junos OS Enterprise MIBs index page (http://www.juniper.net/techpubs/en_US/release-independent/junos/mibs/mibs.html).
2. Click the **TAR** or **ZIP** link under the appropriate release heading to download the Junos MIB package for that release.
3. Decompress the file (**.tar** or **.zip**) using an appropriate utility.
4. Load the standard MIB files (from the **StandardMibs** folder) in the following order:

NOTE: Some of the MIB compilers that are commonly used have the standard MIBs preloaded on them. If the standard MIBs are already loaded on the MIB compiler that you are using, skip this step and proceed to Step 7.

- a. `mib-SNMPv2-SMI.txt`
- b. `mib-SNMPv2-TC.txt`
- c. `mib-IANAifType-MIB.txt`
- d. `mib-IANA-RTPROTO-MIB.txt`
- e. `mib-rfc1907.txt`
- f. `mib-rfc2011a.txt`
- g. `mib-rfc2012a.txt`
- h. `mib-rfc2013a.txt`
- i. `mib-rfc2863a.txt`

5. Load the remaining standard MIB files.

NOTE: You must follow the order specified in this procedure, and ensure that all standard MIBs are loaded before you load the enterprise-specific MIBs. There might be dependencies that require a particular MIB to be present on the compiler before loading some other MIB. You can find such dependencies listed in the **IMPORT** section of the MIB file.

6. Load the Juniper Networks enterprise-specific SMI MIB, `mib-jnx-smi.txt`, and the following optional SMI MIBs based on your requirements:

- `mib-jnx-js-smi.txt`—(Optional) For Juniper Security MIB tree objects
- `mib-jnx-ex-smi.txt`—(Optional) For EX Series Ethernet Switches
- `mib-jnx-exp.txt`—(Recommended) For Juniper Networks experimental MIB objects

7. Load the remaining enterprise-specific MIBs from the **JuniperMibs** folder.

TIP: While loading a MIB file, if the compiler returns an error message saying that any of the objects is undefined, open the MIB file using a text editor and ensure that all the MIB files listed in the **IMPORT** section are loaded on the compiler. If any of the MIB files listed in the **IMPORT** section is not loaded on the compiler, load that MIB file, and then try to load the MIB file that failed to load.

For example, the enterprise-specific PING MIB, `mib-jnx-ping.txt`, has dependencies on RFC 2925, DiSMAN-PING-MIB, `mib-rfc2925a.txt`. If you try to load `mib-jnx-ping.txt` before loading `mib-rfc2925a.txt`, the compiler returns an error message saying that certain objects in `mib-jnx-ping.txt` are undefined. Load `mib-rfc2925a.txt`, and then try to load `mib-jnx-ping.txt`. The enterprise-specific PING MIB, `mib-jnx-ping.txt`, then loads without any issue.

Configuration Statements at the [edit snmp] Hierarchy Level

This topic shows all possible configuration statements at the **[edit snmp]** hierarchy level and their level in the configuration hierarchy. When you are configuring Junos OS, your current hierarchy level is shown in the banner on the line preceding the **user@host#** prompt.

Optimizing the Network Management System Configuration for the Best Results

You can modify your network management system configuration to optimize the response time for SNMP queries. The following sections contain a few tips on how you can configure the network management system:

- [Changing the Polling Method from Column-by-Column to Row-by-Row on page 1467](#)
- [Reducing the Number of Variable Bindings per PDU on page 1468](#)
- [Increasing Timeout Values in Polling and Discovery Intervals on page 1468](#)
- [Reducing Incoming Packet Rate at the snmpd on page 1468](#)

Changing the Polling Method from Column-by-Column to Row-by-Row

You can configure the network management system to use the row-by-row method for SNMP data polling. It has been proven that the row-by-row and multiple row-by-multiple-row polling methods are more efficient than column-by-column polling. By configuring the network management system to use the row-by-row data polling method, you can ensure that data for only one interface is polled in a request instead of

a single request polling data for multiple interfaces, as is the case with column-by-column polling. Row-by-row polling also reduces the risk of requests timing out.

Reducing the Number of Variable Bindings per PDU

By reducing the number of variable bindings per protocol data unit (PDU), you can improve the response time for SNMP requests. A request that polls for data related to multiple objects, which are mapped to different index entries, translates into multiple requests at the device-end because the subagent might have to poll different modules to obtain data that are linked to different index entries. The recommended method is to ensure that a request has only objects that are linked to one index entry instead of multiple objects linked to different index entries.

NOTE: If responses from a device are slow, avoid using the **GetBulk** option for the device, because a **GetBulk** request might contain objects that are linked to various index entries and might further increase the response time.

Increasing Timeout Values in Polling and Discovery Intervals

By increasing the timeout values for polling and discovery intervals, you can increase the queuing time at the device end and reduce the number of throttle drops that occur because of the request timing out.

Reducing Incoming Packet Rate at the snmpd

By reducing the frequency of sending SNMP requests to a device, you can reduce the risk of SNMP requests piling up at any particular device. Apart from reducing the frequency of sending SNMP requests to a device, you can also increase the polling interval, control the use of **GetNext** requests, and reduce the number of polling stations per device.

- *Managing Traps and Informs*
- *Using the Enterprise-Specific Utility MIB to Enhance SNMP Coverage*

Configuring Options on Managed Devices for Better SNMP Response Time

The following sections contain information about configuration options on the managed devices that can enhance SNMP performance:

- [Enabling the stats-cache-lifetime Option on page 1469](#)
- [Filtering Out Duplicate SNMP Requests on page 1469](#)
- [Excluding Interfaces That Are Slow in Responding to SNMP Queries on page 1470](#)

Enabling the stats-cache-lifetime Option

The Junos OS provides you with an option to configure the length of time an SNMP request stays active and queued so as to reduce the possibility of request drops during slow response times. You can use the **stats-cache-lifetime seconds** option at the **[edit snmp]** hierarchy level to specify the length of time that an SNMP request remains queued. The recommended value for the **stats-cache-lifetime** option is in the range of 30 to 60 seconds.

NOTE: The **set snmp stats-cache-lifetime seconds** command is a hidden command and is supported only on devices running Junos OS Release 9.3 and later.

Filtering Out Duplicate SNMP Requests

If a network management station retransmits a **Get**, **GetNext**, or **GetBulk** SNMP request too frequently to a device, that request might interfere with the processing of previous requests and slow down the response time of the agent. Filtering these duplicate requests improves the response time of the SNMP agent. The Junos OS enables you to filter out duplicate **Get**, **GetNext**, and **GetBulk** SNMP requests. The Junos OS uses the following information to determine if an SNMP request is a duplicate:

- Source IP address of the SNMP request
- Source UDP port of the SNMP request
- Request ID of the SNMP request

NOTE: By default, filtering of duplicate SNMP requests is disabled on devices running the Junos OS.

To enable filtering of duplicate SNMP requests on devices running the Junos OS, include the **filter-duplicates** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
filter-duplicates;
```

Excluding Interfaces That Are Slow in Responding to SNMP Queries

An interface that is slow in responding to SNMP requests for interface statistics can delay kernel responses to SNMP requests. You can review the mib2d log file to find out how long the kernel takes to respond to various SNMP requests. For more information about reviewing the log file for kernel response data, see “Checking Kernel and Packet Forwarding Engine Response” under “[Monitoring SNMP Activity and Tracking Problems That Affect SNMP Performance on a Device Running Junos OS](#)” on page 1579. If you notice that a particular interface is slow in responding, and think that it is slowing down the kernel from responding to SNMP requests, exclude that interface from the SNMP queries to the device. You can exclude an interface from the SNMP queries either by configuring the **filter-interface** statement or by modifying the SNMP view settings.

The following example shows a sample configuration for excluding interfaces from the SNMP **Get**, **GetNext**, and **Set** operations:

```
[edit]
snmp {
  filter-interfaces {
    interfaces { # exclude the specified interfaces
      interface1;
      interface2;
    }
    all-internal-interfaces; # exclude all internal interfaces
  }
}
```

The following example shows the SNMP view configuration for excluding the interface with an interface index (ifIndex) value of 312 from a request for information related to the ifTable and ifXtable objects:

```
[edit snmp]
view test {
  oid .1 include;
  oid ifTable.1.*.312 exclude;
  oid ifXTable.1.*.312 exclude
}
```

Alternatively, you can take the interface that is slow in responding offline.

Configuring SNMP on Devices Running Junos OS

The following sections contain information about basic SNMP configuration and a few examples of configuring the basic SNMP operations on devices running Junos OS:

- [Configuring Basic Settings for SNMPv1 and SNMPv2 on page 1471](#)
- [Configuring Basic Settings for SNMPv3 on page 1471](#)
- [Configuring System Name, Location, Description, and Contact Information on page 1473](#)

Configuring Basic Settings for SNMPv1 and SNMPv2

By default, SNMP is not enabled on devices running Junos OS. To enable SNMP on devices running Junos OS, include the **community public** statement at the **[edit snmp]** hierarchy level.

Enabling SNMPv1 and
SNMPv2 Get and
GetNext Operations

```
[edit]
snmp {
  community public;
}
```

A community that is defined as public grants access to all MIB data to any client.

To enable SNMPv1 and SNMPv2 **Set** operations on the device, you must include the following statements at the **[edit snmp]** hierarchy level:

Enabling SNMPv1 and
SNMPv2 Set
Operations

```
[edit snmp]
view all {
  oid .1;
}
community private {
  view all;
  authorization read-write;
}
```

The following example shows the basic minimum configuration for SNMPv1 and SNMPv2 traps on a device:

Configuring SNMPv1
and SNMPv2 Traps

```
[edit snmp]
trap-group jnpr {
  targets {
    192.168.69.179;
  }
}
```

Configuring Basic Settings for SNMPv3

The following example shows the minimum SNMPv3 configuration for enabling **Get**, **GetNext**, and **Set** operations on a device (note that the configuration has authentication set to **md5** and privacy to **none**):

Enabling SNMPv3 Get,
GetNext, and Set
Operations

```
[edit snmp]
v3 {
  usm {
    local-engine {
```

```

        user jnpruser {
            authentication-md5 {
                authentication-key "$9$guaDiQFnAuOQzevMWx7ikqP"; ## SECRET-DATA
            }
            privacy-none;
        }
    }
}
vacm {
    security-to-group {
        security-model usm {
            security-name jnpruser {
                group grpnm;
            }
        }
    }
}
access {
    group grpnm {
        default-context-prefix {
            security-model any {
                security-level authentication {
                    read-view all;
                    write-view all;
                }
            }
        }
    }
}
}
}
}
}
view all {
    oid .1;
}
}

```

The following example shows the basic configuration for SNMPv3 informs on a device (the configuration has authentication and privacy set to **none**):

Configuring SNMPv3 Informs	<pre> [edit snmp] v3 { usm { remote-engine 00000063000100a2c0a845b3 { user RU2_v3_sha_none { authentication-none; privacy-none; } } } } vacm { security-to-group { security-model usm { security-name RU2_v3_sha_none { group gl_usm_auth; } } } } access { </pre>
---------------------------------------	--

```

group g1_usm_auth {
  default-context-prefix {
    security-model usm {
      security-level authentication {
        read-view all;
        write-view all;
        notify-view all;
      }
    }
  }
}

target-address TA2_v3_sha_none {
  address 192.168.69.179;
  tag-list tl1;
  address-mask 255.255.252.0;
  target-parameters TP2_v3_sha_none;
}

target-parameters TP2_v3_sha_none {
  parameters {
    message-processing-model v3;
    security-model usm;
    security-level none;
    security-name RU2_v3_sha_none;
  }
  notify-filter nf1;
}

notify N1_all_tl1_informs {
  type inform; # Replace inform with trap to convert informs to traps.
  tag tl1;
}

notify-filter nf1 {
  oid .1 include;
}

view all {
  oid .1 include;
}

```

You can convert the SNMPv3 informs to traps by setting the value of the **type** statement at the **[edit snmp v3 notify N1_all_tl1_informs]** hierarchy level to **trap** as shown in the following example:

Converting Informs to Traps

```
user@host# set snmp v3 notify N1_all_tl1_informs type trap
```

Configuring System Name, Location, Description, and Contact Information

Junos OS enables you to include the name and location of the system, administrative contact information, and a brief description of the system in the SNMP configuration.

NOTE: Always keep the name, location, contact, and description information configured and updated for all your devices that are managed by SNMP.

The following example shows a typical configuration.

TIP: Use quotation marks to enclose the system name, contact, location, and description information that contain spaces.

```
[edit]
snmp {
  name "snmp 001"; # Overrides the system name.
  contact "Juniper Berry, (650) 555 1234"; # Specifies the name and phone number of
    the administrator.
  location "row 11, rack C"; # Specifies the location of the device.
  description "M40 router with 8 FPCs" # Configures a description for the device.
}
```

Configuring the System Contact on a Device Running Junos OS

You can specify an administrative contact for each system being managed by SNMP. This name is placed into the MIB II **sysContact** object. To configure a contact name, include the **contact** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
contact contact;
```

If the name contains spaces, enclose it in quotation marks (" ").

To define a system contact name that contains spaces:

```
[edit]
snmp {
  contact "Juniper Berry, (650) 555-1234";
}
```

Configuring the System Location for a Device Running Junos OS

You can specify the location of each system being managed by SNMP. This string is placed into the MIB II **sysLocation** object. To configure a system location, include the **location** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
location location;
```

If the location contains spaces, enclose it in quotation marks (" ").

To specify the system location:

```
[edit]
snmp {
  location "Row 11, Rack C";
}
```

Configuring the System Description on a Device Running Junos OS

You can specify a description for each system being managed by SNMP. This string is placed into the MIB II **sysDescription** object. To configure a description, include the **description** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
description description;
```

If the description contains spaces, enclose it in quotation marks (" ").

To specify the system description:

```
[edit]
snmp {
  description "M40 router with 8 FPCs";
}
```

Configuring SNMP Details

You can use SNMP to store basic administrative details, such as a contact name and the location of the device. Your management system can then retrieve this information remotely, when you are troubleshooting an issue or performing an audit. In SNMP terminology, these are the `sysContact`, `sysDescription`, and `sysLocation` objects found within the system group of MIB-2 (as defined in RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II*). You can set initial values directly in the Junos OS configuration for each system being managed by SNMP.

To set the system contact details:

1. Set the system contact details by including the **contact** statement at the **[edit snmp]** hierarchy level, or in an appropriate configuration group as shown here.

This administrative contact is placed into the MIB II **sysContact** object.

If the name contains spaces, enclose it in quotation marks (" ").

```
[edit groups global snmp]
user@host# set contact contact
```

For example:

```
[edit groups global snmp]
user@host# set contact "Enterprise Support, (650) 555-1234"
```

2. Configure a system description.

This string is placed into the MIB II **sysDescription** object. If the description contains spaces, enclose it in quotation marks (" ").

```
[edit groups global snmp]
user@host# set description description
```

For example:

```
[edit groups global snmp]
user@host# set description "M10i router with 8 FPCs"
```

3. Configure a system location.

This string is placed into the MIB II **sysLocation** object. If the location contains spaces, enclose it in quotation marks (" ").

To specify the system location:

```
[edit]
snmp {
  location "Row 11, Rack C";
}

[edit groups global snmp]
user@host# set location location
```

For example:

```
[edit groups global snmp]
user@host# set location "London Corporate Office, Lab 5, Row 11, Rack C"
```

4. At the top level of the configuration, apply the configuration group.

If you use a configuration group, you must apply it for it to take effect.

```
[edit]
user@host# set apply-groups global
```

5. Commit the configuration.

```
user@host# commit
```

6. To verify the configuration, enter the **show snmp mib walk system** operational-mode command.

The **show snmp mib walk system** command performs a MIB walk through of the system table (from MIB-2 as defined in RFC 1213). The SNMP agent in Junos OS responds by printing each row in the table and its associated value. You can use the same command to perform a MIB walk through any part of the MIB tree supported by the agent.

```
user@host> show snmp mib walk system
sysDescr.0    = M10i router with 8 FPCs
sysObjectID.0 = jnxProductNameM10i
sysUpTime.0   = 173676474
sysContact.0  = Enterprise Support, (650) 555-1234
sysName.0     = host
sysLocation.0 = London Corporate Office, Lab 5, Row 11, Rack C
sysServices.0 = 4
```

Related Documentation

Configuring a Different System Name

Junos OS enables you to override the system name by including the **name** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
name name;
```

If the name contains spaces, enclose it in quotation marks (" ").

To specify the system name override:

```
[edit]
snmp {
  name "snmp1";
}
```

- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Configuring the Commit Delay Timer

When a router or switch first receives an SNMP nonvolatile **Set** request, a Junos OS XML protocol session opens and prevents other users or applications from changing the candidate configuration (equivalent to the command-line interface [CLI] **configure exclusive** command). If the router does not receive new SNMP **Set** requests within 5 seconds (the default value), the candidate configuration is committed and the Junos OS XML protocol session closes (the configuration lock is released). If the router receives new SNMP **Set** requests while the candidate configuration is being committed, the SNMP **Set** request is rejected and an error is generated. If the router receives new SNMP **Set** requests before 5 seconds have elapsed, the commit-delay timer (the length of time between when the last SNMP request is received and the commit is requested) resets to 5 seconds.

By default, the timer is set to 5 seconds. To configure the timer for the SNMP **Set** reply and start of the commit, include the **commit-delay** statement at the **[edit snmp nonvolatile]** hierarchy level:

```
[edit snmp nonvolatile]
  commit-delay seconds;
```

seconds is the length of the time between when the SNMP request is received and the commit is requested for the candidate configuration. For more information about the **configure exclusive** command and locking the configuration, see the *CLI User Guide*.

Related Documentation

- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Filtering Duplicate SNMP Requests

By default, filtering duplicate **get**, **getNext**, and **getBulk** SNMP requests is disabled on devices running Junos OS. If a network management station retransmits a **Get**, **GetNext**, or **GetBulk** SNMP request too frequently to the router, that request might interfere with the processing of previous requests and slow down the response time of the agent. Filtering these duplicate requests improves the response time of the SNMP agent. Junos OS uses the following information to determine if an SNMP request is a duplicate:

- Source IP address of the SNMP request
- Source UDP port of the SNMP request
- Request ID of the SNMP request

To filter duplicate SNMP requests, include the **filter-duplicates** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
  filter-duplicates;
```

 - [Filtering Interface Information Out of SNMP Get and GetNext Output on page 1495](#)
 - [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Configuring SNMP Communities

Configuring the SNMP agent in Junos OS is a straightforward task that shares many familiar settings common to other managed devices in your network. For example, you need to configure Junos OS with an SNMP community string and a destination for traps. Community strings are administrative names that group collections of devices and the agents that are running on them together into common management domains. If a manager and an agent share the same community, they can communicate with each other. An SNMP community defines the level of authorization granted to its members, such as which MIB objects are available, which operations (read-only or read-write) are valid for those objects, and which SNMP clients are authorized, based on their source IP addresses.

The SNMP community string defines the relationship between an SNMP server system and the client systems. This string acts like a password to control the clients' access to the server.

To create a read-only SNMP community:

1. Enter the SNMP community used in your network.

If the community name contains spaces, enclose it in quotation marks (" ").

Community names must be unique.

NOTE: You cannot configure the same community name at the [edit snmp community] and [edit snmp v3 snmp-community *community-index*] hierarchy levels.

```
[edit groups global]
user@host# set snmp community name
```

This example uses the standard name **public** to create a community that gives limited read-only access.

```
[edit groups global]
user@host# set snmp community public
```

2. Define the authorization level for the community.

The default authorization level for a community is **read-only**.

To allow **Set** requests within a community, you need to define that community as **authorization read-write**. For **Set** requests, you also need to include the specific MIB objects that are accessible with read-write privileges using the **view** statement. The

default view includes all supported MIB objects that are accessible with read-only privileges. No MIB objects are accessible with read-write privileges. For more information about the **view** statement, see [“Configuring MIB Views” on page 1496](#).

```
[edit groups global snmp community name]  
user@host# set authorization authorization
```

This example confines the public community to read-only access. Any SNMP client (for example, an SNMP management system) that belongs to the public community can read MIB variables but cannot set (change) them.

```
[edit groups global snmp community public]  
user@host# set authorization read-only
```

3. Define a list of clients in the community who are authorized to communicate with the SNMP agent in Junos OS.

The **clients** statement lists the IP addresses of the clients (community members) that are allowed to use this community. List the clients by IP address and prefix. Typically, the list includes the SNMP network management system in your network or the address of your management network. If no **clients** statement is present, all clients are allowed. For **address**, you must specify an IPv4 or IPv6 address, not a hostname.

```
[edit groups global snmp community name]  
user@host# set clients address
```

The following statement defines the hosts in the 192.168.1.0/24 network as being authorized in the public community.

```
[edit groups global snmp community public]  
user@host# set clients 192.168.1.0/24
```

4. Define the clients that are not authorized within the community by specifying their IP address, followed by the **restrict** statement.

```
[edit groups global snmp community name]  
user@host# set clients address restrict
```

The following statement defines all other hosts as being restricted from the public community.

```
[edit groups global snmp community public]  
user@host# set clients 0/0 restrict
```

5. At the top level of the configuration, apply the configuration group.

If you use a configuration group, you must apply it for it to take effect.

```
[edit]  
user@host# set apply-groups global
```

6. Commit the configuration.

```
user@host# commit
```

To create a read-write SNMP community:

1. Enter the SNMP community used in your network.

```
[edit groups global]  
user@host# set snmp community name
```

This example standard community string **private** to identify the community granted read-write access to the SNMP agent running on the device.

```
[edit groups global]
user@host# set snmp community private
```

2. Define the authorization level for the community.

```
[edit groups global snmp community name]
user@host# set authorization authorization
```

This example confines the public community to read-only access. Any SNMP client (for example, an SNMP management system) that belongs to the public community can read MIB variables but cannot set (change) them.

```
[edit groups global snmp community public]
user@host# set authorization read-write
```

3. Define a list of clients in the community who are authorized to make changes to the SNMP agent in Junos OS.

List the clients by IP address and prefix.

```
[edit groups global snmp community name]
user@host# set clients address
```

For example:

```
[edit groups global snmp community private]
user@host# set clients 192.168.1.15/24
user@host# set clients 192.168.1.18/24
```

4. Define the clients that are not authorized within the community by specifying their IP address, followed by the **restrict** statement.

```
[edit groups global snmp community name]
user@host# set clients address restrict
```

The following statement defines all other hosts as being restricted from the public community.

```
[edit groups global snmp community private]
user@host# set clients 0/0 restrict
```

5. At the top level of the configuration, apply the configuration group.

If you use a configuration group, you must apply it for it to take effect.

```
[edit]
user@host# set apply-groups global
```

6. Commit the configuration.

```
user@host# commit
```

Related Documentation

- [Adding a Group of Clients to an SNMP Community on page 1482](#)
- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)
- [Examples: Configuring the SNMP Community String on page 1482](#)

Examples: Configuring the SNMP Community String

Grant read-only access to all clients. With the following configuration, the system responds to SNMP **Get**, **GetNext**, and **GetBulk** requests that contain the community string **public**:

```
[edit]
snmp {
  community public {
    authorization read-only;
  }
}
```

Grant all clients read-write access to the ping MIB and **jnxPingMIB**. With the following configuration, the system responds to SNMP **Get**, **GetNext**, **GetBulk**, and **Set** requests that contain the community string **private** and specify an OID contained in the ping MIB or **jnxPingMIB** hierarchy:

```
[edit]
snmp {
  view ping-mib-view {
    oid pingMIB include;
    oid jnxPingMIB include;
    community private {
      authorization read-write;
      view ping-mib-view;
    }
  }
}
```

The following configuration allows read-only access to clients with IP addresses in the range **1.2.3.4/24**, and denies access to systems in the range **fe80::1:2:3:4/64**:

```
[edit]
snmp {
  community field-service {
    authorization read-only;
    clients {
      default restrict; # Restrict access to all SNMP clients not explicitly
                        # listed on the following lines.
      1.2.3.4/24; # Allow access by all clients in 1.2.3.4/24 except
      fe80::1:2:3:4/64 restrict; # fe80::1:2:3:4/64.
    }
  }
}
```

- [Configuring SNMP Communities on page 1479](#)

Adding a Group of Clients to an SNMP Community

Junos OS enables you to add one or more groups of clients to an SNMP community. You can include the **client-list-name** *name* statement at the **[edit snmp community community-name]** hierarchy level to add all the members of the client list or prefix list to an SNMP community.

To define a list of clients, include the **client-list** statement followed by the IP addresses of the clients at the **[edit snmp]** hierarchy level:

```
[edit snmp]
  client-list client-list-name {
    ip-addresses;
  }
```

You can configure a prefix list at the **[edit policy options]** hierarchy level. Support for prefix lists in the SNMP community configuration enables you to use a single list to configure the SNMP and routing policies. For more information about the **prefix-list** statement, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

To add a client list or prefix list to an SNMP community, include the **client-list-name** statement at the **[edit snmp community community-name]** hierarchy level:

```
[edit snmp community community-name]
  client-list-name client-list-name;
```

NOTE: The client list and prefix list must not have the same name.

The following example shows how to define a client list:

```
[edit]
snmp {
  client-list clentlist1 {
    10.1.1.1/32;
    10.2.2.2/32;
  }
}
```

The following example shows how to add a client list to an SNMP community:

```
[edit]
snmp {
  community community1 {
    authorization read-only;
    client-list-name clientlist1;
  }
}
```

The following example shows how to add a prefix list to an SNMP community:

```
[edit]
policy-options {
  prefix-list prefixlist {
    10.3.3.3/32;
    10.5.5.5/32;
  }
}
snmp {
  community community2 {
    client-list-name prefixlist;
  }
}
```

- Related Documentation**
- *client-list*
 - *client-list-name*

Configuring a Proxy SNMP Agent

Junos OS enables you to assign one of the devices in the network as a proxy SNMP agent through which the network management system (NMS) can query other devices in the network. When you configure a proxy, you can specify the names of devices to be managed through the proxy SNMP agent.

When the NMS queries the proxy SNMP agent, the NMS specifies the community name (for SNMPv1 and SNMPv2) or the context and security name (for SNMPv3) associated with the device from which it requires the information.

NOTE: If you have configured authentication and privacy methods and passwords for SNMPv3, those parameters are also specified in the query for SNMPv3 information.

To configure a proxy SNMP agent and specify devices to be managed by the proxy SNMP agent, you can include the following configuration statements at the `[edit snmp]` hierarchy level:

```
proxy proxy-name{
  device-name device-name;
  logical-system logical-system {
    routing-instance routing-instance;
  }
  routing-instance routing-instance;
  <version-v1 | version-v2c> {
    snmp-community community-name;
    no-default-comm-to-v3-config;
  }
  version-v3 {
    security-name security-name;
    context context-name;
  }
}
```

- The **proxy** statement enables you to specify a unique name for the proxy configuration.
- The **version-v1**, **version-v2c**, and **version-v3** statements enable you to specify the SNMP version.
- The **no-default-comm-to-v3-config** statement is an optional statement at the `[edit snmp proxy proxy-name <version-v1 | version-v2c>]` hierarchy level that when included in the configuration requires you to manually configure the statements at the `[edit snmp v3 snmp-community community-name]` and `[edit snmp v3 vacm]` hierarchy levels.

If the **no-default-comm-to-v3-config** statement is not included at the `[edit snmp proxy proxy-name <version-v1 | version-v2c>]` hierarchy level, the `[edit snmp v3`

`snmp-community community-name`] and `[edit snmp v3 vacm]` hierarchy level configurations are automatically initialized.

- The **logical-system** and **routing-instance** statements are optional statements that enable you to specify logical system and routing instance names if you want to create proxies for logical systems or routing instances on the device.

NOTE: The community and security configuration for the proxy should match the corresponding configuration on the device that is to be managed.

NOTE: Because the proxy SNMP agent does not have trap forwarding capabilities, the devices that are managed by the proxy SNMP agent send the traps directly to the network management system.

You can use the **show snmp proxy** operational mode command to view proxy details on a device. The **show snmp proxy** command returns the proxy names, device names, SNMP version, community/security, and context information.

- [proxy \(snmp\) on page 2061](#)

Configuring SNMP Traps

Traps are unsolicited messages sent from an SNMP agent to remote network management systems or trap receivers. Many enterprises use SNMP traps as part of a fault-monitoring solution, in addition to system logging. In Junos OS, SNMP traps are not forwarded by default, so you must configure a trap-group if you wish to use SNMP traps.

You can create and name a group of one or more types of SNMP traps and then define which systems receive the group of SNMP traps. The name of the trap group is embedded in SNMP trap notification packets as one variable binding (varbind) known as the community name.

To configure an SNMP trap:

1. Create a single, consistent source address that Junos OS applies to all outgoing traps in your device.

A source address is useful, because although most Junos OS devices have a number of outbound interfaces, using one source address helps a remote NMS to associate the source of the traps with an individual device

```
[edit groups global snmp]
user@host# set trap-options source-address address
```

This example uses the IP address of the loopback interface (lo0) as the source address for all the SNMP traps that originate from the device.

```
[edit groups global snmp]
user@host# set trap-options source-address lo0
```

2. Create a trap group in which you can list the types of traps to be forwarded and the targets (addresses) of the receiving remote management systems.

```
[edit groups global snmp trap-group group-name]
user@host# set version (all | v1 | v2) targets address
```

This example creates a trap group called **managers**, allows SNMP version 2-formatted notifications (traps) to be sent to the host at address 192.168.1.15. This statement forwards all categories of traps.

```
[edit groups global snmp trap-group managers]
user@host# set version v2 targets 192.168.1.15
```

3. Define the specific subset of trap categories to be forwarded.

For a list of categories, see [“Configuring SNMP Trap Groups” on page 1491](#).

```
[edit groups global snmp trap-group group-name]
user@host# set categories category
```

The following statement configures the standard MIB-II authentication failures on the agent (the device).

```
[edit groups global snmp trap-group managers]
user@host# set categories authentication
```

4. At the top level of the configuration, apply the configuration group.

If you use a configuration group, you must apply it for it to take effect.

```
[edit]
user@host# set apply-groups global
```

5. Commit the configuration.

```
user@host# commit
```

6. To verify the configuration, generate an authentication failure trap.

This means that the SNMP agent received a request with an unknown community. Other traps types can also be spoofed as well.

This feature enables you to trigger SNMP traps from routers and ensure that they are processed correctly within your existing network management infrastructure. This is also useful for testing and debugging SNMP behavior on the switch or NMS.

Using the **monitor traffic** command, you can verify that the trap is sent to the network management system.

```
user@host> request snmp spoof-trap spoof-trap authenticationFailure
Spoof-trap request result: trap sent successfully
```

Related Documentation

Configuring SNMP Trap Options and Groups on a Device Running Junos OS

Some carriers have more than one trap receiver that forwards traps to a central NMS. This allows for more than one path for SNMP traps from a router to the central NMS through different trap receivers. A device running Junos OS can be configured to send the same copy of each SNMP trap to every trap receiver configured in the trap group.

The source address in the IP header of each SNMP trap packet is set to the address of the outgoing interface by default. When a trap receiver forwards the packet to the central NMS, the source address is preserved. The central NMS, looking only at the source address of each SNMP trap packet, assumes that each SNMP trap came from a different source.

In reality, the SNMP traps came from the same router, but each left the router through a different outgoing interface.

The statements discussed in the following sections are provided to allow the NMS to recognize the duplicate traps and to distinguish SNMPv1 traps based on the outgoing interface.

To configure SNMP trap options and trap groups, include the **trap-options** and **trap-group** statements at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
  source-address address;
}
trap-group group-name {
  categories {
    category;
  }
  destination-port port-number;
  targets {
    address;
  }
  version (all | v1 | v2);
}
```

Related Documentation

- [Configuring SNMP Trap Options on page 1487](#)
- [Configuring SNMP Trap Groups on page 1491](#)
- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Configuring SNMP Trap Options

Using SNMP trap options, you can set the source address of every SNMP trap packet sent by the router to a single address regardless of the outgoing interface. In addition, you can set the agent address of the SNMPv1 traps. For more information about the contents of SNMPv1 traps, see RFC 1157.

NOTE: SNMP cannot be associated with any routing instances other than the master routing instance.

To configure SNMP trap options, include the **trap-options** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-options {
  agent-address outgoing-interface;
  enterprise-oid
  logical-system
  routing-instance
  source-address address;
}
```

You must also configure a trap group for the trap options to take effect. For information about trap groups, see “Configuring SNMP Trap Groups” on page 1491.

This topic contains the following sections:

- [Configuring the Source Address for SNMP Traps on page 1488](#)
- [Configuring the Agent Address for SNMP Traps on page 1490](#)
- [Adding snmpTrapEnterprise Object Identifier to Standard SNMP Traps on page 1491](#)

Configuring the Source Address for SNMP Traps

You can configure the source address of trap packets in many ways: **lo0**, a valid IPv4 address or IPv6 address configured on one of the router interfaces, a logical-system address, or the address of a routing-instance. The value **lo0** indicates that the source address of the SNMP trap packets is set to the lowest loopback address configured on the interface **lo0**.

NOTE: If the source address is an invalid IPv4 or IPv6 address or is not configured, SNMP traps are not generated.

You can configure the source address of trap packets in one of the following formats:

- A valid IPv4 address configured on one of the router interfaces
- A valid IPv6 address configured on one of the router interfaces
- **lo0**; that is, the lowest loopback address configured on the interface **lo0**
- A logical-system name
- A routing-instance name

A Valid IPv4 Address As the Source Address

To specify a valid IPv4 interface address as the source address for SNMP traps on one of the router interfaces, include the **source-address** statement at the **[edit snmp trap-options]** hierarchy level:

```
[edit snmp trap-options]
```

```
source-address address;
```

address is a valid IPv4 address configured on one of the router interfaces.

A Valid IPv6 Address As the Source Address

To specify a valid IPv6 interface address as the source address for SNMP traps on one of the router interfaces, include the **source-address** statement at the **[edit snmp trap-options]** hierarchy level:

```
[edit snmp trap-options]
source-address address;
```

address is a valid IPv6 address configured on one of the router interfaces.

The Lowest Loopback Address As the Source Address

To specify the source address of the SNMP traps so that they use the lowest loopback address configured on the interface **lo0** as the source address, include the **source-address** statement at the **[edit snmp trap-options]** hierarchy level:

```
[edit snmp trap-options]
source-address lo0;
```

To enable and configure the loopback address, include the **address** statement at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level:

```
[edit interfaces]
lo0 {
  unit 0 {
    family inet {
      address ip-address;
    }
  }
}
```

To configure the loopback address as the source address of trap packets:

```
[edit snmp]
trap-options {
  source-address lo0;
}
trap-group "urgent-dispatcher" {
  version v2;
  categories link startup;
  targets {
    192.168.10.22;
    172.17.1.2;
  }
}
[edit interfaces]
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
      address 127.0.0.1/32;
    }
  }
}
```

In this example, the IP address **10.0.0.1** is the source address of every trap sent from this router.

Logical System Name as the Source Address To specify a logical system name as the source address of SNMP traps, include the **logical-system** *logical-system-name* statement at the **[edit snmp trap-options]** hierarchy level.

For example, the following configuration sets logical system name **ls1** as the source address of SNMP traps:

```
[edit snmp]
  trap-options {
    logical-system ls1;
  }
```

Routing Instance Name as the Source Address To specify a routing instance name as the source address of SNMP traps, include the **routing-instance** *routing-instance-name* statement at the **[edit snmp trap-options]** hierarchy level.

For example, the following configuration sets the routing instance name **ri1** as the source address for SNMP traps:

```
[edit snmp]
  trap-options {
    routing-instance ri1;
  }
```

Configuring the Agent Address for SNMP Traps

The agent address is only available in SNMPv1 trap packets (see RFC 1157). By default, the router's default local address is not specified in the agent address field of the SNMPv1 trap. To configure the agent address, include the **agent-address** statement at the **[edit snmp trap-options]** hierarchy level. Currently, the agent address can only be the address of the outgoing interface:

```
[edit snmp]
  trap-options {
    agent-address outgoing-interface;
  }
```

To configure the outgoing interface as the agent address:

```
[edit snmp]
  trap-options {
    agent-address outgoing-interface;
  }
  trap-group "urgent-dispatcher" {
    version v1;
    categories link startup;
    targets {
      192.168.10.22;
      172.17.1.2;
    }
  }
```

In this example, each SNMPv1 trap packet sent has its agent address value set to the IP address of the outgoing interface.

Adding snmpTrapEnterprise Object Identifier to Standard SNMP Traps

The **snmpTrapEnterprise** object helps you identify the enterprise that has defined the trap. Typically, the **snmpTrapEnterprise** object appears as the last varbind in enterprise-specific SNMP version 2 traps. However, starting Release 10.0, Junos OS enables you to add the **snmpTrapEnterprise** object identifier to standard SNMP traps as well.

To add **snmpTrapEnterprise** to standard traps, include the **enterprise-oid** statement at the **[edit snmp trap-options]** hierarchy level. If the **enterprise-oid** statement is not included in the configuration, **snmpTrapEnterprise** is added only for enterprise-specific traps.

```
[edit snmp]
trap-options {
  enterprise-oid;
}
```

Related Documentation

- [Configuring SNMP Trap Options and Groups on a Device Running Junos OS on page 1487](#)
- [Configuring SNMP Trap Groups on page 1491](#)
- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Configuring SNMP Trap Groups

You can create and name a group of one or more types of SNMP traps and then define which systems receive the group of SNMP traps. The trap group must be configured for SNMP traps to be sent. To create an SNMP trap group, include the **trap-group** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
trap-group group-name {
  categories {
    category;
  }
  destination-port port-number;
  routing-instance instance;
  targets {
    address;
  }
  version (all | v1 | v2);
}
```

The trap group name can be any string and is embedded in the community name field of the trap. To configure your own trap group port, include the **destination-port** statement. The default destination port is port 162.

For each trap group that you define, you must include the **target** statement to define at least one system as the recipient of the SNMP traps in the trap group. Specify the IPv4 or IPv6 address of each recipient, not its hostname.

Specify the types of traps the trap group can receive in the **categories** statement. For information about the category to which the traps belong, see the [“Standard SNMP Traps Supported on Devices Running Junos OS” on page 1456](#) and [“Juniper Networks Enterprise-Specific SNMP Traps” on page 1456](#) topics.

Specify the routing instance used by the trap group in the **routing-instance** statement. All targets configured in the trap group use this routing instance.

A trap group can receive the following categories:

- **authentication**—Authentication failures
- **chassis**—Chassis or environment notifications
- **configuration**—Configuration notifications
- **link**—Link-related notifications (up-down transitions, DS-3 and DS-1 line status change, IPv6 interface state change, and Passive Monitoring PIC overload)

NOTE: To send Passive Monitoring PIC overload interface traps, select the **link** trap category.

- **remote-operations**—Remote operation notifications
- **rmon-alarm**—Alarm for RMON events
- **routing**—Routing protocol notifications
- **sonet-alarms**—SONET/SDH alarms

NOTE: If you omit the SONET/SDH subcategories, all SONET/SDH trap alarm types are included in trap notifications.

- **loss-of-light**—Loss of light alarm notification
- **pll-lock**—PLL lock alarm notification
- **loss-of-frame**—Loss of frame alarm notification
- **loss-of-signal**—Loss of signal alarm notification
- **severely-errored-frame**—Severely errored frame alarm notification
- **line-ais**—Line alarm indication signal (AIS) alarm notification
- **path-ais**—Path AIS alarm notification
- **loss-of-pointer**—Loss of pointer alarm notification
- **ber-defect**—SONET/SDH bit error rate alarm defect notification
- **ber-fault**—SONET/SDH error rate alarm fault notification
- **line-remote-defect-indication**—Line remote defect indication alarm notification
- **path-remote-defect-indication**—Path remote defect indication alarm notification

- **remote-error-indication**—Remote error indication alarm notification
- **unequipped**—Unequipped alarm notification
- **path-mismatch**—Path mismatch alarm notification
- **loss-of-cell**—Loss of cell delineation alarm notification
- **vt-ais**—Virtual tributary (VT) AIS alarm notification
- **vt-loss-of-pointer**—VT loss of pointer alarm notification
- **vt-remote-defect-indication**—VT remote defect indication alarm notification
- **vt-unequipped**—VT unequipped alarm notification
- **vt-label-mismatch**—VT label mismatch error notification
- **vt-loss-of-cell**—VT loss of cell delineation notification
- **startup**—System warm and cold starts
- **timing-events**—Timing events and defects notification
- **vrp-events**—Virtual Router Redundancy Protocol (VRRP) events such as new-master or authentication failures
- **startup**—System warm and cold starts
- **vrp-events**—Virtual Router Redundancy Protocol (VRRP) events such as new-master or authentication failures

If you include SONET/SDH subcategories, only those SONET/SDH trap alarm types are included in trap notifications.

The **version** statement allows you to specify the SNMP version of the traps sent to targets of the trap group. If you specify **v1** only, SNMPv1 traps are sent. If you specify **v2** only, SNMPv2 traps are sent. If you specify **all**, both an SNMPv1 and an SNMPv2 trap are sent for every trap condition. For more information about the **version** statement, see [version \(SNMP\)](#).

- [Configuring SNMP Trap Options on page 1487](#)
- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)
- [Example: Configuring SNMP Trap Groups on page 1493](#)

Example: Configuring SNMP Trap Groups

Set up a trap notification list named **urgent-dispatcher** for link and startup traps. This list is used to identify the network management hosts (1.2.3.4 and fe80::1:2:3:4) to which traps generated by the local router should be sent. The name specified for a trap group is used as the SNMP community string when the agent sends traps to the listed targets.

[edit]

```
snmp {
  trap-group "urgent-dispatcher" {
    version v2;
    categories link startup;
    targets {
      1.2.3.4;
      fe80::1:2:3:4;
    }
  }
}
```

- Related Documentation**

 - [Configuring SNMP Trap Options on page 1487](#)

Configuring the Interfaces on Which SNMP Requests Can Be Accepted

By default, all router or switch interfaces have SNMP access privileges. To limit the access through certain interfaces only, include the **interface** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
interface [ interface-names ];
```

Specify the names of any logical or physical interfaces that should have SNMP access privileges. Any SNMP requests entering the router or switch from interfaces not listed are discarded.

- Related Documentation**
- [Configuring SNMP on a Device Running Junos OS](#)
 - [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)
 - [Example: Configuring Secured Access List Checking on page 1494](#)

Example: Configuring Secured Access List Checking

SNMP access privileges are granted to only devices on interfaces **so-0/0/0** and **at-1/0/1**. The following example does this by configuring a list of logical interfaces:

```
[edit]
snmp {
  interface [ so-0/0/0.0 so-0/0/0.1 at-1/0/1.0 at-1/0/1.1 ];
}
```

The following example grants the same access by configuring a list of physical interfaces:

```
[edit]
snmp {
  interface [ so-0/0/0 at-1/0/1 ];
}
```

- Related Documentation**
- [Configuring the Interfaces on Which SNMP Requests Can Be Accepted on page 1494](#)

- [Filtering Interface Information Out of SNMP Get and GetNext Output on page 1495](#)
- [Configuring SNMP on a Device Running Junos OS](#)
- [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Filtering Interface Information Out of SNMP Get and GetNext Output

Junos OS enables you to filter out information related to specific interfaces from the output of SNMP **Get** and **GetNext** requests performed on interface-related MIBs such as IF MIB, ATM MIB, RMON MIB, and the Juniper Networks enterprise-specific IF MIB.

You can use the following options of the **filter-interfaces** statement at the **[edit snmp]** hierarchy level to specify the interfaces that you want to exclude from SNMP **Get** and **GetNext** queries:

- **interfaces**—Interfaces that match the specified regular expressions.
- **all-internal-interfaces**—Internal interfaces.

```
[edit]
snmp {
  filter-interfaces {
    interfaces {
      interface-name 1;
      interface-name 2;
    }
    all-internal-interfaces;
  }
}
```

Starting with Release 12.1, Junos OS provides an except option (! operator) that enables you to filter out all interfaces except those interfaces that match all the regular expressions prefixed with the ! mark.

For example, to filter out all interfaces except the **ge** interfaces from the SNMP **get** and **get-next** results, enter the following command:

```
[edit snmp]
user@host# set filter-interfaces interfaces "!^~ge-.*"
user@host# commit
```

When this is configured, Junos OS filters out all interfaces except the **ge** interfaces from the SNMP **get** and **get-next** results.

NOTE: The ! mark is supported only as the first character of the regular expression. If it appears anywhere else in a regular expression, Junos OS considers the regular expression invalid, and returns an error.

However, note that these settings are limited to SNMP operations, and the users can continue to access information related to the interfaces (including those hidden using

the **filter-interfaces** options) using the appropriate Junos OS command-line interface (CLI) commands.

- Related Documentation**
- [Configuring the Interfaces on Which SNMP Requests Can Be Accepted on page 1494](#)

 - [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)

Configuring MIB Views

SNMPv3 defines the concept of MIB views in RFC 3415, *View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)*. MIB views provide an agent better control over who can access specific branches and objects within its MIB tree. A view consists of a name and a collection of SNMP object identifiers, which are either explicitly included or excluded. Once defined, a view is then assigned to an SNMPv3 group or SNMPv1/v2c community (or multiple communities), automatically masking which parts of the agent's MIB tree members of the group or community can (or cannot) access.

By default, an SNMP community grants read access and denies write access to all supported MIB objects (even communities configured as **authorization read-write**). To restrict or grant read or write access to a set of MIB objects, you must configure a MIB view and associate the view with a community.

To configure MIB views, include the **view** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
view view-name {
  oid object-identifier (include | exclude);
}
```

The **view** statement defines a MIB view and identifies a group of MIB objects. Each MIB object of a view has a common object identifier (OID) prefix. Each object identifier represents a subtree of the MIB object hierarchy. The subtree can be represented either by a sequence of dotted integers (such as **1.3.6.1.2.1.2**) or by its subtree name (such as **interfaces**). A configuration statement uses a view to specify a group of MIB objects on which to define access. You can also use a wildcard character asterisk (*) to include OIDs that match a particular pattern in the SNMP view. To enable a view, you must associate the view with a community.

NOTE: To remove an OID completely, use the **delete view all oid oid-number** command but omit the **include** parameter.

To associate MIB views with a community, include the **view** statement at the **[edit snmp community community-name]** hierarchy level:

```
[edit snmp community community-name]
view view-name;
```

For more information about the Ping MIB, see RFC 2925 and the *PING MIB* topic.

 - [Configuring SNMP on a Device Running Junos OS](#)
 - [Configuration Statements at the \[edit snmp\] Hierarchy Level on page 1464](#)
 - [Example: Ping Proxy MIB on page 1497](#)
 - [view \(Configuring a MIB View\) on page 2070](#)
 - [view \(Associating MIB View with a Community\)](#)
 - [oid on page 2060](#)

Example: Ping Proxy MIB

Restrict the **ping-mib** community to read and write access of the Ping MIB and **jnxpingMIB** only. Read or write access to any other MIB using this community is not allowed.

```
[edit snmp]
view ping-mib-view {
  oid 1.3.6.1.2.1.80 include; #pingMIB
  oid jnxPingMIB include; #jnxPingMIB
}
community ping-mib {
  authorization read-write;
  view ping-mib-view;
}
```

The following configuration prevents the **no-ping-mib** community from accessing Ping MIB and **jnxPingMIB** objects. However, this configuration does not prevent the **no-ping-mib** community from accessing any other MIB object that is supported on the device.

```
[edit snmp]
view no-ping-mib-view {
  oid 1.3.6.1.2.1.80 exclude; # deny access to pingMIB objects
  oid jnxPingMIB exclude; # deny access to jnxPingMIB objects
}
community no-ping-mib {
  authorization read-write;
  view ping-mib-view;
}
```

Complete SNMPv3 Configuration Statements

To configure SNMPv3, include the following statements at the `[edit snmp v3]` and `[edit snmp]` hierarchy levels:

```
[edit snmp]
engine-id {
  (local engine-id | use-mac-address | use-default-ip-address);
}
view view-name {
  oid object-identifier (include | exclude);
}

[edit snmp v3]
notify name {
  tag tag-name;
  type (trap | inform);
}
notify-filter profile-name {
  oid object-identifier (include | exclude);
}
snmp-community community-index {
  community-name community-name;
  security-name security-name;
  tag tag-name;
}
target-address target-address-name {
  address address;
  address-mask address-mask;
  logical-system logical-system;
  port port-number;
  retry-count number;
  routing-instance instance;
  tag-list tag-list;
  target-parameters target-parameters-name;
  timeout seconds;
}
target-parameters target-parameters-name {
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
usm {
  (local-engine | remote-engine engine-id) {
    user username {
      authentication-md5 {
        authentication-password authentication-password;
      }
      authentication-none;
      authentication-sha {
        authentication-password authentication-password;
      }
    }
  }
}
```

```

    }
    privacy-3des {
        privacy-password privacy-password;
    }
    privacy-aes128 {
        privacy-password privacy-password;
    }
    privacy-des {
        privacy-password privacy-password;
    }
    privacy-none;
}
}
}
vacm {
    access {
        group group-name {
            (default-context-prefix | context-prefix context-prefix){
                security-model (any | usm | v1 | v2c) {
                    security-level (authentication | none | privacy) {
                        notify-view view-name;
                        read-view view-name;
                        write-view view-name;
                    }
                }
            }
        }
    }
}
security-to-group {
    security-model (usm | v1 | v2c) {
        security-name security-name {
            group group-name;
        }
    }
}
}
}

```

Minimum SNMPv3 Configuration on a Device Running Junos OS

To configure the minimum requirements for SNMPv3, include the following statements at the `[edit snmp v3]` and `[edit snmp]` hierarchy levels:

NOTE: You must configure at least one view (notify, read, or write) at the `[edit snmp view-name]` hierarchy level.

```
[edit snmp]
view view-name {
  oid object-identifier (include | exclude);
}
[edit snmp v3]
notify name {
  tag tag-name;
}
notify-filter profile-name {
  oid object-identifier (include | exclude);
}
snmp-community community-index {
  security-name security-name;
}
target-address target-address-name {
  address address;
  target-parameters target-parameters-name;
}
target-parameters target-parameters-name {
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | v3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }
}
usm {
  local-engine {
    user username {
    }
  }
}
vacm {
  access {
    group group-name {
      (default-context-prefix | context-prefix context-prefix){
        security-model (any | usm | v1 | v2c) {
          security-level (authentication | none | privacy) {
            notify-view view-name;
            read-view view-name;
            write-view view-name;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}
security-to-group {
  security-model (usm | v1 | v2c) {
    security-name security-name {
      group group-name;
    }
  }
}
}
}

```

Example: SNMPv3 Configuration

Define an SNMPv3 configuration:

```

[edit snmp]
engine-id {
  use-mac-address;
}
view jnxAlarms {
  oid 1.3.6.1.4.1.2636.3.4 include;
}
view interfaces {
  oid 1.3.6.1.2.1.2 include;
}
view ping-mib {
  oid 1.3.6.1.2.1.80 include;
}
[edit snmp v3]
notify n1 {
  tag router1; # Identifies a set of target addresses
  type trap; # Defines type of notification
}
notify n2 {
  tag host1;
  type trap;
}
notify-filter nf1 {
  oid .1 include; # Defines which traps to send
} # In this case, includes all traps
notify-filter nf2 {

```

```

    oid 1.3.6.1.4.1 include; # Sends enterprise-specific traps only
  }
  notify-filter nf3 {
    oid 1.3.6.1.2.1.1.5 include; # Sends BGP traps only
  }
  snmp-community index1 {
    community-name "$9$JOZi.QF/AtOz3"; # SECRET-DATA
    security-name john; # Matches the security name at the target parameters
    tag host1; # Finds the addresses that are allowed to be used with
  }
  target-address ta1 { # Associates the target address with the group
    # san-francisco.
    address 10.1.1.1;
    address-mask 255.255.255.0; # Defines the range of addresses
    port 162;
    tag-list router1;
    target-parameters tp1; # Applies configured target parameters
  }
  target-address ta2 {
    address 10.1.1.2;
    address-mask 255.255.255.0;
    port 162;
    tag-list host1;
    target-parameters tp2;
  }
  target-address ta3 {
    address 10.1.1.3;
    address-mask 255.255.255.0;
    port 162;
    tag-list "router1 host1";
    target-parameters tp3;
  }
  target-parameters tp1 { # Defines the target parameters
    notify-filter nf1; # Specifies which notify filter to apply
    parameters {
      message-processing-model v1;
      security-model v1;
      security-level none;
      security-name john; # Matches the security name configured at the
    } # [edit snmp v3 snmp-community community-index hierarchy level.
  }
  target-parameters tp2 {
    notify-filter nf2;
    parameters {
      message-processing-model v1;
      security-model v1;
      security-level none;
      security-name john;
    }
  }
  target-parameters tp3 {
    notify-filter nf3;
    parameters {
      message-processing-model v1;
      security-model v1;
      security-level none;

```

```

        security-name john;
    }
}
usm {
    local-engine { #Defines authentication and encryption for SNMPv3 users
        user user1 {
            authentication-md5 {
                authentication-password authentication-password;
            }
            privacy-des {
                privacy-password privacy-password;
            }
        }
        user user2 {
            authentication-sha {
                authentication-password authentication-password;
            }
            privacy-none;
        }
        user user3 {
            authentication-none;
            privacy-none;
        }
        user user4 {
            authentication-sha {
                authentication-password authentication-password;
            }
            privacy-aes128 {
                privacy-password privacy-password;
            }
        }
        user user5 {
            authentication-sha {
                authentication-password authentication-password;
            }
            privacy-none;
        }
    }
}
vacm {
    access {
        group san-francisco { #Defines the access privileges for the group
            default-context-prefix { # called san-francisco
                security-model v1 {
                    security-level none {
                        notify-view ping-mib;
                        read-view interfaces;
                        write-view jnxAlarms;
                    }
                }
            }
        }
    }
}
security-to-group {
    security-model v1 {
        security-name john { # Assigns john to the security group

```

```

        group san-francisco; # called san-francisco
    }
    security-name bob {
        group new-york;
    }
    security-name elizabeth {
        group chicago;
    }
}
}
}

```

Configuring the Local Engine ID

By default, the local engine ID uses the default IP address of the router. The local engine ID is the administratively unique identifier for the SNMPv3 engine. This statement is optional. To configure the local engine ID, include the **engine-id** statement at the **[edit snmp]** hierarchy level:

```

[edit snmp]
engine-id {
    (local engine-id-suffix | use-default-ip-address | use-mac-address);
}

```

- **local engine-id-suffix**—The engine ID suffix is explicitly configured.
- **use-default-ip-address**—The engine ID suffix is generated from the default IP address.
- **use-mac-address**—The SNMP engine identifier is generated from the Media Access Control (MAC) address of the management interface on the router.

The local engine ID is defined as the administratively unique identifier of an SNMPv3 engine, and is used for identification, not for addressing. There are two parts of an engine ID: prefix and suffix. The prefix is formatted according to the specifications defined in RFC 3411, *An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks*. You can configure the suffix here.

NOTE: SNMPv3 authentication and encryption keys are generated based on the associated passwords and the engine ID. If you configure or change the engine ID, you must commit the new engine ID before you configure SNMPv3 users. Otherwise the keys generated from the configured passwords are based on the previous engine ID. For the engine ID, we recommend using the master IP address of the device if the device has multiple routing engines and has the master IP address configured. Alternatively, you can use the MAC address of the management port if the device has only one Routing Engine.

- Related Documentation**

 - [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)
 - [Example: SNMPv3 Configuration on page 1503](#)

Creating SNMPv3 Users

For each SNMPv3 user, you can specify the username, authentication type, authentication password, privacy type, and privacy password. After a user enters a password, a key based on the engine ID and password is generated and is written to the configuration file. After the generation of the key, the password is deleted from this configuration file.

NOTE: You can configure only one encryption type for each SNMPv3 user.

To create users, include the **user** statement at the **[edit snmp v3 usm local-engine]** hierarchy level:

```
[edit snmp v3 usm local-engine]
user username;
```

username is the name that identifies the SNMPv3 user.

To configure user authentication and encryption, include the following statements at the **[edit snmp v3 usm local-engine user username]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
authentication-md5 {
    authentication-password authentication-password;
}
authentication-sha {
    authentication-password authentication-password;
}
authentication-none;
privacy-aes128 {
    privacy-password privacy-password;
}
privacy-des {
    privacy-password privacy-password;
}
privacy-3des {
    privacy-password privacy-password;
}
privacy-none;
```

- Related Documentation**
- [Complete SNMPv3 Configuration Statements on page 1500](#)
 - [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)
 - [Example: Creating SNMPv3 Users on page 1508](#)
 - [Example: SNMPv3 Configuration on page 1503](#)

Example: Creating SNMPv3 Users

Define SNMPv3 users:

```
[edit]
snmp {
  v3 {
    usm {
      local-engine {
        user user1 {
          authentication-md5 {
            authentication-password authentication-password;
          }
          privacy-des {
            privacy-password password;
          }
        }
        user user2 {
          authentication-sha {
            authentication-password authentication-password;
          }
          privacy-none;
        }
        user user3 {
          authentication-none;
          privacy-none;
        }
        user user4 {
          authentication-md5 {
            authentication-password authentication-password;
          }
          privacy-des {
            privacy-password authentication-password;
          }
        }
        user user5 {
          authentication-sha {
            authentication-password authentication-password;
          }
          privacy-aes128 {
            privacy-password authentication-password;
          }
        }
      }
    }
  }
}
```

Related Documentation

- [Complete SNMPv3 Configuration Statements on page 1500](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)

Configuring the SNMPv3 Authentication Type

By default, in a Junos OS configuration the SNMPv3 authentication type is set to none.

This topic includes the following sections:

- [Configuring MD5 Authentication on page 1509](#)
- [Configuring SHA Authentication on page 1509](#)
- [Configuring No Authentication on page 1510](#)

Configuring MD5 Authentication

To configure the message digest algorithm (MD5) as the authentication type for an SNMPv3 user, include the **authentication-md5** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
authentication-md5 {  
    authentication-password authentication-password;  
}
```

authentication-password is the password used to generate the key used for authentication.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Configuring SHA Authentication

To configure the secure hash algorithm (SHA) as the authentication type for an SNMPv3 user, include the **authentication-sha** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
authentication-sha {  
    authentication-password authentication-password;  
}
```

authentication-password is the password used to generate the key used for authentication.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Configuring No Authentication

To configure no authentication for an SNMPv3 user, include the **authentication-none** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
authentication-none;
```

- [Complete SNMPv3 Configuration Statements on page 1500](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)

Configuring the SNMPv3 Encryption Type

By default, encryption is set to none.

NOTE: Before you configure encryption, you must configure MD5 or SHA authentication.

Before you configure the **privacy-des**, **privacy-3des** and **privacy-aes128** statements, you must install the **jcrypto** package, and either restart the SNMP process or reboot the router.

This topic includes the following sections:

- [Configuring the Advanced Encryption Standard Algorithm on page 1510](#)
- [Configuring the Data Encryption Algorithm on page 1511](#)
- [Configuring Triple DES on page 1511](#)
- [Configuring No Encryption on page 1511](#)

Configuring the Advanced Encryption Standard Algorithm

To configure the Advanced Encryption Standard (AES) algorithm for an SNMPv3 user, include the **privacy-aes128** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]  
privacy-aes128 {  
  privacy-password privacy-password;  
}
```

privacy-password is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Configuring the Data Encryption Algorithm

To configure the data encryption algorithm (DES) for an SNMPv3 user, include the **privacy-des** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
privacy-des {
  privacy-password privacy-password;
}
```

privacy-password is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Configuring Triple DES

To configure triple DES for an SNMPv3 user, include the **privacy-3des** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
privacy-3des {
  privacy-password privacy-password;
}
```

privacy-password is the password used to generate the key used for encryption.

SNMPv3 has special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Configuring No Encryption

To configure no encryption for an SNMPv3 user, include the **privacy-none** statement at the **[edit snmp v3 usm local-engine user *username*]** hierarchy level:

```
[edit snmp v3 usm local-engine user username]
privacy-none;
```

Defining Access Privileges for an SNMP Group

The SNMP version 3 (SNMPv3) uses the view-based access control model (VACM), which allows you to configure the access privileges granted to a group. Access is controlled by filtering the MIB objects available for a specific operation through a predefined view. You assign views to determine the objects that are visible for read, write, and notify operations for a particular group, using a particular context, a particular security model (v1, v2c, or usm), and particular security level (authenticated, privacy, or none). For information about how to configure views, see [“Configuring MIB Views” on page 1496](#).

You define user access to management information at the **[edit snmp v3 vacm]** hierarchy level. All access control within VACM operates on groups, which are collections of users as defined by USM, or community strings as defined in the SNMPv1 and SNMPv2c security models. The term **security-name** refers to these generic end users. The group to which a specific security name belongs is configured at the **[edit snmp v3 vacm security-to-group]** hierarchy level. That security name can be associated with a group defined at the **[edit snmp v3 vacm security-to-group]** hierarchy level. A group identifies a collection of SNMP users that share the same access policy. You then define the access privileges associated with a group at the **[edit snmp v3 vacm access]** hierarchy level. Access privileges are defined using views. For each group, you can apply different views depending on the SNMP operation; for example, read (**get**, **getNext**, or **getBulk**) write (**set**), notifications, the security level used (authentication, privacy, or none), and the security model (v1, v2c, or usm) used within an SNMP request.

You configure members of a group with the **security-name** statement. For v3 packets using USM, the security name is the same as the username. For SNMPv1 or SNMPv2c packets, the security name is determined based on the community string. Security names are specific to a security model. If you are also configuring VACM access policies for SNMPv1 or SNMPv2c packets, you must assign security names to groups for each security model (SNMPv1 or SNMPv2c) at the **[edit snmp v3 vacm security-to-group]** hierarchy level. You must also associate a security name with an SNMP community at the **[edit snmp v3 snmp-community community-index]** hierarchy level.

To configure the access privileges for an SNMP group, include statements at the **[edit snmp v3 vacm]** hierarchy level:

```
[edit snmp v3 vacm]
access {
  group group-name {
    (default-context-prefix | context-prefix context-prefix){
```

```

security-model (any | usm | v1 | v2c) {
  security-level (authentication | none | privacy) {
    notify-view view-name;
    read-view view-name;
    write-view view-name;
  }
}
}
}
}
security-to-group {
  security-model (usm | v1 | v2c) {
    security-name security-name {
      group group-name;
    }
  }
}
}

```

Related Documentation

- [Configuring the SNMPv3 Authentication Type on page 1509](#)

Configuring the Access Privileges Granted to a Group

This topic includes the following sections:

- [Configuring the Group on page 1513](#)
- [Configuring the Security Model on page 1514](#)
- [Configuring the Security Level on page 1514](#)
- [Associating MIB Views with an SNMP User Group on page 1514](#)

Configuring the Group

To configure the access privileges granted to a group, include the **group** statement at the **[edit snmp v3 vacm access]** hierarchy level:

```

[edit snmp v3 vacm access]
group group-name;

```

group-name is a collection of SNMP users that belong to a common SNMP list that defines an access policy. Users belonging to a particular SNMP group inherit all access privileges granted to that group.

Configuring the Security Model

To configure the security model, include the **security-model** statement at the **[edit snmp v3 vacm access group *group-name* (default-context-prefix | context-prefix *context-prefix*)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
context-prefix)]
security-model (any | usm | v1 | v2c);
```

- **any**—Any security model
- **usm**—SNMPv3 security model
- **v1**—SNMPv1 security model
- **v2c**—SNMPv2c security model

Configuring the Security Level

To configure the access privileges granted to packets with a particular security level, include the **security-level** statement at the **[edit snmp v3 vacm access group *group-name* (default-context-prefix | context-prefix *context-prefix*) security-model (any | usm | v1 | v2c)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name default-context-prefix security-model (any
| usm | v1 | v2c)]
security-level (authentication | none | privacy);
```

- **none**—Provides no authentication and no encryption.
- **authentication**—Provides authentication but no encryption.
- **privacy**—Provides authentication and encryption.

NOTE: Access privileges are granted to all packets with a security level equal to or greater than that configured. If you are configuring the SNMPv1 or SNMPv2c security model, use **none** as your security level. If you are configuring the SNMPv3 security model (USM), use the **authentication**, **none**, or **privacy** security level.

Associating MIB Views with an SNMP User Group

MIB views define access privileges for members of a group. Separate views can be applied for each SNMP operation (read, write, and notify) within each security model (usm, v1, and v2c) and each security level (authentication, none, and privacy) supported by SNMP.

To associate MIB views with an SNMP user group, include the following statements at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
  context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
  | privacy)]
  notify-view view-name;
  read-view view-name;
  write-view view-name;
```

NOTE: You must associate at least one view (notify, read, or write) at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level.

You must configure the MIB view at the `[edit snmp view view-name]` hierarchy level. For information about how to configure MIB views, see [“Configuring MIB Views” on page 1496](#).

This section describes the following topics related to this configuration:

- [Configuring the Notify View on page 1515](#)
- [Configuring the Read View on page 1515](#)
- [Configuring the Write View on page 1516](#)

Configuring the Notify View

To associate notify access with an SNMP user group, include the **notify-view** statement at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
  context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
  | privacy)]
  notify-view view-name;
```

view-name specifies the notify access, which is a list of notifications that can be sent to each user in an SNMP group. A view name cannot exceed 32 characters.

Configuring the Read View

To associate a read view with an SNMP group, include the **read-view** statement at the `[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]` hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
  context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
  | privacy)]
  read-view view-name;
```

view-name specifies read access for an SNMP user group. A view name cannot exceed 32 characters.

Configuring the Write View

To associate a write view with an SNMP user group, include the **write-view** statement at the **[edit snmp v3 vacm access group *group-name* (default-context-prefix | context-prefix *context-prefix*) security-model (any | usm | v1 | v2c) security-level (authentication | none | privacy)]** hierarchy level:

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix
context-prefix) security-model (any | usm | v1 | v2c) security-level (authentication | none
| privacy)]
write-view view-name;
```

view-name specifies write access for an SNMP user group. A view name cannot exceed 32 characters.

Related Documentation

- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)
- [Example: Configuring the Access Privileges Granted to a Group on page 1516](#)

Example: Configuring the Access Privileges Granted to a Group

Define access privileges:

```
[edit snmp v3]
access {
  group group1 {
    default-context-prefix {
      security-model usm {          #Define an SNMPv3 security model
        security-level privacy {
          notify-view nv1;
          read-view rv1;
          write-view wv1;
        }
      }
    }
  }
  context-prefix lr1/ri1 { # routing instance ri1 in logical system lr1
    security-model usm {
      security-level privacy {
        notify-view nv1;
        read-view rv1;
        write-view wv1;
      }
    }
  }
}
```

```

group group2 {
  default-context-prefix {
    security-model usm {      #Define an SNMPv3 security model
      security-level authentication {
        read-view rv2;
        write-view wv2;
      }
    }
  }
}
group group3 {
  default-context-prefix {
    security-model v1 {      #Define an SNMPv3 security model
      security-level none {
        read-view rv3;
        write-view wv3;
      }
    }
  }
}

```

Related Documentation

Assigning Security Model and Security Name to a Group

To assign security names to groups, include the following statements at the **[edit snmp v3 vacm security-to-group]** hierarchy level:

```

[edit snmp v3 vacm security-to-group]
security-model (usm | v1 | v2c) {
  security-name security-name {
    group group-name;
  }
}

```

This topic includes the following sections:

- [Configuring the Security Model on page 1517](#)
- [Assigning Security Names to Groups on page 1518](#)
- [Configuring the Group on page 1518](#)

Configuring the Security Model

To configure the security model, include the **security-model** statement at the **[edit snmp v3 vacm security-to-group]** hierarchy level:

```

[edit snmp v3 vacm security-to-group]
security-model (usm | v1 | v2c);

```

- **usm**—SNMPv3 security model

- **v1**—SNMPv1 security model
- **v2c**—SNMPv2 security model

Assigning Security Names to Groups

To associate a security name with an SNMPv3 user, or a v1 or v2 community string, include the **security-name** statement at the **[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c)]** hierarchy level:

```
[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c)]
  security-name security-name;
```

For SNMPv3, the **security-name** is the username configured at the **[edit snmp v3 usm local-engine user username]** hierarchy level. For SNMPv1 and SNMPv2c, the security name is the community string configured at the **[edit snmp v3 snmp-community community-index]** hierarchy level. For information about configuring usernames, see [“Creating SNMPv3 Users” on page 1507](#). For information about configuring a community string, see [“Configuring the SNMPv3 Community” on page 1536](#).

NOTE: The USM security name is separate from the SNMPv1 and SNMPv2c security name. If you support SNMPv1 and SNMPv2c in addition to SNMPv3, you must configure separate security names within the security-to-group configuration at the **[edit snmp v3 vacm access]** hierarchy level.

Configuring the Group

After you have created SNMPv3 users, or v1 or v2 security names, you associate them with a group. A group is a set of security names belonging to a particular security model. A group defines the access rights for all users belonging to it. Access rights define what SNMP objects can be read, written to, or created. A group also defines what notifications a user is allowed to receive.

If you already have a group that is configured with all of the view and access permissions that you want to give a user, you can add the user to that group. If you want to give a user view and access permissions that no other groups have, or if you do not have any groups configured, create a group and add the user to it.

To configure the access privileges granted to a group, include the **group** statement at the **[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c) security-name security-name]** hierarchy level:

```
[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c) security-name
  security-name]
  group group-name;
```

group-name identifies a collection of SNMP security names that share the same access policy. For more information about groups, see [“Defining Access Privileges for an SNMP Group” on page 1512](#).

Example: Security Group Configuration

Assign security names to groups:

```
vacm {
  security-to-group {
    security-model usm {
      security-name user1 {
        group group1;
      }
      security-name user2 {
        group group2;
      }
      security-name user3 {
        group group3;
      }
    }
  }
}
```

Related Documentation

- [Assigning Security Model and Security Name to a Group on page 1517](#)
- [Complete SNMPv3 Configuration Statements on page 1500](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)

Configuring SNMPv3 Traps on a Device Running Junos OS

In SNMPv3, you create traps and informs by configuring the **notify**, **target-address**, and **target-parameters** parameters. Traps are unconfirmed notifications, whereas informs are confirmed notifications. This section describes how to configure SNMP traps. For information about configuring SNMP informs, see [“Configuring SNMP Informs” on page 1529](#).

The target address defines a management application’s address and parameters to be used in sending notifications. Target parameters define the message processing and security parameters that are used in sending notifications to a particular management target. SNMPv3 also lets you define SNMPv1 and SNMPv2c traps.

NOTE: When you configure SNMP traps, make sure your configured access privileges allow the traps to be sent. Access privileges are configured at the `[edit snmp v3 vacm access]` and `[edit snmp v3 vacm security-to-group]` hierarchy levels.

To configure SNMP traps, include the following statements at the `[edit snmp v3]` hierarchy level:

```
[edit snmp v3]
  notify name {
    tag tag-name;
    type trap;
  }
```

```
notify-filter name {  
    oid object-identifier (include | exclude);  
}  
target-address target-address-name {  
    address address;  
    address-mask address-mask;  
    logical-system logical-system;  
    port port-number;  
    routing-instance instance;  
    tag-list tag-list;  
    target-parameters target-parameters-name;  
}  
target-parameters target-parameters-name {  
    notify-filter profile-name;  
    parameters {  
        message-processing-model (v1 | v2c | v3);  
        security-level (authentication | none | privacy);  
        security-model (usm | v1 | v2c);  
        security-name security-name;  
    }  
}
```

Configuring the SNMPv3 Trap Notification

The **notify** statement specifies the type of notification (trap) and contains a single tag. The tag defines a set of target addresses to receive a trap. The tag list contains one or more tags and is configured at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level. If the tag list contains this tag, Junos OS sends a notification to all the target addresses associated with this tag.

To configure the trap notifications, include the **notify** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]  
notify name {  
    tag tag-name;  
    type trap;  
}
```

name is the name assigned to the notification.

tag-name defines the target addresses to which this notification is sent. This notification is sent to all the target-addresses that have this tag in their tag list. The **tag-name** is not included in the notification.

trap is the type of notification.

NOTE: Each notify entry name must be unique.

Junos OS supports two types of notification: **trap** and **inform**.

For information about how to configure the tag list, see “Configuring the Trap Target Address” on page 1524.

Example: Configuring SNMPv3 Trap Notification

Specify three sets of destinations to send traps:

```
[edit snmp v3]
notify n1 {
  tag router1;
  type trap;
}
notify n2 {
  tag router2;
  type trap;
}
notify n3 {
  tag router3;
  type trap;
}
```

- [Complete SNMPv3 Configuration Statements on page 1500](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)

Configuring the Trap Notification Filter

SNMPv3 uses the notify filter to define which traps (or which objects from which traps) are sent to the network management system (NMS). The trap notification filter limits the type of traps that are sent to the NMS.

Each object identifier represents a subtree of the MIB object hierarchy. The subtree can be represented either by a sequence of dotted integers (such as **1.3.6.1.2.1.2**) or by its subtree name (such as **interfaces**). You can also use the wildcard character asterisk (*) in the object identifier (OID) to specify object identifiers that match a particular pattern.

To configure the trap notifications filter, include the **notify-filter** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
  notify-filter profile-name;
```

profile-name is the name assigned to the notify filter.

By default, the OID is set to **include**. To define access to traps (or objects from traps), include the **oid** statement at the **[edit snmp v3 notify-filter *profile-name*]** hierarchy level:

```
[edit snmp v3 notify-filter profile-name]
  oid oid (include | exclude);
```

oid is the object identifier. All MIB objects represented by this statement have the specified OID as a prefix. It can be specified either by a sequence of dotted integers or by a subtree name.

- **include**—Include the subtree of MIB objects represented by the specified OID.
- **exclude**—Exclude the subtree of MIB objects represented by the specified OID.

Configuring the Trap Target Address

The target address defines a management application's address and parameters that are used in sending notifications. It can also identify management stations that are allowed to use specific community strings. When you receive a packet with a recognized community string and a tag is associated with it, Junos OS looks up all the target addresses

with this tag and verifies that the source address of this packet matches one of the configured target addresses.

NOTE: You must configure the address mask when you configure the SNMP community.

To specify where you want the traps to be sent and define what SNMPv1 and SNMPv2cc packets are allowed, include the **target-address** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
  target-address target-address-name;
```

target-address-name is the string that identifies the target address.

To configure the target address properties, include the following statements at the **[edit snmp v3 target-address target-address-name]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  address address;
  address-mask address-mask;
  logical-system logical-system;
  port port-number;
  routing-instance instance;
  tag-list tag-list;
  target-parameters target-parameters-name;
```

This section includes the following topics:

- [Configuring the Address on page 1523](#)
- [Configuring the Address Mask on page 1523](#)
- [Configuring the Port on page 1524](#)
- [Configuring the Routing Instance on page 1524](#)
- [Configuring the Trap Target Address on page 1524](#)
- [Applying Target Parameters on page 1525](#)

Configuring the Address

To configure the address, include the **address** statement at the **[edit snmp v3 target-address target-address-name]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  address address;
```

address is the SNMP target address.

Configuring the Address Mask

The address mask specifies a set of addresses that are allowed to use a community string and verifies the source addresses for a group of target addresses.

To configure the address mask, include the **address-mask** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
  address-mask address-mask;
```

address-mask combined with the address defines a range of addresses. For information about how to configure the community string, see [“Configuring the SNMPv3 Community” on page 1536](#).

Configuring the Port

By default, the UDP port is set to 162. To configure a different port number, include the **port** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
  port port-number;
```

port-number is the SNMP target port number.

Configuring the Routing Instance

Traps are sent over the default routing instance. To configure the routing instance for sending traps, include the **routing-instance** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
  routing-instance instance;
```

instance is the name of the routing instance. To configure a routing instance within a logical system, specify the logical system name followed by the routing instance name. Use a slash (/) to separate the two names (for example, **test-lr/test-ri**). To configure the default routing instance on a logical system, specify the logical system name followed by **default** (for example, **test-lr/default**).

Configuring the Trap Target Address

Each **target-address** statement can have one or more tags configured in its tag list. Each tag can appear in more than one tag list. When a significant event occurs on the network device, the tag list identifies the targets to which a notification is sent.

To configure the tag list, include the **tag-list** statement at the **[edit snmp v3 target-address *target-address-name*]** hierarchy level:

```
[edit snmp v3 target-address target-address-name]  
  tag-list "tag-list";
```

tag-list specifies one or more tags as a space-separated list enclosed within double quotes.

For an example of tag list configuration, see [“Example: Configuring the Tag List” on page 1525](#).

For information about how to specify a tag at the **[edit snmp v3 notify *notify-name*]** hierarchy level, see [“Configuring the SNMPv3 Trap Notification” on page 1520](#).

NOTE: When you configure SNMP traps, make sure your configured access privileges allow the traps to be sent. Configure access privileges at the `[edit snmp v3 vacm access]` hierarchy level.

Applying Target Parameters

The `target-parameters` statement at the `[edit snmp v3]` hierarchy level applies the target parameters configured at the `[edit snmp v3 target-parameters target-parameters-name]` hierarchy level.

To reference configured target parameters, include the `target-parameters` statement at the `[edit snmp v3 target-address target-address-name]` hierarchy level:

```
[edit snmp v3 target-address target-address-name]
  target-parameters target-parameters-name;
```

target-parameters-name is the name associated with the message processing and security parameters that are used in sending notifications to a particular management target.

- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)
- [Example: Configuring the Tag List on page 1525](#)

Example: Configuring the Tag List

In the following example, two tag entries (**router1** and **router2**) are defined at the `[edit snmp v3 notify notify-name]` hierarchy level. When an event triggers a notification, Junos OS sends a trap to all target addresses that have **router1** or **router2** configured in their target-address tag list. This results in the first two targets getting one trap each, and the third target getting two traps.

```
[edit snmp v3]
  notify n1 {
    tag router1; # Identifies a set of target addresses
    type trap; # Defines the type of notification
  }
  notify n2 {
    tag router2;
    type trap;
  }
  target-address ta1 {
    address 10.1.1.1;
```

```

    address-mask 255.255.255.0;
    port 162;
    tag-list router1;
    target-parameters tp1;
  }
  target-address ta2 {
    address 10.1.1.2;
    address-mask 255.255.255.0;
    port 162;
    tag-list router2;
    target-parameters tp2;
  }
  target-address ta3 {
    address 10.1.1.3;
    address-mask 255.255.255.0;
    port 162;
    tag-list "router1 router2"; #Define multiple tags in the target address tag list
    target-parameters tp3;
  }

```

Defining and Configuring the Trap Target Parameters

Target parameters define the message processing and security parameters that are used in sending notifications to a particular management target.

To define a set of target parameters, include the **target-parameters** statement at the **[edit snmp v3]** hierarchy level:

```

[edit snmp v3]
  target-parameters target-parameters-name;

```

target-parameters-name is the name assigned to the target parameters.

To configure target parameter properties, include the following statements at the **[edit snmp v3 target-parameters target-parameter-name]** hierarchy level:

```

[edit snmp v3 target-parameters target-parameter-name]
  notify-filter profile-name;
  parameters {
    message-processing-model (v1 | v2c | V3);
    security-level (authentication | none | privacy);
    security-model (usm | v1 | v2c);
    security-name security-name;
  }

```

This topic includes the following sections:

- [Applying the Trap Notification Filter on page 1527](#)
- [Configuring the Target Parameters on page 1527](#)

Applying the Trap Notification Filter

To apply the trap notification filter, include the **notify-filter** statement at the **[edit snmp v3 target-parameters *target-parameter-name*]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name]  
  notify-filter profile-name;
```

profile-name is the name of a configured notify filter. For information about configuring notify filters, see “[Configuring the Trap Notification Filter](#)” on page 1522.

Configuring the Target Parameters

To configure target parameter properties, include the following statements at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]  
  message-processing-model (v1 | v2c | v3);  
  security-level (authentication | none | privacy);  
  security-model (usm | v1 | v2c);  
  security-name security-name;
```

This section includes the following topics:

- [Configuring the Message Processing Model on page 1527](#)
- [Configuring the Security Model on page 1528](#)
- [Configuring the Security Level on page 1528](#)
- [Configuring the Security Name on page 1528](#)

Configuring the Message Processing Model

The message processing model defines which version of SNMP to use when generating SNMP notifications. To configure the message processing model, include the **message-processing-model** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]  
  message-processing-model (v1 | v2c | v3);
```

- **v1**—SNMPv1 message processing model
- **v2c**—SNMPv2c message processing model
- **v3**—SNMPv3 message processing model

Configuring the Security Model

To define the security model to use when generating SNMP notifications, include the **security-model** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]
  security-model (usm | v1 | v2c);
```

- **usm**—SNMPv3 security model
- **v1**—SNMPv1 security model
- **v2c**—SNMPv2c security model

Configuring the Security Level

The **security-level** statement specifies whether the trap is authenticated and encrypted before it is sent.

To configure the security level to use when generating SNMP notifications, include the **security-level** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]
  security-level (authentication | none | privacy);
```

- **authentication**—Provides authentication but no encryption.
- **none**—No security. Provides no authentication and no encryption.
- **privacy**—Provides authentication and encryption.

NOTE: If you are configuring the SNMPv1 or SNMPv2c security model, use **none** as your security level. If you are configuring the SNMPv3 (USM) security model, use the **authentication** or **privacy** security level.

Configuring the Security Name

To configure the security name to use when generating SNMP notifications, include the **security-name** statement at the **[edit snmp v3 target-parameters *target-parameter-name* parameters]** hierarchy level:

```
[edit snmp v3 target-parameters target-parameter-name parameters]
  security-name security-name;
```

If the USM security model is used, the **security-name** identifies the user that is used when the notification is generated. If the v1 or v2c security models are used, **security-name** identifies the SNMP community used when the notification is generated.

NOTE: The access privileges for the group associated with a security name must allow this notification to be sent.

If you are using the v1 or v2 security models, the security name at the [edit snmp v3 vacm security-to-group] hierarchy level must match the security name at the [edit snmp v3 snmp-community *community-index*] hierarchy level.

- [Configuring SNMP Informs on page 1529](#)
- [Complete SNMPv3 Configuration Statements on page 1500](#)
- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)

Configuring SNMP Informs

Junos OS supports two types of notifications: traps and informs. With traps, the receiver does not send any acknowledgment when it receives a trap. Therefore, the sender cannot determine if the trap was received. A trap may be lost because a problem occurred during transmission. To increase reliability, an inform is similar to a trap except that the inform is stored and retransmitted at regular intervals until one of these conditions occurs:

- The receiver (target) of the inform returns an acknowledgment to the SNMP agent.
- A specified number of unsuccessful retransmissions have been attempted and the agent discards the inform message.

If the sender never receives a response, the inform can be sent again. Thus, informs are more likely to reach their intended destination than traps are. Informs use the same communications channel as traps (same socket and port) but have different protocol data unit (PDU) types.

Informs are more reliable than traps, but they consume more network, router, and switch resources (see [Figure 33](#)). Unlike a trap, an inform is held in memory until a response is received or the timeout is reached. Also, traps are sent only once, whereas an inform may be retried several times. Use informs when it is important that the SNMP manager receive all notifications. However, if you are more concerned about network traffic, or router and switch memory, use traps.

Figure 33: Inform Request and Response

For information about configuring SNMP traps, see [“Configuring SNMPv3 Traps on a Device Running Junos OS”](#) on page 1519.

Related Documentation

- [Configuring SNMPv3 Traps on a Device Running Junos OS](#) on page 1519

- [Complete SNMPv3 Configuration Statements](#) on page 1500
- [Minimum SNMPv3 Configuration on a Device Running Junos OS](#) on page 1502

Configuring the Remote Engine and Remote User

To send inform messages to an SNMPv3 user on a remote device, you must first specify the engine identifier for the SNMP agent on the remote device where the user resides. The remote engine ID is used to compute the security digest for authenticating and encrypting packets sent to a user on the remote host. When sending an inform message, the agent uses the credentials of the user configured on the remote engine (inform target).

To configure a remote engine and remote user to receive and respond to SNMP informs, include the following statements at the `[edit snmp v3]` hierarchy level:

```

[edit snmp v3]
usm {
  remote-engine engine-id {
    user username {
      authentication-md5 {
        authentication-key key;
      }
      authentication-none;
      authentication-sha {
        authentication-key key;
      }
      privacy-3des {
        privacy-key key;
      }
      privacy-aes128 {
        privacy-key key;
      }
      privacy-des {
        privacy-key key;
      }
    }
  }
}
  
```

```

        privacy-none;
    }
}

```

For informs, **remote-engine *engine-id*** is the identifier for the SNMP agent on the remote device where the user resides.

For informs, **user *username*** is the user on a remote SNMP engine who receives the informs.

Informs generated can be **unauthenticated**, **authenticated**, or **authenticated_and_encrypted**, depending on the security level of the SNMPv3 user configured on the remote engine (the inform receiver). The authentication key is used for generating message authentication code (MAC). The privacy key is used to encrypt the inform PDU part of the message.

- [Minimum SNMPv3 Configuration on a Device Running Junos OS on page 1502](#)
- [Example: Configuring the Remote Engine ID and Remote User on page 1531](#)

Example: Configuring the Remote Engine ID and Remote User

This example shows how to configure a remote engine and remote user so you can receive and respond to SNMP inform notifications. Inform notifications can be authenticated and encrypted. They are also more reliable than traps, another type of notification that Junos OS supports. Unlike traps, inform notifications are stored and retransmitted at regular intervals until one of these conditions occurs:

- The target of the inform notification returns an acknowledgment to the SNMP agent.
- A specified number of unsuccessful retransmissions have been attempted.
- [Requirements on page 1531](#)
- [Overview on page 1532](#)
- [Configuration on page 1532](#)
- [Verification on page 1533](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

This feature requires the use of plain-text passwords valid for SNMPv3. SNMPv3 has the following special requirements when you create plain-text passwords on a router or switch:

- The password must be at least eight characters long.
- The password can include alphabetic, numeric, and special characters, but it cannot include control characters.

Although quotation marks are not always required to enclose passwords, it is best to use them. You need quotation marks if the password contains any spaces or possibly in the case of certain special characters or punctuation.

Overview

Inform notifications are supported in SNMPv3 to increase reliability. For example, an SNMP agent receiving an inform notification acknowledges the receipt.

For inform notifications, the remote engine ID identifies the SNMP agent on the remote device where the user resides, and the username identifies the user on a remote SNMP engine who receives the inform notifications.

Consider a scenario in which you have the values in [Table 113](#) to use in configuring the remote engine ID and remote user in this example.

Table 113: Values to Use in Example

Name of Variable	Value
username	u10
remote engine ID	800007E5804089071BC6D10A41
authentication type	authentication-md5
authentication password	qol67R%?
encryption type	privacy-des
privacy password	m*72Jl9v

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands and paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste these commands into the CLI at the **[edit snmp v3]** hierarchy level, and then enter **commit** from configuration mode.

```
set usm remote-engine 800007E5804089071BC6D10A41 user u10 authentication-md5
authentication-key "qol67R%?"
set usm remote-engine 800007E5804089071BC6D10A41 user u10 privacy-des privacy-key
"m*72Jl9v"
```

Configuring the Remote Engine and Remote User

Step-by-Step Procedure The following example requires that you navigate to various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *Junos OS CLI User Guide*.

To configure the remote engine ID and remote user:

1. Configure the remote engine ID, username, and authentication type and password.

```
[edit snmp v3]
user@host# set usm remote-engine 800007E5804089071BC6D10A41 user u10
authentication-md5 authentication-key "qol67R%?"
```

2. Configure the encryption type and privacy password.

You can configure only one encryption type per SNMPv3 user.

```
[edit snmp v3]
user@host# set usm remote-engine 800007E5804089071BC6D10A41 user u10
privacy-des privacy-key "m*72Jl9v"
```

Results

In configuration mode, confirm your configuration by entering the **show** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit snmp v3]
user@ host# show
usm {
  remote-engine 800007E5804089071BC6D10A41 {
    user u10 {
      authentication-md5 {
        authentication-key "$9$Tz/teK8NdsLXk.f5n6p0ORev"; ## SECRET-DATA
      }
      privacy-des {
        privacy-key "$9$/gyNCu1KvWdwYMWw2gJHkRhcrWx"; ## SECRET-DATA
      }
    }
  }
}
```

After you have confirmed that the configuration is correct, enter **commit** from configuration mode.

Verification

Verifying the Configuration of the Remote Engine ID and Username

Purpose Verify the status of the engine ID and user information.

Action Display information about the SNMPv3 engine ID and user.

```
user@host> show snmp v3
Local engine ID: 80 00 0a 4c 01 0a ff 03 e3
Engine boots:      3
Engine time:       769187 seconds
Max msg size:      65507 bytes

Engine ID: 80 00 07 e5 80 40 89 07 1b c6 d1 0a 41
  User                               Auth/Priv  Storage  Status
  u10                               md5/des   nonvolatile active
```

Meaning The output displays the following information:

- Local engine ID and detail about the engine
- Remote engine ID (labeled **Engine ID**)
- Username
- Authentication type and encryption (privacy) type that is configured for the user
- Type of storage for the username, either nonvolatile (configuration saved) or volatile (not saved)
- Status of the new user; only users with an active status can use SNMPv3

- Related Documentation**

Configuring the Inform Notification Type and Target Address

To configure the inform notification type and target information, include the following statements at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
notify name {
  tag tag-name;
  type (trap | inform);
}
target-address target-address-name {
  address address;
  address-mask address-mask;
  logical-system logical-system;
  port port-number;
  retry-count number;
  routing-instance instance;
  tag-list tag-list;
  target-parameters target-parameters-name;
```

```

    timeout seconds;
  }
  target-parameters target-parameters-name {
    notify-filter profile-name;
    parameters {
      message-processing-model (v1 | v2c | v3);
      security-level (authentication | none | privacy);
      security-model (usm | v1 | v2c);
      security-name security-name;
    }
  }
}

```

notify *name* is the name assigned to the notification. Each notify entry name must be unique.

tag *tag-name* defines the target addresses that are sent this notification. The notification is sent to all target addresses that have this tag in their tag list. The **tag-name** is not included in the notification. For information about how to configure the tag list, see [“Configuring the Trap Target Address” on page 1524](#).

type *inform* is the type of notification.

target-address *target-address-name* identifies the target address. The target address defines a management application's address and parameters that are used to respond to informs.

timeout *seconds* is the number of seconds to wait for an acknowledgment. If no acknowledgment is received within the timeout period, the inform is retransmitted. The default timeout is **15** seconds.

retry-count *number* is the maximum number of times an inform is transmitted if no acknowledgment is received. The default is **3**. If no acknowledgment is received after the inform is transmitted the maximum number of times, the inform message is discarded.

message-processing-model defines which version of SNMP to use when SNMP notifications are generated. Informs require a **v3** message processing model.

security-model defines the security model to use when SNMP notifications are generated. Informs require a **usm** security model.

security-model defines the security model to use when SNMP notifications are generated. Informs require a **usm** security model.

security-level specifies whether the inform is authenticated and encrypted before it is sent. For the **usm** security model, the security level must be one of the following:

- **authentication**—Provides authentication but no encryption.
- **privacy**—Provides authentication and encryption.

security-name identifies the username that is used when generating the inform.

Example: Configuring the Inform Notification Type and Target Address

In the following example, target **172.17.20.184** is configured to respond to informs. The inform timeout is **30** seconds and the maximum retransmit count is **3**. The inform is sent to all targets in the **tl1** list. The security model for the remote user is **usm** and the remote engine username is **u10**.

```
[edit snmp v3]
  notify n1 {
    type inform;
    tag tl1;
  }
  notify-filter nf1 {
    oid .1.3 include;
  }
  target-address ta1 {
    address 172.17.20.184;
    retry-count 3;
    tag-list tl1;
    address-mask 255.255.255.0;
    target-parameters tp1;
    timeout 30;
  }
  target-parameters tp1 {
    parameters {
      message-processing-model v3;
      security-model usm;
      security-level privacy;
      security-name u10;
    }
    notify-filter nf1;
  }
```

Configuring the SNMPv3 Community

The SNMP community defines the relationship between an SNMP server system and the client systems. This statement is optional.

To configure the SNMP community, include the **snmp-community** statement at the **[edit snmp v3]** hierarchy level:

```
[edit snmp v3]
snmp-community community-index;
```

community-index is the index for the SNMP community.

To configure the SNMP community properties, include the following statements at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
community-name community-name;
context context-name;
security-name security-name;
tag tag-name;
```

This section includes the following topics:

- [Configuring the Community Name on page 1537](#)
- [Configuring the Context on page 1538](#)
- [Configuring the Security Names on page 1538](#)
- [Configuring the Tag on page 1538](#)

Configuring the Community Name

The community name defines the SNMP community. The SNMP community authorizes SNMPv1 or SNMPv2c clients. The access privileges associated with the configured security name define which MIB objects are available and the operations (read, write, or notify) allowed on those objects.

To configure the SNMP community name, include the **community-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
community-name community-name;
```

community-name is the community string for an SNMPv1 or SNMPv2c community.

If unconfigured, it is the same as the community index.

If the community name contains spaces, enclose it in quotation marks (" ").

NOTE: Community names must be unique. You cannot configure the same community name at the **[edit snmp community]** and **[edit snmp v3 snmp-community community-index]** hierarchy levels. The configured community name at the **[edit snmp v3 snmp-community community-index]** hierarchy level is encrypted. You cannot view the community name after you have configured it and committed your changes. In the command-line interface (CLI), the community name is concealed.

Configuring the Context

An SNMP context defines a collection of management information that is accessible to an SNMP entity. Typically, an SNMP entity has access to multiple contexts. A context can be a physical or logical system, a collection of multiple systems, or even a subset of a system. Each context in a management domain has a unique identifier.

To configure an SNMP context, include the **context context-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
context context-name;
```

NOTE: To query a routing instance or a logical system,

Configuring the Security Names

To assign a community string to a security name, include the **security-name** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
security-name security-name;
```

security-name is used when access control is set up. The **security-to-group** configuration at the **[edit snmp v3 vacm]** hierarchy level identifies the group.

NOTE: This security name must match the security name configured at the **[edit snmp v3 target-parameters target-parameters-name parameters]** hierarchy level when you configure traps.

Configuring the Tag

To configure the tag, include the **tag** statement at the **[edit snmp v3 snmp-community community-index]** hierarchy level:

```
[edit snmp v3 snmp-community community-index]
tag tag-name;
```

tag-name identifies the address of managers that are allowed to use a community string.

Example: Configuring an SNMPv3 Community

Define an SNMP community:

```
[edit snmp v3]
snmp-community index1 {
  community-name "$9$JOZl.QF/AtOz3"; # SECRET-DATA
  security-name john;
  tag router1; # Identifies managers that are allowed to use
  # a community string
  target-address ta1 {
    address 10.1.1.1;
    address-mask 255.255.255.0; # Defines the range of addresses
    port 162;
    tag-list router1;
    target-parameters tp1; # Applies configured target parameters
  }
}
```

- [Configuring Access Lists for SNMP Access over Routing Instances on page 1557](#)

Understanding SNMP Support for Routing Instances

Junos OS enables SNMP managers for all routing instances to request and manage SNMP data related to the corresponding routing instances and logical system networks.

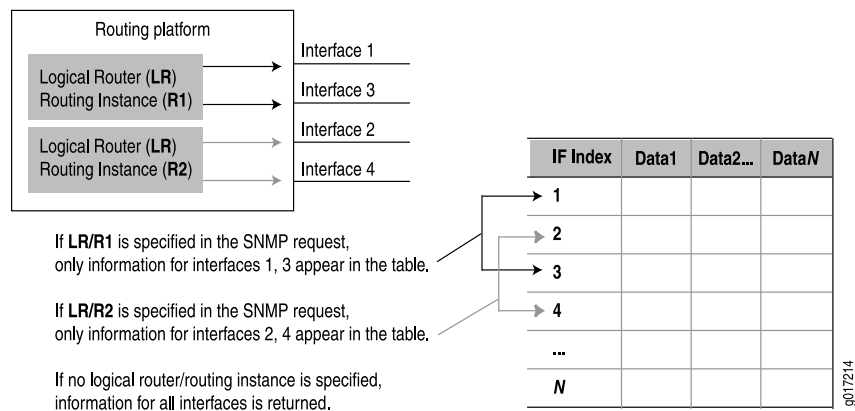

In Junos OS:

- Clients from routing instances other than the default can access MIB objects and perform SNMP operations only on the logical system networks to which they belong.
- Clients from the default routing instance can access information related to all routing instances and logical system networks.

Before Junos OS Release 8.4, only the SNMP manager in the default routing instance (**inet.0**) had access to the MIB objects

With the increase in virtual private network (VPN) service offerings, this feature is useful particularly for service providers who need to obtain SNMP data for specific routing instances (see [Figure 34](#)). Service providers can use this information for their own management needs or export the data for use by their customers.

Figure 34: SNMP Data for Routing Instances

If no routing instance is specified in the request, the SNMP agent operates as before:

- For nonrouting table objects, all instances are exposed.
- For routing table objects, only those associated with the default routing instance are exposed.

NOTE: The actual protocol data units (PDUs) are still exchanged over the default (inet.0) routing instance, but the data contents returned are dictated by the routing instance specified in the request PDUs.

SNMP MIBs Supported for Routing Instances

Table 114 shows enterprise-specific MIB objects supported by Junos OS and provides notes detailing how they are handled when a routing instance is specified in an SNMP request. An en dash (–) indicates that the item is not applicable.

Table 114: MIB Support for Routing Instances (Juniper Networks MIBs)

Object	Support Class	Description/Notes
jnxProducts(1)	–	Product Object IDs
jnxServices(2)	–	Services

Table 114: MIB Support for Routing Instances (Juniper Networks MIBs) (*continued*)

Object	Support Class	Description/Notes
jnxMibs(3) jnxBoxAnatomy(1)	Class 3	Objects are exposed only for the default logical system.
mpls(2)	Class 2	All instances within a logical system are exposed. Data will not be segregated down to the routing instance level.
ifJnx(3)	Class 1	Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.
jnxAlarms(4)	Class 3	Objects are exposed only for the default logical system.
jnxFirewalls(5)	Class 4	Data is not segregated by routing instance. All instances are exposed.
jnxDCUs(6)	Class 1	Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.
jnxPingMIB(7)	Class 3	Objects are exposed only for the default logical system.
jnxTraceRouteMIB(8)	Class 3	Objects are exposed only for the default logical system.
jnxATM(10)	Class 1	Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.
jnxIpv6(11)	Class 4	Data is not segregated by routing instance. All instances are exposed.
jnxIpv4(12)	Class 1	jnxIpv4AddrTable(1) . Only those logical interfaces (and their parent physical interfaces) that belong to a specific routing instance are exposed.
jnxRmon(13)	Class 3	jnxRmonAlarmTable(1) . Objects are exposed only for the default logical system.
jnxLdp(14)	Class 2	jnxLdpTrapVars(1) . All instances within a logical system are exposed. Data will not be segregated down to the routing instance level.

Support Classes for MIB Objects

When a routing instance is specified, all routing-related MIB objects return data maintained by the routing instance in the request. For all other MIB objects, the data returned is segregated according to that routing instance. For example, only those interfaces assigned to that routing instance (for example, the logical interfaces [ifls] as well as their corresponding physical interfaces [ifds]) are exposed by the SNMP agent. Similarly, objects with an unambiguous attachment to an interface (for example, **addresses**) are segregated as well.

For those objects where the attachment is ambiguous (for example, objects in **sysApplMIB**), no segregation is done and all instances are visible in all cases.

Another category of objects is visible only when no logical system is specified (only within the default logical system) regardless of the routing instance within the default logical system. Objects in this category are Chassis MIB objects, objects in the SNMP group,

RMON alarm, event and log groups, Ping MIB objects, configuration management objects, and V3 objects.

In summary, to support routing instances, MIB objects fall into one of the following categories:

- Class 1—Data is segregated according to the routing instance in the request. This is the most granular of the segregation classes.
- Class 2—Data is segregated according to the logical system specified in the request. The same data is returned for all routing instances that belong to a particular logical system. Typically, this applies to routing table objects where it is difficult to extract routing instance information or where routing instances do not apply.
- Class 3—Data is exposed only for the default logical system. The same set of data is returned for all routing instances that belong to the default logical system. If you specify another logical system (not the default), no data is returned. Typically this class applies to objects implemented in subagents that do not monitor logical system changes and register their objects using only the default context (for example, Chassis MIB objects).
- Class 4—Data is not segregated by routing instance. The same data is returned for all routing instances. Typically, this applies to objects implemented in subagents that monitor logical system changes and register or deregister all their objects for each logical system change. Objects whose values cannot be segregated by routing instance fall into this class.

See “[SNMP MIBs Supported for Routing Instances](#)” on page 1542 for a list of the objects associated with each class.

SNMP Traps Supported for Routing Instances

You can restrict the trap receivers from receiving traps that are not related to the logical system networks to which they belong. To do this, include the **logical-system-trap-filter** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]  
logical-system-trap-filter;
```

If the **logical-system-trap-filter** statement is not included in the SNMP configuration, all traps are forwarded to the configured routing instance destinations. However, even when this statement is configured, the trap receiver associated with the default routing instance will receive all SNMP traps.

When configured under the trap-group object, all v1 and v2c traps that apply to routing instances (or interfaces belonging to a routing instance) have the routing instance name encoded in the community string. The encoding is identical to that used in request PDUs.

For traps configured under the v3 framework, the routing instance name is carried in the context field when the v3 message processing model has been configured. For other

message processing models (v1 or v2c), the routing instance name is not carried in the trap message header (and not encoded in the community string).

- [Support Classes for MIB Objects on page 1552](#)
- [SNMP MIBs Supported for Routing Instances on page 1542](#)

Identifying a Routing Instance

With this feature, routing instances are identified by either the context field in v3 requests or encoded in the community string in v1 or v2c requests.

When encoded in a community string, the routing instance name appears first and is separated from the actual community string by the @ character.

To avoid conflicts with valid community strings that contain the @ character, the community is parsed only if typical community string processing fails. For example, if a routing instance named **RI** is configured, an SNMP request with **RI@public** is processed within the context of the **RI** routing instance. Access control (views, source address restrictions, access privileges, and so on) is applied according to the actual community string (the set of data after the @ character—in this case **public**). However, if the community string **RI@public** is configured, the protocol data unit (PDU) is processed according to that community and the embedded routing instance name is ignored.

Logical systems perform a subset of the actions of a physical router and have their own unique routing tables, interfaces, policies, and routing instances. When a routing instance is defined within a logical system, the logical system name must be encoded along with the routing instance using a slash (/) to separate the two. For example, if the routing instance **RI** is configured within the logical system **LS**, that routing instance must be encoded within a community string as **LS/RI@public**. When a routing instance is configured outside a logical system (within the default logical system), no logical system name (or / character) is needed.

Also, when a logical system is created, a default routing instance (named **default**) is always created within the logical system. This name should be used when querying data for that routing instance (for example, **LS/default@public**). For v3 requests, the name **logical system/routing instance** should be identified directly in the context field.

NOTE: To identify a virtual LAN (VLAN) spanning-tree instance (VSTP on MX Series 3D Universal Edge Routers), specify the routing instance name followed by a double colon (::) and the VLAN ID. For example, to identify VSTP instance for VLAN 10 in the global default routing instance, include **default::10@public** in the context (SNMPv3) or community (SNMPv1 or v2) string.

Related Documentation

- [Enabling SNMP Access over Routing Instances on page 1555](#)
- [Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community on page 1555](#)

Enabling SNMP Access over Routing Instances

To enable SNMP managers in routing instances other than the default routing instance to access SNMP information, include the **routing-instance-access** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
routing-instance-access;
```

If this statement is not included in the SNMP configuration, SNMP managers from routing instances other than the default routing instance cannot access SNMP information.

Related Documentation

- [Identifying a Routing Instance on page 1554](#)
- [Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community on page 1555](#)
- [Configuring Access Lists for SNMP Access over Routing Instances on page 1557](#)

Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community

You can specify the routing instance along with the client information when you add a client to an SNMP community. To specify the routing instance to which a client belongs, include the **routing-instance** statement followed by the routing instance name and client information in the SNMP configuration.

The following example shows the configuration statement to add routing instance **test-ri** to SNMP community **community1**.

NOTE: Routing instances specified at the **[edit snmp community community-name]** hierarchy level are added to the default logical system in the community.

```
[edit snmp]
community community1 {
  clients {
    10.209.152.33/32;
  }
  routing-instance test-ri {
    clients {
      10.19.19.1/32;
    }
  }
}
```

If the routing instance is defined within a logical system, include the **routing-instance** statement at the **[edit snmp community *community-name* logical-system *logical-system-name*]** hierarchy level, as in the following example:

```
[edit snmp]
community community1 {
  clients {
    10.209.152.33/32;
  }
  logical-system test-LS {
    routing-instance test-ri {
      clients {
        10.19.19.1/32;
      }
    }
  }
}
```

- [Example: Configuring Interface Settings for a Routing Instance on page 1556](#)

Example: Configuring Interface Settings for a Routing Instance

This example shows an **802.3ad ae0** interface configuration allocated to a routing instance named **INFrtid**:

```
[edit chassis]
aggregated-devices {
  ethernet {
    device-count 5;
  }
}
[edit interfaces ae0]
vlan-tagging;
aggregated-ether-options {
  minimum-links 2;
  link-speed 100m;
}
unit 0 {
  vlan-id 100;
  family inet {
    address 10.1.0.1/24;
  }
}
[edit interfaces fe-1/1/0]
fastether-options {
  802.3ad ae0;
}
[edit interfaces fe-1/1/1]
```

```

fastether-options {
  802.3ad ae0;
}
[edit routing-instances]
INFrt {
  instance-type virtual-router;
  interface fe-1/1/0.0;
  interface fe-1/1/1.0;
  interface fe-1/1/5.0;
  interface ae0.0;
  protocols {
    ospf {
      area 0.0.0.0 {
        interface all;
      }
    }
  }
}

```

The following **snmpwalk** command shows how to retrieve SNMP-related information from **router1** and the 802.3ae bundle interface belonging to routing instance **INFrt** with the SNMP community **public**:

```

router# snmpwalk -Os router1 INFrt@public dot3adAggTable
dot3adAggMACAddress.59 = 0:90:69:92:93:f0
dot3adAggMACAddress.65 = 0:90:69:92:93:f0
dot3adAggActorSystemPriority.59 = 0
dot3adAggActorSystemPriority.65 = 0
dot3adAggActorSystemID.59 = 0:0:0:0:0:0
dot3adAggActorSystemID.65 = 0:0:0:0:0:0
dot3adAggAggregateOrIndividual.59 = true(1)
dot3adAggAggregateOrIndividual.65 = true(1)
dot3adAggActorAdminKey.59 = 0
dot3adAggActorAdminKey.65 = 0
dot3adAggActorOperKey.59 = 0

Configuring Access Lists for SNMP Access over Routing Instances

You can create and maintain access lists to manage access to SNMP information. Access list configuration enables you to allow or deny SNMP access to clients of a specific routing instance.

The following example shows how to create an access list:

```
[edit snmp]
routing-instance-access {
  access-list {
    ri1 restrict;
    ls1/default;
    ls1/ri2;
    ls1*;
  }
}
```

The configuration given in the example:

- Restricts clients in **ri1** from accessing SNMP information.
- Allows clients in **ls1/default**, **ls1/ri2**, and all other routing instances with names starting with **ls1** to access SNMP information.

You can use the wildcard character (*) to represent a string in the routing instance name.

NOTE: You cannot restrict the SNMP manager of the default routing instance from accessing SNMP information.

SNMP Remote Operations Overview

A SNMP remote operation is any process on the router that can be controlled remotely using SNMP. Junos OS currently provides support for two SNMP remote operations: the Ping MIB and Traceroute MIB, defined in RFC 2925. Using these MIBs, an SNMP client in the network management system (NMS) can:

- Start a series of operations on a router
- Receive notification when the operations are complete
- Gather the results of each operation

Junos OS also provides extended functionality to these MIBs in the Juniper Networks enterprise-specific extensions **jnxPingMIB** and **jnxTraceRouteMIB**. For more information about **jnxPingMIB** and **jnxTraceRouteMIB**, see *PING MIB* and *Traceroute MIB*.

This topic covers the following sections:

- [SNMP Remote Operation Requirements on page 1560](#)
- [Setting SNMP Views on page 1560](#)
- [Setting Trap Notification for Remote Operations on page 1561](#)
- [Using Variable-Length String Indexes on page 1561](#)
- [Enabling Logging on page 1562](#)

SNMP Remote Operation Requirements

To use SNMP remote operations, you should be experienced with SNMP conventions. You must also configure Junos OS to allow the use of the remote operation MIBs.

Setting SNMP Views

All remote operation MIBs supported by Junos OS require that the SNMP clients have read-write privileges. The default SNMP configuration of Junos OS does not provide clients with a community string with such privileges.

To set read-write privileges for an SNMP community string, include the following statements at the **[edit snmp]** hierarchy level:

```
[edit snmp]
community community-name {
  authorization authorization;
  view view-name;
}
view view-name {
  oid object-identifier (include | exclude);
}
```

Example: Setting SNMP Views

To create a community named **remote-community** that grants SNMP clients read-write access to the Ping MIB, **jnxPing** MIB, Traceroute MIB, and **jnxTraceRoute** MIB, include the following statements at the **[edit snmp]** hierarchy level:

```
snmp {
  view remote-view {
    oid 1.3.6.1.2.1.80 include; # pingMIB
    oid 1.3.6.1.4.1.2636.3.7 include; # jnxPingMIB
    oid 1.3.6.1.2.1.81 include; # traceRouteMIB
    oid 1.3.6.1.4.1.2636.3.8 include; # jnxTraceRouteMIB
  }
  community remote-community {
    view remote-view;
    authorization read-write;
  }
}
```

For more information about the **community** statement, see [“Configuring SNMP Communities” on page 1479](#) and [community \(SNMP\)](#).

For more information about the **view** statement, see [“Configuring MIB Views” on page 1496](#), [view \(Associating a MIB View with a Community\)](#), and [view \(Configuring a MIB View\)](#).

Setting Trap Notification for Remote Operations

In addition to configuring the remote operations MIB for trap notification, you must also configure Junos OS. You must specify a target host for remote operations traps.

To configure trap notification for SNMP remote operations, include the **categories** and **targets** statements at the **[edit snmp trap-group group-name]** hierarchy level:

```
[edit snmp trap-group group-name]
  categories {
    category;
  }
  targets {
    address;
  }
}
```

Example: Setting Trap Notification for Remote Operations

Specify 172.17.12.213 as a target host for all remote operation traps:

```
snmp {
  trap-group remote-traps {
    categories remote-operations;
    targets {
      172.17.12.213;
    }
  }
}
```

For more information about trap groups, see [“Configuring SNMP Trap Groups” on page 1491](#).

Using Variable-Length String Indexes

All tabular objects in the remote operations MIBs supported by Junos OS are indexed by two variables of type **SnmpAdminString**. For more information about **SnmpAdminString**, see RFC 2571.

Junos OS does not handle **SnmpAdminString** any differently from the octet string variable type. However, the indexes are defined as variable length. When a variable length string is used as an index, the length of the string must be included as part of the object identifier (OID).

Example: Set Variable-Length String Indexes

To reference the **pingCtlTargetAddress** variable of a row in **pingCtlTable** where **pingCtlOwnerIndex** is **bob** and **pingCtlTestName** is **test**, use the following object identifier (OID):

```
pingMIB.pingObjects.pingCtlTable.pingCtlEntry.pingCtlTargetAddress."bob"."test"
1.3.6.1.2.1.80.1.2.1.4.3.98.111.98.4.116.101.115.116
```

For more information about the definition of the Ping MIB, see RFC 2925.

Enabling Logging

The SNMP error code returned in response to SNMP requests can only provide a generic description of the problem. The error descriptions logged by the remote operations process can often provide more detailed information about the problem and help you to solve the problem faster. This logging is not enabled by default. To enable logging, include the **flag general** statement at the **[edit snmp traceoptions]** hierarchy level:

```
[edit]
snmp {
  traceoptions {
    flag general;
  }
}
```

For more information about traceoptions, see “Tracing SNMP Activity on a Device Running Junos OS” on page 1585.

If the remote operations process receives an SNMP request that it cannot accommodate, the error is logged in the **/var/log/rmopd** file. To monitor this log file, issue the **monitor start rmopd** command in operational mode of the command-line interface (CLI).

 - [Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS on page 1569](#)

Using the Ping MIB for Remote Monitoring Devices Running Junos OS

A ping test is used to determine whether packets sent from the local host reach the designated host and are returned. If the designated host can be reached, the ping test provides the approximate round-trip time for the packets. Ping test results are stored in **pingResultsTable** and **pingProbeHistoryTable**.

RFC 2925 is the authoritative description of the Ping MIB in detail and provides the ASN.1 MIB definition of the Ping MIB.

- Related Documentation**
- [SNMP Remote Operations Overview on page 1559](#)
 - [Starting a Ping Test on page 1562](#)
 - [Monitoring a Running Ping Test on page 1564](#)
 - [Gathering Ping Test Results on page 1567](#)
 - [Stopping a Ping Test on page 1568](#)
 - [Interpreting Ping Variables on page 1568](#)

Starting a Ping Test

Before you start a ping test, configure a Ping MIB view. This allows SNMP **Set** requests on **pingMIB**. To start a ping test, create a row in **pingCtlTable** and set **pingCtlAdminStatus**

to **enabled**. The minimum information that must be specified before setting **pingCtlAdminStatus** to **enabled** is:

- **pingCtlOwnerIndexSnmpAdminString**
- **pingCtlTestNameSnmpAdminString**
- **pingCtlTargetAddressInetAddress**
- **pingCtlTargetAddressTypeInetAddressType**
- **pingCtlRowStatusRowStatus**

For all other values, defaults are chosen unless otherwise specified. **pingCtlOwnerIndex** and **pingCtlTestName** are used as the index, so their values are specified as part of the object identifier (OID). To create a row, set **pingCtlRowStatus** to **createAndWait** or **createAndGo** on a row that does not already exist. A value of **active** for **pingCtlRowStatus** indicates that all necessary information has been supplied and the test can begin; **pingCtlAdminStatus** can be set to **enabled**. An SNMP **Set** request that sets **pingCtlRowStatus** to **active** will fail if the necessary information in the row is not specified or is inconsistent. For information about how to configure a view, see [“Setting SNMP Views” on page 1560](#).

There are two ways to start a ping test:

- [Using Multiple Set Protocol Data Units \(PDUs\) on page 1563](#)
- [Using a Single Set PDU on page 1563](#)

Using Multiple Set Protocol Data Units (PDUs)

You can use multiple **Set** request PDUs (multiple PDUs, with one or more varbinds each) and set the following variables in this order to start the test:

- **pingCtlRowStatus** to **createAndWait**
- All appropriate test variables
- **pingCtlRowStatus** to **active**

Junos OS now verifies that all necessary information to run a test has been specified.

- **pingCtlAdminStatus** to **enabled**

Using a Single Set PDU

You can use a single **Set** request PDU (one PDU, with multiple varbinds) to set the following variables to start the test:

- **pingCtlRowStatus** to **createAndGo**
- All appropriate test variables
- **pingCtlAdminStatus** to **enabled**

Monitoring a Running Ping Test

When **pingCtlAdminStatus** is successfully set to **enabled**, the following is done before the acknowledgment of the SNMP **Set** request is sent back to the client:

- **pingResultsEntry** is created if it does not already exist.
- **pingResultsOperStatus** transitions to **enabled**.

For more information, see the following sections:

- [pingResultsTable on page 1564](#)
- [pingProbeHistoryTable on page 1565](#)
- [Generating Traps on page 1566](#)

pingResultsTable

While the test is running, **pingResultsEntry** keeps track of the status of the test. The value of **pingResultsOperStatus** is **enabled** while the test is running and **disabled** when it has stopped.

The value of **pingCtlAdminStatus** remains **enabled** until you set it to **disabled**. Thus, to get the status of the test, you must examine **pingResultsOperStatus**.

The **pingCtlFrequency** variable can be used to schedule many tests for one **pingCtlEntry**. After a test ends normally (you did not stop the test) and the **pingCtlFrequency** number of seconds has elapsed, the test is started again just as if you had set **pingCtlAdminStatus** to **enabled**. If you intervene at any time between repeated tests (you set **pingCtlAdminStatus** to **disabled** or **pingCtlRowStatus** to **notInService**), the repeat feature is disabled until another test is started and ends normally. A value of 0 for **pingCtlFrequency** indicates this repeat feature is not active.

pingResultsIpTgtAddr and **pingResultsIpTgtAddrType** are set to the value of the resolved destination address when the value of **pingCtlTargetAddressType** is **dns**. When a test starts successfully and **pingResultsOperStatus** transitions to **enabled**:

- **pingResultsIpTgtAddr** is set to **null-string**.
- **pingResultsIpTgtAddrType** is set to **unknown**.

pingResultsIpTgtAddr and **pingResultsIpTgtAddrType** are not set until **pingCtlTargetAddress** can be resolved to a numeric address. To retrieve these values, poll **pingResultsIpTgtAddrType** for any value other than **unknown** after successfully setting **pingCtlAdminStatus** to **enabled**.

At the start of a test, **pingResultsSentProbes** is initialized to 1 and the first probe is sent. **pingResultsSentProbes** increases by 1 each time a probe is sent.

As the test runs, every **pingCtlTimeOut** seconds, the following occur:

- **pingProbeHistoryStatus** for the corresponding **pingProbeHistoryEntry** in **pingProbeHistoryTable** is set to **requestTimedOut**.

- A **pingProbeFailed** trap is generated, if necessary.
- An attempt is made to send the next probe.

NOTE: No more than one outstanding probe exists for each test.

For every probe, you can receive one of the following results:

- The target host acknowledges the probe with a response.
- The probe times out; there is no response from the target host acknowledging the probe.
- The probe could not be sent.

Each probe result is recorded in **pingProbeHistoryTable**. For more information about **pingProbeHistoryTable**, see "[pingProbeHistoryTable](#)" on page 1565.

When a response is received from the target host acknowledging the current probe:

- **pingResultsProbeResponses** increases by 1.
- The following variables are updated:
 - **pingResultsMinRtt**—Minimum round-trip time
 - **pingResultsMaxRtt**—Maximum round-trip time
 - **pingResultsAverageRtt**—Average round-trip time
 - **pingResultsRttSumOfSquares**—Sum of squares of round-trip times
 - **pingResultsLastGoodProbe**—Timestamp of the last response

NOTE: Only probes that result in a response from the target host contribute to the calculation of the round-trip time (RTT) variables.

When a response to the last probe is received or the last probe has timed out, the test is complete.

pingProbeHistoryTable

An entry in **pingProbeHistoryTable** (**pingProbeHistoryEntry**) represents a probe result and is indexed by three variables:

- The first two variables, **pingCtlOwnerIndex** and **pingCtlTestName**, are the same ones used for **pingCtlTable**, which identifies the test.
- The third variable, **pingProbeHistoryIndex**, is a counter to uniquely identify each probe result.

The maximum number of **pingProbeHistoryTable** entries created for a given test is limited by **pingCtlMaxRows**. If **pingCtlMaxRows** is set to 0, no **pingProbeHistoryTable** entries are created for that test.

Each time a probe result is determined, a **pingProbeHistoryEntry** is created and added to **pingProbeHistoryTable**. **pingProbeHistoryIndex** of the new **pingProbeHistoryEntry** is 1 greater than the last **pingProbeHistoryEntry** added to **pingProbeHistoryTable** for that test. **pingProbeHistoryIndex** is set to 1 if this is the first entry in the table. The same test can be run multiple times, so this index keeps growing.

If **pingProbeHistoryIndex** of the last **pingProbeHistoryEntry** added is 0xFFFFFFFF, the next **pingProbeHistoryEntry** added has **pingProbeHistoryIndex** set to 1.

The following are recorded for each probe result:

- **pingProbeHistoryResponse**—Time to live (TTL)
- **pingProbeHistoryStatus**—What happened and why
- **pingProbeHistoryLastRC**—Return code (RC) value of ICMP packet
- **pingProbeHistoryTime**—Timestamp when probe result was determined

When a probe cannot be sent, **pingProbeHistoryResponse** is set to 0. When a probe times out, **pingProbeHistoryResponse** is set to the difference between the time when the probe was discovered to be timed out and the time when the probe was sent.

Generating Traps

For any trap to be generated, the appropriate bit of **pingCtlTrapGeneration** must be set. You must also configure a trap group to receive remote operations. A trap is generated under the following conditions:

- A **pingProbeFailed** trap is generated every time **pingCtlTrapProbeFailureFilter** number of consecutive probes fail during the test.
- A **pingTestFailed** trap is generated when the test completes and at least **pingCtlTrapTestFailureFilter** number of probes fail.
- A **pingTestCompleted** trap is generated when the test completes and fewer than **pingCtlTrapTestFailureFilter** probes fail.

NOTE: A probe is considered a failure when **pingProbeHistoryStatus** of the probe result is anything besides **responseReceived**.

For information about how to configure a trap group to receive remote operations, see [“Configuring SNMP Trap Groups” on page 1491](#) and [“Example: Setting Trap Notification for Remote Operations” on page 1561](#).

Gathering Ping Test Results

You can either poll **pingResultsOperStatus** to find out when the test is complete or request that a trap be sent when the test is complete. For more information about **pingResultsOperStatus**, see “[pingResultsTable](#)” on page 1564. For more information about Ping MIB traps, see “[Generating Traps](#)” on page 1566.

The statistics calculated and then stored in **pingResultsTable** include:

- **pingResultsMinRtt**—Minimum round-trip time
- **pingResultsMaxRtt**—Maximum round-trip time
- **pingResultsAverageRtt**—Average round-trip time
- **pingResultsProbeResponses**—Number of responses received
- **pingResultsSentProbes**—Number of attempts to send probes
- **pingResultsRttSumOfSquares**—Sum of squares of round-trip times
- **pingResultsLastGoodProbe**—Timestamp of the last response

You can also consult **pingProbeHistoryTable** for more detailed information about each probe. The index used for **pingProbeHistoryTable** starts at 1, goes to 0xFFFFFFFF, and wraps to 1 again.

For example, if **pingCtlProbeCount** is 15 and **pingCtlMaxRows** is 5, then upon completion of the first run of this test, **pingProbeHistoryTable** contains probes like those in [Table 119](#).

Table 119: Results in pingProbeHistoryTable: After the First Ping Test

pingProbeHistoryIndex	Probe Result
11	Result of 11th probe from run 1
12	Result of 12th probe from run 1
13	Result of 13th probe from run 1
14	Result of 14th probe from run 1
15	Result of 15th probe from run 1

Upon completion of the first probe of the second run of this test, **pingProbeHistoryTable** will contain probes like those in [Table 120](#).

Table 120: Results in pingProbeHistoryTable: After the First Probe of the Second Test

pingProbeHistoryIndex	Probe Result
12	Result of 12th probe from run 1

Table 120: Results in pingProbeHistoryTable: After the First Probe of the Second Test (*continued*)

pingProbeHistoryIndex	Probe Result
13	Result of 13th probe from run 1
14	Result of 14th probe from run 1
15	Result of 15th probe from run 1
16	Result of 1st probe from run 2

Upon completion of the second run of this test, **pingProbeHistoryTable** will contain probes like those in [Table 121](#).

Table 121: Results in pingProbeHistoryTable: After the Second Ping Test

pingProbeHistoryIndex	Probe Result
26	Result of 11th probe from run 2
27	Result of 12th probe from run 2
28	Result of 13th probe from run 2
29	Result of 14th probe from run 2
30	Result of 15th probe from run 2

History entries can be deleted from the MIB in two ways:

- More history entries for a given test are added and the number of history entries exceeds **pingCtlMaxRows**. The oldest history entries are deleted to make room for the new ones.
- You delete the entire test by setting **pingCtlRowStatus** to **destroy**.

Stopping a Ping Test

To stop an active test, set **pingCtlAdminStatus** to **disabled**. To stop the test and remove its **pingCtlEntry**, **pingResultsEntry**, and any **pingHistoryEntry** objects from the MIB, set **pingCtlRowStatus** to **destroy**.

Interpreting Ping Variables

This section clarifies the ranges for the following variables that are not explicitly specified in the Ping MIB:

- **pingCtlDataSize**—The value of this variable represents the total size of the payload (in bytes) of an outgoing probe packet. This payload includes the timestamp (8 bytes) that is used to time the probe. This is consistent with the definition of **pingCtlDataSize** (maximum value of 65,507) and the standard ping application.

If the value of **pingCtlDataSize** is between 0 and 8 inclusive, it is ignored and the payload is 8 bytes (the timestamp). The Ping MIB assumes all probes are timed, so the payload must always include the timestamp.

For example, if you wish to add an additional 4 bytes of payload to the packet, you must set **pingCtlDataSize** to 12.

- **pingCtlDataFill**—The first 8 bytes of the data segment of the packet is for the timestamp. After that, the **pingCtlDataFill** pattern is used in repetition. The default pattern (when **pingCtlDataFill** is not specified) is (00, 01, 02, 03 ... FF, 00, 01, 02, 03 ... FF, ...).
- **pingCtlMaxRows**—The maximum value is 255.
- **pingMaxConcurrentRequests**—The maximum value is 500.
- **pingCtlTrapProbeFailureFilter** and **pingCtlTrapTestFailureFilter**—A value of 0 for **pingCtlTrapProbeFailureFilter** or **pingCtlTrapTestFailureFilter** is not well defined by the Ping MIB. If **pingCtlTrapProbeFailureFilter** is 0, **pingProbeFailed** traps will not be generated for the test under any circumstances. If **pingCtlTrapTestFailureFilter** is 0, **pingTestFailed** traps will not be generated for the test under any circumstances.

Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS

A traceroute test approximates the path packets take from the local host to the remote host.

RFC 2925 is the authoritative description of the Traceroute MIB in detail and provides the ASN.1 MIB definition of the Traceroute MIB.

Related Documentation

- [Gathering Traceroute Test Results on page 1576](#)
- [Stopping a Traceroute Test on page 1577](#)
- [Interpreting Traceroute Variables on page 1578](#)

Starting a Traceroute Test

Before you start a traceroute test, configure a Traceroute MIB view. This allows SNMP **Set** requests on **tracerouteMIB**. To start a test, create a row in **traceRouteCtlTable** and set **traceRouteCtlAdminStatus** to **enabled**. You must specify at least the following before setting **traceRouteCtlAdminStatus** to **enabled**:

- **traceRouteCtlOwnerIndexSnmpAdminString**
- **traceRouteCtlTestNameSnmpAdminString**
- **traceRouteCtlTargetAddressInetAddress**
- **traceRouteCtlRowStatusRowStatus**

For all other values, defaults are chosen unless otherwise specified.

traceRouteCtlOwnerIndex and **traceRouteCtlTestName** are used as the index, so their values are specified as part of the OID. To create a row, set **traceRouteCtlRowStatus** to **createAndWait** or **createAndGo** on a row that does not already exist. A value of **active** for **traceRouteCtlRowStatus** indicates that all necessary information has been specified and the test can begin; **traceRouteCtlAdminStatus** can be set to **enabled**. An SNMP **Set** request that sets **traceRouteCtlRowStatus** to **active** will fail if the necessary information in the row is not specified or is inconsistent. For information about how to configure a view, see [“Setting SNMP Views” on page 1560](#).

There are two ways to start a traceroute test:

- [Using Multiple Set PDUs on page 1570](#)
- [Using a Single Set PDU on page 1570](#)

Using Multiple Set PDUs

You can use multiple **Set** request PDUs (multiple PDUs, with one or more varbinds each) and set the following variables in this order to start the test:

- **traceRouteCtlRowStatus** to **createAndWait**
- All appropriate test variables
- **traceRouteCtlRowStatus** to **active**

The Junos OS now verifies that all necessary information to run a test has been specified.

- **traceRouteCtlAdminStatus** to **enabled**

Using a Single Set PDU

You can use a single **Set** request PDU (one PDU, with multiple varbinds) to set the following variables to start the test:

- **traceRouteCtlRowStatus** to **createAndGo**
- All appropriate test variables

- **traceRouteCtlAdminStatus** to enabled

Related Documentation

- [Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS on page 1569](#)
- [Monitoring a Running Traceroute Test on page 1571](#)

- [Monitoring Traceroute Test Completion on page 1575](#)
- [Gathering Traceroute Test Results on page 1576](#)
- [Stopping a Traceroute Test on page 1577](#)
- [Interpreting Traceroute Variables on page 1578](#)

Monitoring a Running Traceroute Test

When **traceRouteCtlAdminStatus** is successfully set to **enabled**, the following is done before the acknowledgment of the SNMP **Set** request is sent back to the client:

- **traceRouteResultsEntry** is created if it does not already exist.
- **traceRouteResultsOperStatus** transitions to enabled.

For more information, see the following sections:

- [traceRouteResultsTable on page 1571](#)
- [traceRouteProbeResultsTable on page 1572](#)
- [traceRouteHopsTable on page 1573](#)
- [Generating Traps on page 1574](#)

traceRouteResultsTable

While the test is running, this **traceRouteResultsTable** keeps track of the status of the test. The value of **traceRouteResultsOperStatus** is **enabled** while the test is running and **disabled** when it has stopped.

The value of **traceRouteCtlAdminStatus** remains **enabled** until you set it to **disabled**. Thus, to get the status of the test, you must examine **traceRouteResultsOperStatus**.

The **traceRouteCtlFrequency** variable can be used to schedule many tests for one **traceRouteCtlEntry**. After a test ends normally (you did not stop the test) and **traceRouteCtlFrequency** number of seconds has elapsed, the test is started again just as if you had set **traceRouteCtlAdminStatus** to **enabled**. If you intervene at any time between repeated tests (you set **traceRouteCtlAdminStatus** to **disabled** or **traceRouteCtlRowStatus** to **notInService**), the repeat feature is **disabled** until another test is started and ends normally. A value of 0 for **traceRouteCtlFrequency** indicates this repeat feature is not active.

traceRouteResultsIpTgtAddr and **traceRouteResultsIpTgtAddrType** are set to the value of the resolved destination address when the value of **traceRouteCtlTargetAddressType**

is **dns**. When a test starts successfully and **traceRouteResultsOperStatus** transitions to **enabled**:

- **traceRouteResultsIpTgtAddr** is set to null-string.
- **traceRouteResultsIpTgtAddrType** is set to unknown.

traceRouteResultsIpTgtAddr and **traceRouteResultsIpTgtAddrType** are not set until **traceRouteCtlTargetAddress** can be resolved to a numeric address. To retrieve these values, poll **traceRouteResultsIpTgtAddrType** for any value other than **unknown** after successfully setting **traceRouteCtlAdminStatus** to **enabled**.

At the start of a test, **traceRouteResultsCurHopCount** is initialized to **traceRouteCtlInitialTtl**, and **traceRouteResultsCurProbeCount** is initialized to 1. Each time a probe result is determined, **traceRouteResultsCurProbeCount** increases by 1. While the test is running, the value of **traceRouteResultsCurProbeCount** reflects the current outstanding probe for which results have not yet been determined.

The **traceRouteCtlProbesPerHop** number of probes is sent for each time-to-live (TTL) value. When the result of the last probe for the current hop is determined, provided that the current hop is not the destination hop, **traceRouteResultsCurHopCount** increases by 1, and **traceRouteResultsCurProbeCount** resets to 1.

At the start of a test, if this is the first time this test has been run for this **traceRouteCtlEntry**, **traceRouteResultsTestAttempts** and **traceRouteResultsTestSuccesses** are initialized to 0.

At the end of each test execution, **traceRouteResultsOperStatus** transitions to **disabled**, and **traceRouteResultsTestAttempts** increases by 1. If the test was successful in determining the full path to the target, **traceRouteResultsTestSuccesses** increases by 1, and **traceRouteResultsLastGoodPath** is set to the current time.

traceRouteProbeResultsTable

Each entry in **traceRouteProbeHistoryTable** is indexed by five variables:

- The first two variables, **traceRouteCtlOwnerIndex** and **traceRouteCtlTestName**, are the same ones used for **traceRouteCtlTable** and to identify the test.
- The third variable, **traceRouteProbeHistoryIndex**, is a counter, starting from 1 and wrapping at FFFFFFFF. The maximum number of entries is limited by **traceRouteCtlMaxRows**.
- The fourth variable, **traceRouteProbeHistoryHopIndex**, indicates which hop this probe is for (the actual time-to-live or TTL value). Thus, the first **traceRouteCtlProbesPerHop** number of entries created when a test starts have a value of **traceRouteCtlInitialTtl** for **traceRouteProbeHistoryHopIndex**.
- The fifth variable, **traceRouteProbeHistoryProbeIndex**, is the probe for the current hop. It ranges from 1 to **traceRouteCtlProbesPerHop**.

While a test is running, as soon as a probe result is determined, the next probe is sent. A maximum of **traceRouteCtlTimeOut** seconds elapses before a probe is marked with

status **requestTimedOut** and the next probe is sent. There is never more than one outstanding probe per traceroute test. Any probe result coming back after a probe times out is ignored.

Each probe can:

- Result in a response from a host acknowledging the probe
- Time out with no response from a host acknowledging the probe
- Fail to be sent

Each probe status is recorded in **traceRouteProbeHistoryTable** with **traceRouteProbeHistoryStatus** set accordingly.

Probes that result in a response from a host record the following data:

- **traceRouteProbeHistoryResponse**—Round-trip time (RTT)
- **traceRouteProbeHistoryHAddrType**—The type of HAddr (next argument)
- **traceRouteProbeHistoryHAddr**—The address of the hop

All probes, regardless of whether a response for the probe is received, have the following recorded:

- **traceRouteProbeHistoryStatus**—What happened and why
- **traceRouteProbeHistoryLastRC**—Return code (RC) value of the ICMP packet
- **traceRouteProbeHistoryTime**—Timestamp when the probe result was determined

When a probe cannot be sent, **traceRouteProbeHistoryResponse** is set to 0. When a probe times out, **traceRouteProbeHistoryResponse** is set to the difference between the time when the probe was discovered to be timed out and the time when the probe was sent.

traceRouteHopsTable

Entries in **traceRouteHopsTable** are indexed by three variables:

- The first two, **traceRouteCtlOwnerIndex** and **traceRouteCtlTestName**, are the same ones used for **traceRouteCtlTable** and identify the test.
- The third variable, **traceRouteHopsHopIndex**, indicates the current hop, which starts at 1 (not **traceRouteCtlInitialTtl**).

When a test starts, all entries in **traceRouteHopsTable** with the given **traceRouteCtlOwnerIndex** and **traceRouteCtlTestName** are deleted. Entries in this table are only created if **traceRouteCtlCreateHopsEntries** is set to **true**.

A new **traceRouteHopsEntry** is created each time the first probe result for a given TTL is determined. The new entry is created whether or not the first probe reaches a host. The value of **traceRouteHopsHopIndex** is increased by 1 for this new entry.

NOTE: Any `traceRouteHopsEntry` can lack a value for `traceRouteHopsIpTgtAddress` if there are no responses to the probes with the given TTL.

Each time a probe reaches a host, the IP address of that host is available in the probe result. If the value of `traceRouteHopsIpTgtAddress` of the current `traceRouteHopsEntry` is not set, then the value of `traceRouteHopsIpTgtAddress` is set to this IP address. If the value of `traceRouteHopsIpTgtAddress` of the current `traceRouteHopsEntry` is the same as the IP address, then the value does not change. If the value of `traceRouteHopsIpTgtAddress` of the current `traceRouteHopsEntry` is different from this IP address, indicating a path change, a new `traceRouteHopsEntry` is created with:

- `traceRouteHopsHopIndex` variable increased by 1
- `traceRouteHopsIpTgtAddress` set to the IP address

NOTE: A new entry for a test is added to `traceRouteHopsTable` each time a new TTL value is used or the path changes. Thus, the number of entries for a test may exceed the number of different TTL values used.

When a probe result is determined, the value `traceRouteHopsSentProbes` of the current `traceRouteHopsEntry` increases by 1. When a probe result is determined, and the probe reaches a host:

- The value `traceRouteHopsProbeResponses` of the current `traceRouteHopsEntry` is increased by 1.
- The following variables are updated:
 - `traceRouteResultsMinRtt`—Minimum round-trip time
 - `traceRouteResultsMaxRtt`—Maximum round-trip time
 - `traceRouteResultsAverageRtt`—Average round-trip time
 - `traceRouteResultsRttSumOfSquares`—Sum of squares of round-trip times
 - `traceRouteResultsLastGoodProbe`—Timestamp of the last response

NOTE: Only probes that reach a host affect the round-trip time values.

Generating Traps

For any trap to be generated, the appropriate bit of `traceRouteCtlTrapGeneration` must be set. You must also configure a trap group to receive remote operations. Traps are generated under the following conditions:

- **traceRouteHopsIpTgtAddress** of the current probe is different from the last probe with the same TTL value (**traceRoutePathChange**).
- A path to the target could not be determined (**traceRouteTestFailed**).

A path to the target was determined (**traceRouteTestCompleted**).

For information about how to configure a trap group to receive remote operations, see [“Configuring SNMP Trap Groups” on page 1491](#) and [“Example: Setting Trap Notification for Remote Operations” on page 1561](#).

Monitoring Traceroute Test Completion

When a test is complete, **traceRouteResultsOperStatus** transitions from **enabled** to **disabled**. This transition occurs in the following situations:

- The test ends successfully. A probe result indicates that the destination has been reached. In this case, the current hop is the last hop. The rest of the probes for this hop are sent. When the last probe result for the current hop is determined, the test ends.
- **traceRouteCtlMaxTtl** threshold is exceeded. The destination is never reached. The test ends after the number of probes with TTL value equal to **traceRouteCtlMaxttl** have been sent.
- **traceRouteCtlMaxFailures** threshold is exceeded. The number of consecutive probes that end with status **requestTimedOut** exceeds **traceRouteCtlMaxFailures**.
- You end the test. You set **traceRouteCtlAdminStatus** to **disabled** or delete the row by setting **traceRouteCtlRowStatus** to **destroy**.
- You misconfigured the traceroute test. A value or variable you specified in **traceRouteCtlTable** is incorrect and will not allow a single probe to be sent. Because of the nature of the data, this error could not be determined until the test was started; that is, until after **traceRouteResultsOperStatus** transitioned to **enabled**. When this occurs, one entry is added to **traceRouteProbeHistoryTable** with **traceRouteProbeHistoryStatus** set to the appropriate error code.

If **traceRouteCtlTrapGeneration** is set properly, either the **traceRouteTestFailed** or **traceRouteTestCompleted** trap is generated.

- [Stopping a Traceroute Test on page 1577](#)
- [Interpreting Traceroute Variables on page 1578](#)

Gathering Traceroute Test Results

You can either poll **traceRouteResultsOperStatus** to find out when the test is complete or request that a trap be sent when the test is complete. For more information about **traceResultsOperStatus**, see [“traceRouteResultsTable” on page 1571](#). For more information about Traceroute MIB traps, see the Generating Traps section in [“Monitoring a Running Traceroute Test” on page 1571](#).

Statistics are calculated on a per-hop basis and then stored in **traceRouteHopsTable**. They include the following for each hop:

- **traceRouteHopsIpTgtAddressType**—Address type of host at this hop
- **traceRouteHopsIpTgtAddress**—Address of host at this hop
- **traceRouteHopsMinRtt**—Minimum round-trip time
- **traceRouteHopsMaxRtt**—Maximum round-trip time
- **traceRouteHopsAverageRtt**—Average round-trip time
- **traceRouteHopsRttSumOfSquares**—Sum of squares of round-trip times
- **traceRouteHopsSentProbes**—Number of attempts to send probes
- **traceRouteHopsProbeResponses**—Number of responses received
- **traceRouteHopsLastGoodProbe**—Timestamp of last response

You can also consult **traceRouteProbeHistoryTable** for more detailed information about each probe. The index used for **traceRouteProbeHistoryTable** starts at 1, goes to 0xFFFFFFFF, and wraps to 1 again.

For example, assume the following:

- **traceRouteCtlMaxRows** is 10.
- **traceRouteCtlProbesPerHop** is 5.
- There are eight hops to the target (the target being number eight).
- Each probe sent results in a response from a host (the number of probes sent is not limited by **traceRouteCtlMaxFailures**).

In this test, 40 probes are sent. At the end of the test, **traceRouteProbeHistoryTable** would have a history of probes like those in [Table 122](#).

Table 122: traceRouteProbeHistoryTable

HistoryIndex	HistoryHopIndex	HistoryProbeIndex
31	7	1
32	7	2
33	7	3

Table 122: traceRouteProbeHistoryTable (*continued*)

HistoryIndex	HistoryHopIndex	HistoryProbeIndex
34	7	4
35	7	5
36	8	1
37	8	2
38	8	3
39	8	4
40	8	5

Stopping a Traceroute Test

To stop an active test, set **traceRouteCtlAdminStatus** to **disabled**. To stop a test and remove its **traceRouteCtlEntry**, **traceRouteResultsEntry**, **traceRouteProbeHistoryEntry**, and **traceRouteProbeHistoryEntry** objects from the MIB, set **traceRouteCtlRowStatus** to **destroy**.

- [Gathering Traceroute Test Results on page 1576](#)
- [Interpreting Traceroute Variables on page 1578](#)

Interpreting Traceroute Variables

This topic contains information about the ranges for the following variables that are not explicitly specified in the Traceroute MIB:

- **traceRouteCtlMaxRows**—The maximum value for **traceRouteCtlMaxRows** is 2550. This represents the maximum TTL (255) multiplied by the maximum for **traceRouteCtlProbesPerHop** (10). Therefore, the **traceRouteProbeHistoryTable** accommodates one complete test at the maximum values for one **traceRouteCtlEntry**. Usually, the maximum values are not used and the **traceRouteProbeHistoryTable** is able to accommodate the complete history for many tests for the same **traceRouteCtlEntry**.
- **traceRouteMaxConcurrentRequests**—The maximum value is 50. If a test is running, it has one outstanding probe. **traceRouteMaxConcurrentRequests** represents the maximum number of traceroute tests that have **traceRouteResultsOperStatus** with a value of **enabled**. Any attempt to start a test with **traceRouteMaxConcurrentRequests** tests running will result in the creation of one probe with **traceRouteProbeHistoryStatus** set to **maxConcurrentLimitReached** and that test will end immediately.
- **traceRouteCtlTable**—The maximum number of entries allowed in this table is 100. Any attempt to create a 101st entry will result in a **BAD_VALUE** message for SNMPv1 and a **RESOURCE_UNAVAILABLE** message for SNMPv2.

CHAPTER 67

Tracing SNMP Activity

- [Monitoring SNMP Activity and Tracking Problems That Affect SNMP Performance on a Device Running Junos OS on page 1579](#)
- [Tracing SNMP Activity on a Device Running Junos OS on page 1585](#)
- [Example: Tracing SNMP Activity on page 1588](#)

Monitoring SNMP Activity and Tracking Problems That Affect SNMP Performance on a Device Running Junos OS

The following sections contain information about monitoring the SNMP activity on devices running the Junos OS and identifying problems that might impact the SNMP performance on devices running Junos OS:

- [Checking for MIB Objects Registered with the snmpd on page 1579](#)
- [Tracking SNMP Activity on page 1580](#)
- [Monitoring SNMP Statistics on page 1582](#)
- [Checking CPU Utilization on page 1583](#)
- [Checking Kernel and Packet Forwarding Engine Response on page 1584](#)

Checking for MIB Objects Registered with the snmpd

For the SNMP process to be able to access data related to a MIB object, the MIB object must be registered with the snmpd. When an SNMP subagent comes online, it tries to register the associated MIB objects with the snmpd. The snmpd maintains a mapping of the objects and the subagents with which the objects are associated. However, the registration attempt fails occasionally, and the objects remain unregistered with the snmpd until the next time the subagent restarts and successfully registers the objects.

When a network management system polls for data related to objects that are not registered with the snmpd, the snmpd returns either a **noSuchName** error (for SNMPv1 objects) or a **noSuchObject** error (for SNMPv2 objects).

You can use the following commands to check for MIB objects that are registered with the snmpd:

- **show snmp registered-objects**—Creates a `/var/log/snmp_reg_objs` file that contains the list of registered objects and their mapping to various subagents.

- **file show /var/log/snmp_reg_objs**—Displays the contents of the `/var/log/snmp_reg_objs` file.

The following example shows the steps for creating and displaying the `/var/log/snmp_reg_objs` file:

```
user@host> show snmp registered-objects
user@host> file show /var/log/snmp_reg_objs

---(more)---
```

NOTE: The `/var/log/snmp_reg_objs` file contains only those objects that are associated with the Junos OS processes that are up and running and registered with the `snmpd`, at the time of executing the `show snmp registered-objects` command. If a MIB object related to a Junos OS process that is up and running is not shown in the list of registered objects, you might want to restart the software process to retry object registration with the `snmpd`.

Tracking SNMP Activity

SNMP tracing operations track activity of SNMP agents and record the information in log files. The logged event descriptions provide detailed information to help you solve problems faster. By default, Junos OS does not trace any SNMP activity. To enable

A sample `traceoptions` configuration might look like:

When the **traceoptions** flag all statement is included at the **[edit snmp]** hierarchy level, the following log files are created:

- You can use the **show log log-filename** operational mode command to view the contents of the log file. In the snmpd log file (see the following example), a sequence of >>> represents an incoming packet, whereas a sequence of <<< represents an outgoing packet. Note that the request response pair might not follow any sequence if there are multiple network management systems polling the device at the same time. You can use the source and request ID combinations to match requests and responses. However, note that no response log is created in the log file if the SNMP master agent or the SNMP subagent has not responded to a request.

Reviewing a Log File

[illegible]

[illegible]

Monitoring SNMP Statistics

The **show snmp statistics extensive** operational mode command provides you with an option to review SNMP traffic, including traps, on a device. Output for the **show snmp statistics extensive** command shows real-time values and can be used to monitor values such as throttle drops, currently active, max active, not found, time out, max latency, current queued, total queued, and overflows. You can identify slowness in SNMP responses by monitoring the currently active count, because a constant increase in the currently active count is directly linked to slow or no response to SNMP requests.

Sample Output for the show snmp statistics extensive Command

```

user@host> show snmp statistics extensive
SNMP statistics:
Input:
  Packets: 226656, Bad versions: 0, Bad community names: 0,
  Bad community uses: 0, ASN parse errors: 0,
  Too big: 0, No such names: 0, Bad values: 0,
  Read only: 0, General errors: 0,
  Total request varbinds: 1967606, Total set varbinds: 0,
  Get requests: 18478, Get nexts: 75794, Set requests: 0,
  Get responses: 0, Traps: 0,
  Silent drops: 0, Proxy drops: 0, Commit pending drops: 0,
  Throttle drops: 27084, Duplicate request drops: 0
V3 Input:
  Unknown security models: 0, Invalid messages: 0
  Unknown pdu handlers: 0, Unavailable contexts: 0
  Unknown contexts: 0, Unsupported security levels: 0
  Not in time windows: 0, Unknown user names: 0
  Unknown engine ids: 0, Wrong digests: 0, Decryption errors: 0
Output:
  Packets: 226537, Too big: 0, No such names: 0,
  Bad values: 0, General errors: 0,
  Get requests: 0, Get nexts: 0, Set requests: 0,
  Get responses: 226155, Traps: 382
SA Control Blocks:
  Total: 222984, Currently Active: 501, Max Active: 501,
  Not found: 0, Timed Out: 0, Max Latency: 25
SA Registration:
  Registers: 0, Deregisters: 0, Removes: 0
Trap Queue Stats:

Snmp Set Stats:
  Commit pending failures: 0, Config lock failures: 0
  Rpc failures: 0, Journal write failures: 0
  Mgd connect failures: 0, General commit failures: 0

```

Checking CPU Utilization

High CPU usage of the software processes that are being queried, such as `snmpd` or `mib2d`, is another factor that can lead to slow response or no response. You can use the **show system processes extensive** operational mode command to check the CPU usage levels of the Junos OS processes.

Sample Output of show system processes extensive Command

```

user@host> show system processes extensive
last pid: 1415; load averages: 0.00, 0.00, 0.00 up 0+02:20:54 10:26:25
117 processes: 2 running, 98 sleeping, 17 waiting

Mem: 180M Active, 54M Inact, 39M Wired, 195M Cache, 69M Buf, 272M Free
Swap: 1536M Total, 1536M Free

Checking Kernel and Packet Forwarding Engine Response

As mentioned in [“Understanding SNMP Implementation in Junos OS” on page 1403](#), some SNMP MIB data are maintained by the kernel or Packet Forwarding Engine. For such data to be available for the network management system, the kernel has to provide the required information to the SNMP subagent in mib2d. A slow response from the kernel can cause a delay in mib2d returning the data to the network management system. Junos OS adds an entry in the mib2d log file every time that an interface takes more than 10,000 microseconds to respond to a request for interface statistics. You can use the **show log log-filename | grep “kernel response time”** command to find out the response time taken by the kernel.

Checking the Kernel Response Time

```

user@host> show log mib2d | grep “kernel response time”
Aug 17 22:39:37 == kernel response time for
COS_IPVPN_DEFAULT_OUTPUT-t1-7/3/0:10:27.0-o: 9.126471 sec, range
(0.000007, 11.000806)

Aug 17 22:39:53 == kernel response time for
COS_IPVPN_DEFAULT_INPUT-t1-7/2/0:5:15.0-i: 5.387321 sec, range
(0.000007, 11.000806)

Aug 17 22:39:53 == kernel response time for ct1-6/1/0:9:15: 0.695406
sec, range (0.000007, 11.000806)

```

Aug 17 22:40:04 == kernel response time for t1-6/3/0:6:19: 1.878542 sec, range (0.000007, 11.000806)

Aug 17 22:40:22 == kernel response time for lsq-7/0/0: 2.556592 sec, range (0.000007, 11.000806)

Tracing SNMP Activity on a Device Running Junos OS

SNMP tracing operations track activity for SNMP agents and record the information in log files. The logged error descriptions provide detailed information to help you solve problems faster.

By default, Junos OS does not trace any SNMP activity. If you include the **traceoptions** statement at the **[edit snmp]** hierarchy level, the default tracing behavior is:

- Important activities are logged in files located in the **/var/log** directory. Each log is named after the SNMP agent that generates it. Currently, the following log files are created in the **/var/log** directory when the **traceoptions** statement is used:
 - chassisd
 - craftd
 - ilmid
 - mib2d
 - rmopd
 - serviced
 - snmpd
- When a trace file named **filename** reaches its maximum size, it is renamed **filename.0**, then **filename.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. (For more information about how log files are created, see the [System Log Explorer](#).)
- Log files can be accessed only by the user who configured the tracing operation.

You cannot change the directory (`/var/log`) in which trace files are located. However, you can customize the other trace file settings by including the following statements at the `[edit snmp]` hierarchy level:

```
[edit snmp]
traceoptions {
  file <files number> <match regular-expression> <size size> <world-readable |
    no-world-readable>;
  flag flag;
  memory-trace;
  no-remote-trace;
  no-default-memory-trace;
}
```

These statements are described in the following sections:

- [Configuring the Number and Size of SNMP Log Files on page 1586](#)
- [Configuring Access to the Log File on page 1586](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 1587](#)
- [Configuring the Trace Operations on page 1587](#)

Configuring the Number and Size of SNMP Log Files

By default, when the trace file reaches 128 kilobytes (KB) in size, it is renamed *filename.0*, then *filename.1*, and so on, until there are three trace files. Then the oldest trace file (*filename.2*) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the `[edit snmp traceoptions]` hierarchy level:

```
[edit snmp traceoptions]
file files number size size;
```

For example, set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation (*filename*) reaches 2 MB, *filename* is renamed *filename.0*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0* is renamed *filename.1* and *filename* is renamed *filename.0*. This process repeats until there are 20 trace files. Then the oldest file (*filename.19*) is overwritten by the newest file (*filename.0*).

The number of files can be from 2 through 1000 files. The file size of each file can be from 10 KB through 1 gigabyte (GB).

Configuring Access to the Log File

By default, log files can be accessed only by the user who configured the tracing operation.

To specify that any user can read all log files, include the **file world-readable** statement at the `[edit snmp traceoptions]` hierarchy level:

```
[edit snmp traceoptions]
file world-readable;
```

To explicitly set the default behavior, include the **file no-world-readable** statement at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]
file no-world-readable;
```

Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged activities.

You can refine the output by including the **match** statement at the **[edit snmp traceoptions file filename]** hierarchy level and specifying a regular expression (regex) to be matched:

```
[edit snmp traceoptions]
file filename match regular-expression;
```

Configuring the Trace Operations

By default, only important activities are logged. You can specify which trace operations are to be logged by including the following **flag** statement (with one or more tracing flags) at the **[edit snmp traceoptions]** hierarchy level:

```
[edit snmp traceoptions]
flag {
  all;
  configuration;
  database;
  events;
  general;
  interface-stats;
  nonvolatile-sets;
  pdu;
  policy;
  protocol-timeouts;
  routing-socket;
  server;
  subagent;
  timer;
  varbind-error;
}
```

Table 123 describes the meaning of the SNMP tracing flags.

Table 123: SNMP Tracing Flags

Flag	Description	Default Setting
all	Log all operations.	Off
configuration	Log reading of the configuration at the [edit snmp] hierarchy level.	Off
database	Log events involving storage and retrieval in the events database.	Off
events	Log important events.	Off

Table 123: SNMP Tracing Flags (*continued*)

Flag	Description	Default Setting
general	Log general events.	Off
interface-stats	Log physical and logical interface statistics.	Off
nonvolatile-set	Log nonvolatile SNMP set request handling.	Off
pdu	Log SNMP request and response packets.	Off
policy	Log policy processing.	Off
protocol-timeouts	Log SNMP response timeouts.	Off
routing-socket	Log routing socket calls.	Off
server	Log communication with processes that are generating events.	Off
subagent	Log subagent restarts.	Off
timer	Log internal timer events.	Off
varbind-error	Log variable binding errors.	Off

To display the end of the log for an agent, issue the **show log agentd | last** operational mode command:

```
[edit]
user@host# run show log agentd | last
```

where **agent** is the name of an SNMP agent.

Junos OS SNMP FAQ Overview

This document presents the most frequently asked questions about the features and technologies used to implement SNMP services on Juniper Networks devices using the Junos operating system.

SNMP enables users to monitor network devices from a central location. Many network management systems (NMS) are based on SNMP, and support for this protocol is a key feature of most network devices.

Juniper Networks provides many different platforms that support SNMP on the Junos OS. The Junos OS includes an onboard SNMP agent that provides remote management applications with access to detailed information about the devices on the network.

A typical SNMP implementation contains three components:

- Managed devices – Such as routers and switches.
- SNMP agent – Process that resides on a managed device and communicates with the NMS.
- NMS – A combination of hardware and software used to monitor and administer the network; network device that runs SNMP manager software. Also referred to as an SNMP manager.

The SNMP agent exchanges network management information with the SNMP manager (NMS). The agent responds to requests for information and actions from the manager. The SNMP manager collects information about network connectivity, activity, and events by polling managed devices.

SNMP implementation in the Junos OS uses a master SNMP agent (known as an SNMP process or `snmpd`) that resides on the managed device. Various subagents reside on different modules of the Junos OS as well (such as the Routing Engine), and these subagents are managed by the `snmpd`.

Junos OS SNMP Support FAQs

This section presents frequently asked questions and answers related to SNMP support on Junos OS.

Which SNMP versions does Junos OS support?

Junos OS supports SNMP version 1 (SNMPv1), version 2 (SNMPv2c), and version 3 (SNMPv3). By default, SNMP is disabled on a Juniper Networks device.

Which ports (sockets) does SNMP use?

The default port for SNMP queries is port 161. The default port for SNMP traps and informs is port 162. The ports used by SNMP are configurable, and you can configure your system to use ports other than the defaults.

Is SNMP support different among the Junos OS platforms?

No, SNMP support is not different among the Junos OS platforms. SNMP configuration, interaction, and behavior are the same on any Junos OS device. The only difference that might occur across platforms is MIB support.

See also the *SNMP MIBs and Traps Reference* for a list of MIBs that are supported across the Junos OS platforms.

Does Junos OS support the user-based security model (USM)?

Yes, Junos OS supports USM as part of its support for SNMPv3. SNMPv3 contains more security measures than previous versions of SNMP, including providing a defined USM. SNMPv3 USM provides message security through data integrity, data origin authentication, message replay protection, and protection against disclosure of the message payload.

Does Junos OS support the view-based access control model (VACM)?

Yes, Junos OS supports VACM as part of its support for SNMPv3. SNMPv3 contains more security measures than previous versions of SNMP, including providing a defined VACM. SNMPv3 VACM determines whether a specific type of access (read or write) to the management information is allowed.

Does Junos OS support SNMP informs?

Yes, Junos OS supports SNMP informs as part of its support for SNMPv3. SNMP informs are confirmed notifications sent from SNMP agents to SNMP managers when significant events occur on a network device. When an SNMP manager receives an inform, it sends a response to the sender to verify receipt of the inform.

Can I provision or configure a device using SNMP on Junos OS?

No, provisioning or configuring a device using SNMP is not allowed on Junos OS.

Related Documentation

Junos OS MIBs FAQs

This section presents frequently asked questions and answers related to Junos OS MIBs.

What is a MIB?

A management information base (MIB) is a table of definitions for managed objects in a network device. MIBs are used by SNMP to maintain standard definitions of all of the components and their operating conditions within a network device. Each object in the MIB has an identifying code called an object identifier (OID).

MIBs are either standard or enterprise-specific. Standard MIBs are created by the Internet Engineering Task Force (IETF) and documented in various RFCs. Enterprise-specific MIBs are developed and supported by a specific equipment manufacturer.

For a list of supported standard MIBs, see “[Standard SNMP MIBs Supported by Junos OS](#)” on page 1409.

For a list of Juniper Networks enterprise-specific MIBs, see “[Enterprise-Specific SNMP MIBs Supported by Junos OS](#)” on page 1427.

Do MIB files reside on the Junos OS devices?

No, MIB files do not reside on the Junos OS devices. You must download the MIB files from the Juniper Networks Technical Publications page for the required Junos OS release: http://www.juniper.net/techpubs/en_US/release-independent/junos/mibs/mibs.html.

How do I compile and load the Junos OS MIBs onto an SNMP manager or NMS?

For your network management systems (NMSs) to identify and understand the MIB objects used by Junos OS, you must first load the MIB files to your NMS using a MIB compiler. A MIB compiler is a utility that parses the MIB information, such as the MIB object names, IDs, and data types for the NMS.

You can download the Junos OS MIB package from the Enterprise-Specific MIBs and Traps section at

http://www.juniper.net/techpubs/en_US/release-independent/junos/mibs/mibs.html or <http://www.juniper.net/techpubs/software/junos/index.html>.

The Junos OS MIB package has two folders: **StandardMibs**, containing standard MIBs supported on Juniper Networks devices, and **JuniperMibs**, containing Juniper Networks enterprise-specific MIBs. You *must* have the required standard MIBs downloaded and decompressed before downloading any enterprise-specific MIBs. There might be dependencies that require a particular standard MIB to be present on the compiler before loading a particular enterprise-specific MIB.

The Junos OS MIB package is available in **.zip** and **.tar** formats. Download the format appropriate for your requirements.

Use the following steps to load MIB files for devices running Junos OS:

1. Navigate to the appropriate Juniper Networks software download page and locate the **Enterprise MIBs** link under the **Enterprise-Specific MIBs and Traps** section.

NOTE: Although the link is titled **Enterprise MIBs**, both standard MIBs and enterprise-specific MIBs are available for download from this location.

2. Click the **TAR** or **ZIP** link to download the Junos OS MIB package.
3. Decompress the file (**.tar** or **.zip**) using an appropriate utility.

NOTE: Some commonly used MIB compilers are preloaded with standard MIBs. You can skip Step 4 and Step 5 and proceed to Step 6 if you already have the standard MIBs loaded on your system.

4. Load the standard MIB files from the **StandardMibs** folder.

Load the files in the following order:

- a. mib-SNMPv2-SMI.txt
 - b. mib-SNMPv2-TC.txt
 - c. mib-IANAifType-MIB.txt
 - d. mib-IANA-RTPROTO-MIB.txt
 - e. mib-rfc1907.txt
 - f. mib-rfc2011a.txt
 - g. mib-rfc2012a.txt
 - h. mib-rfc2013a.txt
 - i. mib-rfc2863a.txt
5. Load any remaining standard MIB files.

NOTE: You must follow the order specified in this procedure, and ensure that all standard MIBs are loaded before you load the enterprise-specific MIBs. There might be dependencies that require a particular standard MIB to be present on the compiler before loading a particular enterprise-specific MIB. Dependencies are listed in the **IMPORT** section of the MIB file.

6. After loading the standard MIBs, load the Juniper Networks enterprise-specific SMI MIB, **mib-jnx-smi.txt**, and the following optional SMI MIBs based on your requirements:
 - **mib-jnx-exp.txt**—(Recommended) for Juniper Networks experimental MIB objects
 - **mib-jnx-js-smi.txt**—(Optional) for Juniper Security MIB tree objects
 - **mib-jnx-ex-smi.txt**—(Optional) for EX Series Ethernet Switches
7. Load any remaining desired enterprise-specific MIBs from the **JuniperMibs** folder.

TIP: While loading a MIB file, if the compiler returns an error message indicating that any of the objects are undefined, open the MIB file using a text editor and ensure that all the MIB files listed in the **IMPORT** section are loaded on the compiler. If any of the MIB files listed in the **IMPORT** section are not loaded on the compiler, load the missing file or files first, then try to load the MIB file that failed.

The system might return an error if files are not loaded in a particular order.

What is SMI?

Structure of Management Information Version (SMI) is a subset of Abstract Syntax Notation One (ASN.1), which describes the structure of objects. SMI is the notation syntax, or “grammar”, that is the standard for writing MIBs.

Which versions of SMI does Junos OS support?

The Junos OS supports SMIV1 for SNMPv1 MIBs, and SMIV2 for SNMPv2c and enterprise MIBs.

Does Junos OS support MIB II?

Yes, Junos OS supports MIB II, the second version of the MIB standard.

The features of MIB II include:

- Additions that reflect new operational requirements.
- Backward compatibility with the original MIBs and SNMP.
- Improved support for multiprotocol entities.
- Improved readability.

Refer to the relevant release documentation for a list of MIBs that are supported. Go to <http://www.juniper.net/techpubs/software/junos/index.html>.

Are the same MIBs supported across all Juniper Networks devices?

There are some common MIBs supported by all the Junos OS devices, such as the Interface MIB (ifTable), System MIB, and Chassis MIB. Some MIBs are supported only by functionalities on specific platforms. For example, the Bridge MIB is supported on the EX Series Ethernet Switches and the SRX Series Services Gateways for the branch.

What is the system object identifier (SYSOID) of a device? How do I determine the SYSOID of my device?

The jnx-chas-defines (Chassis Definitions for Router Model) MIB has a **jnxProductName** branch for every Junos OS device. The system object ID of a device is identical to the object ID of the **jnxProductName** for the platform. For example, for an M7i Multiservice Edge Router, the jnxProductNameM7i is .1.3.6.1.4.1.2636.1.1.1.2.10 in the jnxProductName branch, which is identical to the SYSOID of the M7i (.1.3.6.1.4.1.2636.1.1.1.2.10).

How can I determine if a MIB is supported on a platform? How can I determine which MIBs are supported by a device?

MIBs device and platform support is listed on the Junos OS Technical Documentation index page. Go to <http://www.juniper.net/techpubs/software/junos/> and select your version or release of Junos OS. Navigate to the *SNMP MIBs and Traps Reference*. The *SNMP MIBs and Traps Reference* specifies which MIBs are supported on the different platforms.

What can I do if the MIB OID query is not responding?

There can be various reasons why the MIB OID query stops responding. One reason could be that the MIB itself is unresponsive. To verify that the MIB responds, use the **show snmp mib walk | get MIB name | MIB OID** command:

- If the MIB responds, the communication issue exists between the SNMP master and SNMP agent. Possible reasons for this issue include network issues, an incorrect community configuration, an incorrect SNMP configuration, and so on.
- If the MIB does not respond, enable SNMP **traceoptions** to log PDUs and errors. All incoming and outgoing SNMP PDUs are logged. Check the **traceoptions** output to see if there are any errors.

If you continue to have problems with the MIB OID query, technical product support is available through the Juniper Networks Technical Assistance Center (JTAC).

What is the enterprise branch number for Junos OS?

The enterprise branch number for Junos OS is 2636. Enterprise branch numbers are used in SNMP MIB configurations, and they are also known as SMI network management private enterprise codes.

Which MIB displays the hardware and chassis details on a Juniper Networks device?

The Chassis MIB (jnxchassis.mib) displays the hardware and chassis details for each Juniper Networks device. It provides information about the router and its components. The Chassis MIB objects represent each component and its status.

For more information about enterprise-specific Chassis MIBs, see *Chassis MIBs* in the *Junos OS SNMP MIBs and Traps Reference* document.

Which MIB objects can I query to determine the CPU and memory utilization of the Routing Engine, Flexible PIC Concentrator (FPC), and PIC components on a device?

Query the Chassis MIB objects `jnxOperatingMemory`, `jnxOperatingtBuffer`, and `jnxOperatingCPU` to find out the CPU and memory utilization of the hardware components of a device.

Is the interface index (ifIndex) persistent?

The ifIndex is persistent when reboots occur if the Junos OS version remains the same, meaning the values assigned to the interfaces in the ifIndex do not change.

When there is a software upgrade, the device tries to keep the ifIndex persistent on a best effort basis. For Junos OS Release 10.0 and earlier, the ifIndex is not persistent when there is a software upgrade to Junos OS Release 10.1 and later.

Is it possible to set the ifAdminStatus?

SNMP is not allowed to set the ifAdminStatus.

Which MIB objects support SNMP set operations?

The Junos OS SNMP set operations are supported in the following MIB tables and variables:

- snmpCommunityTable
- eventTable
- alarmTable
- snmpTargetAddrExtTable
- jnxPingCtlTable
- pingCtlTable
- traceRouteCtlTable
- jnxTraceRouteCtlTable
- sysContact.O
- sysName.O
- sysLocation.O
- pingMaxConcurrentRequests.O
- traceRouteMaxConcurrentRequests.O
- usmUserSpinLock

- usmUserOwnAuthKeyChange
- usmUserPublic
- vacmSecurityToGroupTable (vacmGroupName, vacmSecurityToGroupStorageType, and vacmSecurityToGroupStatus)
- vacmAccessTable (vacmAccessContextMatch, vacmAccessReadViewName, vacmAccessWriteViewName, vacmAccessNotifyViewName, vacmAccessStorageType, and vacmAccessStatus)
- vacmViewSpinLock
- vacmViewTreeFamilyTable (vacmViewTreeFamilyMask, vacmViewTreeFamilyType, vacmViewTreeFamilyStorageType, and vacmViewTreeFamilyStatus)

Does Junos OS support remote monitoring (RMON)?

Yes, Junos OS supports RMON as defined in RFC 2819, *Remote Network Monitoring Management Information Base*. However, remote monitoring version 2 (RMON 2) is not supported.

Can I use SNMP to determine the health of the processes running on the Routing Engine?

Yes, you can use SNMP to determine the health of the Routing Engine processes by configuring the health monitoring feature. On Juniper Networks devices, RMON alarms and events provide much of the infrastructure needed to reduce the polling overhead from the NMS. However, you must set up the NMS to configure specific MIB objects into RMON alarms. This often requires device-specific expertise and customizing the monitoring application. Additionally, some MIB object instances that need monitoring are set only at initialization, or they change at runtime and cannot be configured in advance.

To address these issues, the health monitor extends the RMON alarm infrastructure to provide predefined monitoring for a selected set of object instances, such as file system usage, CPU usage, and memory usage, and includes support for unknown or dynamic object instances, such as Junos OS software processes.

To display the health monitoring configuration, use the **show snmp health-monitor** command:

```
user@host> show snmp health-monitor
interval 300;
rising-threshold 90;
falling-threshold 80;
```

When you configure the health monitor, monitoring information for certain object instances is available, as shown in [Table 124](#).

Table 124: Monitored Object Instances

Object	Description
jnxHrStoragePercentUsed.1	Monitors the following file system on the router or switch: /dev/ad0s1a: This is the root file system mounted on /.
jnxHrStoragePercentUsed.2	Monitors the following file system on the router or switch: /dev/ad0s1e: This is the configuration file system mounted on /config.
jnxOperatingCPU (RE0)	Monitor CPU usage for Routing Engines RE0 and RE1. The index values assigned to the Routing Engines depend on whether the Chassis MIB uses a zero-based or a ones-based indexing scheme. Because the indexing scheme is configurable, the correct index is determined whenever the router is initialized and when there is a configuration change. If the router or switch has only one Routing Engine, the alarm entry monitoring RE1 is removed after five failed attempts to obtain the CPU value.
jnxOperatingCPU (RE1)	
jnxOperatingBuffer (RE0)	Monitor the amount of memory available on Routing Engines RE0 and RE1. Because the indexing of this object is identical to that used for jnxOperatingCPU, index values are adjusted depending on the indexing scheme used in the Chassis MIB. As with jnxOperatingCPU, the alarm entry monitoring RE1 is removed if the router or switch has only one Routing Engine.
jnxOperatingBuffer (RE1)	
sysApplElmtRunCPU	Monitors the CPU usage for each Junos OS software process. Multiple instances of the same process are monitored and indexed separately.
sysApplElmtRunMemory	Monitors the memory usage for each Junos OS software process. Multiple instances of the same process are monitored and indexed separately.

The system log entries generated for any health monitor events, such as thresholds crossed and errors, have a corresponding **HEALTHMONITOR** tag rather than a generic **SNMPD_RMON_EVENTLOG** tag. However, the health monitor sends generic **RMON risingThreshold** and **fallingThreshold** traps.

Are the Ping MIBs returned in decimal notation and ASCII?

Yes, both decimal notation and ASCII are supported, which is the standard implementation in SNMP. All strings are ASCII encoded.

The following example displays the Ping MIB in hexadecimal notation:

```
pingCtlTargetAddress.2.69.72.9.116.99.112.115.97.109.112.108.101 = 0a fa 01 02
```

This translates to ASCII:

```
pingCtlTargetAddress."EH"."tcpsample" = 0a fa 01 02
2=length of the string
69=E
72=H
9=length of second string
116=t
99 =c
112=p
115=s
```

```
97=a
109=m
112 =p
108 =l
101 =e
```

As of Junos OS Release 9.6 and later, the Junos OS CLI returns ASCII values using the command **show snmp mib get | get-next | walk ascii**.

The following example shows the output with the ASCII option:

```
user@host> show snmp mib walk pingCtlTargetAddress ascii
pingCtlTargetAddress."EH"."httpgetsample" = http://www.yahoo.com
pingCtlTargetAddress."p1"."t2" = 74 c5 b3 06
pingCtlTargetAddress."p1"."t3" = 74 c5 b2 0c
```

The following example shows the output without the ASCII option:

```
user@host> show snmp mib walk pingCtlTargetAddress
pingCtlTargetAddress.2.69.72.13.104.116.116.112.103.101.116.115.97.109.112.108.101
= http://www.yahoo.com
pingCtlTargetAddress.2.112.49.2.116.50 = 74 c5 b3 06
pingCtlTargetAddress.2.112.49.2.116.51 = 74 c5 b2 0c
```

You can convert decimal and ASCII values using a decimal ASCII chart like the one at <http://www.asciichart.com>.

Is IPv6 supported by the Ping MIB for remote operations?

No, IPv6 is not supported.

Is there an SNMP MIB to show Address Resolution Protocol (ARP) table information? Are both IP and MAC addresses displayed in the same table?

Yes, the Junos OS supports the standard MIB **ipNetToMediaTable**, which is described in RFC 2011, *SNMPv2 Management Information Base for the Internet Protocol using SMIv2*. This table is used for mapping IP addresses to their corresponding MAC addresses.

Related Documentation

Junos OS SNMP Configuration FAQs

This section presents frequently asked questions and answers related to Junos OS SNMP configuration.

Can the Junos OS be configured for SNMPv1 and SNMPv3 simultaneously?

Yes, SNMP has backward compatibility, meaning that all three versions can be enabled simultaneously.

Can I filter specific SNMP queries on a device?

Yes, you can filter specific SNMP queries on a device using **exclude** and **include** statements.

The following example shows a configuration that blocks read-write operation on all OIDs under .1.3.6.1.2.1.1 for the community **test**:

```
user@host# show snmp
view system-exclude {
  oid .1.3.6.1.2.1.1 exclude;
  oid .1 include;
}
community test {
  view system-exclude;
  authorization read-write;
}
```

Can I change the SNMP agent engine ID?

Yes, the SNMP agent engine ID can be changed to the MAC address of the device, the IP address of the device, or any other desired value. Several examples are included here.

The following example shows how to use the MAC address of a device as the SNMP agent engine ID:

```
user@host# show snmp
engine-id {
  use-mac-address;
}
```

The following example shows how to use the IP address of a device as the SNMP agent engine ID:

```
user@host# show snmp
engine-id {
  use-default-ip-address;
}
```

The following example shows the use of a selected value, **AA** in this case, as the SNMP agent engine ID of a device:

```
user@host# show snmp
engine-id {
  local AA;
}
```

How can I configure a device with dual Routing Engines or a chassis cluster (SRX Series Services Gateways) for continued communication during a switchover?

When configuring for continued communication, the SNMP configuration should be identical between the Routing Engines. However, it is best to have separate Routing Engine IDs configured for each Routing Engine, especially when using SNMPv3.

The following example shows the configuration of the Routing Engines in a dual Routing Engine device. Notice that the Routing Engine IDs are set to the MAC addresses for each Routing Engine:

```
user@host# show groups
re0 {
  system {
    host-name PE3-re0;
  }
}
```

```
interfaces {
  fxp0 {
    unit 0 {
      family inet {
        address 116.197.178.14/27;
        address 116.197.178.29/27 {
          master-only;
        }
      }
    }
  }
}
snmp {
  engine-id {
    use-mac-address;
  }
}
}
rel {
  system {
    host-name PE3-rel;
  }
  interfaces {
    fxp0 {
      unit 0 {
        family inet {
          address 116.197.178.11/27;
          address 116.197.178.29/27 {
            master-only;
          }
        }
      }
    }
  }
  snmp {
    engine-id {
      use-mac-address;
    }
  }
}
```

The following is an example of an SNMPv3 configuration on a dual Routing Engine device:

```
user@host> show snmp name host1
v3 {
  vacm {
    security-to-group {
      security-model usm {
        security-name test123 {
          group test1;
        }
        security-name juniper {
          group test1;
        }
      }
    }
  }
}
```

```

access {
  group test1 {
    default-context-prefix {
      security-model any {
        security-level authentication {
          read-view all;
        }
      }
    }
    context-prefix MGMT_10 {
      security-model any {
        security-level authentication {
          read-view all;
        }
      }
    }
  }
}

target-address server1 {
  address 116.197.178.20;
  tag-list router1;
  routing-instance MGMT_10;
  target-parameters test;
}

target-parameters test {
  parameters {
    message-processing-model v3;
    security-model usm;
    security-level authentication;
    security-name juniper;
  }
  notify-filter filter1;
}

notify server {
  type trap;
  tag router1;
}

notify-filter filter1 {
  oid .1 include;
}

view all {
  oid .1 include;
}

community public {
  view all;
}

community comm1;
community comm2;
community comm3 {
  view all;
  authorization read-only;
  logical-system LDP-VPLS {
    routing-instance vpls-server1;
  }
}

```

```
trap-group server1 {
  targets {
    116.197.179.22;
  }
}
routing-instance-access;
traceoptions {
  flag all;
}
```

How can I track SNMP activities?

SNMP trace operations track activity of SNMP agents and record the information in log files.

A sample **traceoptions** configuration might look like this:

```
[edit snmp]
user@host# set traceoptions flag all
```

When the **traceoptions flag all** statement is included at the **[edit snmp]** hierarchy level, the following log files are created:

- snmpd
- mib2d
- rmopd

SNMPv3 FAQs

This section presents frequently asked questions and answers related to SNMPv3.

Why is SNMPv3 important?

SNMP v3 provides enhanced security compared to the other versions of SNMP. It provides authentication and encryption of data. Enhanced security is important for managing devices at remote sites from the management stations.

In my system, the MIB object snmpEngineBoots is not in sync between two Routing Engines in a dual Routing Engine device. Is this normal behavior?

Yes, this is the expected behavior. Each Routing Engine runs its own SNMP process (snmpd), allowing each Routing Engine to maintain its own engine boots. However, if both routing engines have the same engine ID and the routing engine with lesser **snmpEngineBoots** value is selected as the master routing engine during the switchover process, the **snmpEngineBoots** value of the master routing engine is synchronized with the **snmpEngineBoots** value of the other routing engine.

Do I need the SNMP manager engine object identifier (OID) for informs?

Yes, the engine OID of the SNMP manager is required for authentication, and informs do not work without it.

I see the configuration of informs under the [edit snmp v3] hierarchy. Does this mean I cannot use informs with SNMPv2c?

Informs can be used with SNMPv2c. The following example shows the basic configuration for SNMPv3 informs on a device (note that the authentication and privacy is set to none):

```
[edit snmp]
v3 {
  usm {
    remote-engine 00000063000100a2c0a845b3 {
      user RU2_v3_sha_none {
        authentication-none;
        privacy-none;
      }
    }
  }
  vacm {
    security-to-group {
      security-model usm {
        security-name RU2_v3_sha_none {
          group g1_usm_auth;
        }
      }
    }
  }
  access {
    group g1_usm_auth {
      default-context-prefix {
        security-model usm {
          security-level authentication {
            read-view all;
            write-view all;
            notify-view all;
          }
        }
      }
    }
  }
}
target-address TA2_v3_sha_none {
  address 192.168.69.179;
  tag-list tl1;
  address-mask 255.255.252.0;
  target-parameters TP2_v3_sha_none;
```

```
}
target-parameters TP2_v3_sha_none {
  parameters {
    message-processing-model v3;
    security-model usm;
    security-level none;
    security-name RU2_v3_sha_none;
  }
  notify-filter nfl;
}
notify N1_all_tl1_informs {
  type inform; # Replace "inform" with "trap" to convert informs to traps.
  tag tl1;
}
notify-filter nfl {
  oid .1 include;
}
view all {
  oid .1 include;
}
}
```

You can convert the SNMPv3 informs to traps by setting the value of the **type** statement at the **[edit snmp v3 notify N1_all_tl1_informs]** hierarchy level to **trap** as shown in the following example:

```
user@host# set snmp v3 notify N1_all_tl1_informs type trap
```

SNMP Interaction with Juniper Networks Devices FAQs

This section presents frequently asked questions and answers related to how SNMP interacts with Juniper Networks devices.

How frequently should a device be polled? What is a good polling rate?

It is difficult to give an absolute number for the rate of SNMP polls per second since the rate depends on the following two factors:

- The number of variable bindings in a protocol data unit (PDU)
- The response time for an interface from the Packet Forwarding Engine

In a normal scenario where no delay is being introduced by the Packet Forwarding Engine and there is one variable per PDU (a Get request), the response time is 130+ responses per second. However, with multiple variables in an SNMP request PDU (30 to 40 for GetBulk requests), the number of responses per second is much less. Because the Packet Forwarding Engine load can vary for each system, there is greater variation in how frequently a device should be polled.

Frequent polling of a large number of counters, especially statistics, can impact the device. We recommend the following optimization on the SNMP managers:

- Use the row-by-row polling method, not the column-by-column method.
- Reduce the number of variable bindings per PDU.
- Increase timeout values in polling and discovery intervals.
- Reduce the incoming packet rate at the SNMP process (snmpd).

For better SNMP response on the device, the Junos OS does the following:

- Filters out duplicate SNMP requests.
- Excludes interfaces that are slow in response from SNMP queries.

One way to determine a rate limit is to note an increase in the **Currently Active** count from the **show snmp statistics extensive** command.

The following is a sample output of the **show snmp statistics extensive** command:

```
user@host> show snmp statistics extensive
SNMP statistics:
  Input:
    Packets: 226656, Bad versions: 0, Bad community names: 0,
    Bad community uses: 0, ASN parse errors: 0,
    Too bigs: 0, No such names: 0, Bad values: 0,
    Read onlys: 0, General errors: 0,
    Total request varbinds: 1967606, Total set varbinds: 0,
    Get requests: 18478, Get nexts: 75794, Set requests: 0,
    Get responses: 0, Traps: 0,
    Silent drops: 0, Proxy drops: 0, Commit pending drops: 0,
    Throttle drops: 27084, Duplicate request drops: 0
  V3 Input:
    Unknown security models: 0, Invalid messages: 0
    Unknown pdu handlers: 0, Unavailable contexts: 0
    Unknown contexts: 0, Unsupported security levels: 0
    Not in time windows: 0, Unknown user names: 0
    Unknown engine ids: 0, Wrong digests: 0, Decryption errors: 0
  Output:
    Packets: 226537, Too bigs: 0, No such names: 0,
    Bad values: 0, General errors: 0,
    Get requests: 0, Get nexts: 0, Set requests: 0,
    Get responses: 226155, Traps: 382
  SA Control Blocks:

  Snmp Set Stats:
    Commit pending failures: 0, Config lock failures: 0
    Rpc failures: 0, Journal write failures: 0
    Mgd connect failures: 0, General commit failures: 0
```

Does SNMP open dynamic UDP ports? Why?

The SNMP process opens two additional ports (sockets): one for IPv4 and one for IPv6. This enables the SNMP process to send traps.

I am unable to perform a MIB walk on the ifIndex. Why is this?

Any variable bindings or values with an access level of **not-accessible** cannot be queried directly because they are part of other variable bindings in the SNMP MIB table. The ifIndex has an access level of **not-accessible**. Therefore, it cannot be accessed directly because it is part of the variable bindings. However, the ifIndex can be accessed indirectly through the variable bindings.

I see SNMP_IPC_READ_ERROR messages when the SNMP process restarts on my system and also during Routing Engine switchover. Is this acceptable?

Yes, it is acceptable to see **SNMP_IPC_READ_ERROR** messages when the SNMP process is restarted, the system reboots, or during a Routing Engine switchover. If all the processes come up successfully and the SNMP operations are working properly, then these messages can be ignored.

What is the source IP address used in the response PDUs for SNMP requests? Can this be configured?

The source IP address used in the response PDUs for SNMP requests is the IP address of the outgoing interface to reach the destination. The source IP address cannot be configured for responses. It can only be configured for traps.

Documentation**

SNMP Traps and Informs FAQs

This section presents frequently asked questions and answers related to SNMP traps and informs.

Does the Junos OS impose any rate limiting on SNMP trap generation?

The Junos OS implements a trap-queuing mechanism to limit the number of traps that are generated and sent.

If a trap delivery fails, the trap is added back to the queue, and the delivery attempt counter and the next delivery attempt timer for the queue are reset. Subsequent attempts occur at progressive intervals of 1, 2, 4, and 8 minutes. The maximum delay between the attempts is 8 minutes, and the maximum number of attempts is 10. After 10 unsuccessful attempts, the destination queue and all traps in the queue are deleted.

Junos OS also has a throttle threshold mechanism to control the number of traps sent (default 500 traps) during a particular throttle interval (default 5 seconds). This helps ensure consistency in trap traffic, especially when a large number of traps are generated due to interface status changes.

The throttle interval begins when the first trap arrives at the throttle. All traps within the throttle threshold value are processed, and traps exceeding the threshold value are queued. The maximum size of all trap queues (the throttle queue and the destination

queue) is 40,000 traps. The maximum size of any one queue is 20,000 traps. When a trap is added to the throttle queue, or if the throttle queue has exceeded the maximum size, the trap is moved to the top of the destination queue. Further attempts to send the trap from the destination queue are stopped for a 30-second period, after which the destination queue restarts sending the traps.

NOTE: For the Juniper Networks EX Series Ethernet Switch, the maximum size of all trap queues (the throttle queue and the destination queue) is 1,000 traps. The maximum size for any one queue on the EX Series is 500 traps.

I did not see a trap when I had a syslog entry with a critical severity. Is this normal? Can it be changed?

Not every syslog entry with critical severity is a trap. However, you can convert any syslog entry to a trap using the **event-options** statement.

The following example shows how to configure a **jnxSyslogTrap** whenever an **rpd_ldp_nbrdown** syslog entry message error occurs.

```
user@host> show event-options
policy snmptrap {
  events rpd_ldp_nbrdown;
  then {
    raise-trap;
  }
}
```

Are SNMP traps compliant with the Alarm Reporting Function (X.733) on the Junos OS?

No, SNMP traps on the Junos OS are not X.733 compliant.

Can I set up filters for traps or informs?

Traps and informs can be filtered based on the trap category and the object identifier. You can specify categories of traps to receive per host by using the **categories** statement at the **[edit snmp trap-group trap-group]** hierarchy level. Use this option when you want to monitor only specific modules of the Junos OS.

The following example shows a sample configuration for receiving only **link**, **vrrp-events**, **services**, and **otn-alarms** traps:

```
[edit snmp]
trap-group jnpr {
  categories {
    link;
    vrrp-events;
    services;
    otn-alarms;
  }
  targets {
    192.168.69.179;
  }
}
```

```
}
```

The Junos OS also has a more advanced filter option (**notify-filter**) for filtering specific traps or a group of traps based on their object identifiers.

The SNMPv3 configuration also supports filtering of SNMPv1 and SNMPv2 traps and excluding Juniper Networks enterprise-specific configuration management traps, as shown in the following configuration example:

```
[edit snmp]
v3 {
  vacm {
    security-to-group {
      security-model v2c {
        security-name sn_v2c_trap {
          group gr_v2c_trap;
        }
      }
    }
  }
  access {
    group gr_v2c_trap {
      default-context-prefix {
        security-model v2c {
          security-level none {
            read-view all;
            notify-view all;
          }
        }
      }
    }
  }
}

target-address TA_v2c_trap {
  address 10.209.196.166;
  port 9001;
  tag-list tg1;
  target-parameters TP_v2c_trap;
}

target-parameters TP_v2c_trap {
  parameters {
    message-processing-model v2c;
    security-model v2c;
    security-level none;
    security-name sn_v2c_trap;
  }
  notify-filter nf1;
}

notify v2c_notify {
  type trap;
  tag tg1;
}

notify-filter nf1 {
  oid .1.3.6.1.4.1.2636.4.5 exclude;
  oid .1 include;
}

snmp-community index1 {
```

```

community-name "$9$tDLi01h7Nbw2axN"; ## SECRET-DATA
security-name sn_v2c_trap;
tag tgl;
}
view all {
oid .1 include;
}
}

```

Can I simulate traps on a device?

Yes, you can use the **request snmp spoof-trap *trap name*** command for simulating a trap to the NMS that normally receives your device's traps. You can also add required values using the **variable-bindings** parameter.

The following example shows how to simulate a trap to the local NMS using variable bindings:

```

user@host> request snmp spoof-trap linkDown variable-bindings "ifIndex[116]=116,
ifAdminStatus[116]=1 ,ifOperStatus[116]=2 ,ifName[116]=ge-1/0/1"

```

How do I generate a warm start SNMPv1 trap?

When the SNMP process is restarted under normal conditions, a warm start trap is generated if the system up time is more than 5 minutes. If the system up time is less than 5 minutes, a cold start trap is generated.

The NMS sees only the MIB OIDs and numbers, but not the names of the SNMP traps. Why?

Before the NMS can recognize the SNMP trap details, such as the names of the traps, it must first compile and understand the MIBs and then parse the MIB OIDs.

In the Junos OS, how can I determine to which category a trap belongs?

For a list of common traps and their categories, see *Juniper Networks Enterprise-Specific SNMP Version 1 Traps* and *Juniper Networks Enterprise-Specific SNMP Version 2 Traps* in the *Junos OS SNMP MIBs and Traps Reference* document.

Can I configure a trap to include the source IP address?

Yes, you can configure the **source-address**, **routing-instance**, or **logical-instance** name for the source IP address using the **trap-options** command:

```

user@host> show snmp trap-options
source-address 10.1.1.1;

```

Can I create a custom trap?

Yes, you can use the **jnxEventTrap** event script to create customized traps as needed.

In the following example, a Junos OS operations (op) script is triggered when a **UI_COMMIT_NOT_CONFIRMED** event is received. The Junos OS op script matches the complete message of the event and generates an SNMP trap.

Example: Junos OS Op Script

```

version 1.0;

ns junos = "http://xml.juniper.net/junos/*/junos";
ns xnm = "http://xml.juniper.net/xnm/1.1/xnm";
ns jcs = "http://xml.juniper.net/junos/commit-scripts/1.0";

param $event;
param $message;

match / {

    /*
     * trapm utility wants the following characters in the value to be escaped
     * '[', ']', ' ', '=', and ','
     */
    var $event-escaped = {
        call escape-string($text = $event, $vec = '[] =,');
    }

    var $message-escaped = {
        call escape-string($text = $message, $vec = '[] =,');
    }

    <op-script-results> {
    var $rpc = <request-snmp-spoof-trap> {
        <trap> "jnxEventTrap";
        <variable-bindings> "jnxEventTrapDescr[0]='Event-Trap' , "
        _ "jnxEventAvAttribute[1]='event' , "
        _ "jnxEventAvValue[1]='" _ $event-escaped _ "' , "
        _ "jnxEventAvAttribute[2]='message' , "
        _ "jnxEventAvValue[1]='" _ $message-escaped _ "'";
    }

    var $res = jcs:invoke($rpc);
    }

template escape-string ($text, $vec) {

    if (jcs:empty($vec)) {
        expr $text;

    } else {
        var $index = 1;
        var $from = substring($vec, $index, 1);
        var $changed-value = {
            call replace-string($text, $from) {
                with $to = {
                    expr "\\\";
                    expr $from;
                }
            }
        }

        call escape-string($text = $changed-value, $vec = substring($vec, $index
+ 1));
    }
}

```

```

template replace-string ($text, $from, $to) {

    if (contains($text, $from)) {
        var $before = substring-before($text, $from);
        var $after = substring-after($text, $from);
        var $prefix = $before _ $to;

        expr $before;
        expr $to;
        call replace-string($text = $after, $from, $to);

    } else {
        expr $text;
    }
}

```

After creating your customized trap, you must configure a policy on your device to tell the device what actions to take after it receives the trap.

Here is an example of a configured policy under the **[edit event-options]** hierarchy:

```

[edit event-options]
user@host> show
policy trap-on-event {
    events UI_COMMIT_NOT_CONFIRMED;
    attributes-match {
        UI_COMMIT_NOT_CONFIRMED.message matches complete;
    }
    then {
        event-script ev-syslog-trap.junos-op {
            arguments {
                event UI_COMMIT_NOT_CONFIRMED;
                message "${$.message}";
            }
        }
    }
}

```

Can I disable link up and link down traps on interfaces?

Yes, link up and link down traps can be disabled in the interface configuration. To disable the traps, use the **no-traps** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** and **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchies for physical and logical interfaces.

```
(traps | no-traps);
```

I see the link up traps on logical interfaces, but I do not see the link down traps. Is this normal behavior?

For Ethernet and ATM types of interfaces, Junos OS does not send link down traps for a logical interface if the physical interface is down to prevent flooding alarms for the same root cause. However, when the physical interface and logical interfaces come back up, traps are sent indicating link up. This is because the physical interface coming up does not necessarily mean the logical interfaces are also coming up.

For SONET types of interfaces with PPP encapsulation, Junos OS does send link down traps for a logical interface if the physical interface is down. When the physical interface and logical interfaces come back up, traps are sent for both the physical and logical interfaces indicating link up.

For SONET types of interfaces with HDLC encapsulation, Junos OS does not send link down traps for a logical interface if the physical interface is down. When the physical interface and logical interfaces come back up, traps are sent for both the physical and logical interfaces indicating link up.

For channelize interfaces with PPP encapsulation, Junos OS does send link down traps for a logical interface if the physical interface is down. When the physical interface and logical interfaces come back up, traps are sent for both the physical and logical interfaces indicating link up.

For channelize interfaces with HDLC encapsulation, Junos OS does not send link down traps for a logical interface if the physical interface is down. When the physical interface and logical interfaces come back up, traps are sent for both the physical and logical interfaces indicating link up.

Related Documentation

Junos OS Dual Routing Engine Configuration FAQs

This section presents frequently asked questions and answers related to the configuration of dual Routing Engines.

The SNMP configuration should be identical between the Routing Engines when configuring for continued communication. However, we recommend having separate Routing Engine IDs configured for each Routing Engine, when using SNMPv3.

In my system, the MIB object `snmpEngineBoots` is not in sync between two Routing Engines in a dual Routing Engine device. Is this normal behavior?

Yes. This is the normal behavior. Each Routing Engine runs its own SNMP process (`snmpd`) agent, allowing each Routing Engine to maintain its own engine boots.

Is there a way to identify that an address belongs to RE0, RE1, or the master Routing Engine management interface (`fxp0`) by looking at an SNMP walk?

No. When you do an SNMP walk on the device, it only displays the master Routing Engine management interface address.

What is the best way to tell if the current IP address belongs to `fxp0` or a Routing Engine, from a CLI session?

Routing Engines are mapped with the `fxp0` interface. This means that when you query RE0, the `ifTable` reports the `fxp0` interface address of RE0 only. Similarly, if you query RE1, the `ifTable` reports the `fxp0` interface address of RE1 only.

When there is a failover, the master hostname is changed since the hostname belongs to the Routing Engine. Is this correct?

Yes. You can configure the same hostname or different hostnames. Either would work.

If only the master IP address is configured (for example, 192.168.2.5), and the **sysDescr.0** object has the same string configured on both of the Routing Engines, then even after a switchover, the **sysDescr.0** object returns the same value. The following sample shows the results you get by using the **snmpget** command:

```
bng-junos-pool02: /c/svivek/PR_BRANCH/src> snmpget -c jnpr -v2c 192.168.2.5
sysDescr.0 system.sysDescr.0 = foo
```

SNMP Support for Routing Instances FAQs

This section presents frequently asked questions and answers related to how SNMP supports routing instances.

Can the SNMP manager access data for routing instances?

Yes, the Junos OS enables SNMP managers for all routing instances to request and manage SNMP data related to the corresponding routing instances and logical system networks.

Two different routing instance behaviors can occur, depending on where the clients originate:

- Clients from routing instances other than the default can access MIB objects and perform SNMP operations only on the logical system networks to which they belong.
- Clients from the default routing instance can access information related to all routing instances and logical system networks.

Routing instances are identified by either the context field in SNMPv3 requests or encoded in the community string in SNMPv1 or SNMPv2c requests.

When encoded in a community string, the routing instance name appears first and is separated from the actual community string by the @ character.

To avoid conflicts with valid community strings that contain the @ character, the community is parsed only if typical community string processing fails. For example, if a routing instance named **RI** is configured, an SNMP request with **RI@public** is processed within the context of the **RI** routing instance. Access control (including views, source address restrictions, and access privileges) is applied according to the actual community string (the set of data after the @ character—in this case **public**). However, if the community string **RI@public** is configured, the PDU is processed according to that community, and the embedded routing instance name is ignored.

Logical systems perform a subset of the actions of a physical router and have their own unique routing tables, interfaces, policies, and routing instances. When a routing instance is defined within a logical system, the logical system name must be encoded along with the routing instance using a slash (/) to separate the two. For example, if the routing instance **RI** is configured within the logical system **LS**, that routing instance must be encoded within a community string as **LS/RI@public**. When a routing instance is configured outside a logical system (within the default logical system), no logical system name, or / character, is needed.

Additionally, when a logical system is created, a default routing instance named **default** is always created within the logical system. This name should be used when querying data for that routing instance, for example **LS/default@public**. For SNMPv3 requests, the name **logical system/routing instance** should be identified directly in the context field.

Can I access a list of all routing instances on a device?

Yes, you can access a list of all the routing instances on a device using the `vacmContextName` object in the SNMP-VIEW-BASED-ACM MIB. In SNMP, each routing instance becomes a VACM context; this is why the routing instances appear in the `vacmContextName` object.

Can I access a default routing instance from a client in another logical router or routing instance?

No, the SNMP agent can only access data of the logical router to which it is connected.

Related Documentation

SNMP Counters FAQs

This section presents frequently asked questions and answers related to SNMP counters.

Which MIB should I use for interface counters?

Interface management over SNMP is based on two tables: the **ifTable** and its extension the **ifXTable**. Both are described in RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II* and RFC 2233, *The Interfaces Group MIB using SMIv2*.

Interfaces can have several layers, depending on the media, and each sublayer is represented by a separate row in the table. The relationship between the higher layer and lower layers is described in the **ifStackTable**.

The **ifTable** defines 32-bit counters for inbound and outbound octets (`ifInOctets/ifOutOctets`), packets (`ifInUcastPkts/ifOutUcastPkts`, `ifInNUcastPkts/ifOutNUcastPkts`), errors, and discards.

The **ifXTable** provides similar 64-bit counters, also called high capacity (HC) counters, for inbound and outbound octets (`ifHCInOctets/ifHCOctets`) and inbound packets (`ifHCInUcastPkts`).

When should 64-bit counters be used?

It is always good to use 64-bit counters because they contain statistics for both low and high capacity components.

Are the SNMP counters `ifInOctets` and `ifOutOctets` the same as the command `reference show interfaces statistics in and out counters`?

Yes, these are the same, but only if SNMP is enabled when the router boots up. If you power on a Juniper Networks device and then enable SNMP, the SNMP counters start

from 0. SNMP counters do not automatically receive their statistics from the **show** command output. Similarly, using the **clear statistics** command does not clear the statistics that the SNMP counters collected, which can cause a discrepancy in the data that is seen by both processes.

Do the SNMP counters ifInOctets and ifOutOctets include the framing overhead for Point-to-Point Protocol (PPP) and High-Level Data Link Control (HDLC)?

Yes.

Remote Monitoring (RMON) with SNMP

- [RMON Overview on page 1621](#)
- [Configuring RMON Alarms and Events on page 1625](#)
- [Monitoring RMON Alarms and Events on page 1633](#)
- [Using RMON to Monitor Network Service Quality on page 1639](#)

CHAPTER 69

RMON Overview

- [Understanding RMON Alarms on page 1621](#)
- [Understanding RMON Events on page 1623](#)

Understanding RMON Alarms

An RMON alarm identifies:

- A specific MIB object that is monitored.
- The frequency of sampling.
- The method of sampling.
- The thresholds against which the monitored values are compared.

An RMON alarm can also identify a specific **eventTable** entry to be triggered when a threshold is crossed.

Configuration and operational values are defined in **alarmTable** in RFC 2819. Additional operational values are defined in Juniper Networks enterprise-specific extensions to **alarmTable** (**jnxRmonAlarmTable**).

This topic covers the following sections:

- [alarmTable on page 1621](#)
- [jnxRmonAlarmTable on page 1622](#)

alarmTable

alarmTable in the RMON MIB allows you to monitor and poll the following:

- **alarmIndex**—The index value for **alarmTable** that identifies a specific entry.
- **alarmInterval**—The interval, in seconds, over which data is sampled and compared with the rising and falling thresholds.
- **alarmVariable**—The MIB variable that is monitored by the alarm entry.
- **alarmSampleType**—The method of sampling the selected variable and calculating the value to be compared against the thresholds.

- **alarmValue**—The value of the variable during the last sampling period. This value is compared with the rising and falling thresholds.
- **alarmStartupAlarm**—The alarm sent when the entry is first activated.
- **alarmRisingThreshold**—The upper threshold for the sampled variable.
- **alarmFallingThreshold**—The lower threshold for the sampled variable.
- **alarmRisingEventIndex**—The **eventTable** entry used when a rising threshold is crossed.
- **alarmFallingEventIndex**—The **eventTable** entry used when a falling threshold is crossed.
- **alarmStatus**—Method for adding and removing entries from the table. It can also be used to change the state of an entry to allow modifications.

NOTE: If this object is not set to **valid**, the associated event alarm does not take any action.

jnxRmonAlarmTable

The **jnxRmonAlarmTable** is a Juniper Networks enterprise-specific extension to **alarmTable**. It provides additional operational information and includes the following objects:

- **jnxRmonAlarmGetFailCnt**—The number of times the internal **Get** request for the variable monitored by this entry has failed.
- **jnxRmonAlarmGetFailTime**—The value of **sysUpTime** when an internal **Get** request for the variable monitored by this entry last failed.
- **jnxRmonAlarmGetFailReason**—The reason an internal **Get** request for the variable monitored by this entry last failed.
- **jnxRmonAlarmGetOkTime**—The value of **sysUpTime** when an internal **Get** request for the variable monitored by this entry succeeded and the entry left the **getFailure** state.
- **jnxRmonAlarmState**—The current state of this RMON alarm entry.

To view the Juniper Networks enterprise-specific extensions to the RMON Events and Alarms and Event MIB, see

http://www.juniper.net/techpubs/en_US/junos10.3/topics/reference/mibs/mib-jnx-rmon.txt.

For more information about the Juniper Networks enterprise-specific extensions to the RMON Events and Alarms MIB, see “*RMON Events and Alarms MIB*” in the *Network Management Administration Guide for Routing Devices*.

- [Using alarmTable to Monitor MIB Objects on page 1633](#)

Understanding RMON Events

An RMON event allows you to log the crossing of thresholds of other MIB objects. It is defined in **eventTable** for the RMON MIB.

This section covers the following topics:

- [eventTable on page 1623](#)

eventTable

eventTable contains the following objects:

- **eventIndex**—An index that uniquely identifies an entry in **eventTable**. Each entry defines one event that is generated when the appropriate conditions occur.
- **eventDescription**—A comment describing the event entry.
- **eventType**—Type of notification that the probe makes about this event.
- **eventCommunity**—Trap group used if an SNMP trap is to be sent. If **eventCommunity** is not configured, a trap is sent to each trap group configured with the **rmon-alarm** category.
- **eventLastTimeSent**—Value of **sysUpTime** when this event entry last generated an event.
- **eventOwner**—Any text string specified by the creating management application or the command-line interface (CLI). Typically, it is used to identify a network manager (or application) and can be used for fine access control between participating management applications.
- **eventStatus**—Status of this event entry.

NOTE: If this object is not set to valid, no action is taken by the associated event entry. When this object is set to valid, all previous log entries associated with this entry (if any) are deleted.

Understanding RMON Alarms and Events Configuration

Junos OS supports monitoring routers from remote devices. These values are measured against thresholds and trigger events when the thresholds are crossed. You configure remote monitoring (RMON) alarm and event entries to monitor the value of a MIB object.

To configure RMON alarm and event entries, you include statements at the **[edit snmp]** hierarchy level of the configuration:

```
[edit snmp]
rmon {
  alarm index {
    description text-description;
    falling-event-index index;
    falling-threshold integer;
    falling-threshold-interval seconds;
    interval seconds;
    rising-event-index index;
    rising-threshold integer;
    request-type (get-next-request | get-request | walk-request);
    sample-type (absolute-value | delta-value);
    startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
    syslog-subtag syslog-subtag;
    variable oid-variable;
    event index {
      community community-name;
      description description;
      type type;
    }
  }
}
```

Minimum RMON Alarm and Event Entry Configuration

To enable RMON on the router, you must configure an alarm entry and an event entry. To do this, include the following statements at the **[edit snmp rmon]** hierarchy level:

```
[edit snmp rmon]
alarm index {
  rising-event-index index;
  rising-threshold integer;
  sample-type type;
  variable oid-variable;
}
event index;
```

- Related Documentation**
- [Understanding RMON Alarms and Events Configuration on page 1625](#)
 - [Configuring an Alarm Entry and Its Attributes on page 1626](#)
 - [Configuring an Event Entry and Its Attributes on page 1630](#)

Configuring an Alarm Entry and Its Attributes

An alarm entry monitors the value of a MIB variable. You can configure how often the value is sampled, the type of sampling to perform, and what event to trigger if a threshold is crossed.

This section discusses the following topics:

- [Configuring the Alarm Entry on page 1627](#)
- [Configuring the Description on page 1627](#)
- [Configuring the Falling Event Index or Rising Event Index on page 1627](#)
- [Configuring the Falling Threshold or Rising Threshold on page 1627](#)
- [Configuring the Interval on page 1628](#)
- [Configuring the Falling Threshold Interval on page 1628](#)
- [Configuring the Request Type on page 1629](#)
- [Configuring the Sample Type on page 1629](#)
- [Configuring the Startup Alarm on page 1629](#)
- [Configuring the System Log Tag on page 1630](#)
- [Configuring the Variable on page 1630](#)

Configuring the Alarm Entry

An alarm entry monitors the value of a MIB variable. The **rising-event-index**, **rising-threshold**, **sample-type**, and **variable** statements are mandatory. All other statements are optional.

To configure the alarm entry, include the **alarm** statement and specify an index at the **[edit snmp rmon]** hierarchy level:

```
[edit snmp rmon]
alarm index {
  description description;
  falling-event-index index;
  falling-threshold integer;
  falling-threshold-interval seconds;
  interval seconds;
  rising-event-index index;
  rising-threshold integer;
  sample-type (absolute-value | delta-value);
  startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
  variable oid-variable;
}
```

index is an integer that identifies an alarm or event entry.

Configuring the Description

The description is a text string that identifies the alarm entry.

To configure the description, include the **description** statement and a description of the alarm entry at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
description description;
```

Configuring the Falling Event Index or Rising Event Index

The falling event index identifies the event entry that is triggered when a falling threshold is crossed. The rising event index identifies the event entry that is triggered when a rising threshold is crossed.

To configure the falling event index or rising event index, include the **falling-event-index** or **rising-event-index** statement and specify an index at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
falling-event-index index;
rising-event-index index;
```

index can be from 0 through 65,535. The default for both the falling and rising event index is 0.

Configuring the Falling Threshold or Rising Threshold

The falling threshold is the lower threshold for the monitored variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling

interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold, and the associated startup alarm is equal to **falling-alarm** or **rising-or-falling-alarm**. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the rising threshold. You must specify the falling threshold as an integer. Its default is 20 percent less than the rising threshold.

By default, the rising threshold is 0. The rising threshold is the upper threshold for the monitored variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated **startup-alarm** is equal to **rising-alarm** or **rising-or-falling-alarm**. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. You must specify the rising threshold as an integer.

To configure the falling threshold or rising threshold, include the **falling-threshold** or **rising-threshold** statement at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
  falling-threshold integer;
  rising-threshold integer;
```

integer can be a value from -2,147,483,647 through 2,147,483,647.

Configuring the Interval

The interval represents the period of time, in seconds, over which the monitored variable is sampled and compared with the rising and falling thresholds.

To configure the interval, include the **interval** statement and specify the number of seconds at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
  interval seconds;
```

seconds can be a value from 1 through 2,147,483,647. The default is 60 seconds.

Configuring the Falling Threshold Interval

The falling threshold interval represents the interval between samples when the rising threshold is crossed. Once the alarm crosses the falling threshold, the regular sampling interval is used.

NOTE: You cannot configure the falling threshold interval for alarms that have the request type set to **walk-request**.

To configure the falling threshold interval, include the **falling-threshold interval** statement at the **[edit snmp rmon alarm index]** hierarchy level and specify the number of seconds:

```
[edit snmp rmon alarm index]
  falling-threshold-interval seconds;
```

seconds can be a value from 1 through 2,147,483,647. The default is 60 seconds.

Configuring the Request Type

By default an RMON alarm can monitor only one object instance (as specified in the configuration). You can configure a **request-type** statement to extend the scope of the RMON alarm to include all object instances belonging to a MIB branch or to include the next object instance after the instance specified in the configuration.

To configure the request type, include the **request-type** statement at the **[edit snmp rmon alarm index]** hierarchy level and specify **get-next-request**, **get-request**, or **walk-request**:

```
[edit snmp rmon alarm index]
request-type (get-next-request | get-request | walk-request);
```

walk extends the RMON alarm configuration to all object instances belonging to a MIB branch. **next** extends the RMON alarm configuration to include the next object instance after the instance specified in the configuration.

Configuring the Sample Type

The sample type identifies the method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is **absolute-value**, the value of the selected variable is compared directly with the thresholds at the end of the sampling interval. If the value of this object is **delta-value**, the value of the selected variable at the last sample is subtracted from the current value, and the difference is compared with the thresholds.

To configure the sample type, include the **sample-type** statement and specify the type of sample at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
sample-type (absolute-value | delta-value);
```

- **absolute-value**—Actual value of the selected variable is compared against the thresholds.
- **delta-value**—Difference between samples of the selected variable is compared against the thresholds.

Configuring the Startup Alarm

The startup alarm identifies the type of alarm that can be sent when this entry is first activated. You can specify it as **falling-alarm**, **rising-alarm**, or **rising-or-falling-alarm**.

To configure the startup alarm, include the **startup-alarm** statement and specify the type of alarm at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
startup-alarm (falling-alarm | rising-alarm | rising-or-falling-alarm);
```

- **falling-alarm**—Generated if the first sample after the alarm entry becomes active is less than or equal to the falling threshold.
- **rising-alarm**—Generated if the first sample after the alarm entry becomes active is greater than or equal to the rising threshold.

- **rising-or-falling-alarm**—Generated if the first sample after the alarm entry becomes active satisfies either of the corresponding thresholds.

The default is **rising-or-falling-alarm**.

Configuring the System Log Tag

The **syslog-subtag** statement specifies the tag to be added to the system log message. You can specify a string of not more than 80 uppercase characters as the system log tag.

To configure the system log tag, include the **syslog-subtag** statement at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
syslog-subtag syslog-subtag;
```

Configuring the Variable

The variable identifies the MIB object that is being monitored.

To configure the variable, include the **variable** statement and specify the object identifier or object name at the **[edit snmp rmon alarm index]** hierarchy level:

```
[edit snmp rmon alarm index]
variable oid-variable;
```

oid-variable is a dotted decimal (for example, 1.3.6.1.2.1.2.1.2.2.1.10.1) or MIB object name (for example, ifInOctets.1).

Configuring an Event Entry and Its Attributes

An event entry generates a notification for an alarm entry when its rising or falling threshold is crossed. You can configure the type of notification that is generated. To configure the event entry, include the **event** statement at the **[edit snmp rmon]** hierarchy level. All statements except the **event** statement are optional.

```
[edit snmp rmon]
event index {
  community community-name;
  description description;
  type type;
}
```

index identifies an entry event.

community-name is the trap group that is used when generating a trap. If that trap group has the **rmon-alarm** trap category configured, a trap is sent to all the targets configured for that trap group. The community string in the trap matches the name of the trap group. If nothing is configured, all the trap groups are examined, and traps are sent using each group with the **rmon-alarm** category set.

description is a text string that identifies the entry.

The **type** variable of an event entry specifies where the event is to be logged. You can specify the type as one of the following:

- **log**—Adds the event entry to the **logTable**.
- **log-and-trap**—Sends an SNMP trap and creates a log entry.
- **none**—Sends no notification.
- **snmptrap**—Sends an SNMP trap.

The default for the event entry type is **log-and-trap**.

Example: Configuring an RMON Alarm and Event Entry

Configure an RMON alarm and event entry:

```
[edit snmp]
rmon {
  alarm 100 {
    description "input traffic on fxp0";
    falling-event-index 100;
    falling-threshold 10000;
    interval 60;
    rising-event-index 100;
    rising-threshold 100000;
    sample-type delta-value;
    startup-alarm rising-or-falling-alarm;
    variable ifInOctets.1;
  }
  event 100 {
    community bedrock;
    description "emergency events";
    type log-and-trap;
  }
}
```

Monitoring RMON Alarms and Events

- [Using alarmTable to Monitor MIB Objects on page 1633](#)
- [Using eventTable to Log Alarms on page 1636](#)

Using alarmTable to Monitor MIB Objects

To use **alarmTable** to monitor a MIB object, perform the following tasks:

- [Creating an Alarm Entry on page 1633](#)
- [Configuring the Alarm MIB Objects on page 1633](#)
- [Activating a New Row in alarmTable on page 1636](#)
- [Modifying an Active Row in alarmTable on page 1636](#)
- [Deactivating a Row in alarmTable on page 1636](#)

Creating an Alarm Entry

To create an alarm entry, first create a new row in **alarmTable** using the **alarmStatus** object. For example, create alarm #1 using the UCD command-line utilities:

```
snmpset -Os -v2c router community alarmStatus.1 i createRequest
```

Configuring the Alarm MIB Objects

Once you have created the new row in **alarmTable**, configure the following Alarm MIB objects:

NOTE: Other than **alarmStatus**, you cannot modify any of the objects in the entry if the associated **alarmStatus** object is set to valid.

- [alarmInterval on page 1634](#)
- [alarmVariable on page 1634](#)
- [alarmSampleType on page 1634](#)
- [alarmValue on page 1634](#)
- [alarmStartupAlarm on page 1634](#)
- [alarmRisingThreshold on page 1635](#)

- [alarmFallingThreshold](#) on page 1635
- [alarmOwner](#) on page 1635
- [alarmRisingEventIndex](#) on page 1635
- [alarmFallingEventIndex](#) on page 1635

alarmInterval

The interval, in seconds, over which data is sampled and compared with the rising and falling thresholds. For example, to set **alarmInterval** for alarm #1 to 30 seconds, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmInterval.1 i 30
```

alarmVariable

The object identifier of the variable to be sampled. During a **Set** request, if the supplied variable name is not available in the selected MIB view, a **badValue** error is returned. If at any time the variable name of an established **alarmEntry** is no longer available in the selected MIB view, the probe changes the status of **alarmVariable** to invalid. For example, to identify **ifInOctets.61** as the variable to be monitored, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmVariable.1 o .1.3.6.1.2.1.2.2.1.10.61
```

alarmSampleType

The method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is **absoluteValue**, the value of the selected variable is compared directly with the thresholds at the end of the sampling interval. If the value of this object is **deltaValue**, the value of the selected variable at the last sample is subtracted from the current value, and the difference is compared with the thresholds. For example, to set **alarmSampleType** for alarm #1 to **deltaValue**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmSampleType.1 i deltaValue
```

alarmValue

The value of the variable during the last sampling period. This value is compared with the rising and falling thresholds. If the sample type is **deltaValue**, this value equals the difference between the samples at the beginning and end of the period. If the sample type is **absoluteValue**, this value equals the sampled value at the end of the period.

alarmStartupAlarm

An alarm that is sent when this entry is first set to valid. If the first sample after this entry becomes valid is greater than or equal to **risingThreshold**, and **alarmStartupAlarm** is equal to **risingAlarm** or **risingOrFallingAlarm**, then a single rising alarm is generated. If the first sample after this entry becomes valid is less than or equal to **fallingThreshold** and **alarmStartupAlarm** is equal to **fallingAlarm** or **risingOrFallingAlarm**, then a single falling

alarm is generated. For example, to set **alarmStartupAlarm** for alarm #1 to **risingOrFallingAlarm**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmStartupAlarm.1 i risingOrFallingAlarm
```

alarmRisingThreshold

A threshold for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated **alarmStartupAlarm** is equal to **risingAlarm** or **risingOrFallingAlarm**. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches **alarmFallingThreshold**. For example, to set **alarmRisingThreshold** for alarm #1 to **100000**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmRisingThreshold.1 i 100000
```

alarmFallingThreshold

A threshold for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold, and the associated **alarmStartupAlarm** is equal to **fallingAlarm** or **risingOrFallingAlarm**. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches **alarmRisingThreshold**. For example, to set **alarmFallingThreshold** for alarm #1 to **10000**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmFallingThreshold.1 i 10000
```

alarmOwner

Any text string specified by the creating management application or the command-line interface (CLI). Typically, it is used to identify a network manager (or application) and can be used for fine access control between participating management applications.

alarmRisingEventIndex

The index of the **eventEntry** object that is used when a rising threshold is crossed. If there is no corresponding entry in **eventTable**, then no association exists. If this value is zero, no associated event is generated because zero is not a valid event index. For example, to set **alarmRisingEventIndex** for alarm #1 to **10**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmRisingEventIndex.1 i 10
```

alarmFallingEventIndex

The index of the **eventEntry** object that is used when a falling threshold is crossed. If there is no corresponding entry in **eventTable**, then no association exists. If this value is zero, no associated event is generated because zero is not a valid event index. For example, to set **alarmFallingEventIndex** for alarm #1 to **10**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community alarmFallingEventIndex.1 i 10
```

Activating a New Row in alarmTable

To activate a new row in **alarmTable**, set **alarmStatus** to **valid** using an SNMP **Set** request:

```
snmpset -Os -v2c router community alarmStatus.1 i valid
```

Modifying an Active Row in alarmTable

To modify an active row, first set **alarmStatus** to **underCreation** using an SNMP **Set** request:

```
snmpset -Os -v2c router community alarmStatus.1 i underCreation
```

Then change the row contents using an SNMP **Set** request:

```
snmpset -Os -v2c router community alarmFallingThreshold.1 i 1000
```

Finally, activate the row by setting **alarmStatus** to **valid** using an SNMP **Set** request:

```
snmpset -Os -v2c router community alarmStatus.1 i valid
```

Deactivating a Row in alarmTable

To deactivate a row in **alarmTable**, set **alarmStatus** to **invalid** using an SNMP **Set** request:

```
snmpset -Os -v2c router community alarmStatus.1 i invalid
```

Related Documentation

- [Understanding RMON Alarms on page 1621](#)
- [Understanding RMON Events on page 1623](#)
- [Configuring an Alarm Entry and Its Attributes on page 1626](#)

Using eventTable to Log Alarms

To use **eventTable** to log alarms, perform the following tasks:

- [Creating an Event Entry on page 1636](#)
- [Configuring the MIB Objects on page 1637](#)
- [Activating a New Row in eventTable on page 1638](#)
- [Deactivating a Row in eventTable on page 1638](#)

Creating an Event Entry

The RMON **eventTable** controls the generation of notifications from the router. Notifications can be logs (entries to **logTable** and **syslogs**) or SNMP traps. Each event entry can be configured to generate any combination of these notifications (or no notification). When an event specifies that an SNMP trap is to be generated, the trap group that is used when sending the trap is specified by the value of the associated **eventCommunity** object. Consequently, the community in the trap message will match the value specified by **eventCommunity**. If nothing is configured for **eventCommunity**, a trap is sent using each trap group that has the **rmon-alarm** category configured.

Configuring the MIB Objects

Once you have created the new row in **eventTable**, set the following objects:

NOTE: The **eventType** object is required. All other objects are optional.

- [eventType](#) on page 1637
- [eventCommunity](#) on page 1637
- [eventOwner](#) on page 1637
- [eventDescription](#) on page 1638

eventType

The type of notification that the router generates when the event is triggered.

This object can be set to the following values:

- **log**—Adds the event entry to **logTable**.
- **log-and-trap**—Sends an SNMP trap and creates a log entry.
- **none**—Sends no notification.
- **snmptrap**—Sends an SNMP trap.

For example, to set **eventType** for event #1 to **log-and-trap**, use the following SNMP Set request:

```
snmpset -Os -v2c router community eventType.1 i log-and-trap
```

eventCommunity

The trap group that is used when generating a trap (if **eventType** is configured to send traps). If that trap group has the **rmon-alarm** trap category configured, a trap is sent to all the targets configured for that trap group. The community string in the trap matches the name of the trap group (and hence, the value of **eventCommunity**). If nothing is configured, traps are sent to each group with the **rmon-alarm** category set. For example, to set **eventCommunity** for event #1 to **boy-elroy**, use the following SNMP Set request:

```
snmpset -Os -v2c router community eventCommunity.1 s "boy-elroy"
```

NOTE: The **eventCommunity** object is optional. If you do not set this object, then the field is left blank.

eventOwner

Any text string specified by the creating management application or the command-line interface (CLI). Typically, it is used to identify a network manager (or application) and can be used for fine access control between participating management applications.

For example, to set **eventOwner** for event #1 to **george jetson**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community eventOwner.1 s "george jetson"
```

NOTE: The **eventOwner** object is optional. If you do not set this object, then the field is left blank.

eventDescription

Any text string specified by the creating management application or the command-line interface (CLI). The use of this string is application dependent.

For example, to set **eventDescription** for event #1 to **spacelys sprockets**, use the following SNMP **Set** request:

```
snmpset -Os -v2c router community eventDescription.1 s "spacelys sprockets"
```

NOTE: The **eventDescription** object is optional. If you do not set this object, then the field is left blank.

Activating a New Row in eventTable

To activate the new row in **eventTable**, set **eventStatus** to **valid** using an SNMP **Set** request such as:

```
snmpset -Os -v2c router community eventStatus.1 i valid
```

Deactivating a Row in eventTable

To deactivate a row in **eventTable**, set **eventStatus** to **invalid** using an SNMP **Set** request such as:

```
snmpset -Os -v2c router community eventStatus.1 i invalid
```

Understanding RMON for Monitoring Service Quality

Health and performance monitoring can benefit from the remote monitoring of SNMP variables by the local SNMP agents running on each router. The SNMP agents compare MIB values against predefined thresholds and generate exception alarms without the need for polling by a central SNMP management platform. This is an effective mechanism for proactive management, as long as the thresholds have baselines determined and set correctly. For more information, see RFC 2819, *Remote Network Monitoring MIB*.

This topic includes the following sections:

- [Setting Thresholds on page 1639](#)
- [RMON Command-Line Interface on page 1640](#)
- [RMON Event Table on page 1641](#)
- [RMON Alarm Table on page 1641](#)
- [Troubleshooting RMON on page 1642](#)

Setting Thresholds

By setting a rising and a falling threshold for a monitored variable, you can be alerted whenever the value of the variable falls outside of the allowable operational range. (See [Figure 35](#).)

Figure 35: Setting Thresholds

g041661

Events are only generated when the threshold is first crossed in any one direction rather than after each sample period. For example, if a rising threshold crossing event is raised, no more threshold crossing events will occur until a corresponding falling event. This considerably reduces the quantity of alarms that are produced by the system, making it easier for operations staff to react when alarms do occur.

To configure remote monitoring, specify the following pieces of information:

- The variable to be monitored (by its SNMP object identifier)
- The length of time between each inspection
- A rising threshold
- A falling threshold
- A rising event
- A falling event

Before you can successfully configure remote monitoring, you should identify what variables need to be monitored and their allowable operational range. This requires some period of baselining to determine the allowable operational ranges. An initial baseline period of at least three months is not unusual when first identifying the operational ranges and defining thresholds, but baseline monitoring should continue over the life span of each monitored variable.

RMON Command-Line Interface

Junos OS provides two mechanisms you use to control the Remote Monitoring agent on the router: command-line interface (CLI) and SNMP. To configure an RMON entry using the CLI, include the following statements at the **[edit snmp]** hierarchy level:

```
rmon {
  alarm index {
    description;
    falling-event-index;
    falling-threshold;
    intervals;
    rising-event-index;
```

```

    rising-threshold;
    sample-type (absolute-value | delta-value);
    startup-alarm (falling | rising | rising-or-falling);
    variable;
  }
  event index {
    community;
    description;
    type (log | trap | log-and-trap | none);
  }
}

```

If you do not have CLI access, you can configure remote monitoring using the SNMP Manager or management application, assuming SNMP access has been granted. (See [Table 125](#).) To configure RMON using SNMP, perform SNMP **Set** requests to the RMON event and alarm tables.

RMON Event Table

Set up an event for each type that you want to generate. For example, you could have two generic events, *rising* and *falling*, or many different events for each variable that is being monitored (for example, *temperature rising* event, *temperature falling* event, *firewall hit* event, *interface utilization* event, and so on). Once the events have been configured, you do not need to update them.

Table 125: RMON Event Table

Field	Description
eventDescription	Text description of this event
eventType	Type of event (for example, log , trap , or log and trap)
eventCommunity	Trap group to which to send this event (as defined in the Junos OS configuration, which is not the same as the community)
eventOwner	Entity (for example, manager) that created this event
eventStatus	Status of this row (for example, valid , invalid , or createRequest)

RMON Alarm Table

The RMON alarm table stores the SNMP object identifiers (including their instances) of the variables that are being monitored, together with any rising and falling thresholds and their corresponding event indexes. To create an RMON request, specify the fields shown in [Table 126](#).

Table 126: RMON Alarm Table

Field	Description
alarmStatus	Status of this row (for example, valid , invalid , or createRequest)

Table 126: RMON Alarm Table (*continued*)

Field	Description
alarmInterval	Sampling period (in seconds) of the monitored variable
alarmVariable	OID (and instance) of the variable to be monitored
alarmValue	Actual value of the sampled variable
alarmSampleType	Sample type (absolute or delta changes)
alarmStartupAlarm	Initial alarm (rising , falling , or either)
alarmRisingThreshold	Rising threshold against which to compare the value
alarmFallingThreshold	Falling threshold against which to compare the value
alarmRisingEventIndex	Index (row) of the rising event in the event table
alarmFallingEventIndex	Index (row) of the falling event in the event table

Both the **alarmStatus** and **eventStatus** fields are **entryStatus** primitives, as defined in RFC 2579, *Textual Conventions for SMIV2*.

Troubleshooting RMON

You troubleshoot the RMON agent, **rmopd**, that runs on the router by inspecting the contents of the Juniper Networks enterprise RMON MIB, **jnxRmon**, which provides the extensions listed in [Table 127](#) to the RFC 2819 **alarmTable**.

Table 127: jnxRmon Alarm Extensions

Field	Description
jnxRmonAlarmGetFailCnt	Number of times the internal Get request for the variable failed
jnxRmonAlarmGetFailTime	Value of sysUpTime when the last failure occurred
jnxRmonAlarmGetFailReason	Reason why the Get request failed
jnxRmonAlarmGetOkTime	Value of sysUpTime when the variable moved out of failure state
jnxRmonAlarmState	Status of this alarm entry

Monitoring the extensions in this table provides clues as to why remote alarms may not behave as expected.

Understanding Measurement Points, Key Performance Indicators, and Baseline Values

This chapter topic provides guidelines for monitoring the service quality of an IP network. It describes how service providers and network administrators can use information provided by Juniper Networks routers to monitor network performance and capacity. You should have a thorough understanding of the SNMP and the associated MIB supported by Junos OS.

NOTE: For a good introduction to the process of monitoring an IP network, see RFC 2330, *Framework for IP Performance Metrics*.

This topic contains the following sections:

- [Measurement Points on page 1643](#)
- [Basic Key Performance Indicators on page 1644](#)
- [Setting Baselines on page 1644](#)

Measurement Points

Defining the measurement points where metrics are measured is equally as important as defining the metrics themselves. This section describes measurement points within the context of this chapter and helps identify where measurements can be taken from a service provider network. It is important to understand exactly where a measurement point is. Measurement points are vital to understanding the implication of what the actual measurement means.

An IP network consists of a collection of routers connected by physical links that are all running the Internet Protocol. You can view the network as a collection of routers with an ingress (entry) point and an egress (exit) point. See [Figure 36](#).

- Network-centric measurements are taken at measurement points that most closely map to the ingress and egress points for the network itself. For example, to measure delay across the provider network from Site A to Site B, the measurement points should be the ingress point to the provider network at Site A and the egress point at Site B.
- Router-centric measurements are taken directly from the routers themselves, but be careful to ensure that the correct router subcomponents have been identified in advance.

Figure 36: Network Entry Points

9017042

NOTE: [Figure 36](#) does not show the client networks at customer premises, but they would be located on either side of the ingress and egress points. Although this chapter does not discuss how to measure network services as perceived by these client networks, you can use measurements taken for the service provider network as input into such calculations.

Basic Key Performance Indicators

For example, you could monitor a service provider network for three basic key performance indicators (KPIs):

- *Availability* measures the “reachability” of one measurement point from another measurement point at the network layer (for example, using ICMP ping). The underlying routing and transport infrastructure of the provider network will support the availability measurements, with failures highlighted as unavailability.
- *Health* measures the number and type of errors that are occurring on the provider network, and can consist of both router-centric and network-centric measurements, such as hardware failures or packet loss.
- *Performance* of the provider network measures how well it can support IP services (for example, in terms of delay or utilization).

Setting Baselines

How well is the provider network performing? We recommend an initial three-month period of monitoring to identify a network’s normal operational parameters. With this information, you can recognize exceptions and identify abnormal behavior. You should continue baseline monitoring for the lifetime of each measured metric. Over time, you must be able to recognize performance trends and growth patterns.

Within the context of this chapter, many of the metrics identified do not have an allowable operational range associated with them. In most cases, you cannot identify the allowable operational range until you have determined a baseline for the actual variable on a specific network.

- [Measuring Performance on page 1656](#)

Defining and Measuring Network Availability

This topic includes the following sections:

- [Defining Network Availability on page 1645](#)
- [Measuring Availability on page 1647](#)

Defining Network Availability

Availability of a service provider's IP network can be thought of as the reachability between the regional points of presence (POP), as shown in [Figure 37](#).

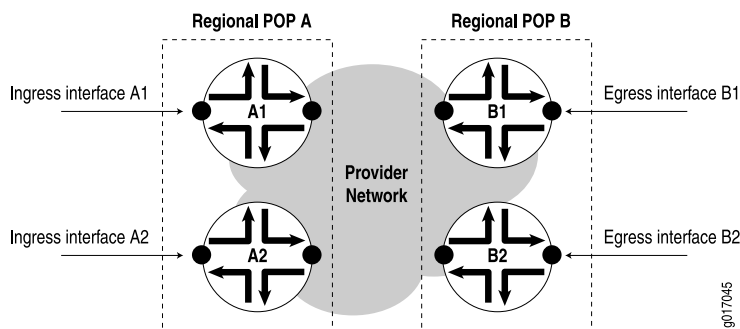

Figure 37: Regional Points of Presence

With the example above, when you use a full mesh of measurement points, where every POP measures the availability to every other POP, you can calculate the total availability of the service provider's network. This KPI can also be used to help monitor the service level of the network, and can be used by the service provider and its customers to determine if they are operating within the terms of their service-level agreement (SLA).

Where a POP may consist of multiple routers, take measurements to each router as shown in [Figure 38](#).

Figure 38: Measurements to Each Router

Measurements include:

- Path availability—Availability of an egress interface **B1** as seen from an ingress interface **A1**.
- Router availability—Percentage of path availability of all measured paths terminating on the router.
- POP availability—Percentage of router availability between any two regional POPs, **A** and **B**.
- Network availability—Percentage of POP availability for all regional POPs in the service provider's network.

To measure POP availability of **POP A** to **POP B** in [Figure 38](#), you must measure the following four paths:

Path A1 => B1
Path A1 => B2
Path A2 => B1
Path A2 => B2

Measuring availability from **POP B** to **POP A** would require a further four measurements, and so on.

A full mesh of availability measurements can generate significant management traffic. From the sample diagram above:

- Each POP has two co-located provider edge (PE) routers, each with 2xSTM1 interfaces, for a total of 18 PE routers and 36xSTM1 interfaces.
- There are six core provider (P) routers, four with 2xSTM4 and 3xSTM1 interfaces each, and two with 3xSTM4 and 3xSTM1 interfaces each.

This makes a total of 68 interfaces. A full mesh of paths between every interface is:

$[n \times (n-1)] / 2$ gives $[68 \times (68-1)] / 2 = 2278$ paths

To reduce management traffic on the service provider's network, instead of generating a full mesh of interface availability tests (for example, from each interface to every other interface), you can measure from each router's loopback address. This reduces the number of availability measurements required to a total of one for each router, or:

$[n \times (n-1)] / 2$ gives $[24 \times (24-1)] / 2 = 276$ measurements

This measures availability from each router to every other router.

Monitoring the SLA and the Required Bandwidth

A typical SLA between a service provider and a customer might state:

A Point of Presence is the connection of two back-to-back provider edge routers to separate core provider routers using different links for resilience. The system is considered to be unavailable when either an entire POP becomes unavailable or for the duration of a Priority 1 fault.

An SLA availability figure of 99.999 percent for a provider's network would relate to a down time of approximately 5 minutes per year. Therefore, to measure this proactively,

you would have to take availability measurements at a granularity of less than one every five minutes. With a standard size of 64 bytes per ICMP ping request, one ping test per minute would generate 7680 bytes of traffic per hour per destination, including ping responses. A full mesh of ping tests to 276 destinations would generate 2,119,680 bytes per hour, which represents the following:

- On an OC3/STM1 link of 155.52 Mbps, a utilization of 1.362 percent
- On an OC12/STM4 link of 622.08 Mbps, a utilization of 0.340 percent

With a size of 1500 bytes per ICMP ping request, one ping test per minute would generate 180,000 bytes per hour per destination, including ping responses. A full mesh of ping tests to 276 destinations would generate 49,680,000 bytes per hour, which represents the following:

- On an OC3/STM1 link, 31.94 percent utilization
- On an OC12/STM4 link, 7.986 percent utilization

Each router can record the results for every destination tested. With one test per minute to each destination, a total of $1 \times 60 \times 24 \times 276 = 397,440$ tests per day would be performed and recorded by each router. All ping results are stored in the **pingProbeHistoryTable** (see RFC 2925) and can be retrieved by an SNMP performance reporting application (for example, service performance management software from InfoVista, Inc., or Concord Communications, Inc.) for post processing. This table has a maximum size of 4,294,967,295 rows, which is more than adequate.

Measuring Availability

There are two methods you can use to measure availability:

- Proactive—Availability is automatically measured as often as possible by an operational support system.
- Reactive—Availability is recorded by a Help desk when a fault is first reported by a user or a fault monitoring system.

This section discusses real-time performance monitoring as a proactive monitoring solution.

Real-Time Performance Monitoring

Juniper Networks provides a real-time performance monitoring (RPM) service to monitor real-time network performance. Use the J-Web Quick Configuration feature to configure real-time performance monitoring parameters used in real-time performance monitoring tests. (J-Web Quick Configuration is a browser-based GUI that runs on Juniper Networks routers. For more information, see the *J-Web Interface User Guide*.)

Configuring Real-Time Performance Monitoring

Some of the most common options you can configure for real-time performance monitoring tests are shown in [Table 128](#).

Table 128: Real-Time Performance Monitoring Configuration Options

Field	Description
Request Information	
Probe Type	Type of probe to send as part of the test. Probe types can be: <ul style="list-style-type: none"> • http-get • http-get-metadata • icmp-ping • icmp-ping-timestamp • tcp-ping • udp-ping
Interval	Wait time (in seconds) between each probe transmission. The range is 1 to 255 seconds.
Test Interval	Wait time (in seconds) between tests. The range is 0 to 86400 seconds.
Probe Count	Total number of probes sent for each test. The range is 1 to 15 probes.
Destination Port	TCP or UDP port to which probes are sent. Use number 7—a standard TCP or UDP port number—or select a port number from 49152 through 65535.
DSCP Bits	Differentiated Services code point (DSCP) bits. This value must be a valid 6-bit pattern. The default is 000000.
Data Size	Size (in bytes) of the data portion of the ICMP probes. The range is 0 to 65507 bytes.
Data Fill	Contents of the data portion of the ICMP probes. Contents must be a hexadecimal value. The range is 1 to 800h.
Maximum Probe Thresholds	
Successive Lost Probes	Total number of probes that must be lost successively to trigger a probe failure and generate a system log message. The range is 0 to 15 probes.
Lost Probes	Total number of probes that must be lost to trigger a probe failure and generate a system log message. The range is 0 to 15 probes.
Round Trip Time	Total round-trip time (in microseconds) from the Services Router to the remote server, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Jitter	Total jitter (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.

Table 128: Real-Time Performance Monitoring Configuration Options (*continued*)

Field	Description
Standard Deviation	Maximum allowable standard deviation (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Egress Time	Total one-way time (in microseconds) from the router to the remote server, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Ingress Time	Total one-way time (in microseconds) from the remote server to the router, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Jitter Egress Time	Total outbound-time jitter (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Jitter Ingress Time	Total inbound-time jitter (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Egress Standard Deviation	Maximum allowable standard deviation of outbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.
Ingress Standard Deviation	Maximum allowable standard deviation of inbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. The range is 0 to 60,000,000 microseconds.

Displaying Real-Time Performance Monitoring Information

For each real-time performance monitoring test configured on the router, monitoring information includes the round-trip time, jitter, and standard deviation. To view this information, select **Monitor > RPM** in the J-Web interface, or enter the **show services rpm** command-line interface (CLI) command.

To display the results of the most recent real-time performance monitoring probes, enter the **show services rpm probe-results** CLI command:

```

user@host> show services rpm probe-results
Owner: p1, Test: t1
Target address: 10.8.4.1, Source address: 10.8.4.2, Probe type: icmp-ping
Destination interface name: lt-0/0/0.0
Test size: 10 probes
Probe results:
  Response received, Sun Jul 10 19:07:34 2005
  Rtt: 50302 usec
Results over current test:
```

```

Probes sent: 2, Probes received: 1, Loss percentage: 50
Measurement: Round trip time
  Minimum: 50302 usec, Maximum: 50302 usec, Average: 50302 usec,
  Jitter: 0 usec, Stddev: 0 usec
Results over all tests:
Probes sent: 2, Probes received: 1, Loss percentage: 50
Measurement: Round trip time
  Minimum: 50302 usec, Maximum: 50302 usec, Average: 50302 usec,
  Jitter: 0 usec, Stddev: 0 usec

```

Measuring Health

You can monitor health metrics reactively by using fault management software such as SMARTS InCharge, Micromuse Netcool Omnibus, or Concord Live Exceptions. We recommend that you monitor the health metrics shown in [Table 129](#).

Table 129: Health Metrics

Metric:	Errors in
Description	Number of inbound packets that contained errors, preventing them from being delivered
MIB name	IF-MIB (RFC 2233)
Variable name	ifInErrors
Variable OID	.1.3.6.1.31.2.2.1.14
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	Logical interfaces
Metric:	Errors out
Description	Number of outbound packets that contained errors, preventing them from being transmitted
MIB name	IF-MIB (RFC 2233)
Variable name	ifOutErrors

Table 129: Health Metrics (*continued*)

Variable OID	.1.3.6.1.31.2.2.1.20
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	Logical interfaces
Metric:	Discards in
Description	Number of inbound packets discarded, even though no errors were detected
MIB name	IF-MIB (RFC 2233)
Variable name	ifInDiscards
Variable OID	.1.3.6.1.31.2.2.1.13
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	Logical interfaces
Metric:	Unknown protocols
Description	Number of inbound packets discarded because they were of an unknown protocol
MIB name	IF-MIB (RFC 2233)
Variable name	ifInUnknownProtos
Variable OID	.1.3.6.1.31.2.2.1.15
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	Logical interfaces
Metric:	Interface operating status
Description	Operational status of an interface
MIB name	IF-MIB (RFC 2233)
Variable name	ifOperStatus

Table 129: Health Metrics (*continued*)

Variable OID	.1.3.6.1.31.2.2.1.8
Frequency (mins)	15
Allowable range	1 (up)
Managed objects	Logical interfaces
Metric:	Label Switched Path (LSP) state
Description	Operational state of an MPLS label-switched path
MIB name	MPLS-MIB
Variable name	mplsLspState
Variable OID	mplsLspEntry.2
Frequency (mins)	60
Allowable range	2 (up)
Managed objects	All label-switched paths in the network
Metric:	Component operating status
Description	Operational status of a router hardware component
MIB name	JUNIPER-MIB
Variable name	jnxOperatingState
Variable OID	.1.3.6.1.4.1.2636.1.13.1.6
Frequency (mins)	60
Allowable range	2 (running) or 3 (ready)
Managed objects	All components in each Juniper Networks router
Metric:	Component operating temperature
Description	Operational temperature of a hardware component, in Celsius
MIB name	JUNIPER-MIB
Variable name	jnxOperatingTemp
Variable OID	.1.3.6.1.4.1.2636.1.13.1.7

Table 129: Health Metrics (*continued*)

Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All components in a chassis
Metric:	System up time
Description	Time, in milliseconds, that the system has been operational.
MIB name	MIB-2 (RFC 1213)
Variable name	sysUpTime
Variable OID	.1.3.6.1.1.3
Frequency (mins)	60
Allowable range	Increasing only (decrement indicates a restart)
Managed objects	All routers
Metric:	No IP route errors
Description	Number of packets that could not be delivered because there was no IP route to their destination.
MIB name	MIB-2 (RFC 1213)
Variable name	ipOutNoRoutes
Variable OID	ip.12
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	Each router
Metric:	Wrong SNMP community names
Description	Number of incorrect SNMP community names received
MIB name	MIB-2 (RFC 1213)
Variable name	snmpInBadCommunityNames
Variable OID	snmp.4

Table 129: Health Metrics (*continued*)

Frequency (hours)	24
Allowable range	To be baselined
Managed objects	Each router
Metric:	SNMP community violations
Description	Number of valid SNMP communities used to attempt invalid operations (for example, attempting to perform SNMP Set requests)
MIB name	MIB-2 (RFC 1213)
Variable name	snmpInBadCommunityUses
Variable OID	snmp.5
Frequency (hours)	24
Allowable range	To be baselined
Managed objects	Each router
Metric:	Redundancy switchover
Description	Total number of redundancy switchovers reported by this entity
MIB name	JUNIPER-MIB
Variable name	jnxRedundancySwitchoverCount
Variable OID	jnxRedundancyEntry.8
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All Juniper Networks routers with redundant Routing Engines
Metric:	FRU state
Description	Operational status of each field-replaceable unit (FRU)
MIB name	JUNIPER-MIB
Variable name	jnxFruState
Variable OID	jnxFruEntry.8

Table 129: Health Metrics (*continued*)

Frequency (mins)	15
Allowable range	2 through 6 for ready/online states. See jnxFruOfflineReason in the event of a FRU failure.
Managed objects	All FRUs in all Juniper Networks routers.
Metric:	Rate of tail-dropped packets
Description	Rate of tail-dropped packets per output queue, per forwarding class, per interface.
MIB name	JUNIPER-COS-MIB
Variable name	jnxCosIfqTailDropPktRate
Variable OID	jnxCosIfqStatsEntry.12
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	For each forwarding class per interface in the provider network, when CoS is enabled.
Metric:	Interface utilization: octets received
Description	Total number of octets received on the interface, including framing characters.
MIB name	IF-MIB
Variable name	ifInOctets
Variable OID	.1.3.6.1.2.1.2.2.1.10.x
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All operational interfaces in the network
Metric:	Interface utilization: octets transmitted
Description	Total number of octets transmitted out of the interface, including framing characters.
MIB name	IF-MIB
Variable name	ifOutOctets

Table 129: Health Metrics (*continued*)

Variable OID	.1.3.6.1.2.1.2.2.1.16.x
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All operational interfaces in the network

NOTE: Byte counts vary depending on interface type, encapsulation used and PIC supported. For example, with vlan-ccc encapsulation on a 4xFE, GE, or GE IQ PIC, the byte count includes framing and control word overhead. (See [Table 130](#).)

Table 130: Counter Values for vlan-ccc Encapsulation

PIC Type	Encapsulation	Input (Unit Level)	Output (Unit Level)	SNMP
4xFE	vlan-ccc	Frame (no frame check sequence [FCS])	Frame (including FCS and control word)	ifInOctets, ifOutOctets
GE	vlan-ccc	Frame (no FCS)	Frame (including FCS and control word)	ifInOctets, ifOutOctets
GE IQ	vlan-ccc	Frame (no FCS)	Frame (including FCS and control word)	ifInOctets, ifOutOctets

SNMP traps are also a good mechanism to use for health management. For more information, see “[Standard SNMP Traps Supported on Devices Running Junos OS](#)” on [page 1456](#) and “[Juniper Networks Enterprise-Specific SNMP Traps](#)” on [page 1456](#) in the *SNMP MIBs and Traps Reference*.

Measuring Performance

The performance of a service provider's network is usually defined as how well it can support services, and is measured with metrics such as delay and utilization. We suggest that you monitor the following performance metrics using applications such as InfoVista Service Performance Management or Concord Network Health (see [Table 131](#)).

Table 131: Performance Metrics

Metric:	Average delay
Description	Average round-trip time (in milliseconds) between two measurement points.
MIB name	DISMAN-PING-MIB (RFC 2925)
Variable name	pingResultsAverageRtt
Variable OID	pingResultsEntry.6
Frequency (mins)	15 (or depending upon ping test frequency)
Allowable range	To be baselined
Managed objects	Each measured path in the network
Metric:	Interface utilization
Description	Utilization percentage of a logical connection.
MIB name	IF-MIB
Variable name	(ifInOctets & ifOutOctets) * 8 / ifSpeed
Variable OID	ifTable entries
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All operational interfaces in the network
Metric:	Disk utilization
Description	Utilization of disk space within the Juniper Networks router
MIB name	HOST-RESOURCES-MIB (RFC 2790)
Variable name	hrStorageSize – hrStorageUsed
Variable OID	hrStorageEntry.5 – hrStorageEntry.6
Frequency (mins)	1440
Allowable range	To be baselined
Managed objects	All Routing Engine hard disks

Table 131: Performance Metrics (*continued*)

Metric:	Memory utilization
Description	Utilization of memory on the Routing Engine and FPC.
MIB name	JUNIPER-MIB (Juniper Networks enterprise Chassis MIB)
Variable name	jnxOperatingHeap
Variable OID	Table for each component
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All Juniper Networks routers
Metric:	CPU load
Description	Average utilization over the past minute of a CPU.
MIB name	JUNIPER-MIB (Juniper Networks enterprise Chassis MIB)
Variable name	jnxOperatingCPU
Variable OID	Table for each component
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All Juniper Networks routers
Metric:	LSP utilization
Description	Utilization of the MPLS label-switched path.
MIB name	MPLS-MIB
Variable name	mplsPathBandwidth / (mplsLspOctets * 8)
Variable OID	mplsLspEntry.21 and mplsLspEntry.3
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	All label-switched paths in the network
Metric:	Output queue size

Table 131: Performance Metrics (*continued*)

Description	Size, in packets, of each output queue per forwarding class, per interface.
MIB name	JUNIPER-COS-MIB
Variable name	jnxCosIfqQedPkts
Variable OID	jnxCosIfqStatsEntry.3
Frequency (mins)	60
Allowable range	To be baselined
Managed objects	For each forwarding class per interface in the network, once CoS is enabled.

This section includes the following topics:

- [Measuring Class of Service on page 1659](#)
- [Inbound Firewall Filter Counters per Class on page 1660](#)
- [Monitoring Output Bytes per Queue on page 1661](#)
- [Dropped Traffic on page 1662](#)

Measuring Class of Service

You can use class-of-service (CoS) mechanisms to regulate how certain classes of packets are handled within your network during times of peak congestion. Typically you must perform the following steps when implementing a CoS mechanism:

- Identify the type of packets that is applied to this class. For example, include all customer traffic from a specific ingress edge interface within one class, or include all packets of a particular protocol such as voice over IP (VoIP).
- Identify the required deterministic behavior for each class. For example, if VoIP is important, give VoIP traffic the highest priority during times of network congestion. Conversely, you can downgrade the importance of Web traffic during congestion, as it may not impact customers too much.

With this information, you can configure mechanisms at the network ingress to monitor, mark, and police traffic classes. Marked traffic can then be handled in a more deterministic way at egress interfaces, typically by applying different queuing mechanisms for each class during times of network congestion. You can collect information from the network to provide customers with reports showing how the network is behaving during times of congestion. (See [Figure 39](#).)

Figure 39: Network Behavior During Congestion

To generate these reports, routers must provide the following information:

- Submitted traffic—Amount of traffic received per class.
- Delivered traffic—Amount of traffic transmitted per class.
- Dropped traffic—Amount of traffic dropped because of CoS limits.

The following section outlines how this information is provided by Juniper Networks routers.

Inbound Firewall Filter Counters per Class

Firewall filter counters are a very flexible mechanism you can use to match and count inbound traffic per class, per interface. For example:

```
firewall {
  filter f1 {
    term t1 {
      from {
        dscp af11;
      }
      then {
        # Assured forwarding class 1 drop profile 1 count inbound-af11;
        accept;
      }
    }
  }
}
```

For example, [Table 132](#) shows additional filters used to match the other classes.

Table 132: Inbound Traffic Per Class

DSCP Value	Firewall Match Condition	Description
10	af11	Assured forwarding class 1 drop profile 1
12	af12	Assured forwarding class 1 drop profile 2

Table 132: Inbound Traffic Per Class (*continued*)

DSCP Value	Firewall Match Condition	Description
18	af21	Best effort class 2 drop profile 1
20	af22	Best effort class 2 drop profile 2
26	af31	Best effort class 3 drop profile 1

Any packet with a CoS DiffServ code point (DSCP) conforming to RFC 2474 can be counted in this way. The Juniper Networks enterprise-specific Firewall Filter MIB presents the counter information in the variables shown in [Table 133](#).

Table 133: Inbound Counters

Indicator Name	Inbound Counters
MIB	jnxFirewalls
Table	jnxFirewallCounterTable
Index	jnxFWFilter.jnxFWCounter
Variables	jnxFWCounterPacketCount jnxFWCounterByteCount
Description	Number of bytes being counted pertaining to the specified firewall filter counter
SNMP version	SNMPv2

This information can be collected by any SNMP management application that supports SNMPv2. Products from vendors such as Concord Communications, Inc., and InfoVista, Inc., provide support for the Juniper Networks Firewall MIB with their native Juniper Networks device drivers.

Monitoring Output Bytes per Queue

You can use the Juniper Networks enterprise ATM CoS MIB to monitor outbound traffic, per virtual circuit forwarding class, per interface. (See [Table 134](#).)

Table 134: Outbound Counters for ATM Interfaces

Indicator Name	Outbound Counters
MIB	JUNIPER-ATM-COS-MIB
Variable	jnxCosAtmVcQstatsOutBytes
Index	ifIndex.atmVclVpi.atmVclVci.jnxCosFcid

Table 134: Outbound Counters for ATM Interfaces (*continued*)

Indicator Name	Outbound Counters
Description	Number of bytes belonging to the specified forwarding class that were transmitted on the specified virtual circuit.
SNMP version	SNMPv2

Non-ATM interface counters are provided by the Juniper Networks enterprise-specific CoS MIB, which provides information shown in [Table 135](#).

Table 135: Outbound Counters for Non-ATM Interfaces

Indicator Name	Outbound Counters
MIB	JUNIPER-COS-MIB
Table	jnxCosIfqStatsTable
Index	jnxCosIfqIfIndex.jnxCosIfqFc
Variables	jnxCosIfqTxedBytes jnxCosIfqTxedPkts
Description	Number of transmitted bytes or packets per interface per forwarding class
SNMP version	SNMPv2

Dropped Traffic

You can calculate the amount of dropped traffic by subtracting the outbound traffic from the incoming traffic:

$$\text{Dropped} = \text{Inbound Counter} - \text{Outbound Counter}$$

You can also select counters from the CoS MIB, as shown in [Table 136](#).

Table 136: Dropped Traffic Counters

Indicator Name	Dropped Traffic
MIB	JUNIPER-COS-MIB
Table	jnxCosIfqStatsTable
Index	jnxCosIfqIfIndex.jnxCosIfqFc
Variables	jnxCosIfqTailDropPkts jnxCosIfqTotalRedDropPkts

Table 136: Dropped Traffic Counters (*continued*)

Indicator Name	Dropped Traffic
Description	The number of tail-dropped or RED-dropped packets per interface per forwarding class
SNMP version	SNMPv2

- [Example: Configuring Health Monitoring on page 1670](#)

Configuring Health Monitoring on Devices Running Junos OS

As the number of devices managed by a typical network management system (NMS) grows and the complexity of the devices themselves increases, it becomes increasingly impractical for the NMS to use polling to monitor the devices. A more scalable approach is to rely on network devices to notify the NMS when something requires attention.

On Juniper Networks routers, RMON alarms and events provide much of the infrastructure needed to reduce the polling overhead from the NMS. However, with this approach, you must set up the NMS to configure specific MIB objects into RMON alarms. This often requires device-specific expertise and customizing of the monitoring application. In addition, some MIB object instances that need monitoring are set only at initialization or change at runtime and cannot be configured in advance.

To address these issues, the health monitor extends the RMON alarm infrastructure to provide predefined monitoring for a selected set of object instances (for file system usage, CPU usage, and memory usage) and includes support for unknown or dynamic object instances (such as Junos OS processes).

Health monitoring is designed to minimize user configuration requirements. To configure health monitoring entries, include the **health-monitor** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
health-monitor {
  falling-threshold percentage;
  interval seconds;
  rising-threshold percentage;
}
```

You can use the **show snmp health-monitor** operational command to view information about health monitor alarms and logs.

This topic describes the minimum required configuration and discusses the following tasks for configuring the health monitor:

- [Monitored Objects on page 1668](#)
- [Minimum Health Monitoring Configuration on page 1669](#)
- [Configuring the Falling Threshold or Rising Threshold on page 1669](#)
- [Configuring the Interval on page 1669](#)
- [Log Entries and Traps on page 1670](#)

Monitored Objects

When you configure the health monitor, monitoring information for certain object instances is available, as shown in [Table 137](#).

Table 137: Monitored Object Instances

Object	Description
<code>jnxHrStoragePercentUsed.1</code>	Monitors the following file system on the router or switch: /dev/ad0s1a: This is the root file system mounted on <code>/</code> .
<code>jnxHrStoragePercentUsed.2</code>	Monitors the following file system on the router or switch: /dev/ad0s1e: This is the configuration file system mounted on <code>/config</code> .
<code>jnxOperatingCPU (RE0)</code> <code>jnxOperatingCPU (RE1)</code>	Monitors CPU usage for Routing Engines (RE0 and RE1). The index values assigned to Routing Engines depend on whether the Chassis MIB uses a zero-based or ones-based indexing scheme. Because the indexing scheme is configurable, the proper index is determined when the router or switch is initialized and when there is a configuration change. If the router or switch has only one Routing Engine, the alarm entry monitoring RE1 is removed after five failed attempts to obtain the CPU value.
<code>jnxOperatingBuffer (RE0)</code> <code>jnxOperatingBuffer (RE1)</code>	Monitors the amount of memory available on Routing Engines (RE0 and RE1). Because the indexing of this object is identical to that used for <code>jnxOperatingCPU</code> , index values are adjusted depending on the indexing scheme used in the Chassis MIB. As with <code>jnxOperatingCPU</code> , the alarm entry monitoring RE1 is removed if the router or switch has only one Routing Engine.
<code>sysAppElmtRunCPU</code>	Monitors the CPU usage for each Junos OS process (also called daemon). Multiple instances of the same process are monitored and indexed separately.
<code>sysAppElmtRunMemory</code>	Monitors the memory usage for each Junos OS process. Multiple instances of the same process are monitored and indexed separately.

Minimum Health Monitoring Configuration

To enable health monitoring on the router or switch, include the **health-monitor** statement at the **[edit snmp]** hierarchy level:

```
[edit snmp]
health-monitor;
```

Configuring the Falling Threshold or Rising Threshold

The falling threshold is the lower threshold (expressed as a percentage of the maximum possible value) for the monitored variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the rising threshold. You must specify the falling threshold as a percentage of the maximum possible value. The default is **70** percent.

By default, the rising threshold is **80** percent of the maximum possible value for the monitored object instance. The rising threshold is the upper threshold for the monitored variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. You must specify the rising threshold as a percentage of the maximum possible value for the monitored variable.

To configure the falling threshold or rising threshold, include the **falling-threshold** or **rising-threshold** statement at the **[edit snmp health-monitor]** hierarchy level:

```
[edit snmp health-monitor]
falling-threshold percentage;
rising-threshold percentage;
```

percentage can be a value from 1 through 100.

The falling and rising thresholds apply to all object instances monitored by the health monitor.

Configuring the Interval

The interval represents the period of time, in seconds, over which the object instance is sampled and compared with the rising and falling thresholds.

To configure the interval, include the **interval** statement and specify the number of seconds at the **[edit snmp health-monitor]** hierarchy level:

```
[edit snmp health-monitor]
interval seconds;
```

seconds can be a value from 1 through 2147483647. The default is **300** seconds (5 minutes).

Log Entries and Traps

The system log entries generated for any health monitor events (thresholds crossed, errors, and so on) have a corresponding **HEALTHMONITOR** tag rather than a generic **SNMPD_RMON_EVENTLOG** tag. However, the health monitor sends generic RMON **risingThreshold** and **fallingThreshold** traps.

Example: Configuring Health Monitoring

Configure the health monitor:

```
[edit snmp]
health-monitor {
  falling-threshold 85;
  interval 600;
  rising-threshold 75;
}
```

In this example, the sampling interval is every **600** seconds (10 minutes), the falling threshold is **85** percent of the maximum possible value for each object instance monitored, and the rising threshold is **75** percent of the maximum possible value for each object instance monitored.

Accounting Options Overview

An accounting profile represents common characteristics of collected accounting data, including the following:

- Collection interval
- File to contain accounting data
- Specific fields and counter names on which to collect statistics

You can configure multiple accounting profiles, as described in [Table 138](#).

Table 138: Types of Accounting Profiles

Type of Profile	Description
Interface profile	Collects the specified error and statistic information.
Filter profile	Collects the byte and packet counts for the counter names specified in the filter profile.
MIB profile	Collects selected MIB statistics and logs them to a specified file.
Routing Engine profile	Collects selected Routing Engine statistics and logs them to a specified file.
Class usage profile	Collects class usage statistics and logs them to a specified file.

Understanding Source Class Usage and Destination Class Usage Options

You can maintain packet counts based on the entry and exit points for traffic passing through your network. Entry and exit points are identified by source and destination prefixes grouped into disjoint sets defined as source classes and *destination classes*. You can define classes based on a variety of parameters, such as routing neighbors, autonomous systems, and route filters.

Source class usage (SCU) counts packets sent to customers by performing lookups on the IP source address and the IP destination address. SCU makes it possible to track traffic originating from specific prefixes on the provider core and destined for specific prefixes on the customer edge. You must enable SCU accounting on both the inbound and outbound physical interfaces.

Destination class usage (DCU) counts packets from customers by performing lookups of the IP destination address. DCU makes it possible to track traffic originating from the customer edge and destined for specific prefixes on the provider core router.

On T Series Core Routers and M320 Multiservice Edge Routers, the source class and destination classes are not carried across the platform fabric. The implications of this are as follows:

- On T Series and M320 routers, SCU and DCU accounting is performed before the packet enters the fabric.
- On T Series and M320 routers, DCU is performed before output filters are evaluated.
- On M Series platforms, DCU is performed after output filters are evaluated.
- If an output filter drops traffic on M Series devices, the dropped packets are excluded from DCU statistics.
- If an output filter drops traffic on T Series and M320 routers, the dropped packets are included in DCU statistics.

NOTE: SCU and DCU is supported on PTX series routers only when third-generation FPCs are installed on the router and *enhanced-mode* is configured on the chassis.

On MX Series platforms with MPC/MIC interfaces, SCU and DCU are performed after output filters are evaluated. Packets dropped by output filters are not included in SCU or DCU statistics.

On MX Series platforms with non-MPC/MIC interfaces, SCU and DCU are performed before output filters are evaluated. Packets dropped by output filters are included in SCU and DCU statistics.

On Enhanced Scaling FPCs (T640-FPC1-ES, T640-FPC2-ES, T640-FPC3-ES, T640-FPC4-1P-ES, and T1600-FPC4-ES), the source class accounting is performed at ingress. Starting with Junos OS Release 14.2, the SCU accounting is performed at ingress on a T4000 Type 5 FPC. The implications of this are as follows:

- SCU accounting is performed when packets traverse from T4000 Type 5 FPC (ingress FPC) to Enhanced Scaling FPCs (egress FPC).
- SCU accounting is performed when packets traverse from Enhanced Scaling FPCs (ingress FPC) to T4000 Type 5 FPC (egress FPC).

NOTE: When the interface statistics are cleared and then the routing engine is replaced, the SCU and DCU statistics will not match the statistics of the previous routing engine.

For more information about source class usage, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*, the *Junos OS Network Interfaces Library for Routing Devices*, and the *Junos OS, Release 15.1*.

Configuration Statements at the [edit accounting-options] Hierarchy Level

This topic shows all possible configuration statements at the **[edit accounting-options]** hierarchy level and their level in the configuration hierarchy. When you are configuring Junos OS, your current hierarchy level is shown in the banner on the line preceding the **user@host#** prompt.

```
[edit]
accounting-options {
  class-usage-profile profile-name {
    file filename;
    interval minutes;
    destination-classes {
      destination-class-name;
    }
    source-classes {
      source-class-name;
    }
  }
}
```

```
}
file filename {
  archive-sites {
  }
  files number;
  nonpersistent;
  size bytes;
  start-time time;
  transfer-interval minutes;
}
filter-profile profile-name {
  counters {
    counter-name;
  }
  file filename;
  interval minutes;
}
}
interface-profile profile-name {
  fields {
    field-name;
  }
  file filename;
  interval minutes;
}
mib-profile profile-name {
  file filename;
  interval seconds;
  object-names {
    mib-object-name;
  }
  operation operation-name;
}
routing-engine-profile profile-name {
  fields {
    field-name;
  }
  file filename;
  interval minutes;
}
```

- Related Documentation**

Accounting Options Configuration

This topic contains the following sections:

- [Accounting Options—Full Configuration on page 1679](#)
- [Minimum Accounting Options Configuration on page 1680](#)

Accounting Options—Full Configuration

To configure accounting options, include the following statements at the `[edit accounting-options]` hierarchy level:

```
accounting-options {
  class-usage-profile profile-name {
    file filename;
    interval minutes;
    destination-classes {
      destination-class-name;
    }
    source-classes {
      source-class-name;
    }
    file filename {
      archive-sites {
        site-name;
      }
      files number;
      nonpersistent;
      size bytes;
      source-classes time
      transfer-interval minutes;
    }
    filter-profile profile-name {
      counters {
        counter-name;
      }
      file filename;
      interval minutes;
    }
  }
  interface-profile profile-name {
    fields {
      field-name;
    }
    file filename;
    interval minutes;
  }
  mib-profile profile-name {
    file filename;
    interval seconds;
    object-names {
      mib-object-name;
    }
    operation operation-name;
  }
  routing-engine-profile profile-name {
    fields {
      field-name;
    }
    file filename;
    interval minutes;
  }
}
```

}

By default, accounting options are disabled.

NOTE: Do not configure MIB objects related to interface octets or packets for a MIB profile, because it can cause the SNMP walk or a CLI show command to time out.

Minimum Accounting Options Configuration

To enable accounting options on the router, you must perform at least the following tasks:

- Configure accounting options by including a **file** statement and one or more **source-class-usage**, **destination-class-profile**, **filter-profile**, **interface-profile**, **mib-profile**, or **routing-engine-profile** statements at the **[edit accounting-options]** hierarchy level:

```
[edit]
accounting-options {
  class-usage-profile profile-name {
    file filename;
    interval minutes;
    source-classes {
      source-class-name;
      destination-classes {
        destination-class-name;
      }
    }
  }
  file filename {
    archive-sites {
      site-name;
    }
    files number;
    size bytes;
    transfer-interval minutes;
  }
  filter-profile profile-name {
    counters {
      counter-name;
    }
    file filename;
    interval minutes;
  }
  interface-profile profile-name {
    fields {
      field-name;
    }
    file filename;
    interval minutes;
  }
  mib-profile profile-name {
    file filename;
    interval minutes;
    object-names {
```

```

        mib-object-name;
    }
    operation operation-name;
}
routing-engine-profile profile-name {
    fields {
        field-name;
    }
    file filename;
    interval minutes;
}
}
}

```

- Apply the profiles to the chosen interfaces or filters.

Apply an interface profile to a physical or logical interface by including the **accounting-profile** statement at either the **[edit interfaces *interface-name*]** or the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

```

[edit interfaces]
interface-name {
    accounting-profile profile-name;
    unit logical-unit-number {
        accounting-profile profile-name;
    }
}

```

NOTE: You do not apply destination class profiles to interfaces. Although the interface needs to have the **destination-class-usage** statement configured, the destination class profile automatically finds all interfaces with the destination class configured.

Apply a filter profile to a firewall filter by including the **accounting-profile** statement at the **[edit firewall filter *filter-name*]** hierarchy level:

```

[edit firewall]
filter filter-name {
    accounting-profile profile-name;
}

```

You do not need to apply the Routing Engine profile to an interface because the statistics are collected on the Routing Engine itself.

Related Documentation

- [Accounting Options Overview on page 1673](#)
- [Understanding Device Management Functions in Junos OS on page 1393](#)
- [Configuring Accounting-Data Log Files on page 1682](#)
- [Configuring the Interface Profile on page 1685](#)
- [Configuring the Filter Profile on page 1687](#)
- [Configuration Statements at the \[edit accounting-options\] Hierarchy Level on page 1677](#)

Configuring Accounting-Data Log Files

An accounting profile specifies what statistics should be collected and written to a log file. To configure an accounting-data log file, include the **file** statement at the **[edit accounting-options]** hierarchy level:

```
[edit accounting-options]
file filename {
  archive-sites {
    site-name;
  }
  files number;
  nonpersistent;
  size bytes;
  start-time time;
  transfer-interval minutes;
}
```

filename is the name of the file in which to write accounting data.

If the filename contains spaces, enclose it in quotation marks (" "). The filename cannot contain a forward slash (/). The file is created in the **/var/log** directory and can contain data from multiple profiles.

All accounting-data log files include header and trailer sections that start with a **#** in the first column. The header contains the file creation time, the hostname, and the columns that appear in the file. The trailer contains the time that the file was closed.

Whenever any configured value changes that affects the columns in a file, the file creates a new profile layout record that contains a new list of columns.

You must configure the file size; all other properties are optional.

- [Configuring the Storage Location of the File on page 1682](#)
- [Configuring the Maximum Size of the File on page 1683](#)
- [Configuring the Maximum Number of Files on page 1683](#)
- [Configuring the Start Time for File Transfer on page 1683](#)
- [Configuring the Transfer Interval of the File on page 1683](#)
- [Configuring Archive Sites on page 1684](#)

Configuring the Storage Location of the File

To configure the storage location of the files in the **mfs/var/log** directory (on DRAM) instead of the **cf/var/log** directory (on the compact flash drive), include the **nonpersistent** statement at the **[edit accounting-options file filename]** hierarchy level:

```
[edit accounting-options file filename]
nonpersistent;
```

This feature is useful for minimizing read/write traffic on the router's compact flash drive.

NOTE: If log files for accounting data are stored on DRAM, these files are lost when you reboot the router. Therefore, you should back up these files periodically.

Configuring the Maximum Size of the File

To configure the maximum size of the files, include the **size** statement at the **[edit accounting-options file *filename*]** hierarchy level:

```
[edit accounting-options file filename]  
size bytes;
```

The **size** statement is the maximum size of the log file, in bytes, kilobytes (KB), megabytes (MB), or gigabytes (GB). The minimum value for **bytes** is 256 KB. You must configure **bytes**; the remaining attributes are optional.

Configuring the Maximum Number of Files

To configure the maximum number of files, include the **files** statement at the **[edit accounting-options file *filename*]** hierarchy level:

```
[edit accounting-options file filename]  
files number;
```

When a log file (for example, **profilelog**) reaches its maximum size, it is renamed **profilelog.0**, then **profilelog.1**, and so on, until the maximum number of log files is reached. Then the oldest log file is overwritten. The minimum value for **number** is 3 and the default value is 10.

Configuring the Start Time for File Transfer

To configure the start time for transferring files, include the **start-time** statement at the **[edit accounting-options file *filename*]** hierarchy level:

```
[edit accounting-options file filename]  
start-time time;
```

The start-time statement specifies a start time for file transfer (**YYYY-MM-DD.hh:mm**). For example, 10:00 a.m. on January 30, 2007 is represented as **2007-01-30.10:00**.

Configuring the Transfer Interval of the File

To configure the transfer interval of the files, include the **transfer-interval** statement at the **[edit accounting-options file *filename*]** hierarchy level:

```
[edit accounting-options file filename]  
transfer-interval minutes;
```

The range for **transfer-interval** is 5 through 2880 minutes. The default is 30 minutes.

TIP:

Junos OS saves the existing log file and creates a new file at the configured transfer-intervals irrespective of:

- Whether the file has reached the maximum size or not
- Whether an archive site is configured or not

When you have a relatively smaller transfer-interval configured and if no archive site is configured, data can be lost as Junos OS overwrites the log files when the maximum number of log files is reached. To ensure that the log information is saved for a reasonably long time:

- Configure an archive site to archive the log files every time a new log file is created.
- Configure the maximum value (2880 minutes) for transfer-interval so that new files are created less frequently; that is, only when the file exceeds the maximum size limit or once in 2 days.

Configuring Archive Sites

After a file reaches its maximum size or the **transfer-interval** time is exceeded, the file is closed, renamed, and, if you configured an archive site, transferred to a remote host. To configure archive sites, include the **archive-sites** statement at the **[edit accounting-options file filename]** hierarchy level:

```
[edit accounting-options file filename]
archive-sites {
  site-name;
}
```

site-name is any valid FTP URL. For more information about specifying valid FTP URLs, see the *Junos OS Administration Library for Routing Devices*. You can specify more than one URL, in any order. When a file is archived, the router or switch attempts to transfer the file to the first URL in the list, trying the next site in the list only if the transfer does not succeed. The log file is stored at the archive site with a filename of the format **router-name_log-filename_timestamp**.

- [Understanding Device Management Functions in Junos OS on page 1393](#)
- [Accounting Options Configuration on page 1678](#)
- [Configuring the Interface Profile on page 1685](#)
- [Configuring the Filter Profile on page 1687](#)
- [Configuration Statements at the \[edit accounting-options\] Hierarchy Level on page 1677](#)

Configuring the Interface Profile

An interface profile specifies the information collected and written to a log file. You can configure a profile to collect error and statistic information for input and output packets on a particular physical or logical interface.

To configure an interface profile, include the **interface-profile** statement at the **[edit accounting-options]** hierarchy level:

```
[edit accounting-options]
interface-profile profile-name {
  fields {
    field-name;
  }
  file filename;
  interval minutes;
}
```

By default, the Packet Forwarding Engine (PFE) periodically collects the statistics for all interfaces. To improve the performance, you can optionally disable the periodic refresh by including the **periodic-refresh disable** statement at the **[edit accounting-options]** hierarchy level.

Each accounting profile must have a unique **profile-name**. To apply a profile to a physical or logical interface, include the **accounting-profile** statement at either the **[edit interfaces interface-name]** or the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level. You can also apply an accounting profile at the **[edit firewall family family-type filter filter-name]** hierarchy level. For more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

To configure an interface profile, perform the tasks described in the following sections:

- [Configuring Fields on page 1685](#)
- [Configuring the File Information on page 1685](#)
- [Configuring the Interval on page 1686](#)
- [Example: Configuring the Interface Profile on page 1686](#)

Configuring Fields

An interface profile must specify what statistics are collected. To configure which statistics should be collected for an interface, include the **fields** statement at the **[edit accounting-options interface-profile profile-name]** hierarchy level:

```
[edit accounting-options interface-profile profile-name]
fields {
  field-name;
}
```

Configuring the File Information

Each accounting profile logs its statistics to a file in the **/var/log** directory.

To configure which file to use, include the **file** statement at the **[edit accounting-options interface-profile *profile-name*]** hierarchy level:

```
[edit accounting-options interface-profile profile-name]  
file filename;
```

You must specify a **file** statement for the interface profile that has already been configured at the **[edit accounting-options]** hierarchy level.

Configuring the Interval

Each interface with an accounting profile enabled has statistics collected once per interval time specified for the accounting profile. Statistics collection time is scheduled evenly over the configured interval. To configure the interval, include the **interval** statement at the **[edit accounting-options interface-profile *profile-name*]** hierarchy level:

```
[edit accounting-options interface-profile profile-name]  
interval minutes;
```

NOTE: The minimum interval allowed is 1 minute. Configuring a low interval in an accounting profile for a large number of interfaces might cause serious performance degradation.

The range for the **interval** statement is 1 through 2880 minutes. The default is 30 minutes.

Example: Configuring the Interface Profile

Configure the interface profile:

```
[edit]  
accounting-options {  
  file if_stats {  
    size 40 files 5;  
  }  
  interface-profile if_profile1 {  
    file if_stats;  
    interval 30;  
    fields {  
      input-bytes;  
      output-bytes;  
      input-packets;  
      output-packets;  
      input-multicast;  
      output-multicast;  
    }  
  }  
  interface-profile if_profile2 {  
    file if_stats;  
    interval 30;  
    fields {  
      input-bytes;  
      output-bytes;  
      input-packets;  
      output-packets;  
      input-multicast;  
    }  
  }  
}
```

```

        output-multicast;
    }
}
interfaces {
    xe-1/0/0 {
        accounting-profile if_profile1;
        unit 0 {
            accounting-profile if_profile2;
            ...
        }
    }
}
}

```

The two interface profiles, **if-profile1** and **if-profile2**, write data to the same file, **if-stats**. The **if-stats** file might look like the following:

```

#FILE CREATED 976823478 2000-12-14-19:51:18
#hostname host
#profile-layout
if_profile2,epoch-timestamp,interface-name,snmp-index,input-bytes,output-bytes,
input-packets,output-packets,input-multicast,output-multicast
#profile-layout
if_profile1,epoch-timestamp,interface-name,snmp-index,input-bytes,output-bytes,
input-packets
if_profile2,976823538,xe-1/0/0.0,8,134696815,3681534,501088,40723,0,0
if_profile1,976823538,xe-1/0/0,7,134696815,3681534,501088
...
#FILE CLOSED 976824378 2000-12-14-20:06:18

```

Related Documentation

- [Accounting Options Overview on page 1673](#)
- [Understanding Device Management Functions in Junos OS on page 1393](#)
- [Accounting Options Configuration on page 1678](#)
- [Configuring Accounting-Data Log Files on page 1682](#)
- [Configuring the Filter Profile on page 1687](#)
- [Configuration Statements at the \[edit accounting-options\] Hierarchy Level on page 1677](#)

Configuring the Filter Profile

A filter profile specifies error and statistics information collected and written to a file. A filter profile must specify counter names for which statistics are collected.

To configure a filter profile, include the **filter-profile** statement at the **[edit accounting-options]** hierarchy level:

```

[edit accounting-options]
filter-profile profile-name {
    counters {
        counter-name;
    }
    file filename;
    interval minutes;
}

```

```
}
```

To apply the filter profile, include the **accounting-profile** statement at the **[edit firewall filter *filter-name*]** hierarchy level.

To configure a filter profile, perform the tasks described in the following sections:

- [Configuring the Counters on page 1688](#)
- [Configuring the File Information on page 1688](#)
- [Configuring the Interval on page 1689](#)

Configuring the Counters

Statistics are collected for all counters specified in the filter profile. To configure the counters, include the **counters** statement at the **[edit accounting-options filter-profile *profile-name*]** hierarchy level:

```
[edit accounting-options filter-profile profile-name]  
counters {  
}
```

Configuring the File Information

Each accounting profile logs its statistics to a file in the **/var/log** directory.

To configure which file to use, include the **file** statement at the **[edit accounting-options filter-profile *profile-name*]** hierarchy level:

```
[edit accounting-options filter-profile profile-name]  
file filename;
```

You must specify a filename for the filter profile that has already been configured at the **[edit accounting-options]** hierarchy level.

NOTE: The limit on the total number of characters per line in a log file equals 1023. If this limit is exceeded, the output written to the log file is incomplete. Ensure that you limit the number of counters or requested data so that this character limit is not exceeded.

NOTE: If the configured file size or transfer interval is exceeded, Junos OS closes the file and starts a new one. By default, the transfer interval value is 30 minutes. If the transfer interval is not configured, Junos OS closes the file and starts a new one when the file size exceeds its configured value or the default transfer interval value exceeds 30 minutes. To avoid transferring files every 30 minutes, specify a different value for the transfer interval.

Configuring the Interval

Each filter with an accounting profile enabled has statistics collected once per interval time specified for the accounting profile. Statistics collection time is scheduled evenly over the configured interval. To configure the interval, include the **interval** statement at the **[edit accounting-options filter-profile *profile-name*]** hierarchy level:

```
[edit accounting-options filter-profile profile-name]  
interval;
```

NOTE: The minimum interval allowed is 1 minute. Configuring a low interval in an accounting profile for a large number of filters might cause serious performance degradation.

The range for the **interval** statement is 1 through 2880 minutes. The default is 30 minutes.

Related Documentation

- [Accounting Options Overview on page 1673](#)
- [Understanding Device Management Functions in Junos OS on page 1393](#)
- [Accounting Options Configuration on page 1678](#)
- [Configuring Accounting-Data Log Files on page 1682](#)

Example: Configuring a Filter Profile

Configure a filter profile:

```
[edit]  
accounting-options {  
  file fw_accounting {  
    size 500k files 4;  
  }  
  filter-profile fw_profile1 {  
    file fw_accounting;  
    interval 60;  
    counters {  
      counter1;  
      counter2;  
      counter3;  
    }  
  }  
}  
firewall {  
  filter myfilter {  
    accounting-profile fw_profile1;  
    ...  
    term accept-all {  
      then {  
        count counter1;  
        accept;  
      }  
    }  
  }  
}
```

```
}  
}
```

The filter profile, **fw-profile1**, writes data to the file **fw_accounting**. The file might look like the following:

```
#FILE CREATED 976825278 2000-12-14-20:21:18  
#hostname host  
#profile-layout  
fw_profile1,epoch-timestamp,filter-name,counter-name,packet-count,byte-count  
fw_profile1,976826058,myfilter,counter1,163,10764  
...  
#FILE CLOSED 976826178 2000-12-14-20:36:18
```

**Related
Documentation**

- [Configuring the Filter Profile on page 1687](#)
- [Example: Configuring Interface-Specific Firewall Counters and Filter Profiles on page 1690](#)

Example: Configuring Interface-Specific Firewall Counters and Filter Profiles

To collect and log count statistics collected by firewall filters on a per-interface basis, you must configure a filter profile and include the interface-specific statement at the **[edit firewall filter *filter-name*]** hierarchy level.

Configure the firewall filter accounting profile:

```
[edit accounting-options]  
file cust1_accounting {  
    size 500k;  
}  
filter-profile cust1_profile {  
    file cust1_accounting;  
    interval 1;  
    counters {  
        r1;  
    }  
}
```

Configure the interface-specific firewall counter:

```
[edit firewall]  
filter f3 {  
    accounting-profile cust1_profile;  
    interface-specific;  
    term f3-term {  
        then {  
            count r1;  
            accept;  
        }  
    }  
}
```

Apply the firewall filter to an interface:

```
[edit interfaces]  
xe-1/0/0 {  
    unit 0 {
```

```

family inet {
  filter {
    input f3;
    output f3;
  }
  address 20.20.20.30/24;
}
}

```

The following example shows the contents of the **cust1_accounting** file in the **/var/log** folder that might result from the preceding configuration:

```

#FILE CREATED 995495212 2001-07-18-22:26:52
#hostname host
#profile-layout cust1_profile,epoch-timestamp,interfaces,filter-name,
counter-name,packet-count,byte-count
cust1_profile,995495572,xe-1/0/0.0,f3-xe-1/0/0.0-i,r1-xe-1/0/0.0-i,5953,1008257
cust1_profile,995495602,xe-1/0/0.0,f3-xe-1/0/0.0-o,r1-xe-1/0/0.0-o,5929,1006481
...

```

If the **interface-specific** statement is not included in the configuration, the following output might result:

```

#FILE CREATED 995495212 2001-07-18-22:26:52
#hostname host
#profile-layout cust1_profile,epoch-timestamp,interfaces,filter-name,
counter-name,packet-count,byte-count
cust1_profile,995495572,xe-1/0/0.0,f3,r1,5953,1008257
cust1_profile,995495632,xe-1/0/0.0,f3,r1,5929,1006481

```

Related Documentation

- [Configuring the Filter Profile on page 1687](#)
- [Configuring the Interface Profile on page 1685](#)

Configuring SCU or DCU

To configure SCU or DCU, perform the following tasks described in this section:

NOTE: We recommend that you stop the network traffic on an interface before you modify the DCU or SCU configuration for that interface. Modifying the DCU or SCU configuration without stopping the traffic might corrupt the DCU or SCU statistics. Before you restart the traffic after modifying the configuration, enter the **clear interfaces statistics** command.

- [Creating Prefix Route Filters in a Policy Statement on page 1692](#)
- [Applying the Policy to the Forwarding Table on page 1692](#)
- [Enabling Accounting on Inbound and Outbound Interfaces on page 1692](#)

Creating Prefix Route Filters in a Policy Statement

To define prefix router filters:

```
[edit policy-options]
policy-statement scu-1 {
  term term1;
  from {
    route-filter 192.0.2.0/24 or longer;
  }
  then source-class gold;
}
```

Applying the Policy to the Forwarding Table

To apply the policy to the forwarding table:

```
[edit]
routing-options {
  forwarding-table {
    export scu-1;
  }
}
```

Enabling Accounting on Inbound and Outbound Interfaces

To enable accounting on inbound and outbound interfaces:

```
[edit]
interfaces {
  so-6/1/0 {
    unit 0 {
      family inet;
      accounting {
        destination-class-usage;
        source-class-usage {
          output;
        }
      }
    }
  }
}
[edit]
interfaces {
  xe-0/1/0 {
    unit 0 {
      family inet6 {
        accounting {
          source-class-usage {
            input;
          }
        }
      }
    }
  }
}
```

Optionally, you can include the input and output statements on a single interface as shown:

```
[edit]
interfaces {
  xe-0/1/2 {
    unit 0 {
      family inet6 {
        accounting {
          source-class-usage {
            input;
            output;
          }
        }
      }
    }
  }
}
```

For more information about configuring route filters and source classes in a routing policy, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices* and the *Junos OS Network Interfaces Library for Routing Devices*.

Related Documentation

- [Understanding Source Class Usage and Destination Class Usage Options on page 1674](#)
- [Configuring SCU on a Virtual Loopback Tunnel Interface on page 1693](#)
- [Configuring Class Usage Profiles on page 1695](#)
- [Configuring the MIB Profile on page 1697](#)
- [Configuring the Routing Engine Profile on page 1699](#)

Configuring SCU on a Virtual Loopback Tunnel Interface

To configure source class usage on the virtual loopback tunnel interface, perform the tasks described in the following sections:

- [Example: Configuring a Virtual Loopback Tunnel Interface on a Provider Edge Router Equipped with a Tunnel PIC on page 1693](#)
- [Example: Mapping the VRF Instance Type to the Virtual Loopback Tunnel Interface on page 1694](#)
- [Example: Sending Traffic Received from the Virtual Loopback Interface Out the Source Class Output Interface on page 1694](#)

Example: Configuring a Virtual Loopback Tunnel Interface on a Provider Edge Router Equipped with a Tunnel PIC

Define a virtual loop interface on a provider edge router with a Tunnel PIC:

```
[edit interfaces]
vt-0/3/0 {
  unit 0 {
    family inet {
      accounting {
```

```

        source-class-usage {
            input;
        }
    }
}

```

Example: Mapping the VRF Instance Type to the Virtual Loopback Tunnel Interface

Map the VRF instance type to the virtual loopback tunnel interface:

```

[edit]
routing-instances {
  VPN-A {
    instance-type vrf;
    interface at-2/1/1.0;
    interface vt-0/3/0.0;
    route-distinguisher 10.255.14.225;
    vrf-import import-policy-name;
    vrf-export export-policy-name;
    protocols {
      bgp {
        group to-r4 {
          local-address 10.27.253.1;
          peer-as 400;
          neighbor 10.27.253.2;
        }
      }
    }
  }
}

```

NOTE: For SCU and DCU to work, do not include the `vrf-table-label` statement at the `[edit routing-instances instance-name]` hierarchy level.

Example: Sending Traffic Received from the Virtual Loopback Interface Out the Source Class Output Interface

Send traffic received from the virtual loopback tunnel interface out of the source class output interface:

```

[edit interfaces]
at-1/1/0 {
  unit 0 {
    family inet {
      accounting {
        source-class-usage {
          output;
        }
      }
    }
  }
}

```

For more information about configuring source class usage on the virtual loopback tunnel interface, see the *Junos OS Network Interfaces Library for Routing Devices*.

**Related
Documentation**

- [Understanding Source Class Usage and Destination Class Usage Options on page 1674](#)
- [Configuring SCU or DCU on page 1691](#)
- [Configuring Class Usage Profiles on page 1695](#)
- [Configuring the MIB Profile on page 1697](#)
- [Configuring the Routing Engine Profile on page 1699](#)

Configuring Class Usage Profiles

To collect class usage statistics, perform the tasks described in these sections:

- [Configuring a Class Usage Profile on page 1695](#)
- [Configuring the File Information on page 1695](#)
- [Configuring the Interval on page 1696](#)
- [Creating a Class Usage Profile to Collect Source Class Usage Statistics on page 1696](#)
- [Creating a Class Usage Profile to Collect Destination Class Usage Statistics on page 1696](#)

Configuring a Class Usage Profile

You can configure the class usage profile to collect statistics for particular source and destination classes.

To configure the class usage profile to filter by source classes, include the **source-classes** statement at the **[edit accounting-options class-usage-profile *profile-name*]** hierarchy level:

```
[edit accounting-options class-usage-profile profile-name]  
source-classes {  
    source-class-name;  
}
```

To configure the class usage profile to filter by destination classes, include the **destination-classes** statement at the **[edit accounting-options class-usage-profile *profile-name*]** hierarchy level:

```
[edit accounting-options class-usage-profile profile-name]  
destination-classes {  
    destination-class-name;  
}
```

Configuring the File Information

Each accounting profile logs its statistics to a file in the **/var/log** directory.

To specify which file to use, include the **file** statement at the **[edit accounting-options class-usage-profile *profile-name*]** hierarchy level:

```
[edit accounting-options class-usage-profile profile-name]  
file filename;
```

You must specify a filename for the source class usage profile that has already been configured at the **[edit accounting-options]** hierarchy level. You can also specify a filename for the destination class usage profile configured at the **[edit accounting-options]** hierarchy level.

Configuring the Interval

Each interface with a class usage profile enabled has statistics collected once per interval specified for the accounting profile. Statistics collection time is scheduled evenly over the configured interval. To configure the interval, include the **interval** statement at the **[edit accounting-options class-usage-profile *profile-name*]** hierarchy level:

```
[edit accounting-options class-usage-profile profile-name]  
interval;
```

Creating a Class Usage Profile to Collect Source Class Usage Statistics

To create a class usage profile to collect source class usage statistics:

```
[edit]  
accounting-options {  
  class-usage-profile scu-profile1;  
  file usage-stats;  
  interval 15;  
  source-classes {  
    gold;  
    silver;  
    bronze;  
  }  
}
```

The class usage profile, **scu-profile1**, writes data to the file **usage_stats**. The file might look like the following:

```
#FILE CREATED 976825278 2000-12-14-20:21:18  
#profile-layout, scu_profile, epoch-timestamp, interface-name, source-class,  
packet-count, byte-count  
scu_profile, 980313078, xe-1/0/0.0, gold, 82, 6888  
scu_profile, 980313078, xe-1/0/0.0, silver, 164, 13776  
scu_profile, 980313078, xe-1/0/0.0, bronze, 0, 0  
scu_profile, 980313678, xe-1/0/0.0, gold, 82, 6888  
scu_profile, 980313678, xe-1/0/0.0, silver, 246, 20664  
scu_profile, 980313678, xe-1/0/0.0, bronze, 0, 0
```

Creating a Class Usage Profile to Collect Destination Class Usage Statistics

To create a class usage profile to collect destination class usage statistics:

```
[edit]  
accounting-options {  
  class-usage-profile dcu-profile1;  
  file usage-stats  
  interval 15;  
  destination-classes {  
    gold;  
    silver;  
    bronze;
```

```
}
}
```

The class usage profile, **dcu-profile1**, writes data to the file **usage-stats**. The file might look like the following:

```
#FILE CREATED 976825278 2000-12-14-20:21:18
#profile-layout, dcu_profile,epoch-timestamp,interface-name,destination-class,
packet-count,byte-count
dcu_profile,980313078,xe-1/0/0.0,gold,82,6888
dcu_profile,980313078,xe-1/0/0.0,silver,164,13776
dcu_profile,980313078,xe-1/0/0.0,bronze,0,0
dcu_profile,980313678,xe-1/0/0.0,gold,82,6888
dcu_profile,980313678,xe-1/0/0.0,silver,246,20664
dcu_profile,980313678,xe-1/0/0.0,bronze,0,0
...
#FILE CLOSED 976826178 2000-12-14-20:36:18
```

Configuring the MIB Profile

The MIB profile collects MIB statistics and logs them to a file. The MIB profile specifies the SNMP operation and MIB object names for which statistics are collected.

To configure a MIB profile, include the **mib-profile** statement at the **[edit accounting-options]** hierarchy level:

```
[edit accounting-options]
mib-profile profile-name {
  file filename;
  interval minutes;
  object-names {
    mib-object-name;
  }
  operation operation-name;
}
```

To configure a MIB profile, perform the tasks described in the following sections:

- [Configuring the File Information on page 1697](#)
- [Configuring the Interval on page 1698](#)
- [Configuring the MIB Operation on page 1698](#)
- [Configuring MIB Object Names on page 1698](#)
- [Example: Configuring a MIB Profile on page 1698](#)

Configuring the File Information

Each accounting profile logs its statistics to a file in the **/var/log** directory.

To configure which file to use, include the **file** statement at the **[edit accounting-options mib-profile *profile-name*]** hierarchy level:

```
[edit accounting-options mib-profile profile-name]  
  file filename;
```

You must specify a ***filename*** for the MIB profile that has already been configured at the **[edit accounting-options]** hierarchy level.

Configuring the Interval

A MIB profile has statistics collected once per interval time specified for the profile. Statistics collection time is scheduled evenly over the configured interval. To configure the interval, include the **interval** statement at the **[edit accounting-options mib-profile *profile-name*]** hierarchy level:

```
[edit accounting-options mib-profile profile-name]  
  interval;
```

The range for the **interval** statement is 1 through 2880 minutes. The default is 30 minutes.

Configuring the MIB Operation

A MIB profile must specify the operation that is used to collect MIB statistics. To configure which operation is used to collect MIB statistics, include the **operation** statement at the **[edit accounting-options mib-profile *profile-name*]** hierarchy level:

```
[edit accounting-options mib-profile profile-name]  
  operation operation-name;
```

You can configure a **get**, **get-next**, or **walk** operation. The default operation is **walk**.

Configuring MIB Object Names

A MIB profile must specify the MIB objects for which statistics are to be collected. To configure the MIB objects for which statistics are collected, include the **objects-names** statement at the **[edit accounting-options mib-profile *profile-name*]** hierarchy level:

```
[edit accounting-options mib-profile profile-name]  
  object-names {  
    mib-object-name;  
  }
```

You can include multiple MIB object names in the configuration.

NOTE: Do not configure MIB objects related to interface octets or packets for a MIB profile, because it can cause the SNMP walk or a CLI show command to time out.

Example: Configuring a MIB Profile

Configure a MIB profile:

```
[edit accounting-options]  
  mib-profile mstatistics {  
    file stats;
```

```
interval 60;
operation walk;
objects-names {
  ipCidrRouteStatus;
}
}
```

- [Configuring the Routing Engine Profile on page 1699](#)

Configuring the Routing Engine Profile

The Routing Engine profile collects Routing Engine statistics and logs them to a file. The Routing Engine profile specifies the fields for which statistics are collected.

To configure a Routing Engine profile, include the **routing-engine-profile** statement at the **[edit accounting-options]** hierarchy level:

```
[edit accounting-options]
routing-engine-profile profile-name {
  fields {
    field-name;
  }
  file filename;
  interval minutes;
}
```

To configure a Routing Engine profile, perform the tasks described in the following sections:

- [Configuring Fields on page 1699](#)
- [Configuring the File Information on page 1700](#)
- [Configuring the Interval on page 1700](#)
- [Example: Configuring a Routing Engine Profile on page 1700](#)

Configuring Fields

A Routing Engine profile must specify what statistics are collected. To configure which statistics should be collected for the Routing Engine, include the **fields** statement at the **[edit accounting-options routing-engine-profile *profile-name*]** hierarchy level:

```
[edit accounting-options routing-engine-profile profile-name]
fields {
  field-name;
}
```

Configuring the File Information

Each accounting profile logs its statistics to a file in the `/var/log` directory.

To configure which file to use, include the `file` statement at the `[edit accounting-options routing-engine-profile profile-name]` hierarchy level:

```
[edit accounting-options routing-engine-profile profile-name]  
file filename;
```

You must specify a *filename* for the Routing Engine profile that has already been configured at the `[edit accounting-options]` hierarchy level.

Configuring the Interval

A Routing Engine profile has statistics collected once per interval time specified for the profile. Statistics collection time is scheduled evenly over the configured interval. To configure the interval, include the `interval` statement at the `[edit accounting-options routing-engine-profile profile-name]` hierarchy level:

```
[edit accounting-options routing-engine-profile profile-name]  
interval;
```

The range for `interval` is 1 through 2880 minutes. The default is 30 minutes.

Example: Configuring a Routing Engine Profile

Configure a Routing Engine profile:

```
[edit accounting-options]  
file my-file {  
  size 300k;  
}  
routing-engine-profile profile-1 {  
  file my-file;  
  fields {  
    host-name;  
    date;  
    time-of-day;  
    uptime;  
    cpu-load-1;  
    cpu-load-5;  
    cpu-load-15;  
  }  
}
```

PART 21

Configuring Monitoring Options

- [Configuring Interface Alarms on page 1703](#)
- [Using RPM to Measure Network Performance on page 1715](#)
- [Configuring IP Monitoring on page 1741](#)

CHAPTER 76

Configuring Interface Alarms

- [Alarm Overview on page 1703](#)
- [Example: Configuring Interface Alarms on page 1709](#)
- [Monitoring Active Alarms on a Device on page 1711](#)
- [Monitoring Alarms on page 1712](#)

Alarm Overview

Alarms alert you to conditions on a network interface, on the device chassis, or in the system software that might prevent the device from operating normally. You can set the conditions that trigger alarms on an interface. Chassis and system alarm conditions are preset.

An active alarm lights the **ALARM** LED on the front panel of the device. You can monitor active alarms from the J-Web user interface or the CLI. When an alarm condition triggers an alarm, the device lights the yellow (amber) **ALARM** LED on the front panel. When the condition is corrected, the light turns off.

This section contains the following topics:

- [Alarm Types on page 1703](#)
- [Alarm Severity on page 1704](#)
- [Alarm Conditions on page 1704](#)

Alarm Types

The device supports three types of alarms:

- Interface alarms indicate a problem in the state of the physical links on fixed or installed Physical Interface Modules (PIMs). To enable interface alarms, you must configure them.
- Chassis alarms indicate a failure on the device or one of its components. Chassis alarms are preset and cannot be modified.
- System alarms indicate a missing rescue configuration or software license, where valid. System alarms are preset and cannot be modified, although you can configure them to appear automatically in the J-Web user interface or CLI.

Starting with Junos OS Release 15.1X49-D60, a new system alarm is introduced to indicate that the PICs (I/O card or SPC) have failed to come online during system start time.

NOTE: Run the following commands when the CLI prompt indicates that an alarm has been raised:

- `show system alarms`
- `show chassis alarms`
- `show chassis fpc pic-status`

For more information about the CLI commands, see [show system alarms](#), [show chassis alarms](#), and [show chassis fpc \(View\)](#).

Alarm Severity

Alarms have two severity levels:

- **Major (red)**—Indicates a critical situation on the device that has resulted from one of the following conditions. A red alarm condition requires immediate action.
 - One or more hardware components have failed.
 - One or more hardware components have exceeded temperature thresholds.
 - An alarm condition configured on an interface has triggered a critical warning.
- **Minor (yellow)**—Indicates a noncritical condition on the device that, if left unchecked, might cause an interruption in service or degradation in performance. A yellow alarm condition requires monitoring or maintenance.

A missing rescue configuration or software license generates a yellow system alarm.

Alarm Conditions

To enable alarms on a device interface, you must select an alarm condition and an alarm severity. In contrast, alarm conditions and severity are preconfigured for chassis alarms and system alarms.

NOTE: For information about chassis alarms for your device, see the [Hardware Guide](#) for your device.

This section contains the following topics:

- [Interface Alarm Conditions on page 1705](#)
- [System Alarm Conditions on page 1708](#)

Interface Alarm Conditions

Table 139 lists the interface conditions, sorted by interface type, that you can configure for an alarm. You can configure each alarm condition to trigger either a major (red) alarm or minor a (yellow) alarm. The corresponding configuration option is included.

For the services stateful firewall filters (NAT, IDP, and IPsec), which operate on an internal adaptive services module within a device, you can configure alarm conditions on the integrated services and services interfaces.

Table 139: Interface Alarm Conditions

Interface	Alarm Condition	Description	Configuration Option
DS1 (T1)	Alarm indication signal (AIS)	The normal T1 traffic signal contained a defect condition and has been replaced by the AIS. A transmission interruption occurred at the remote endpoint or upstream of the remote endpoint. This all-ones signal is transmitted to prevent consequential downstream failures or alarms.	ais
	Yellow alarm	The remote endpoint is in yellow alarm failure. This condition is also known as a far-end alarm failure.	ylw
Ethernet	Link is down	The physical link is unavailable.	link-down
Integrated services	Hardware or software failure	On the adaptive services module, either the hardware associated with the module or the software that drives the module has failed.	failure

Table 139: Interface Alarm Conditions (*continued*)

Interface	Alarm Condition	Description	Configuration Option
Serial	Clear-to-send (CTS) signal absent	The remote endpoint of the serial link is not transmitting a CTS signal. The CTS signal must be present before data can be transmitted across a serial link.	cts-absent
	Data carrier detect (DCD) signal absent	The remote endpoint of the serial link is not transmitting a DCD signal. Because the DCD signal transmits the state of the device, no signal probably indicates that the remote endpoint of the serial link is unavailable.	dcd-absent
	Data set ready (DSR) signal absent	The remote endpoint of the serial link is not transmitting a DSR signal. The DSR signal indicates that the remote endpoint is ready to receive and transmit data across the serial link.	dsr-absent
	Loss of receive clock	The clock signal from the remote endpoint is not present. Serial connections require clock signals to be transmitted from one endpoint and received by the other endpoint of the link.	loss-of-rx-clock
	Loss of transmit clock	The local clock signal is not present. Serial connections require clock signals to be transmitted from one endpoint and received by the other endpoint of the link.	loss-of-tx-clock
Services	Services module hardware down	A hardware problem has occurred on the device's services module. This error typically means that one or more of the CPUs on the module has failed.	hw-down
	Services link down	The link between the device and its services module is unavailable.	linkdown
	Services module held in reset	The device's services module is stuck in reset mode. If the services module fails to start up five or more times in a row, the services module is held in reset mode. Startup fails when the amount of time from CPU release to CPU halt is less than 300 seconds.	pic-hold-reset
	Services module reset	The device's services module is resetting. The module resets after it crashes or is reset from the CLI, or when it takes longer than 60 seconds to start up.	pic-reset
	Services module software down	A software problem has occurred on the device's services module.	sw-down

Table 139: Interface Alarm Conditions (*continued*)

Interface	Alarm Condition	Description	Configuration Option
E3	Alarm indication signal (AIS)	The normal E3 traffic signal contained a defect condition and has been replaced by the AIS. A transmission interruption occurred at the remote endpoint or upstream of the remote endpoint. This all-ones signal is transmitted to prevent consequential downstream failures or alarms.	ais
	Loss of signal (LOS)	No remote E3 signal is being received at the E3 interface.	los
	Out of frame (OOF)	An OOF condition has existed for 10 seconds. This alarm applies only to E3 interfaces configured in frame mode. The OOF failure is cleared when no OOF or LOS defects have occurred for 20 seconds.	oof
	Remote defect indication	An AIS, LOS, or OOF condition exists. This alarm applies only to E3 interfaces configured in frame mode.	rdi

Table 139: Interface Alarm Conditions (*continued*)

Interface	Alarm Condition	Description	Configuration Option
T3 (DS3)	Alarm indication signal	The normal T3 traffic signal contained a defect condition and has been replaced by the AIS. A transmission interruption occurred at the remote endpoint or upstream of the remote endpoint. This all-ones signal is transmitted to prevent consequential downstream failures or alarms.	ais
	Excessive number of zeros	The bit stream received from the upstream host has more consecutive zeros than are allowed in a T3 frame.	exz
	Far-end receive failure (FERF)	The remote endpoint of the connection has failed. A FERF differs from a yellow alarm, because the failure can be any failure, not just an OOF or LOS failure.	ferf
	Idle alarm	The Idle signal is being received from the remote endpoint.	idle
	Line code violation	Either the line encoding along the T3 link is corrupted or a mismatch between the encoding at the local and remote endpoints of a T3 connection occurred.	lcv
	Loss of frame (LOF)	An OOF or loss-of-signal LOS condition has existed for 10 seconds. The LOF failure is cleared when no OOF or LOS defects have occurred for 20 seconds. A LOF failure is also called a red failure.	lof
	Loss of signal (LOS)	No remote T3 signal is being received at the T3 interface.	los
	Phase-locked loop out of lock	The clocking signals for the local and remote endpoints no longer operate in lock-step.	pll
	Yellow alarm	The remote endpoint is in yellow alarm failure. This condition is also known as a far-end alarm failure.	ylw

System Alarm Conditions

Table 140 lists the two preset system alarms, the condition that triggers each alarm, and the action you take to correct the condition.

Table 140: System Alarm Conditions and Corrective Actions

Alarm Type	Alarm Condition	Corrective Action
Configuration	The rescue configuration is not set.	Set the rescue configuration.

Table 140: System Alarm Conditions and Corrective Actions (*continued*)

Alarm Type	Alarm Condition	Corrective Action
License	<p>You have configured at least one software feature that requires a feature license, but no valid license for the feature is currently installed.</p> <p>NOTE: This alarm indicates that you are in violation of the software license agreement. You must install a valid license key to be in compliance with all agreements.</p>	Install a valid license key.

- Related Documentation**
- [Example: Configuring Interface Alarms on page 1709](#)
 - [Monitoring Active Alarms on a Device on page 1711](#)
 - [Monitoring Alarms on page 1712](#)
 - [System Log Messages](#)

Example: Configuring Interface Alarms

This example shows how to configure interface alarms.

- [Requirements on page 1709](#)
- [Overview on page 1709](#)
- [Configuration on page 1710](#)
- [Verification on page 1711](#)

Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Select the network interface on which to apply an alarm and the condition you want to trigger the alarm. See [“Alarm Overview” on page 1703](#).

Overview

In this example, you enable interface alarms by explicitly setting alarm conditions. You configure the system to generate a red interface alarm when a yellow alarm is detected on a DS1 link. You configure the system to generate a red interface alarm when a link-down failure is detected on an Ethernet link.

For a serial link, you set cts-absent and dcd-absent to yellow to signify either the CST or the DCD signal is not detected. You set loss-of-rx-clock and loss-of-tx-clock to red alarm to signify either the receiver clock signal or the transmission clock signal is not detected.

For a T3 link, you set the interface alarm to red when the remote endpoint is experiencing a failure. You set exz to yellow alarm when the upstream bit has more consecutive zeros than are permitted in a T3 interface. You then set a red alarm when there is loss-of-signal on the interface.

Finally, you configure the system to display active system alarms whenever a user with the login class admin logs in to the device.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis alarm ds1 ylw red
set chassis alarm ethernet link-down red
set chassis alarm serial cts-absent yellow dcd-absent yellow
set chassis alarm serial loss-of-rx-clock red loss-of-tx-clock red
set chassis alarm t3 ylw red exz yellow los red
set system login class admin login-alarms
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure interface alarms:

1. Configure an alarm.

```
[edit]
user@host# edit chassis alarm
```

2. Specify the interface alarms on a DS1 and an Ethernet link.

```
[edit chassis alarm]
user@host# set ds1 ylw red
user@host# set ethernet link-down red
```

3. Specify the interface alarms on a serial link.

```
[edit chassis alarm]
user@host# set serial cts-absent yellow
user@host# set serial dcd-absent yellow
user@host# set serial loss-of-rx-clock red
user@host# set serial loss-of-tx-clock red
```

4. Specify the interface alarms on a T3 link.

```
[edit chassis alarm]
user@host# set t3 ylw red
user@host# set t3 exz yellow
user@host# set t3 los red
```

5. Configure the system to display active system alarms.

```
[edit]
user@host# edit system login
```

```
user@host# set class admin login-alarms
```

Results From configuration mode, confirm your configuration by entering the **show chassis alarms** and **show system login** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show chassis alarms
t3 {
  exz yellow;
  los red;
  ylw red;
}
ds1 {
  ylw red;
}
ethernet {
  link-down red;
}
serial {
  loss-of-rx-clock red;
  loss-of-tx-clock red;
  dcd-absent yellow;
  cts-absent yellow;
}
[edit]
user@host# show system login
show system login
show system login
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Verifying the Alarm Configurations

Purpose Confirm that the configuration is working properly.

Verify that the alarms are configured.

Action From configuration mode, enter the **show chassis alarms** command. Verify that the output shows the intended configuration of the alarms.

Related Documentation

- [Alarm Overview on page 1703](#)
- [Monitoring Active Alarms on a Device on page 1711](#)
- [Monitoring Alarms on page 1712](#)

Monitoring Active Alarms on a Device

Purpose Use to monitor and filter alarms on a Juniper Networks device.

Action Select **Monitor>Events and Alarms>View Alarms** in the J-Web user interface. The J-Web View Alarms page displays the following information about preset system and chassis alarms:

- Type—Type of alarm: System, Chassis, or All.
- Severity—Severity class of the alarm: Minor or Major.
- Description—Description of the alarm.
- Time—Time that the alarm was registered.

To filter which alarms appear, use the following options:

- Alarm Type—Specifies which type of alarm to monitor: System, Chassis, or All. System alarms include FRU detection alarms (power supplies removed, for instance). Chassis alarms indicate environmental alarms such as temperature.
- Severity—Specifies the alarm severity that you want to monitor: Major, Minor, or All. A major (red) alarm condition requires immediate action. A minor (yellow) condition requires monitoring and maintenance.
- Description—Specifies the alarms you want to monitor. Enter a brief synopsis of the alarms that you want to monitor.
- Date From—Specifies the beginning of the date range that you want to monitor. Set the date using the calendar pick tool.
- To—Specifies the end of the date range that you want to monitor. Set the date using the calendar pick tool.
- Go—Executes the options that you specified.
- Reset—Clears the options that you specified.

Alternatively, you can enter the following **show** commands in the CLI editor:

- **show chassis alarms**
- **show system alarms**

Monitoring Alarms

Purpose Use the monitoring functionality to view the alarms page.

Action To monitor alarms select **Monitor>Events and Alarms>View Alarms** in the J-Web user interface.

Meaning [Table 141](#) summarizes key output fields in the alarms page.

Table 141: Alarms Monitoring Page

Field	Value	Additional Information
Alarm Filter		
Alarm Type	Specifies the type of alarm to monitor: <ul style="list-style-type: none"> • System— System alarms include FRU detection alarms (power supplies removed, for instance). • Chassis— Chassis alarms indicate environmental alarms such as temperature. • All— Indicates to display all the types of alarms. 	—
Severity	Specifies the alarm severity that you want to monitor <ul style="list-style-type: none"> • Major— A major (red) alarm condition requires immediate action. • Minor— A minor (yellow) condition requires monitoring and maintenance. • All— Indicates to display all the severities. 	—
Description	Enter a brief synopsis of the alarms you want to monitor.	—
Date From	Specifies the beginning of the date range that you want to monitor. Set the date using the calendar pick tool.	—
To	Specifies the end of the date range that you want to monitor. Set the date using the calendar pick tool.	—
Go	Executes the options that you specified.	—
Reset	Clears the options that you specified.	—
Alarm Details	Displays the following information about each alarm: <ul style="list-style-type: none"> • Type— Type of alarm: System, Chassis, or All. • Severity— Severity class of the alarm: Minor or Major. • Description— Description of the alarm. • Time— Time that the alarm was registered. 	—

- [Tuning RPM Probes on page 1732](#)
- [RPM Configuration Options on page 1732](#)
- [Monitoring RPM Probes on page 1736](#)

RPM Overview

The real-time performance monitoring (RPM) feature allows network operators and their customers to accurately measure the performance between two network endpoints. With the RPM tool, you configure and send probes to a specified target and monitor the analyzed results to determine packet loss, round-trip time, and jitter.

RPM allows you to perform service-level monitoring. When RPM is configured on a device, the device calculates network performance based on packet response time, jitter, and packet loss. These values are gathered by Hypertext Transfer Protocol (HTTP) GET requests, Internet Control Message Protocol (ICMP) requests, and TCP and UDP requests, depending on the configuration.

This section contains the following topics:

- [RPM Probes on page 1716](#)
- [RPM Tests on page 1716](#)
- [Probe and Test Intervals on page 1716](#)

- [Jitter Measurement with Hardware Timestamping on page 1717](#)
- [RPM Statistics on page 1717](#)
- [RPM Thresholds and Traps on page 1718](#)
- [RPM for BGP Monitoring on page 1719](#)

RPM Probes

You gather RPM statistics by sending out probes to a specified probe target, identified by an IP address or URL. When the target receives the probe, it generates responses, which are received by the device. By analyzing the transit times to and from the remote server, the device can determine network performance statistics.

The device sends out the following probe types:

- HTTP GET request at a target URL
- HTTP GET request for metadata at a target URL
- ICMP echo request to a target address (the default)
- ICMP timestamp request to a target address
- UDP ping packets to a target device
- UDP timestamp requests to a target address
- TCP ping packets to a target device

UDP and TCP probe types require that the remote server be configured as an RPM receiver so that it generates responses to the probes.

The RPM probe results are also available in the form of MIB objects through the SNMP protocol.

RPM Tests

Each probed target is monitored over the course of a test. A test represents a collection of probes, sent out at regular intervals, as defined in the configuration. Statistics are then returned for each test. Because a test is a collection of probes that have been monitored over some amount of time, test statistics such as standard deviation and jitter can be calculated and included with the average probe statistics.

Probe and Test Intervals

Within a test, RPM probes are sent at regular intervals, configured in seconds. When the total number of probes has been sent and the corresponding responses received, the test is complete. You can manually set the probe interval for each test to control how the RPM test is conducted.

After all the probes for a particular test have been sent, the test begins again. The time between tests is the test interval. You can manually set the test interval to tune RPM performance.

NOTE: On SRX340 Low Memory devices and SRX340 High Memory devices, the RPM server operation does not work when the probe is configured with the option destination-interface.

Jitter Measurement with Hardware Timestamping

Jitter is the difference in relative transit time between two consecutive probes.

You can timestamp the following RPM probes to improve the measurement of latency or jitter:

- ICMP ping
- ICMP ping timestamp
- UDP ping
- UDP ping timestamp

NOTE: The device supports hardware timestamping of UDP ping and UDP ping timestamp RPM probes only if the destination port is UDP-ECHO (port 7).

Timestamping takes place during the forwarding process of the device originating the probe (the RPM client), but not on the remote device that is the target of the probe (the RPM server).

The supported encapsulations on a device for timestamping are Ethernet including VLAN, synchronous PPP, and Frame Relay. The only logical interface supported is an *lt* services interface.

RPM probe generation with hardware timestamp can be retrieved through the SNMP protocol.

RPM Statistics

At the end of each test, the device collects the statistics for packet round-trip time, packet inbound and outbound times (for ICMP timestamp probes only), and probe loss as shown in [Table 142](#).

Table 142: RPM Statistics

RPM Statistics	Description
Round-Trip Times	
Minimum round-trip time	Shortest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test
Maximum round-trip time	Longest round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test

Table 142: RPM Statistics (*continued*)

RPM Statistics	Description
Average round-trip time	Average round-trip time from the Juniper Networks device to the remote server, as measured over the course of the test
Standard deviation round-trip time	Standard deviation of the round-trip times from the Juniper Networks device to the remote server, as measured over the course of the test
Jitter	Difference between the maximum and minimum round-trip times, as measured over the course of the test
Inbound and Outbound Times (ICMP Timestamp Probes Only)	
Minimum egress time	Shortest one-way time from the Juniper Networks device to the remote server, as measured over the course of the test
Maximum ingress time	Shortest one-way time from the remote server to the Juniper Networks device, as measured over the course of the test
Average egress time	Average one-way time from the Juniper Networks device to the remote server, as measured over the course of the test
Average ingress time	Average one-way time from the remote server to the Juniper Networks device, as measured over the course of the test
Standard deviation egress time	Standard deviation of the one-way times from the Juniper Networks device to the remote server, as measured over the course of the test
Standard deviation ingress time	Standard deviation of the one-way times from the remote server to the Juniper Networks device, as measured over the course of the test
Egress jitter	Difference between the maximum and minimum outbound times, as measured over the course of the test
Ingress jitter	Difference between the maximum and minimum inbound times, as measured over the course of the test
Probe Counts	
Probes sent	Total number of probes sent over the course of the test
Probe responses received	Total number of probe responses received over the course of the test
Loss percentage	Percentage of probes sent for which a response was not received

RPM Thresholds and Traps

You can configure RPM threshold values for the round-trip times, ingress (inbound) times, and egress (outbound) times that are measured for each probe, as well as for the standard deviation and jitter values that are measured for each test. Additionally, you can configure threshold values for the number of successive lost probes within a test and the total number of lost probes within a test.

If the result of a probe or test exceeds any threshold, the device generates a system log message and sends any Simple Network Management Protocol (SNMP) notifications (traps) that you have configured.

RPM for BGP Monitoring

When managing peering networks that are connected using Border Gateway Protocol (BGP), you might need to find out if a path exists between the Juniper Networks device and its configured BGP neighbors. You can ping each BGP neighbor manually to determine the connection status, but this method is not practical when the device has a large number of BGP neighbors configured.

In the device, you can configure RPM probes to monitor the BGP neighbors and determine if they are active.

Related Documentation

- [RPM Configuration Options on page 1732](#)

IPv6 RPM Probes

Starting with Junos OS Release 15.1X49-D10, Route Engine-based RPM can send and receive IPv6 probe packets to monitor performance on IPv6 networks.

A probe request is a standard IPv6 packet with corresponding TCP, UDP, and ICMPv6 headers. A probe response is also a standard IPv6 packet with corresponding TCP, UDP, and ICMPv6 headers. No RPM header is appended to the standard packet for RE-based RPM. An IPv6-based RPM test occurs between an IPv6 RPM client and IPv6 RPM server.

NOTE: You can have both IPv4 tests and IPv6 tests in the same probe.

Guidelines for Configuring RPM Probes for IPv6

Keep the following guidelines in mind when you configure IPv6 addresses for RPM destinations or servers:

- IPv6 RPM uses ICMPv6 probe requests. You cannot configure ICMP or ICMP timestamp probe types.
- Only Routing Engine-based RPM is supported for IPv6 targets including VRF support, specification of the size of the data portion of ICMPv6 probes, data pattern, and traffic class.
- You can configure probes with a combination of IPv4 and IPv6 tests. However, an individual test must be either IPv4 or IPv6.
- Routing Engine-based RPM does not support hardware-based, or one-way hardware-based timestamping.
- We recommend that you include the **probe-limit** statement at the **[edit services rpm]** hierarchy level to set the limit on concurrent probes to 10. Higher concurrent probes can result in higher spikes.
- SNMP set operation is permitted only on ICMP probes and it is not supported for other probe types.
- The following table describes the IPv6 special address prefixes that you cannot configure in a probe.

IPv6 Address Type	IPv6 Address Prefix
Node-Scoped Unicast	::1/128 is the loopback address ::/128 is the unspecified address
IPv4-Mapped Addresses	::FFFF:0:0/96
IPv4-Compatible Addresses	:<ipv4-address>/96
Link-Scoped Unicast	fe80::/10
Unique-Local	fc00::/7
Documentation Prefix	2001:db8::/32
6to4	2002::/16
6bone	5f00::/8
ORCHID	2001:10::/28
Teredo	2001::/32
Default Route	::/0
Multicast	ff00::/8

- In Routing Engine-based RPM, route-trip time (RTT) spikes might occur because of queuing delays, even with a single test.
- Since RPM might open TCP and UDP ports to communicate between the RPM server and RPM client, we recommend that you use firewalls and distributed denial-of-service (DDoS) attack filters to protect against security threats.

RPM Support for VPN Routing and Forwarding

Real-time performance monitoring (RPM) is supported on all Juniper Network devices.

VRF in a Layer 3 VPN implementation allows multiple instances of a routing table to coexist within the same device at the same time. Because the routing instances are independent, the same or overlapping IPv4 or IPv6 addresses can be used without conflicting each other.

RPM ICMP and UDP probe with VPN routing and forwarding (VRF) has been improved. In previous releases, the RPM probes specified to a VRF table were not handled by the real-time forwarding process (FWDD-RT). In Junos OS Release 10.0, RPM probes specified to a VRF table are handled by the FWDD-RT, thereby providing more accurate results.

This feature supports RPM ICMP and UDP probes configured with routing instances of type VRF.

Example: Configuring Basic RPM Probes

This example shows how to configure basic RPM probes to measure performance between two network endpoints.

- [Requirements on page 1721](#)
- [Overview on page 1722](#)
- [Configuration on page 1722](#)
- [Verification on page 1724](#)

Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

Overview

In this example, you configure basic probes for two RPM owners, customerA and customerB. You configure the RPM test as icmp-test for customerA with a test interval of 15 seconds and specify a probe type as icmp-ping-timestamp, a probe timestamp, and a target address as 192.178.16.5. You then configure the RPM thresholds and corresponding SNMP traps to catch ingress (inbound) times greater than 3000 microseconds.

Then you configure the RPM test as http-test for customerB with a test interval of 30 seconds and specify a probe type as http-get and a target URL as http://customerB.net. Finally, you configure RPM thresholds and corresponding SNMP traps as probe-failure and test-failure to catch three or more successive lost probes and total lost probes of 10.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm probe customerA test icmp-test probe-interval 15
set services rpm probe customerA test icmp-test probe-type icmp-ping-timestamp
set services rpm probe customerA test icmp-test hardware-timestamp
set services rpm probe customerA test icmp-test target address 192.178.16.5
set services rpm probe customerA test icmp-test thresholds ingress-time 3000
set services rpm probe customerA test icmp-test traps ingress-time-exceeded
set services rpm probe customerB test http-test probe-interval 30
set services rpm probe customerB test http-test probe-type http-get
set services rpm probe customerB test http-test target url http://customerB.net
set services rpm probe customerB test http-test thresholds successive-loss 3
set services rpm probe customerB test http-test thresholds total-loss 10
set services rpm probe customerB test http-test traps probe-failure
set services rpm probe customerB test http-test traps test-failure
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure basic RPM probes:

1. Configure the RPM.

```
[edit]
user@host# edit services rpm
```
2. Configure the RPM owners.

```
[edit services rpm]
user@host# set probe customerA
user@host# set probe customerB
```
3. Configure the RPM test for customerA.

- ```
[edit services rpm]
user@host# edit probe customerA
user@host# set test icmp-test probe-interval 15
user@host# set test icmp-test probe-type icmp-ping-timestamp
```
4. Specify a probe timestamp and a target address.
 

```
[edit services rpm probe customerA]
user@host# set test icmp-test hardware-timestamp
user@host# set test icmp-test target address 192.178.16.5
```
  5. Configure RPM thresholds and corresponding SNMP traps.
 

```
[edit services rpm probe customerA]
user@host# set test icmp-test thresholds ingress-time 3000
user@host# set test icmp-test traps ingress-time-exceeded
```
  6. Configure the RPM test for customerB.
 

```
[edit]
user@host# edit services rpm probe customerB
user@host# set test http-test probe-interval 30
```
  7. Specify a probe type and a target URL.
 

```
[edit services rpm probe customerB]
user@host# set test http-test probe-type http-get
user@host# set test http-test target url http://customerB.net
```
  8. Configure RPM thresholds and corresponding SNMP traps.
 

```
[edit services rpm probe customerB]
user@host# set test http-test thresholds successive-loss 3
user@host# set test http-test thresholds total-loss 10
user@host# set test http-test traps probe-failure
user@host# set test http-test traps test-failure
```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services rpm
probe customerA {
 test icmp-test {
 probe-type icmp-ping-timestamp;
 target address 192.0.2.2;
 probe-interval 15;
 thresholds {
 ingress-time 3000;
 }
 traps ingress-time-exceeded;
 hardware-timestamp;
 }
}
probe customerB {
 test http-test {
 probe-type http-get
 target url http://customerB.net;
```

```
 probe-interval 30;
 thresholds {
 successive-loss 3;
 total-loss 10;
 }
 traps [probe-failure test-failure];
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying RPM Services on page 1724](#)
- [Verifying RPM Statistics on page 1724](#)

---

### Verifying RPM Services

**Purpose** Verify that the RPM configuration is within the expected values.

**Action** From configuration mode, enter the **show services rpm** command. The output shows the values that are configured for RPM on the device.

---

### Verifying RPM Statistics

**Purpose** Verify that the RPM probes are functioning and that the RPM statistics are within expected values.

**Action** From configuration mode, enter the **show services rpm probe-results** command.

```
user@host> show services rpm probe-results
```

```
Owner: customerD, Test: icmp-test
Probe type: icmp-ping-timestamp
Minimum Rtt: 312 usec, Maximum Rtt: 385 usec, Average Rtt: 331 usec,
Jitter Rtt: 73 usec, Stddev Rtt: 27 usec

## Example: Configuring RPM Using TCP and UDP Probes

This example shows how to configure RPM using TCP and UDP probes.

- [Requirements on page 1725](#)
- [Overview on page 1725](#)
- [Configuration on page 1726](#)
- [Verification on page 1727](#)

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.
- Configure the probe owner, the test, and the specific parameters of the RPM probe. See [“Example: Configuring Basic RPM Probes” on page 1721](#).

### Overview

In this example, you configure both the host (device A) and the remote device (device B) to act as TCP and UDP servers. You configure a probe for customerC, which uses TCP packets. Device B is configured as an RPM server for both TCP and UDP packets, using an *lt* services interface as the destination interface, and ports 50000 and 50037, respectively.

**CAUTION:** Use probe classification with caution, because improper configuration can cause packets to be dropped.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
{device A}
set services rpm probe customerC test tcp-test probe-interval 5
set services rpm probe customerC test tcp-test probe-type tcp-ping
set services rpm probe customerC test tcp-test target address 192.162.45.6
set services rpm probe customerC test tcp-test destination-interface lt-0/0/0
set services rpm probe customerC test tcp-test destination-port 50000

{device B}
set services rpm probe-server tcp port 50000
set services rpm probe-server udp port 50037
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure RPM using TCP and UDP probes:

1. Configure the RPM owner on device A.

```
{device A}
[edit]
user@host# edit services rpm
user@host# set probe customerC
```

2. Configure the RPM test.

```
{device A}
[edit services rpm]
user@host# edit services rpm probe customerC
user@host# set test tcp-test probe-interval 5
```

3. Set the probe type.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test probe-type tcp-ping
```

4. Specify the target address.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test target address 192.162.45.6
```

5. Configure the destination interface.

```
{device A}
[edit services rpm probe customerC]
user@host# set test tcp-test destination-interface lt-0/0/0
```

6. Configure port 50000 as the TCP port to which the RPM probes are sent.

```
{device A}
```

```
[edit services rpm probe customerC]
user@host# set test tcp-test destination-port 50000
```

7. Configure device B to act as a TCP server using port 50000.

```
{device B}
[edit]
user@host# edit services rpm
user@host# set probe-server tcp port 50000
```

8. Configure device B to act as a UDP server using port 50037.

```
{device B}
[edit services rpm]
user@host# set probe-server udp port 50037
```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services rpm
probe customerC {
 test tcp-test {
 probe-type tcp-ping;
 target address 192.162.45.6;
 probe-interval 5;
 destination-port 50000;
 destination-interface lt-0/0/0.0;
 }
}
probe-server {
 tcp {
 port 50000;
 }
 udp {
 port 50037;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying RPM Probe Servers

**Purpose** Confirm that the configuration is working properly.

Verify that the device is configured to receive and transmit TCP and UDP RPM probes on the correct ports.

**Action** From configuration mode, enter the **show services rpm active-servers** command. The output shows a list of the protocols and corresponding ports for which the device is configured as an RPM server.

```
user@host> show services rpm active-servers
```

```
Protocol: TCP, Port: 50000
```

```
Protocol: UDP, Port: 50037
```

## Example: Configuring RPM Probes for BGP Monitoring

This example shows how to configure RPM probes to monitor BGP neighbors.

- [Requirements on page 1728](#)
- [Overview on page 1728](#)
- [Configuration on page 1729](#)
- [Verification on page 1730](#)

### Requirements

Before you begin:

- Configure the BGP parameters under RPM configuration to send RPM probes to BGP neighbors. See [“Example: Configuring Basic RPM Probes” on page 1721](#).
- Use TCP or UDP probes by configure both the probe server (Juniper Networks device) and the probe receiver (the remote device) to transmit and receive RPM probes on the same TCP or UDP port. See [“Example: Configuring RPM Using TCP and UDP Probes” on page 1725](#).

### Overview

In this example, you specify a hexadecimal value that you want to use for the data portion of the RPM probe as ABCD123. ( It ranges from 1 through 2048 characters.) You specify the data size of the RPM probe as 1024 bytes. ( The value ranges from 0 through 65,507.)

Then you configure destination port 50000 as the TCP port to which the RPM probes are sent. You specify the number of probe results to be saved in the probe history as 25. (It ranges from 0 through 255, and the default is 50.) You set the probe count to 5 and probe interval as 1. (The probe count ranges from 1 through 15, and the default is 1; and the probe interval ranges from 1 through 255, and the default is 3.) You then specify tcp-ping as the type of probe to be sent as part of the test.

Finally, you set the test interval as 60. The value ranges from 0 through 86,400 seconds for the interval between tests.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm bgp data-fill ABCD123 data-size 1024
set services rpm bgp destination-port 50000 history-size 25
set services rpm bgp probe-count 5 probe-interval 1
set services rpm bgp probe-type tcp-ping test-interval 60
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure RPM probes to monitor BGP neighbors:

1. Configure the RPM and BGP.  

```
[edit]
user@host# edit services rpm bgp
```
2. Specify a hexadecimal value.  

```
[edit services rpm bgp]
user@host# set data-fill ABCD123
```
3. Specify the data size of the RPM probe.  

```
[edit services rpm bgp]
user@host# set data-size 1024
```
4. Configure the destination port.  

```
[edit services rpm bgp]
user@host# set destination-port 50000
```
5. Specify the number of probes.  

```
[edit services rpm bgp]
user@host# set history-size 25
```
6. Set the probe count and probe interval.  

```
[edit services rpm bgp]
user@host# set probe-count 5 probe-interval 1
```
7. Specify the type of probe.  

```
[edit services rpm bgp]
user@host# set probe-type tcp-ping
```

**NOTE:** If you do not specify the probe type the default ICMP probes are sent.

8. Set the test interval.

```
[edit services rpm bgp]
user@host# set test-interval 60
```

**Results** From configuration mode, confirm your configuration by entering the **show services rpm** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services rpm
bgp {
 probe-type tcp-ping;
 probe-count 5;
 probe-interval 1;
 test-interval 60;
 destination-port 50000;
 history-size 25;
 data-size 1024;
 data-fill ABCD123;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying RPM Probes for BGP Monitoring

---

**Purpose** Confirm that the configuration is working properly.

Verify that the RPM probes for BGP monitoring is configured.

**Action** From configuration mode, enter the **show services rpm** command.

- Related Documentation**
- [RPM Overview on page 1715](#)
  - [RPM Configuration Options on page 1732](#)
  - [Directing RPM Probes to Select BGP Devices on page 1730](#)
  - [Tuning RPM Probes on page 1732](#)

## Directing RPM Probes to Select BGP Devices

---

If a device has a large number of BGP neighbors configured, you can direct (filter) the RPM probes to a selected group of BGP neighbors rather than to all the neighbors. To identify the BGP devices to receive RPM probes, you can configure routing instances.

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To direct RPM probes to select BGP neighbors:

1. Configure routing instance **R11** to send RPM probes to BGP neighbors within the routing instance.

```
[edit services rpm bgp]
user@host# set routing-instances R11
```

2. If you are done configuring the device, enter **commit** from configuration mode.

## Configuring IPv6 RPM Probes

You can configure IPv6 source and destination addresses for an IPv6-based RPM probe test.

To configure an IPv6 RPM test:

1. Specify the RPM probe owner for the probe you want to configure as an IPv6 test.

```
[edit services rpm]
user@host# edit probe customerA
```

2. Specify a name for the test.

```
[edit services rpm probe customerA]
user@host# edit test ipv6-test
```

3. Specify the probe type.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set probe-type icmp6-ping
```

4. Specify the source address for the test.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set source-address 2001:db8:1a:1112::20
```

5. Specify the target address for the test.

```
[edit services rpm probe customerA test ipv6-test]
user@host# set target inet6-address 2001:db8:1a:1112::1
```

6. Configure the remaining RPM test parameters.

- Related Documentation**
- [Guidelines for Configuring RPM Probes for IPv6 on page 1719](#)

## Tuning RPM Probes

---

After configuring an RPM probe, you can set parameters to control probe functions, such as the interval between probes, the total number of concurrent probes that a system can handle, and the source address used for each probe packet. See [“Example: Configuring Basic RPM Probes” on page 1721](#).

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To tune RPM probes:

1. Set the maximum number of concurrent probes allowed on the system to **10**.

```
[edit services rpm]
user@host# set probe-limit 10
```

2. Access the ICMP probe of customer A.

```
[edit]
user@host# edit services rpm probe customerA test icmp-test
```

3. Set the time between probe transmissions to 15 seconds.

```
[edit services rpm probe customerA test icmp-test]
user@host# set probe-interval 15
```

4. Set the number of probes within a test to **10**.

```
[edit services rpm probe customerA test icmp-test]
user@host# set probe-count 10
```

5. Set the source address for each probe packet to **192.168.2.9**. If you do not explicitly configure a source address, the address on the outgoing interface through which the probe is sent is used as the source address.

```
[edit services rpm probe customerA test icmp-test]
user@host# set source-address 192.168.2.9
```

6. If you are done configuring the device, enter **commit** from configuration mode.

## RPM Configuration Options

---

You can configure real-time performance monitoring (RPM) parameters. See [Table 143](#) for a summary of the configuration options.

Table 143: RPM Configuration Summary

| Field                              | Function                                                                                                                                                                                                        | Your Action                                                                                                                                                                                                                                                                                               |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Performance Probe Owners</b>    |                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                           |
| Owner Name (required)              | Identifies an RPM owner for which one or more RPM tests are configured. In most implementations, the owner name identifies a network on which a set of tests is being run (a particular customer, for example). | Type the name of the RPM owner.                                                                                                                                                                                                                                                                           |
| <b>Identification</b>              |                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                           |
| Test name (required)               | Uniquely identifies the RPM test                                                                                                                                                                                | Type the name of the RPM test.                                                                                                                                                                                                                                                                            |
| Target (Address or URL) (required) | IPv4 or IPv6 address or URL of probe target                                                                                                                                                                     | Type the IPv4 address, in dotted decimal notation, IPv6 address, or the URL of the probe target. If the target is a URL, type a fully formed URL that includes <b>http://</b> .                                                                                                                           |
| Source Address                     | Explicitly configured IPv4 or IPv6 address to be used as the probe source address                                                                                                                               | Type the source address to be used for the probe. If the source address is not one of the device's assigned addresses, the packet uses the outgoing interface's address as its source.                                                                                                                    |
| Routing Instance                   | Particular routing instance over which the probe is sent                                                                                                                                                        | Type the routing instance name. The routing instance applies only to probes of type <b>icmp</b> , <b>icmp6-ping</b> , and <b>icmp-timestamp</b> . The default routing instance is <b>inet.0</b> .                                                                                                         |
| History Size                       | Number of probe results saved in the probe history                                                                                                                                                              | Type a number between 0 and 255. The default history size is 50 probes.                                                                                                                                                                                                                                   |
| <b>Request Information</b>         |                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                           |
| Probe Type (required)              | Specifies the type of probe to send as part of the test.                                                                                                                                                        | Select the desired probe type from the list: <ul style="list-style-type: none"> <li>• <b>http-get</b></li> <li>• <b>http-get-metadata</b></li> <li>• <b>icmp6-ping</b></li> <li>• <b>icmp-ping</b></li> <li>• <b>icmp-ping-timestamp</b></li> <li>• <b>tcp-ping</b></li> <li>• <b>udp-ping</b></li> </ul> |
| Interval                           | Sets the wait time (in seconds) between each probe transmission                                                                                                                                                 | Type a number between 1 and 255 (seconds).                                                                                                                                                                                                                                                                |
| Test Interval (required)           | Sets the wait time (in seconds) between tests.                                                                                                                                                                  | Type a number between 0 and 86400 (seconds).                                                                                                                                                                                                                                                              |
| Probe Count                        | Sets the total number of probes to be sent for each test.                                                                                                                                                       | Type a number between 1 and 15.                                                                                                                                                                                                                                                                           |

Table 143: RPM Configuration Summary (*continued*)

| Field                           | Function                                                                                                                                                                                                                                                                                                                                                                      | Your Action                                                                                    |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| Destination Port                | <p>Specifies the TCP or UDP port to which probes are sent.</p> <p>To use TCP or UDP probes, you must configure the remote server as a probe receiver. Both the probe server and the remote server must be Juniper Networks devices configured to receive and transmit RPM probes on the same TCP or UDP port.</p>                                                             | Type the number 7—a standard TCP or UDP port number—or a port number from 49152 through 65535. |
| DSCP Bits                       | <p>Specifies the Differentiated Services code point (DSCP) bits. This value must be a valid 6-bit pattern. The default is <b>000000</b>.</p>                                                                                                                                                                                                                                  | Type a valid 6-bit pattern.                                                                    |
| Data Size                       | Specifies the size of the data portion of the ICMP probes.                                                                                                                                                                                                                                                                                                                    | Type a size (in bytes) between 0 and 65507.                                                    |
| Data Fill                       | Specifies the contents of the data portion of the ICMP probes.                                                                                                                                                                                                                                                                                                                | Type a hexadecimal value between 1 and 800h to use as the contents of the ICMP probe data.     |
| Hardware Timestamp              | <p>Enables timestamping of RPM probe messages. You can timestamp the following RPM probes to improve the measurement of latency or jitter:</p> <ul style="list-style-type: none"> <li>• ICMP ping</li> <li>• ICMP ping timestamp</li> <li>• UDP ping—destination port UDP-ECHO (port 7) only</li> <li>• UDP ping timestamp—destination port UDP-ECHO (port 7) only</li> </ul> | To enable timestamping, select the check box.                                                  |
| <b>Maximum Probe Thresholds</b> |                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                |
| Successive Lost Probes          | Sets the total number of probes that must be lost successively to trigger a probe failure and generate a system log message.                                                                                                                                                                                                                                                  | Type a number between 0 and 15.                                                                |
| Lost Probes                     | Sets the total number of probes that must be lost to trigger a probe failure and generate a system log message.                                                                                                                                                                                                                                                               | Type a number between 0 and 15.                                                                |
| Round Trip Time                 | Sets the total round-trip time (in microseconds), from the device to the remote server, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                     | Type a number between 0 and 60,000,000 (microseconds).                                         |
| Jitter                          | Sets the total jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                                                                                                                                                                                                                                        | Type a number between 0 and 60,000,000 (microseconds).                                         |
| Standard Deviation              | Sets the maximum allowable standard deviation (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message.                                                                                                                                                                                                                  | Type a number between 0 and 60,000,000 (microseconds).                                         |

Table 143: RPM Configuration Summary (*continued*)

| Field                               | Function                                                                                                                                                                       | Your Action                                                                                                                                                           |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress Time                         | Sets the total one-way time (in microseconds), from the device to the remote server, that triggers a probe failure and generates a system log message.                         | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| Ingress Time                        | Sets the total one-way time (in microseconds), from the remote server to the device, that triggers a probe failure and generates a system log message.                         | Type a number between 0 and 60,000,000 (microseconds)                                                                                                                 |
| Jitter Egress Time                  | Sets the total outbound-time jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                           | Type a number between 0 and 60,000,000 (microseconds)                                                                                                                 |
| Jitter Ingress Time                 | Sets the total inbound-time jitter (in microseconds), for a test, that triggers a probe failure and generates a system log message.                                            | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| Egress Standard Deviation           | Sets the maximum allowable standard deviation of outbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message. | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| Ingress Standard Deviation          | Sets the maximum allowable standard deviation of inbound times (in microseconds) for a test, which, if exceeded, triggers a probe failure and generates a system log message.  | Type a number between 0 and 60,000,000 (microseconds).                                                                                                                |
| <b>Traps</b>                        |                                                                                                                                                                                |                                                                                                                                                                       |
| Egress Jitter Exceeded              | Generates SNMP traps when the threshold for jitter in outbound time is exceeded.                                                                                               | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Egress Standard Deviation Exceeded  | Generates SNMP traps when the threshold for standard deviation in outbound times is exceeded.                                                                                  | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Egress Time Exceeded                | Generates SNMP traps when the threshold for maximum outbound time is exceeded.                                                                                                 | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Jitter Exceeded             | Generates SNMP traps when the threshold for jitter in inbound time is exceeded.                                                                                                | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Standard Deviation Exceeded | Generates SNMP traps when the threshold for standard deviation in inbound times is exceeded.                                                                                   | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Ingress Time Exceeded               | Generates traps when the threshold for maximum inbound time is exceeded.                                                                                                       | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |

Table 143: RPM Configuration Summary (*continued*)

| Field                           | Function                                                                                   | Your Action                                                                                                                                                           |
|---------------------------------|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Jitter Exceeded                 | Generates traps when the threshold for jitter in round-trip time is exceeded.              | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| Probe Failure                   | Generates traps when the threshold for the number of successive lost probes is reached.    | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |
| RTT Exceeded                    | Generates traps when the threshold for maximum round-trip time is exceeded.                | <ul style="list-style-type: none"> <li>To enable SNMP traps for this condition, select the check box.</li> <li>To disable SNMP traps, clear the check box.</li> </ul> |

## Monitoring RPM Probes

The RPM information includes the round-trip time, jitter, and standard deviation values for each configured RPM test on the device. To view these RPM properties, select **Troubleshoot > RPM > View RPM** in the J-Web user interface, or in configuration mode enter the **show** command:

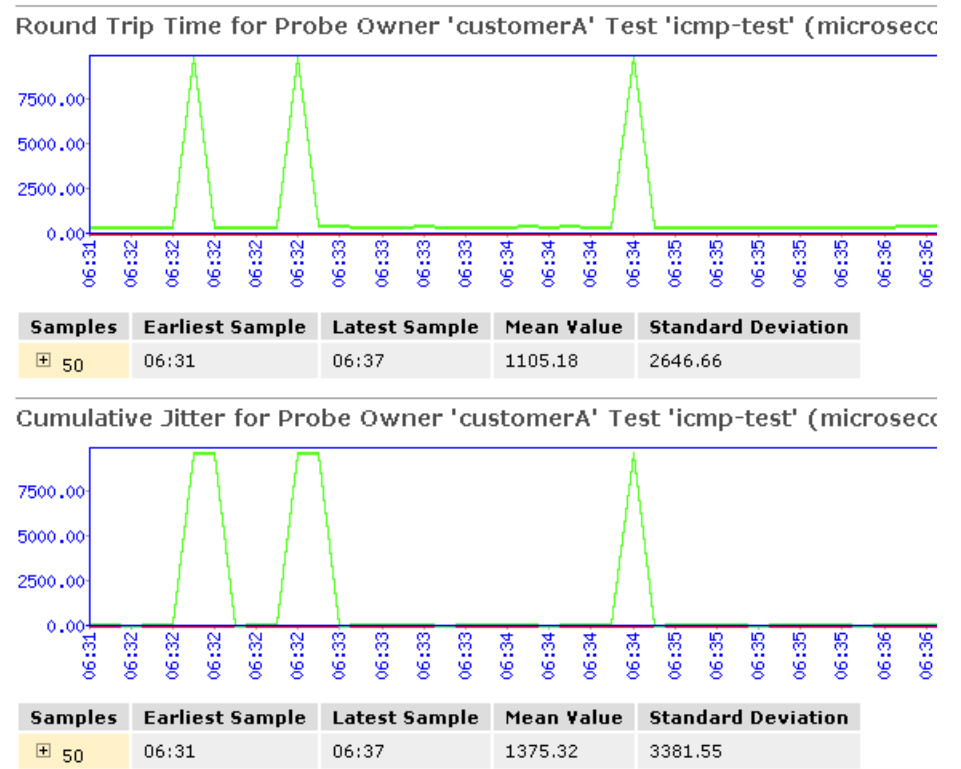

[edit]

```
user@host# run show services rpm probe-results
```

In addition to the RPM statistics for each RPM test, the J-Web user interface displays the round-trip times and cumulative jitter graphically. Figure 40 shows sample graphs for an RPM test.

Figure 40: Sample RPM Graphs

In Figure 40, the round-trip time and jitter values are plotted as a function of the system time. Large spikes in round-trip time or jitter indicate a slower outbound (egress) or inbound (ingress) time for the probe sent at that particular time.

Table 144 summarizes key output fields in RPM displays.

Table 144: Summary of Key RPM Output Fields

| Field                   | Values                                 | Additional Information                                                                                                          |
|-------------------------|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Currently Running Tests |                                        |                                                                                                                                 |
| Graph                   |                                        | Click the <b>Graph</b> link to display the graph (if it is not already displayed) or to update the graph for a particular test. |

## IP Monitoring Overview

---

This feature monitors IP on standalone SRX Series devices or a chassis cluster redundant Ethernet (reth) interface. Existing RPM probes are sent to an IP address to check for reachability. The user takes action based on the reachability result. Supported action currently is preferred static route injection to system route table.

The actions supported are:

- Adding or deleting a new static route that has a higher priority (lower preference) value than a route configured through the CLI command **set routing-options static route**
- Defining multiple probe names under the same IP monitoring policy. If any probe fails, the action is taken. If all probes are reachable, the action is reverted
- Configuring multiple tests in one RPM probe. All tests must fail for the RPM probe to be considered unreachable. If at least one test reaches its target, the RPM probe is considered reachable
- Configuring multiple failure thresholds in one RPM test. If one threshold is reached, the test fails. If no thresholds are reached, the test succeeds.
- Specifying the no-preempt option. If the no-preempt option is specified, the policy does not perform preemptive failback when it is in a failover state or when the RPM probe test recovers from a failure.
- Setting preferred metric values. If the preferred metric value is set, during failover, the route is injected with the set preferred metric value.
- Enabling and disabling interfaces.

- **Interface-Enable**—On a physical or logical interface, when the interface-enable action is configured, the initial state of the interface is disable after startup, and it continues to remain in the disable state as long as the associated RPM probe is in the pass state. When the associated RPM probe fails, the configured physical and logical interfaces are enabled.
- **Interface-Disable**—On a physical or logical interface, when the interface-disable action is configured, the interface state remains unchanged. When the associated RPM probe fails, the physical and logical interfaces are disabled.

**NOTE:** Multiple probe names and actions can be defined for the same IP monitoring policy.

## Understanding IP Monitoring Test Parameters

Each probed target is monitored over the course of a test, which represents a collection of probes during which statistics such as standard deviation and jitter are collected are calculated. During a test, probes are generated and responses collected at a rate defined by the probe interval, the number of seconds between probes.

**NOTE:** To avoid flap, an action is reverted only at the end of a test cycle. During the test cycle, if no threshold is reached, the action is reverted. Although action-failover takes place based on a predefined condition of a monitored IP, when the condition is reversed, the IP becomes reachable on the original route, and the newly added route is deleted. Recovery is performed only when all RPM probes report the IP as reachable.

Table 145 lists the test parameters and its default values:

**Table 145: Test Parameters and Default Values**

| Parameter      | Default Value |
|----------------|---------------|
| probe-count    | 1             |
| probe-interval | 3 seconds     |
| test-interval  | 1 second      |

Table 146 lists the supported threshold and its description:

Table 146: Threshold Supported and Description

| Threshold       | Description                     |
|-----------------|---------------------------------|
| Successive-Loss | Successive loss count of probes |
| Total-Loss      | Total probe lost count          |

## Example: Configuring IP Monitoring on Branch SRX Series Devices

This example shows how to monitor IP on branch SRX Series devices.

- [Requirements on page 1743](#)
- [Overview on page 1743](#)
- [Configuration on page 1743](#)
- [Verification on page 1745](#)

### Requirements

Before you begin:

Configure the following RPM options for RPM test:

- target-address
- probe-count
- probe-interval
- test-interval
- thresholds
- next-hop

### Overview

This example shows how to set up IP monitoring on an SRX Series for the branch device.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services rpm probe Probe-Payment-Server test paysvr target address 1.1.1.10
set services rpm probe Probe-Payment-Server test paysvr probe-count 10
set services rpm probe Probe-Payment-Server test paysvr probe-interval 5
set services rpm probe Probe-Payment-Server test paysvr test-interval 5
set services rpm probe Probe-Payment-Server test paysvr thresholds successive-loss 10
```

```

set services rpm probe Probe-Payment-Server test paysvr next-hop 2.2.2.1
set services ip-monitoring policy Payment-Server-Tracking match rpm-probe
Probe-Payment-Server
set services ip-monitoring policy Payment-Server-Tracking then preferred-route route
1.1.1.0/24 next-hop 1.1.1.99

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure IP monitoring on an SRX Series Services Gateway:

1. Configure the target address under the RPM probe.  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr target address
1.1.1.10

```
2. Configure the probe count under the RPM probe.  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr probe-count
10

```
3. Configure the probe interval (in seconds) under the RPM probe.  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr probe-interval
5

```
4. Configure the test interval (in seconds) under the RPM probe.  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr test-interval
5

```
5. Configure the threshold successive loss count under the RPM  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr thresholds
successive-loss 10

```
6. Configure the next-hop IP address under the RPM probe.  

```

[edit]
user@host# set services rpm probe Probe-Payment-Server test paysvr next-hop
2.2.2.1

```
7. Configure the IP monitoring policy under services.  

```

[edit]
user@host# set services ip-monitoring policy Payment-Server-Tracking match
rpm-probe Probe-Payment-Server

```

**NOTE:** The following steps are not mandatory. You can configure interface actions and route actions independently, or you can configure both the interface action and the route action together in one IP monitoring policy.

8. Configure the IP monitoring preferred route under services.

```
[edit]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
preferred-route route 1.1.1.0/24 preferred-metric 4
```

9. Configure the IP monitoring interface actions.

- Enable

```
[edit]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
interface ge-0/0/1 enable
```

- Disable

```
[edit]
user@host# set services ip-monitoring policy Payment-Server-Tracking then
interface fe-0/0/[4-6] disable
```

10. Configure the no-preempt option.

```
[edit]
user@host# set services ip-monitoring policy Payment-Server-Tracking no-preempt
```

## Verification

### Verifying IP Monitoring

**Purpose** Verify the IP monitoring status of a policy.

**Action** To verify the configuration is working properly, enter the following command:

```
show services ip-monitoring status <policy-name>
```

## Understanding IP Monitoring Through Redundant Ethernet Interface Link Aggregation Groups

IP monitoring checks the reachability of an upstream device. It is designed to check the end-to-end connectivity of configured IP addresses and allows a redundancy group (RG) to automatically failover when the monitored IP address is not reachable through the redundant Ethernet. Both the primary and secondary devices in the chassis cluster monitor specific IP addresses to determine whether an upstream device in the network is reachable.

A redundant Ethernet interface contains physical interfaces from both the primary and secondary nodes in the SRX Series chassis cluster. In a redundant Ethernet interface, two physical interfaces are configured with each node contributing one physical interface. In a redundant Ethernet interface LAG, more than two physical interfaces are configured in the redundant Ethernet interface.

---

## Example: Configuring IP Monitoring on High-End SRX Series Devices

---

This example shows how to monitor IP on a high-end SRX Series device with chassis cluster enabled.

- [Requirements on page 1746](#)
- [Overview on page 1746](#)
- [Configuration on page 1747](#)
- [Verification on page 1749](#)

### Requirements

- You need two SRX5800 Services Gateways with identical hardware configurations, one SRX Series device and one EX8208 Ethernet Switch.
- Physically connect the two SRX5800 devices (back-to-back for the fabric and control ports) and ensure that they are the same models. Configure/add these two devices in a cluster.

### Overview

IP address monitoring checks end-to-end reachability of configured IP address and allows a redundancy group to automatically fail over when not reachable through the child link of redundant Ethernet interface (known as a reth) interface. Redundancy groups on both devices in a cluster can be configured to monitor specific IP addresses to determine whether an upstream device in the network is reachable.

This example shows how to set up IP monitoring on a high-end SRX Series device.

NOTE: IP monitoring is not supported on an NP-IOC card.

---

### Topology

---

Figure 41 shows the topology used in this example.

**Figure 41: IP Monitoring on a High-End SRX Series Device Topology Example**

In this example, two SRX5800 devices in a chassis cluster are connected to an SRX650 device through an EX8208 Ethernet Switch. The example shows how the redundancy groups can be configured to monitor key upstream resources reachable through redundant Ethernet interfaces on either node in a cluster.

## Configuration

- [Configuring IP Monitoring on a High-End SRX Series Device on page 1748](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set chassis cluster reth-count 1
set chassis cluster redundancy-group 0 node 0 priority 254
set chassis cluster redundancy-group 0 node 1 priority 1
set chassis cluster redundancy-group 1 node 0 priority 200
set chassis cluster redundancy-group 1 node 1 priority 199
set chassis cluster redundancy-group 1 ip-monitoring global-weight 255
set chassis cluster redundancy-group 1 ip-monitoring global-threshold 80
set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
set chassis cluster redundancy-group 1 ip-monitoring family inet 111.111.111.111
weight 80
set chassis cluster redundancy-group 1 ip-monitoring family inet 111.111.111.111
interface reth0.0 secondary-ip-address 12.1.1.3
set interfaces ge-0/0/1 gigether-options redundant-parent reth0
```

```

set interfaces ge-4/0/1 gigether-options redundant-parent reth0
set interfaces reth0 redundant-ether-options redundancy-group 1
set interfaces reth0 unit 0 family inet address 12.1.1.1/24
set routing-options static route 111.111.111.111/32 next-hop 12.1.1.2

```

### Configuring IP Monitoring on a High-End SRX Series Device

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure IP monitoring on a high-end SRX Series device:

1. Specify the number of redundant Ethernet interfaces.  

```

{primary:node0}[edit]
user@host# set chassis cluster reth-count 1

```
2. Specify a redundancy group's priority for primacy on each node of the cluster. The higher number takes precedence.  

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 0 node 0 priority 254
user@host# set chassis cluster redundancy-group 0 node 1 priority 1
user@host# set chassis cluster redundancy-group 1 node 0 priority 200
user@host# set chassis cluster redundancy-group 1 node 1 priority 199

```
3. Configure the redundant Ethernet interfaces to redundancy-group 1.  

```

{primary:node0}[edit]
user@host# set interfaces reth0 redundant-ether-options redundancy-group 1
user@host# set interfaces reth0 unit 0 family inet address 12.1.1.1/24

```
4. Assign child interfaces for the redundant Ethernet interfaces from node 0 and node 1.  

```

{primary:node0}[edit]
user@host# set interfaces ge-0/0/1 gigether-options redundant-parent reth0
user@host# set interfaces ge-4/0/1 gigether-options redundant-parent reth0

```
5. Configure the static route to the IP address that is to be monitored.  

```

{primary:node0}[edit]
user@host# set routing-options static route 111.111.111.111/32 next-hop 12.1.1.2

```
6. Configure IP monitoring under redundancy-group 1 with global weight and global threshold.  

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-weight 255
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-threshold 80

```
7. Specify the retry interval.  

```

{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3

```
8. Specify the retry count.  

```

{primary:node0}[edit]

```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
```

9. Assign a weight to the IP address to be monitored, and configure a secondary IP address that will be used to send ICMP packets from the secondary node to track the IP being monitored.

```
{primary:node0}[edit]
```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet
111.111.111.111 weight 80
```

```
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet
111.111.111.111 interface reth0.0 secondary-ip-address 12.1.1.3
```

**NOTE:**

- The redundant Ethernet (reth0) IP address, 12.1.1.1/24, is used to send ICMP packets from node 0 to check the reachability of the monitored IP.
- The secondary IP address, 12.1.1.3, should belong to the same network as the reth0 IP address.
- The secondary IP address is used to send ICMP packets from node 1 to check the reachability of the monitored IP.

## Verification

Confirm the configuration is working properly.

### Verifying Chassis Cluster Status—Before Failover

**Purpose** Verify the chassis cluster status, failover status, and redundancy group information before failover.

**Action** From operational mode, enter the **show chassis cluster status** command.

```
show chassis cluster status
```

Cluster ID: 11

| Node | Priority | Status | Preempt | Manual failover |
|------|----------|--------|---------|-----------------|
|------|----------|--------|---------|-----------------|

Redundancy group: 0 , Failover count: 0

|       |     |           |    |    |
|-------|-----|-----------|----|----|
| node0 | 254 | primary   | no | no |
| node1 | 1   | secondary | no | no |

Redundancy group: 1 , Failover count: 0

|       |     |           |    |    |
|-------|-----|-----------|----|----|
| node0 | 200 | primary   | no | no |
| node1 | 199 | secondary | no | no |

### Verifying Chassis Cluster IP Monitoring Status—Before Failover

**Purpose** Verify the IP status being monitored from both nodes and the failover count for both nodes before failover.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status redundancy-group 1** command.

```
show chassis cluster ip-monitoring status redundancy-group 1
```

node0:

-----

Redundancy group: 1

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

node1:

-----

Redundancy group: 1

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

### Verifying Chassis Cluster Status—After Failover

**Purpose** Verify the chassis cluster status, failover status, and redundancy group information after failover.

**NOTE:** If the IP address is not reachable, the following output will be displayed.

**Action** From operational mode, enter the **show chassis cluster status** command.

```
show chassis cluster status
```

```
Cluster ID: 11
Node Priority Status Preempt Manual failover

Redundancy group: 0 , Failover count: 0
 node0 254 primary no no
 node1 1 secondary no no

Redundancy group: 1 , Failover count: 1
 node0 0 secondary no no
 node1 199 primary no no
```

### Verifying Chassis Cluster IP Monitoring Status—After Failover

**Purpose** Verify the IP status being monitored from both nodes and the failover count for both nodes after failover.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status redundancy-group 1** command.

```
show chassis cluster ip-monitoring status redundancy-group 1
```

```
node0:
```

```
Redundancy group: 1
```

| IP address      | Status      | Failure count | Reason  |
|-----------------|-------------|---------------|---------|
| 111.111.111.111 | unreachable | 1             | unknown |

```
node1:
```

```
Redundancy group: 1
```

| IP address      | Status    | Failure count | Reason |
|-----------------|-----------|---------------|--------|
| 111.111.111.111 | reachable | 0             | n/a    |

## Example: Configuring Chassis Cluster Redundancy Group IP Address Monitoring

This example shows how to configure redundancy group IP address monitoring for an SRX Series device in a chassis cluster.

- [Requirements on page 1752](#)
- [Overview on page 1752](#)

- [Configuration on page 1753](#)
- [Verification on page 1754](#)

## Requirements

Before you begin:

- Set the chassis cluster node ID and cluster ID. See [Example: Setting the Chassis Cluster Node ID and Cluster ID for Branch SRX Series Devices](#) or [Example: Setting the Chassis Cluster Node ID and Cluster ID](#).
- Configure the chassis cluster management interface. See [Example: Configuring the Chassis Cluster Management Interface](#).
- Configure the chassis cluster fabric. See [Example: Configuring the Chassis Cluster Fabric Interfaces](#).

## Overview

You can configure redundancy groups to monitor upstream resources by pinging specific IP addresses that are reachable through redundant Ethernet interfaces on either node in a cluster. You can also configure global threshold, weight, retry interval, and retry count parameters for a redundancy group. When a monitored IP address becomes unreachable, the weight of that monitored IP address is deducted from the redundancy group IP address monitoring global threshold. When the global threshold reaches 0, the global weight is deducted from the redundancy group threshold. The retry interval determines the ping interval for each IP address monitored by the redundancy group. The pings are sent as soon as the configuration is committed. The retry count sets the number of allowed consecutive ping failures for each IP address monitored by the redundancy group.

In this example, you configure the following settings for redundancy group 1:

- IP address to monitor—10.1.1.10
- IP address monitoring global-weight—100
- IP address monitoring global-threshold—200

**NOTE:** The threshold applies cumulatively to all IP addresses monitored by the redundancy group.

---

- IP address retry-interval—3 seconds
- IP address retry-count—10
- Weight—150
- Redundant Ethernet interface—reth1.0
- Secondary IP address—10.1.1.101

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
{primary:node0}[edit]
user@host#
set chassis cluster redundancy-group 1 ip-monitoring global-weight 100
set chassis cluster redundancy-group 1 ip-monitoring global-threshold 200
set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
set chassis cluster redundancy-group 1 ip-monitoring family inet 10.1.1.10 weight 150
interface reth1.0 secondary-ip-address 10.1.1.101
```

**Step-by-Step Procedure** To configure redundancy group IP address monitoring:

1. Specify a global monitoring weight.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-weight
100
```

2. Specify the global monitoring threshold.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring global-threshold
200
```

3. Specify the retry interval.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-interval 3
```

4. Specify the retry count.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring retry-count 10
```

5. Specify the IP address to be monitored, weight, redundant Ethernet interface, and secondary IP address.

```
{primary:node0}[edit]
user@host# set chassis cluster redundancy-group 1 ip-monitoring family inet 10.1.1.10
weight 100 interface reth1.0 secondary-ip-address 10.1.1.101
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis cluster redundancy-group 1** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
{primary:node0}[edit]
user@host# show chassis cluster redundancy-group 1
ip-monitoring {
 global-weight 100;
 global-threshold 200;
 family {
```

```

 inet {
 10.1.1.10 {
 weight 100;
 interface reth1.0 secondary-ip-address 10.1.1.101;
 }
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Status of Monitored IP Addresses for a Redundancy Group

**Purpose** Verify the status of monitored IP addresses for a redundancy group.

**Action** From operational mode, enter the **show chassis cluster ip-monitoring status** command. For information about a specific group, enter the **show chassis cluster ip-monitoring status redundancy-group** command.

```

{primary:node0}
user@host> show chassis cluster ip-monitoring status
node0:

```

```

Redundancy group: 1
Global threshold: 200
Current threshold: -120

```

| IP address | Status    | Failure count | Reason | Weight |
|------------|-----------|---------------|--------|--------|
| 10.1.1.10  | reachable | 0             | n/a    | 220    |
| 10.1.1.101 | reachable | 0             | n/a    | 100    |

```

node1:

```

```

Redundancy group: 1
Global threshold: 200
Current threshold: -120

```

| IP address | Status    | Failure count | Reason | Weight |
|------------|-----------|---------------|--------|--------|
| 10.1.1.10  | reachable | 0             | n/a    | 220    |
| 10.1.1.101 | reachable | 0             | n/a    | 100    |

## Displaying Real-Time Monitoring Information

To display real-time monitoring information about each device between the device and a specified destination host, enter the **traceroute monitor** command with the following syntax:

```
user@host> traceroute monitor host <count number> <inet | inet6> <interval seconds>
<no-resolve> <size bytes> <source source-address> <summary>
```

[Table 147](#) describes the **traceroute monitor** command options.

**Table 147: CLI traceroute monitor Command Options**

| Option                  | Description                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>             | Sends traceroute packets to the hostname or IP address you specify.                                                                                                       |
| <i>count number</i>     | (Optional) Limits the number of ping requests, in packets, to send in summary mode. If you do not specify a count, ping requests are continuously sent until you press Q. |
| <i>inet</i>             | (Optional) Forces the traceroute packets to an IPv4 destination.                                                                                                          |
| <i>inet6</i>            | (Optional) Forces the traceroute packets to an IPv6 destination.                                                                                                          |
| <i>interval seconds</i> | (Optional) Sets the interval between ping requests, in seconds. The default value is 1 second.                                                                            |
| <i>no-resolve</i>       | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                                                            |
| <i>size bytes</i>       | (Optional) Sets the size of the ping request packet. The size can be from 0 through 65,468 bytes. The default packet size is 64 bytes.                                    |
| <i>source address</i>   | (Optional) Uses the source address that you specify, in the traceroute packet.                                                                                            |
| <i>summary</i>          | (Optional) Displays the summary traceroute information.                                                                                                                   |

To quit the **traceroute monitor** command, press Q.

The following is sample output from a **traceroute monitor** command:

```

user@host> traceroute monitor host2

My traceroute [v0.69]
host (0.0.0.0)(tos=0x0 psize=64 bitpattern=0x00)
 Wed Mar 14 23:14:11 2007

## Displaying Multicast Path Information

To display information about a multicast path from a source to the device, enter the **mtrace from-source** command with the following syntax:

```
user@host> mtrace from-source source host <extra-hops number> <group address>
<interval seconds> <max-hops number> <max-queries number> <response host>
<routing-instance routing-instance-name> <tll number> <wait-time seconds> <loop>
<multicast-response | unicast-response> <no-resolve> <no-router-alert> <brief |
detail>
```

Table 149 describes the **mtrace from-source** command options.

Table 149: CLI mtrace from-source Command Options

| Option                   | Description                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>source host</b>       | Traces the path to the specified hostname or IP address.                                                          |
| <b>extra-hops number</b> | (Optional) Sets the number of extra hops to trace past nonresponsive devices. Specify a value from 0 through 255. |
| <b>group address</b>     | (Optional) Traces the path for the specified group address. The default value is 192.0.2.0.                       |
| <b>interval seconds</b>  | (Optional) Sets the interval between statistics gathering. The default value is 10.                               |

Table 149: CLI mtrace from-source Command Options (*continued*)

| Option                                               | Description                                                                                                                                                                                                                                          |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>max-hops <i>number</i></b>                        | (Optional) Sets the maximum number of hops to trace toward the source. Specify a value from 0 through 255. The default value is 32.                                                                                                                  |
| <b>max-queries <i>number</i></b>                     | (Optional) Sets the maximum number of query attempts for any hop. Specify a value from 1 through 32. The default value is 3.                                                                                                                         |
| <b>response <i>host</i></b>                          | (Optional) Sends the response packets to the specified hostname or IP address. By default, the response packets are sent to the device.                                                                                                              |
| <b>routing-instance <i>routing-instance-name</i></b> | (Optional) Traces the routing instance you specify.                                                                                                                                                                                                  |
| <b>ttl <i>number</i></b>                             | (Optional) Sets the time-to-live (TTL) value in the IP header of the query packets. Specify a hop count from 0 through 255. The default value for local queries to the <b>all routers</b> multicast group is 1. Otherwise, the default value is 127. |
| <b>wait-time <i>seconds</i></b>                      | (Optional) Sets the time to wait for a response packet. The default value is 3 seconds.                                                                                                                                                              |
| <b>loop</b>                                          | (Optional) Loops indefinitely, displaying rate and loss statistics. To quit the <b>mtrace</b> command, press Ctrl-C.                                                                                                                                 |
| <b>multicast-response</b>                            | (Optional) Forces the responses to use multicast.                                                                                                                                                                                                    |
| <b>unicast-response</b>                              | (Optional) Forces the response packets to use unicast.                                                                                                                                                                                               |
| <b>no-resolve</b>                                    | (Optional) Does not display hostnames.                                                                                                                                                                                                               |
| <b>no-router-alert</b>                               | (Optional) Does not use the device alert IP option in the IP header.                                                                                                                                                                                 |
| <b>brief</b>                                         | (Optional) Does not display packet rates and losses.                                                                                                                                                                                                 |
| <b>detail</b>                                        | (Optional) Displays packet rates and losses if a group address is specified.                                                                                                                                                                         |

The following is sample output from the **mtrace from-source** command:

```

user@host> mtrace from-source source 192.1.4.1 group 224.1.1.1

Mtrace from 192.1.4.1 to 192.1.30.2 via group 224.1.1.1 Querying full reverse

```

Each line of the trace display is usually in the following format (depending on the options selected and the responses from the devices along the path):

*hop-number host (ip-address) protocolttl*

Table 150 summarizes the output fields of the display.

**NOTE:** The packet statistics gathered from Juniper Networks devices and routing nodes always display as 0.

Table 150: CLI mtrace from-source Command Output Summary

| Field                                  | Description                                                                                                                                     |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hop-number</i>                      | Number of the hop (device) along the path.                                                                                                      |
| <i>host</i>                            | Hostname, if available, or IP address of the device. If the <b>no-resolve</b> option was entered in the command, the hostname is not displayed. |
| <i>ip-address</i>                      | IP address of the device.                                                                                                                       |
| <i>protocol</i>                        | Protocol used.                                                                                                                                  |
| <i>ttl</i>                             | TTL threshold.                                                                                                                                  |
| Round trip time <i>milliseconds ms</i> | Total time between the sending of the query packet and the receiving of the response packet.                                                    |
| total ttl of <i>number</i> required    | Total number of hops required to reach the source.                                                                                              |
| Source                                 | Source IP address of the response packet.                                                                                                       |
| Response Dest                          | Response destination IP address.                                                                                                                |
| Overall                                | Average packet rate for all traffic at each hop.                                                                                                |
| Packet Statistics For Traffic From     | Number of packets lost, number of packets sent, percentage of packets lost, and average packet rate at each hop.                                |
| Receiver                               | IP address receiving the multicast packets.                                                                                                     |
| Query Source                           | IP address of the host sending the query packets.                                                                                               |

## Monitoring H.323 ALG Information

**Purpose** View the H.323 ALG counters information.

**Action** Select **Monitor>ALGs>H323** in the J-Web user interface, or enter the **show security alg h323 counters** command.

[Table 151](#) summarizes key output fields in the H.323 counters display.

**Table 151: Summary of Key H.323 Counters Output Fields**

| Field                             | Values                                                                                                                           | Additional Information |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>H.323 Counters Information</b> |                                                                                                                                  |                        |
| Packets received                  | Number of H.323 ALG packets received.                                                                                            | —                      |
| Packets dropped                   | Number of H.323 ALG packets dropped.                                                                                             | —                      |
| RAS message received              | Number of incoming RAS (Endpoint Registration, Admission, and Status) messages per second per gatekeeper received and processed. | —                      |

Table 151: Summary of Key H.323 Counters Output Fields (*continued*)

| Field                       | Values                                              | Additional Information                                                                                                                                                                                                            |
|-----------------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Q.931 message received      | Counter for Q.931 message received.                 | —                                                                                                                                                                                                                                 |
| H.245 message received      | Counter for H.245 message received.                 | —                                                                                                                                                                                                                                 |
| Number of calls             | Total number of H.323 ALG calls.                    | —                                                                                                                                                                                                                                 |
| Number of active calls      | Number of active H.323 ALG calls.                   | This counter displays the number of call legs and might not display the exact number of voice calls that are active. For instance, for a single active voice call between two endpoints, this counter might display a value of 2. |
| <b>H.323 Error Counters</b> |                                                     |                                                                                                                                                                                                                                   |
| Decoding errors             | Number of decoding errors.                          | —                                                                                                                                                                                                                                 |
| Message flood dropped       | Error counter for message flood dropped.            | —                                                                                                                                                                                                                                 |
| NAT errors                  | H.323 ALG Network Address Translation (NAT) errors. | —                                                                                                                                                                                                                                 |
| Resource manager errors     | H.323 ALG resource manager errors.                  | —                                                                                                                                                                                                                                 |

## Monitoring MGCP ALGs

This section contains the following topics:

- [Monitoring MGCP ALG Calls on page 1764](#)
- [Monitoring MGCP ALG Counters on page 1765](#)
- [Monitoring MGCP ALG Endpoints on page 1766](#)

### Monitoring MGCP ALG Calls

**Purpose** View information about MGCP ALG calls.

**Action** Select **Monitor>ALGs>MGCP>Calls** in the J-Web user interface. To view detailed information, select the endpoint on the MGCP calls page.

Alternatively, enter the **show security alg mgcp calls** command.

Table 152 summarizes key output fields in the MGCP calls display.

**Table 152: Summary of Key MGCP Calls Output Fields**

| Field                          | Values                                                                                                           | Additional Information |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>MGCP Calls Information</b>  |                                                                                                                  |                        |
| Endpoint@GW                    | Endpoint name.                                                                                                   | —                      |
| Zone                           | <ul style="list-style-type: none"> <li><b>trust</b>—Trust zone.</li> <li><b>untrust</b>—Untrust zone.</li> </ul> | —                      |
| Call ID                        | Call identifier for ALG MGCP.                                                                                    | —                      |
| RM Group                       | Resource manager group ID.                                                                                       | —                      |
| Call Duration                  | Duration for which connection is active.                                                                         | —                      |
| Connection Id                  | Connection identifier for MGCP ALG calls.                                                                        | —                      |
| <b>Calls Details: Endpoint</b> |                                                                                                                  |                        |
| Local SDP                      | IP address of the MGCP ALG local call owner, as per the Session Description Protocol (SDP).                      | —                      |
| Remote SDP                     | Remote IP address of the MGCP ALG remote call owner, as per the Session Description Protocol (SDP).              | —                      |

## Monitoring MGCP ALG Counters

**Purpose** View MGCP ALG counters information.

**Action** Select **Monitor>ALGs>MGCP>Counters** in the J-Web user interface, or enter the **show security alg mgcp counters** command.

Table 153 summarizes key output fields in the MGCP counters display.

**Table 153: Summary of Key MGCP Counters Output Fields**

| Field                            | Values                               | Additional Information |
|----------------------------------|--------------------------------------|------------------------|
| <b>MGCP Counters Information</b> |                                      |                        |
| Packets received                 | Number of MGCP ALG packets received. | —                      |
| Packets dropped                  | Number of MGCP ALG packets dropped.  | —                      |

Table 153: Summary of Key MGCP Counters Output Fields (*continued*)

| Field                         | Values                                             | Additional Information |
|-------------------------------|----------------------------------------------------|------------------------|
| Message received              | Number of MGCP ALG messages received.              | —                      |
| Number of connections         | Number of MGCP ALG connections.                    | —                      |
| Number of active connections  | Number of active MGCP ALG connections.             | —                      |
| Number of calls               | Number of MGCP ALG calls.                          | —                      |
| Number of active calls        | Number of MGCP ALG active calls.                   | —                      |
| Number of active transactions | Number of active transactions.                     | —                      |
| Number of re-transmission     | Number of MGCP ALG retransmissions.                | —                      |
| <b>Error Counters</b>         |                                                    |                        |
| Unknown-method                | MGCP ALG unknown method errors.                    | —                      |
| Decoding error                | MGCP ALG decoding errors.                          | —                      |
| Transaction error             | MGCP ALG transaction errors.                       | —                      |
| Call error                    | MGCP ALG counter errors.                           | —                      |
| Connection error              | MGCP ALG connection errors.                        | —                      |
| Connection flood drop         | MGCP ALG connection flood drop errors.             | —                      |
| Message flood drop            | MGCP ALG message flood drop errors.                | —                      |
| IP resolve error              | MGCP ALG IP address resolution errors.             | —                      |
| NAT error                     | MGCP ALG Network Address Translation (NAT) errors. | —                      |
| Resource manager error        | MGCP ALG resource manager errors.                  | —                      |

## Monitoring MGCP ALG Endpoints

**Purpose** View information about MGCP ALG endpoints.

**Action** Select **Monitor>ALGs>MGCP>Endpoints** in the J-Web user interface. To view detailed information, select the gateway on the MGCP endpoints page.

Alternatively, enter the **show security alg mgcp endpoints** command.

Table 154 summarizes key output fields in the MGCP endpoints display.

**Table 154: Summary of Key MGCP Endpoints Output Fields**

| Field                          | Values                                                                                                           | Additional Information |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>MGCP Endpoints</b>          |                                                                                                                  |                        |
| Gateway                        | IP address of the gateway.                                                                                       | —                      |
| Zone                           | <ul style="list-style-type: none"> <li><b>trust</b>—Trust zone.</li> <li><b>untrust</b>—Untrust zone.</li> </ul> | —                      |
| IP                             | IP address.                                                                                                      | —                      |
| <b>Endpoints: Gateway name</b> |                                                                                                                  |                        |
| Endpoint                       | Endpoint name.                                                                                                   | —                      |
| Transaction #                  | Transaction identifier.                                                                                          | —                      |

## Monitoring SCCP ALGs

This section contains the following topics:

- [Monitoring SCCP ALG Calls on page 1767](#)
- [Monitoring SCCP ALG Counters on page 1768](#)

### Monitoring SCCP ALG Calls

**Purpose** View information about SCCP ALG calls.

**Action** Select **Monitor>ALGs>SCCP>Calls** in the J-Web user interface. To view detailed information, select the client IP address on the SCCP calls page.

Alternatively, enter the **show security alg sccp calls** command.

Table 155 summarizes key output fields in the SCCP calls display.

Table 155: Summary of Key SCCP Calls Output Fields

| Field                         | Values                             | Additional Information |
|-------------------------------|------------------------------------|------------------------|
| <b>SCCP Calls Information</b> |                                    |                        |
| Client IP                     | IP address of the client.          | —                      |
| Zone                          | Client zone identifier.            | —                      |
| Call Manager                  | IP address of the call manager.    | —                      |
| Conference ID                 | Conference call identifier.        | —                      |
| RM Group                      | Resource manager group identifier. | —                      |

## Monitoring SCCP ALG Counters

**Purpose** View SCCP ALG counters information.

**Action** Select **Monitor>ALGs>SCCP>Count** in the J-Web user interface, or enter the **show security alg sccp counters** command.

Table 156 summarizes key output fields in the SCCP counters display.

Table 156: Summary of Key SCCP Counters Output Fields

| Field                            | Values                                                   | Additional Information |
|----------------------------------|----------------------------------------------------------|------------------------|
| <b>SCCP Counters Information</b> |                                                          |                        |
| Clients currently registered     | Number of SCCP ALG clients currently registered.         | —                      |
| Active calls                     | Number of active SCCP ALG calls.                         | —                      |
| Total calls                      | Total number of SCCP ALG calls.                          | —                      |
| Packets received                 | Number of SCCP ALG packets received.                     | —                      |
| PDUs processed                   | Number of SCCP ALG protocol data units (PDUs) processed. | —                      |
| Current call rate                | Number of calls per second.                              | —                      |
| <b>Error counters</b>            |                                                          |                        |
| Packets dropped                  | Number of packets dropped by the SCCP ALG.               | —                      |

Table 156: Summary of Key SCCP Counters Output Fields (*continued*)

| Field                      | Values                                                                      | Additional Information |
|----------------------------|-----------------------------------------------------------------------------|------------------------|
| Decode errors              | SCCP ALG decoding errors.                                                   | —                      |
| Protocol errors            | Number of protocol errors.                                                  | —                      |
| Address translation errors | Number of Network Address Translation (NAT) errors encountered by SCCP ALG. | —                      |
| Policy lookup errors       | Number of packets dropped because of a failed policy lookup.                | —                      |
| Unknown PDUs               | Number of unknown protocol data units (PDUs).                               | —                      |
| Maximum calls exceed       | Number of times the maximum SCCP calls limit was exceeded.                  | —                      |
| Maximum call rate exceed   | Number of times the maximum SCCP call rate exceeded.                        | —                      |
| Initialization errors      | Number of initialization errors.                                            | —                      |
| Internal errors            | Number of internal errors.                                                  | —                      |
| Unsupported feature        | Number of unsupported feature errors.                                       | —                      |
| Non specific error         | Number of nonspecific errors.                                               | —                      |

## Monitoring SIP ALGs

This section contains the following topics:

- [Monitoring SIP ALG Calls on page 1770](#)
- [Monitoring SIP ALG Counters on page 1770](#)

- [Monitoring SIP ALG Rate Information on page 1772](#)
- [Monitoring SIP ALG Transactions on page 1773](#)

## Monitoring SIP ALG Calls

**Purpose** View information about SIP ALG calls.

**Action** Select **Monitor>ALGs>SIP>Calls** in the J-Web user interface. To view detailed information, select the Call Leg on the SIP calls page.

Alternatively, enter the **show security alg sip calls detail** command.

[Table 157](#) summarizes key output fields in the SIP calls display.

**Table 157: Summary of Key SIP Calls Output Fields**

| Field                        | Values                                        | Additional Information |
|------------------------------|-----------------------------------------------|------------------------|
| <b>SIP Calls Information</b> |                                               |                        |
| Call Leg                     | Call length identifier.                       | —                      |
| Zone                         | Client zone identifier.                       | —                      |
| RM Group                     | Resource manager group identifier.            | —                      |
| Local Tag                    | Local tag for the SIP ALG User Agent server.  | —                      |
| Remote Tag                   | Remote tag for the SIP ALG User Agent server. | —                      |

## Monitoring SIP ALG Counters

**Purpose** View SIP ALG counters information.

**Action** Select **Monitor>ALGs>SIP>Count** in the J-Web user interface, or enter the **show security alg sip counters** command.

[Table 158](#) summarizes key output fields in the SIP counters display.

**Table 158: Summary of Key SIP Counters Output Fields**

| Field                           | Values                          | Additional Information                                                                                                                                                                                              |
|---------------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SIP Counters Information</b> |                                 |                                                                                                                                                                                                                     |
| INVITE                          | Number of INVITE requests sent. | An INVITE request is sent to invite another user to participate in a session.                                                                                                                                       |
| CANCEL                          | Number of CANCEL requests sent. | A user can send a CANCEL request to cancel a pending INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE had sent a final response for the INVITE before it received the CANCEL. |

Table 158: Summary of Key SIP Counters Output Fields (*continued*)

| Field                     | Values                             | Additional Information                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACK                       | Number of ACK requests sent.       | The user from whom the INVITE originated sends an ACK request to confirm reception of the final response to the INVITE request.                                                                                                                                                     |
| BYE                       | Number of BYE requests sent.       | A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.                                                                                                                                                               |
| REGISTER                  | Number of REGISTER requests sent.  | A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. A SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user. |
| OPTIONS                   | Number of OPTIONS requests sent.   | An OPTION message is used by the User Agent (UA) to obtain information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.                                             |
| INFO                      | Number of INFO requests sent.      | An INFO message is used to communicate mid-session signaling information along the signaling path for the call.                                                                                                                                                                     |
| MESSAGE                   | Number of MESSAGE requests sent.   | SIP messages consist of requests from a client to a server and responses to the requests from a server to a client with the purpose of establishing a session (or a call).                                                                                                          |
| NOTIFY                    | Number of NOTIFY requests sent.    | A NOTIFY message is sent to inform subscribers of changes in state to which the subscriber has a subscription.                                                                                                                                                                      |
| REFER                     | Number of REFER requests sent.     | A REFER request is used to refer the recipient (identified by the Request-URI) to a third party by the contact information provided in the request.                                                                                                                                 |
| SUBSCRIBE                 | Number of SUBSCRIBE requests sent. | A SUBSCRIBE request is used to request current state and state updates from a remote node.                                                                                                                                                                                          |
| UPDATE                    | Number of UPDATE requests sent.    | An UPDATE request is used to create a temporary opening in the firewall (pinhole) for new or updated Session Description Protocol (SDP) information. The following header fields are modified: Via, From, To, Call-ID, Contact, Route, and Record-Route.                            |
| <b>SIP Error Counters</b> |                                    |                                                                                                                                                                                                                                                                                     |
| Total Pkt-in              | SIP ALG total packets received.    | —                                                                                                                                                                                                                                                                                   |

Table 158: Summary of Key SIP Counters Output Fields (*continued*)

| Field                       | Values                                                                            | Additional Information |
|-----------------------------|-----------------------------------------------------------------------------------|------------------------|
| Total Pkt dropped on error  | Number of packets dropped by the SIP ALG.                                         | —                      |
| Transaction error           | SIP ALG transaction errors.                                                       | —                      |
| Call error                  | SIP ALG call errors.                                                              | —                      |
| IP resolve error            | SIP ALG IP address resolution errors.                                             | —                      |
| NAT error                   | SIP ALG NAT errors.                                                               | —                      |
| Resource manager error      | SIP ALG resource manager errors.                                                  | —                      |
| RR header exceeded max      | Number of times the SIP ALG RR (Record-Route) headers exceeded the maximum limit. | —                      |
| Contact header exceeded max | Number of times the SIP ALG contact header exceeded the maximum limit.            | —                      |
| Call dropped due to limit   | SIP ALG calls dropped because of call limits.                                     | —                      |
| SIP stack error             | SIP ALG stack errors.                                                             | —                      |

## Monitoring SIP ALG Rate Information

**Purpose** View SIP ALG rate information.

**Action** Select **Monitor>ALGs>SIP>Rate** in the J-Web user interface, or enter the **show security alg sip rate** command.

Table 159 summarizes key output fields in the SIP rate display.

Table 159: Summary of Key SIP Rate Output Fields

| Field                | Values | Additional Information |
|----------------------|--------|------------------------|
| SIP Rate Information |        |                        |

Table 159: Summary of Key SIP Rate Output Fields (*continued*)

| Field                                              | Values                                                                                                                                       | Additional Information |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| CPU ticks per microseconds is                      | SIP ALG CPU ticks per microsecond.                                                                                                           | –                      |
| Time taken for the last message in microseconds is | Time, in microseconds, that the last SIP ALG message needed to transit the network.                                                          | –                      |
| Number of messages in 10 minutes                   | Total number of SIP ALG messages transiting the network in 10 minutes.                                                                       | –                      |
| Time taken by the messages in 10 minutes           | Total time, in microseconds, during an interval of less than 10 minutes for the specified number of SIP ALG messages to transit the network. | –                      |
| Rate                                               | Number of SIP ALG messages per second transiting the network.                                                                                | –                      |

## Monitoring SIP ALG Transactions

**Purpose** View information about SIP ALG transactions.

**Action** Select **Monitor>ALGs>SIP>Transactions** in the J-Web user interface, or enter the **show security alg sip transactions** command.

Table 160 summarizes key output fields in the SIP transactions display.

Table 160: Summary of Key SIP Transactions Output Fields

| Field                               | Values                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|

## Monitoring Voice ALG H.323

**Purpose** Use the monitoring functionality to view the ALG H.323 page.

**Action** To monitor ALG H.323 select **Monitor>Security>Voice ALGs>H.323** in the J-Web user interface.

**Meaning** [Table 161](#) summarizes key output fields in the ALG H.323 page.

**Table 161: ALG H.323 Monitoring Page**

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Display the list of virtual chassis member.      | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | —                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>clear</b> to clear the monitor summary.  |

### H.323 Counter Summary

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |   |

## Monitoring Voice ALG MGCP

**Purpose** Use the monitoring functionality to view the voice ALG MGCP page.

**Action** To monitor ALG MGCP, select **Monitor>Security>Voice ALGs>MGCP** in the J-Web user interface.

**Meaning** [Table 162](#) summarizes key output fields in the voice ALG MGCP page.

**Table 162: Voice ALG MGCP Monitoring Page**

| Field                        | Value                                            | Additional Information                            |
|------------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member       | Displays the list of virtual chassis member.     | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec)    | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                      | Displays the option to refresh the page.         | —                                                 |
| Clear                        | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |
| <b>Counters</b>              |                                                  |                                                   |
| <b>MGCP Counters Summary</b> |                                                  |                                                   |

Table 162: Voice ALG MGCP Monitoring Page (*continued*)

| Field    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Additional Information |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Category | Displays the following categories: <ul style="list-style-type: none"> <li>• <b>Packets Received</b>—Number of ALG MGCP packets received.</li> <li>• <b>Packets Dropped</b>— Number of ALG MGCP packets dropped.</li> <li>• <b>Message received</b>— Number of ALG MGCP messages received.</li> <li>• <b>Number of connections</b>— Number of ALG MGCP connections.</li> <li>• <b>Number of active connections</b>— Number of active ALG MGCP connections.</li> <li>• <b>Number of calls</b>— Number of ALG MGCP calls.</li> <li>• <b>Number of active calls</b>— Number of active ALG MGCP calls.</li> <li>• <b>Number of active transactions</b>— Number of active transactions.</li> <li>• <b>Number of transactions</b>— Number of transactions.</li> <li>• <b>Number of re-transmission</b>—Number of ALG MGCP retransmissions.</li> <li>• <b>Number of active endpoints</b>— Number of MGCP active endpoints.</li> <li>• <b>Number of DSCP marked</b>— Number of MGCP DSCPs marked.</li> </ul> | —                      |
| Count    | Provides the count of response codes for each MGCP counter summary category.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | —                      |

## Monitoring Voice ALG SCCP

**Purpose** Use the monitoring functionality to view the voice ALG SCCP page.

**Action** To monitor voice ALG SCCP, select **Monitor>Security>Voice ALGs>SCCP** in the J-Web user interface.

**Meaning** [Table 163](#) summarizes key output fields in the voice ALG SCCP page.

Table 163: Voice ALG SCCP Monitoring Page

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Displays the list of virtual chassis member.     | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | —                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |

## Monitoring Voice ALG SIP

**Purpose** Use the monitoring functionality to view the voice ALG SIP page.

**Action** To monitor voice ALG SIP select **Monitor>Security>Voice ALGs>SIP** in the J-Web user interface.

**Meaning** [Table 164](#) summarizes key output fields in the voice ALG SIP page.

**Table 164: Voice ALG SIP Monitoring Page**

| Field                     | Value                                            | Additional Information                            |
|---------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member    | Displays the list of virtual chassis members.    | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec) | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                   | Displays the option to refresh the page.         | –                                                 |
| Clear                     | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |

| Field  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Additional Information |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Method | <p>Displays the SIP counter information. The available options are:</p> <ul style="list-style-type: none"><li>• <b>BYE</b>— Number of BYE requests sent. A user sends a BYE request to abandon a session. A BYE request from either user automatically terminates the session.</li><li>• <b>REGISTER</b>— Number of REGISTER requests sent. A user sends a REGISTER request to a SIP registrar server to inform it of the current location of the user. The SIP registrar server records all the information it receives in REGISTER requests and makes this information available to any SIP server attempting to locate a user.</li><li>• <b>OPTIONS</b>— Number of OPTIONS requests sent. An OPTION message is used by the User Agent (UA) to obtain information about the capabilities of the SIP proxy. A server responds with information about what methods, session description protocols, and message encoding it supports.</li><li>• <b>INFO</b>— Number of INFO requests sent. An INFO message is used to communicate mid-session signaling information along the signaling path for the call.</li><li>• <b>MESSAGE</b>— Number of MESSAGE requests sent. SIP messages consist of requests from a client to the server and responses to the requests from the server to a client for the purpose of establishing a session (or a call).</li></ul> | —                      |

SIP Counters Information (continued)

Table 164: Voice ALG SIP Monitoring Page (*continued*)

| Field        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Additional Information |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Method       | <ul style="list-style-type: none"> <li>• <b>NOTIFY</b>— Number of NOTIFY requests sent. A NOTIFY message is sent to inform subscribers about the change in state of the subscription.</li> <li>• <b>PRACK</b>— Number of PRACK requests sent. The PRACK request plays the same role as the ACK request, but for provisional responses.</li> <li>• <b>PUBLISH</b>— Number of PUBLISH requests sent. The PUBLISH request is used for publishing the event state. PUBLISH is similar to REGISTER that allows a user to create, modify, and remove state in another entity which manages this state on behalf of the user.</li> <li>• <b>REFER</b>— Number of REFER requests sent. A REFER request is used to refer the recipient (identified by the Request-URI) to a third party identified by the contact information provided in the request.</li> <li>• <b>SUBSCRIBE</b>— Number of SUBSCRIBE requests sent. A SUBSCRIBE request is used to request current state and state information updates from a remote node.</li> <li>• <b>UPDATE</b>— Number of UPDATE requests sent. An UPDATE request is used to create a temporary opening in the firewall (pinhole) for new or updated Session Description Protocol (SDP) information. The following header fields are modified: Via, From, To, Call-ID, Contact, Route, and Record-Route.</li> <li>• <b>BENOTIFY</b>— Number of BENOTIFY requests sent. A BENOTIFY request is used to reduce the unnecessary SIP signaling traffic on application servers. Applications that do not need a response for a NOTIFY request can enhance performance by enabling BENOTIFY.</li> <li>• <b>SERVICE</b>— Number of SERVICE requests sent. The SERVICE method is used by a SIP client to request a service from a SIP server. It is a standard SIP message and will be forwarded until it reaches the server or end user that is performing the service.</li> <li>• <b>OTHER</b>— Number of OTHER requests sent.</li> </ul> | —                      |
| T, RT        | Displays the transmit and retransmit method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                      |
| 1xx, RT      | Displays one transmit and retransmit method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                      |

## Monitoring Voice ALG Summary

**Purpose** Use the monitoring functionality to view the voice ALG summary page.

**Action** To monitor voice ALG summary, select **Monitor>Security>Voice ALGs>Summary** in the J-Web user interface.

**Meaning** [Table 165](#) summarizes key output fields in the voice ALG summary page.

**Table 165: Voice ALG Summary Monitoring Page**

| Field                      | Value                                            | Additional Information                            |
|----------------------------|--------------------------------------------------|---------------------------------------------------|
| Virtual Chassis Member     | Display the list of virtual chassis member.      | Select one of the virtual chassis members listed. |
| Refresh Interval (30 sec)  | Displays the time interval set for page refresh. | Select the time interval from the drop-down list. |
| Refresh                    | Displays the option to refresh the page.         | –                                                 |
| Clear                      | Provides an option to clear the monitor summary. | Click <b>Clear</b> to clear the monitor summary.  |
| Protocol Name              | Displays the protocols configured.               | –                                                 |
| Total Calls                | Displays the total number of calls.              | –                                                 |
| Number of Active Calls     | Displays the number of active calls.             | –                                                 |
| Number of Received Packets | Displays the number of packets received.         | –                                                 |
| Number of Errors           | Displays the number of errors.                   | –                                                 |
| H.323 Calls Chart          | Displays the H.323 calls chart.                  | –                                                 |
| MGCP Calls Chart           | Displays the MGCP calls chart.                   | –                                                 |
| SCCP Calls Chart           | Displays the SCCP calls chart.                   | –                                                 |
| SIP Calls Chart            | Displays the SIP calls chart.                    | –                                                 |

## Displaying Real-Time Interface Information

---

Enter the **monitor interface** command to display real-time traffic, error, alarm, and filter statistics about a physical or logical interface:

```
user@host> monitor interface (interface-name | traffic)
```

Replace ***interface-name*** with the name of a physical or logical interface. If you specify the **traffic** option, statistics for all active interfaces display.

The real-time statistics update every second. The **Current delta** and **Delta** columns display the amount the statistics counters have changed since the **monitor interface** command was entered or since you cleared the delta counters. [Table 166](#) and [Table 167](#) list the keys you use to control the display using the ***interface-name*** and **traffic** options. (The keys are not case sensitive.)

**Table 166: CLI monitor interface Output Control Keys**

| Key | Action                                                                                                                |
|-----|-----------------------------------------------------------------------------------------------------------------------|
| c   | Clears (returns to 0) the delta counters in the <b>Current delta</b> column. The statistics counters are not cleared. |

Table 166: CLI monitor interface Output Control Keys (*continued*)

| Key      | Action                                                                                                                                                                                                   |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| f        | Freezes the display, halting the update of the statistics and delta counters.                                                                                                                            |
| i        | Displays information about a different interface. You are prompted for the name of a specific interface.                                                                                                 |
| n        | Displays information about the next interface. The device scrolls through the physical and logical interfaces in the same order in which they are displayed by the <b>show interfaces terse</b> command. |
| q or ESC | Quits the command and returns to the command prompt.                                                                                                                                                     |
| t        | Thaws the display, resuming the update of the statistics and delta counters.                                                                                                                             |

Table 167: CLI monitor interface traffic Output Control Keys

| Key      | Action                                                                                                        |
|----------|---------------------------------------------------------------------------------------------------------------|
| b        | Displays the statistics in units of bytes and bytes per second (bps).                                         |
| c        | Clears (returns to 0) the delta counters in the <b>Delta</b> column. The statistics counters are not cleared. |
| d        | Displays the <b>Delta</b> column instead of the rate column—in bps or packets per second (pps).               |
| p        | Displays the statistics in units of packets and packets per second (pps).                                     |
| q or ESC | Quits the command and returns to the command prompt.                                                          |
| r        | Displays the rate column—in bps and pps—instead of the <b>Delta</b> column.                                   |

The following are sample displays from the **monitor interface** command:

```
user@host> monitor interface fe-0/0/0
```

```

host1 Seconds: 5 Time: 04:38:40
 Delay: 3/0/10

Interface: fe-0/0/0, Enabled, Link is Up
Encapsulation: Ethernet, Speed: 1000mbps
Traffic statistics: Current delta
 Input bytes: 885405423 (3248 bps) [2631]
 Output bytes: 137411893 (3344 bps) [10243]
 Input packets: 7155064 (2 pps) [28]
 Output packets: 636071 (1 pps) [23]
Error statistics:
 Input errors: 0 [0]
 Input drops: 0 [0]
 Input framing errors: 0 [0]
 Policed discards: 0 [0]
 L3 incompletes: 0 [0]
```

```

L2 channel errors: 0 [0]
L2 mismatch timeouts: 0 [0]
Carrier transitions: 1 [0]
Output errors: 0 [0]
Output drops: 0 [0]
Aged packets: 0 [0]
Active alarms : None
Active defects: None
Input MAC/Filter statistics:
 Unicast packets 73083 [16]
 Broadcast packets 3629058 [5]
 Multicast packets 3511364 [3]
 Oversized frames 0 [0]
 Packet reject count 0 [0]
 DA rejects 0 [0]
 SA rejects 0 [0]
Output MAC/Filter Statistics:
 Unicast packets 629555 [28]
 Broadcast packets 6494 Multicast packet [0]

```

**NOTE:** The output fields that display when you enter the **monitor interface** *interface-name* command are determined by the interface you specify.

```
user@host> monitor interface traffic
```

| Interface | Link | Input packets | (pps)   | Output packets | (pps)   |
|-----------|------|---------------|---------|----------------|---------|
| fe-0/0/0  | Up   | 42334         | (5)     | 23306          | (3)     |
| fe-0/0/1  | Up   | 587525876     | (12252) | 589621478      | (12891) |

## Monitoring Address Pools

**Purpose** Use the monitoring functionality to view the Address Pools page.

**Action** To monitor Address Pools, select **Monitor>Access>Address Pools** in the J-Web user interface.

**Meaning** [Table 168](#) summarizes key output fields in the Address Pools page.

**Table 168: Address Pools Monitoring Page**

| Field                          | Values                                                                        | Additional Information |
|--------------------------------|-------------------------------------------------------------------------------|------------------------|
| <b>Address Pool Properties</b> |                                                                               |                        |
| Address Pool Name              | Displays the name of the address pool.                                        | -                      |
| Network Address                | Displays the IP network address of the address pool.                          | -                      |
| Address Ranges                 | Displays the name, the lower limit, and the upper limit of the address range. | -                      |

Table 168: Address Pools Monitoring Page (*continued*)

| Field                                  | Values                                                    | Additional Information                                                                 |
|----------------------------------------|-----------------------------------------------------------|----------------------------------------------------------------------------------------|
| Primary DNS                            | Displays the primary-dns IP address.                      | -                                                                                      |
| Secondary DNS                          | Displays the secondary-dns IP address.                    | -                                                                                      |
| Primary WINS                           | Displays the primary-wins IP address.                     | -                                                                                      |
| Secondary WINS                         | Displays the secondary-wins IP address.                   | -                                                                                      |
| <b>Address Pool Address Assignment</b> |                                                           |                                                                                        |
| IP Address                             | Displays the IP address of the address pool.              | -                                                                                      |
| Hardware Address                       | Displays the hardware MAC address of the address pool.    | -                                                                                      |
| Host/User                              | Displays the user name using the address pool.            | -                                                                                      |
| Type                                   | Displays the authentication type used by the address pool | The authentication types can be extended authentication (XAuth) or IKE Authentication. |

## Monitoring Ethernet Switching

**Purpose** View information about the Ethernet Switching interface details.

**Action** Select **Monitor>Switching>Ethernet Switching** in the J-Web user interface, or enter the following CLI commands:

- **show ethernet-switching table**
- **show ethernet-switching mac-learning-log**

Table 169 summarizes the Ethernet Switching output fields.

Table 169: Summary of Ethernet Switching Output Fields

| Field | Values                                            | Additional Information |
|-------|---------------------------------------------------|------------------------|
| VLAN  | The VLAN for which Ethernet Switching is enabled. | -                      |

Table 169: Summary of Ethernet Switching Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                                                                             | Additional Information |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| MAC Address | The MAC address associated with the VLAN. If a VLAN range has been configured for a VLAN, the output displays the MAC addresses for the entire series of VLANs that were created with that name.                                                                                                   | -                      |
| Type        | The type of MAC address. Values are: <ul style="list-style-type: none"> <li>static—The MAC address is manually created.</li> <li>learn—The MAC address is learned dynamically from a packet's source MAC address.</li> <li>flood—The MAC address is unknown and flooded to all members.</li> </ul> | -                      |
| Age         | The time remaining before the entry ages out and is removed from the Ethernet switching table.                                                                                                                                                                                                     | -                      |
| Interfaces  | Interface associated with learned MAC addresses or All-members (flood entry).                                                                                                                                                                                                                      | -                      |
| VLAN-ID     | The VLAN ID.                                                                                                                                                                                                                                                                                       | -                      |
| MAC Address | The learned MAC address.                                                                                                                                                                                                                                                                           | -                      |
| Time        | Timestamp when the MAC address was added or deleted from the log.                                                                                                                                                                                                                                  | -                      |
| State       | Indicates the MAC address learned on the interface.                                                                                                                                                                                                                                                | -                      |

## Monitoring GVRP

**Purpose** Use the monitoring functionality to view the GVRP page.

**Action** To monitor GVRP select **Monitor>Switching>GVRP** in the J-Web user interface.

**Meaning** [Table 170](#) summarizes key output fields in the GVRP page.

Table 170: GVRP Monitoring Page

| Field                     | Value                                         | Additional Information |
|---------------------------|-----------------------------------------------|------------------------|
| Global GVRP Configuration |                                               |                        |
| GVRP Status               | Displays whether GVRP is enabled or disabled. | —                      |

Table 170: GVRP Monitoring Page (*continued*)

| Field                         | Value                                                                                                                                                                 | Additional Information |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| GVRP Timer                    | Displays the GVRP timer in millisecond.                                                                                                                               | —                      |
| Join                          | The number of milliseconds the interfaces must wait before sending VLAN advertisements.                                                                               | —                      |
| Leave                         | The number of milliseconds an interface must wait after receiving a Leave message to remove the interface from the VLAN specified in the message.                     | —                      |
| Leave All                     | The interval in milliseconds at which Leave All messages are sent on interfaces. Leave All messages maintain current GVRP VLAN membership information in the network. | —                      |
| <b>GVRP Interface Details</b> |                                                                                                                                                                       |                        |
| Interface Name                | The interface on which GVRP is configured.                                                                                                                            | —                      |
| Protocol Status               | Displays whether GVRP is enabled or disabled.                                                                                                                         | —                      |

## Monitoring Interfaces

**Purpose** View general information about all physical and logical interfaces for a device.

**Action** Select **Monitor>Interfaces** in the J-Web user interface. The J-Web Interfaces page displays the following details about each device interface:

- Port—Indicates the interface name.
- Admin Status—Indicates whether the interface is enabled (Up) or disabled (Down).
- Link Status—Indicates whether the interface is linked (Up) or not linked (Down).
- Address—Indicates the IP address of the interface.
- Zone—Indicates whether the zone is an untrust zone or a trust zone.
- Services—Indicates services that are enabled on the device, such as HTTP and SSH.
- Protocols—Indicates protocols that are enabled on the device, such as BGP and IGMP.
- Input Rate graph—Displays interface bandwidth utilization. Input rates are shown in bytes per second.

- Output Rate graph—Displays interface bandwidth utilization. Output rates are shown in bytes per second.
- Error Counters chart—Displays input and output error counters in the form of a bar chart.
- Packet Counters chart—Displays the number of broadcast, unicast, and multicast packet counters in the form of a pie chart. (Packet counter charts are supported only for interfaces that support MAC statistics.)

To change the interface display, use the following options:

- Port for FPC—Controls the member for which information is displayed.
- Start/Stop button—Starts or stops monitoring the selected interfaces.
- Show Graph—Displays input and output packet counters and error counters in the form of charts.
- Pop-up button—Displays the interface graphs in a separate pop-up window.
- Details—Displays extensive statistics about the selected interface, including its general status, traffic information, IP address, I/O errors, class-of-service data, and statistics.
- Refresh Interval—Indicates the duration of time after which you want the data on the page to be refreshed.
- Clear Statistics—Clears the statistics for the selected interface.

Alternatively, you can enter the following **show** commands in the CLI to view interface status and traffic statistics:

- **show interfaces terse**

**NOTE:** On SRX Series devices, on configuring identical IPs on a single interface, you will not see a warning message; instead, you will see a syslog message.

- **show interfaces detail**
- **show interfaces extensive**
- **show interfaces *interface-name***

## Monitoring MPLS Traffic Engineering Information

This section contains the following topics:

- [Monitoring MPLS Interfaces on page 1796](#)
- [Monitoring MPLS LSP Information on page 1796](#)
- [Monitoring MPLS LSP Statistics on page 1797](#)

- [Monitoring RSVP Session Information on page 1798](#)
- [Monitoring MPLS RSVP Interfaces Information on page 1799](#)

## Monitoring MPLS Interfaces

**Purpose** View the interfaces on which MPLS is configured, including operational state and any administrative groups applied to an interface.

**Action** Select **Monitor>MPLS>Interfaces** in the J-Web user interface, or enter the **show mpls interface** command.

[Table 171](#) summarizes key output fields in the MPLS interface information display.

**Table 171: Summary of Key MPLS Interface Information Output Fields**

| Field                 | Values                                                                         | Additional Information |
|-----------------------|--------------------------------------------------------------------------------|------------------------|
| Interface             | Name of the interface on which MPLS is configured.                             | —                      |
| State                 | State of the specified interface: <b>Up</b> or <b>Dn</b> (down).               | —                      |
| Administrative groups | Administratively assigned colors of the MPLS link configured on the interface. | —                      |

## Monitoring MPLS LSP Information

**Purpose** View all label-switched paths (LSPs) configured on the services router, including all inbound (ingress), outbound (egress), and transit LSP information.

**Action** Select **Monitor>MPLS>LSP Information** in the J-Web user interface, or enter the **show mpls lsp** command.

[Table 172](#) summarizes key output fields in the MPLS LSP information display.

**Table 172: Summary of Key MPLS LSP Information Output Fields**

| Field       | Values                                                                                  | Additional Information                                                                                       |
|-------------|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Ingress LSP | Information about LSPs on the inbound device. Each session has one line of output.      | —                                                                                                            |
| Egress LSP  | Information about the LSPs on the outbound device. Each session has one line of output. | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| Transit LSP | Number of LSPs on the transit routers and the state of these paths.                     | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| To          | Destination (outbound device) of the session.                                           | —                                                                                                            |

Table 172: Summary of Key MPLS LSP Information Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                             | Additional Information                                                                                                                                                                           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| From        | Source (inbound device) of the session.                                                                                                                                                                                                            | —                                                                                                                                                                                                |
| State       | State of the path. It can be <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                                                                                                                         | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                                            |
| Rt          | Number of active routes (prefixes) installed in the routing table.                                                                                                                                                                                 | For inbound RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and outbound RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ). |
| Active Path | Name of the active path: <b>Primary</b> or <b>Secondary</b> .                                                                                                                                                                                      | This field is used for inbound LSPs only.                                                                                                                                                        |
| P           | An asterisk (*) in this column indicates that the LSP is a primary path.                                                                                                                                                                           | This field is used for inbound LSPs only.                                                                                                                                                        |
| LSPname     | Configured name of the LSP.                                                                                                                                                                                                                        | —                                                                                                                                                                                                |
| Style       | RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | This field is used for outbound and transit LSPs only.                                                                                                                                           |
| Labelin     | Incoming label for this LSP.                                                                                                                                                                                                                       | —                                                                                                                                                                                                |
| Labelout    | Outgoing label for this LSP.                                                                                                                                                                                                                       | —                                                                                                                                                                                                |
| Total       | Total number of LSPs displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> .                                                                                                                    | —                                                                                                                                                                                                |

## Monitoring MPLS LSP Statistics

**Purpose** Display statistics for LSP sessions currently active on the device, including the total number of packets and bytes forwarded through an LSP.

**Action** Select **Monitor>MPLS>LSP Statistics** in the J-Web user interface, or enter the **show mpls lsp statistics** command.

**NOTE:** Statistics are not available for LSPs on the outbound device, because the penultimate device in the LSP sets the label to 0. Also, as the packet arrives at the outbound device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

Table 173 summarizes key output fields in the MPLS LSP statistics display.

**Table 173: Summary of Key MPLS LSP Statistics Output Fields**

| Field       | Values                                                                                                                          | Additional Information                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Ingress LSP | Information about LSPs on the inbound device. Each session has one line of output.                                              | —                                                                                                            |
| Egress LSP  | Information about the LSPs on the outbound device. Each session has one line of output.                                         | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| Transit LSP | Number of LSPs on the transit routers and the state of these paths.                                                             | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information. |
| To          | Destination (outbound device) of the session.                                                                                   | —                                                                                                            |
| From        | Source (inbound device) of the session.                                                                                         | —                                                                                                            |
| State       | State of the path: <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                        |
| Packets     | Total number of packets received on the LSP from the upstream neighbor.                                                         | —                                                                                                            |
| Bytes       | Total number of bytes received on the LSP from the upstream neighbor.                                                           | —                                                                                                            |
| LSPname     | Configured name of the LSP.                                                                                                     | —                                                                                                            |
| Total       | Total number of LSPs displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> . | —                                                                                                            |

## Monitoring RSVP Session Information

**Purpose** View information about RSVP-signaled LSP sessions currently active on the device, including inbound (ingress) and outbound (egress) addresses, LSP state, and LSP name.

**Action** Select **Monitor>MPLS>RSVP Sessions** in the J-Web user interface, or enter the **show rsvp session** command.

Table 174 summarizes key output fields in the RSVP session information display.

**Table 174: Summary of Key RSVP Session Information Output Fields**

| Field       | Values                                                                        | Additional Information |
|-------------|-------------------------------------------------------------------------------|------------------------|
| Ingress LSP | Information about inbound RSVP sessions. Each session has one line of output. | —                      |

Table 174: Summary of Key RSVP Session Information Output Fields (*continued*)

| Field       | Values                                                                                                                                                                                                                                             | Additional Information                                                                                                                                                                           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress LSP  | Information about outbound RSVP sessions. Each session has one line of output.                                                                                                                                                                     | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information.                                                                                     |
| Transit LSP | Information about transit RSVP sessions.                                                                                                                                                                                                           | MPLS learns this information by querying RSVP, which holds all the transit and outbound session information.                                                                                     |
| To          | Destination (outbound device) of the session.                                                                                                                                                                                                      | —                                                                                                                                                                                                |
| From        | Source (inbound device) of the session.                                                                                                                                                                                                            | —                                                                                                                                                                                                |
| State       | State of the path: <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> .                                                                                                                                                                                   | <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                                            |
| Rt          | Number of active routes (prefixes) installed in the routing table.                                                                                                                                                                                 | For inbound RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and outbound RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ). |
| Style       | RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | This field is used for outbound and transit LSPs only.                                                                                                                                           |
| Labelin     | Incoming label for this RSVP session.                                                                                                                                                                                                              | —                                                                                                                                                                                                |
| Labelout    | Outgoing label for this RSVP session.                                                                                                                                                                                                              | —                                                                                                                                                                                                |
| LSPname     | Configured name of the LSP.                                                                                                                                                                                                                        | —                                                                                                                                                                                                |
| Total       | Total number of RSVP sessions displayed for the particular type— <b>ingress</b> (inbound), <b>egress</b> (outbound), or <b>transit</b> .                                                                                                           | —                                                                                                                                                                                                |

## Monitoring MPLS RSVP Interfaces Information

**Purpose** View information about the interfaces on which RSVP is enabled, including the interface name, total bandwidth through the interface, and total current reserved and reservable (available) bandwidth on the interface.

**Action** Select **Monitor>MPLS>RSVP Interfaces** in the J-Web user interface, or enter the **show rsvp interface** command.

Table 175 summarizes key output fields in the RSVP interfaces information display.

Table 175: Summary of Key RSVP Interfaces Information Output Fields

| Field          | Values                                                                                                                                                                                                                                                                                                                       | Additional Information |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| RSVP Interface | Number of interfaces on which RSVP is active. Each interface has one line of output.                                                                                                                                                                                                                                         | —                      |
| Interface      | Name of the interface.                                                                                                                                                                                                                                                                                                       | —                      |
| State          | State of the interface: <ul style="list-style-type: none"> <li>• <b>Disabled</b>—No traffic engineering information is displayed.</li> <li>• <b>Down</b>—The interface is not operational.</li> <li>• <b>Enabled</b>—Displays traffic engineering information.</li> <li>• <b>Up</b>—The interface is operational.</li> </ul> | —                      |
| Active resv    | Number of reservations that are actively reserving bandwidth on the interface.                                                                                                                                                                                                                                               | —                      |
| Subscription   | User-configured subscription factor.                                                                                                                                                                                                                                                                                         | —                      |
| Static BW      | Total interface bandwidth, in bits per second (bps).                                                                                                                                                                                                                                                                         | —                      |
| Available BW   | Amount of bandwidth that RSVP is allowed to reserve, in bits per second (bps). It is equal to <b>(static bandwidth X subscription factor)</b> .                                                                                                                                                                              | —                      |
| Reserved BW    | Currently reserved bandwidth, in bits per second (bps).                                                                                                                                                                                                                                                                      | —                      |
| Highwater mark | Highest bandwidth that has ever been reserved on this interface, in bits per second (bps).                                                                                                                                                                                                                                   | —                      |

## Monitoring PPP

- Purpose** Display PPP monitoring information, including PPP address pool information, session status for PPP interfaces, cumulative statistics for all PPP interfaces, and a summary of PPP sessions.

**NOTE:** PPP monitoring information is available only in the CLI. The J-Web user interface does not include pages for displaying PPP monitoring information.

**Action** Enter the following CLI commands:

- `show ppp address-pool pool-name`
- `show ppp interface interface-name`
- `show ppp statistics`
- `show ppp summary`

## Monitoring PPPoE

**Purpose** Display the session status for PPPoE interfaces, cumulative statistics for all PPPoE interfaces on the device, and the PPPoE version configured on the device.

**Action** Select **Monitor>PPPoE** in the J-Web user interface. To view interface-specific properties in the J-Web interface, select the interface name on the PPPoE page.

[Table 176](#) summarizes key output fields in PPPoE displays.

**Table 176: Summary of Key PPPoE Output Fields**

| Field                   | Values                                           | Additional Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PPPoE Interfaces</b> |                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Interface               | Name of the PPPoE interface.                     | Click the interface name to display PPPoE information for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| State                   | State of the PPPoE session on the interface.     | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session ID              | Unique session identifier for the PPPoE session. | To establish a PPPoE session, first the device acting as a PPPoE client obtains the Ethernet address of the PPPoE server or access concentrator, and then the client and the server negotiate a unique session ID. This process is referred to as PPPoE active discovery and is made up of four steps: initiation, offer, request, and session confirmation. The access concentrator generates the session ID for session confirmation and sends it to the PPPoE client in a PPPoE Active Discovery Session-Confirmation (PADS) packet. |

Table 176: Summary of Key PPPoE Output Fields (*continued*)

| Field                   | Values                                                                                                              | Additional Information                                                                                                                                                  |
|-------------------------|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Name            | Type of service required from the access concentrator.                                                              | Service Name identifies the type of service provided by the access concentrator, such as the name of the Internet service provider (ISP), class, or quality of service. |
| Configured AC Name      | Configured access concentrator name.                                                                                | —                                                                                                                                                                       |
| Session AC Names        | Name of the access concentrator.                                                                                    | —                                                                                                                                                                       |
| AC MAC Address          | Media access control (MAC) address of the access concentrator.                                                      | —                                                                                                                                                                       |
| Session Uptime          | Number of seconds the current PPPoE session has been running.                                                       | —                                                                                                                                                                       |
| Auto-Reconnect Timeout  | Number of seconds to wait before reconnecting after a PPPoE session is terminated.                                  | —                                                                                                                                                                       |
| Idle Timeout            | Number of seconds a PPPoE session can be idle without disconnecting.                                                | —                                                                                                                                                                       |
| Underlying Interface    | Name of the underlying logical Ethernet or ATM interface on which PPPoE is running—for example, <b>ge-0/0/0.1</b> . | —                                                                                                                                                                       |
| <b>PPPoE Statistics</b> |                                                                                                                     |                                                                                                                                                                         |
| Active PPPoE Sessions   | Total number of active PPPoE sessions.                                                                              | —                                                                                                                                                                       |

Table 176: Summary of Key PPPoE Output Fields (*continued*)

| Field                | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Additional Information |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Packet Type          | Packets sent and received during the PPPoE session, categorized by packet type and packet error: <ul style="list-style-type: none"> <li>• <b>PADI</b>—PPPoE Active Discovery Initiation packets.</li> <li>• <b>PADO</b>—PPPoE Active Discovery Offer packets.</li> <li>• <b>PADR</b>—PPPoE Active Discovery Request packets.</li> <li>• <b>PADS</b>—PPPoE Active Discovery Session-Confirmation packets.</li> <li>• <b>PADT</b>—PPPoE Active Discovery Terminate packets.</li> <li>• <b>Service Name Error</b>—Packets for which the Service-Name request could not be honored.</li> <li>• <b>AC System Error</b>—Packets for which the access concentrator experienced an error in processing the host request. For example, the host had insufficient resources to create a virtual circuit.</li> <li>• <b>Generic Error</b>—Packets that indicate an unrecoverable error occurred.</li> <li>• <b>Malformed Packet</b>—Malformed or short packets that caused the packet handler to disregard the frame as unreadable.</li> <li>• <b>Unknown Packet</b>—Unrecognized packets.</li> </ul> | —                      |
| Sent                 | Number of the specific type of packet sent from the PPPoE client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | —                      |

| Maximum Sessions     | Maximum number of active PPPoE sessions the device can support. The default is 256 sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | —                      |

Table 176: Summary of Key PPPoE Output Fields (*continued*)

| Field                         | Values                                                                                                                                                                           | Additional Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PADI Resend Timeout           | Initial time, (in seconds) the device waits to receive a PADO packet for the PADI packet sent—for example, 2 seconds. This timeout doubles for each successive PADI packet sent. | The PPPoE Active Discovery Initiation (PADI) packet is sent to the access concentrator to initiate a PPPoE session. Typically, the access concentrator responds to a PADI packet with a PPPoE Active Discovery Offer (PADO) packet. If the access concentrator does not send a PADO packet, the device sends the PADI packet again after timeout period is elapsed. The PADI Resend Timeout doubles for each successive PADI packet sent. For example, if the PADI Resend Timeout is 2 seconds, the second PADI packet is sent after 2 seconds, the third after 4 seconds, the fourth after 8 seconds, and so on. |
| PADR Resend Timeout           | Initial time (in seconds) the device waits to receive a PADS packet for the PADR packet sent. This timeout doubles for each successive PADR packet sent.                         | The PPPoE Active Discovery Request (PADR) packet is sent to the access concentrator in response to a PADO packet, and to obtain the PPPoE session ID. Typically, the access concentrator responds to a PADR packet with a PPPoE Active Discovery Session-Confirmation (PADS) packet, which contains the session ID. If the access concentrator does not send a PADS packet, the device sends the PADR packet again after the PADR Resend Timeout period is elapsed. The PADR Resend Timeout doubles for each successive PADR packet sent.                                                                         |
| Maximum Resend Timeout        | Maximum value (in seconds) that the PADI or PADR resend timer can accept—for example, 64 seconds. The maximum value is 64.                                                       | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Maximum Configured AC Timeout | Time (in seconds), within which the configured access concentrator must respond.                                                                                                 | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Alternatively, enter the following CLI commands:

- **show pppoe interfaces**
- **show pppoe statistics**
- **show pppoe version**

You can also view status information about the PPPoE interface by entering the **show interfaces pp0** command in the CLI editor.

## Monitoring Spanning Tree

**Purpose** Use the monitoring functionality to view the Spanning Tree page.

**Action** To monitor spanning tree, select **Monitor>Switching>Spanning Tree** in the J-Web user interface.

**Meaning** [Table 177](#) summarizes key output fields in the spanning tree page.

**Table 177: Spanning Tree Monitoring Page**

| Field                      | Value                                                                                  | Additional Information                                                                      |
|----------------------------|----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Bridge parameters</b>   |                                                                                        |                                                                                             |
| Context ID                 | An internally generated identifier.                                                    | —                                                                                           |
| Enabled Protocol           | Spanning tree protocol type enabled.                                                   | —                                                                                           |
| Root ID                    | Bridge ID of the elected spanning tree root bridge.                                    | The bridge ID consists of a configurable bridge priority and the MAC address of the bridge. |
| Bridge ID                  | Locally configured bridge ID.                                                          | —                                                                                           |
| Inter instance ID          | An internally generated instance identifier.                                           | —                                                                                           |
| Extended system ID         | Extended system generated instance identifier.                                         | —                                                                                           |
| Maximum age                | Maximum age of received bridge protocol data units (BPDUs).                            | —                                                                                           |
| Number of topology changes | Total number of STP topology changes detected since the switch last booted.            | —                                                                                           |
| Forward delay              | Spanning tree forward delay.                                                           | —                                                                                           |
| <b>Interface List</b>      |                                                                                        |                                                                                             |
| Interface Name             | Interface configured to participate in the STP instance.                               | —                                                                                           |
| Port ID                    | Logical interface identifier configured to participate in the STP instance.            | —                                                                                           |
| Designated Port ID         | Port ID of the designated port for the LAN segment to which the interface is attached. | —                                                                                           |
| Port Cost                  | Configured cost for the interface.                                                     | —                                                                                           |
| State                      | STP port state. Forwarding (FWD), blocking (BLK), listening, learning, or disabled.    | —                                                                                           |

Table 177: Spanning Tree Monitoring Page (*continued*)

| Field | Value                                                                               | Additional Information |
|-------|-------------------------------------------------------------------------------------|------------------------|
| Role  | MSTP or RSTP port role. Designated (DESG), backup (BKUP), alternate (ALT), or root. | –                      |

## Monitoring the WAN Acceleration Interface

**Purpose** View status information and traffic statistics for the WAN acceleration interface.

**Action** Select **Monitor>WAN Acceleration** in the J-Web user interface, or select **Monitor>Interfaces** and select the interface name (**wx-slot/0/0**). Alternatively, enter the following CLI command:

```
[edit]
user@host# show interfaces wx-slot/0/0 detail
```

### Monitoring Source NAT Information

**Purpose** Display configured information about source Network Address Translation (NAT) rules, pools, persistent NAT, and paired addresses.

**Action** Select **Monitor>NAT>Source NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat source summary**
- **show security nat source pool *pool-name***
- **show security nat source persistent-nat-table**
- **show security nat source paired-address**

[Table 178](#) describes the available options for monitoring source NAT.

Table 178: Source NAT Monitoring Page

| Field         | Description                 | Action                                                                |
|---------------|-----------------------------|-----------------------------------------------------------------------|
| Rules         |                             |                                                                       |
| Rule-set Name | Name of the rule set.       | Select all rule sets or a specific rule set to display from the list. |
| Total rules   | Number of rules configured. | —                                                                     |

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                   | Action |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| ID                                     | Rule ID number.                                                                                                                                                                                                                                                                                                                               | —      |
| Name                                   | Name of the rule .                                                                                                                                                                                                                                                                                                                            | —      |
| From                                   | Name of the routing instance/zone/interface from which the packet flows.                                                                                                                                                                                                                                                                      | —      |
| To                                     | Name of the routing instance/zone/interface to which the packet flows.                                                                                                                                                                                                                                                                        | —      |
| Source address range                   | Source IP address range in the source pool.                                                                                                                                                                                                                                                                                                   | —      |
| Destination address range              | Destination IP address range in the source pool.                                                                                                                                                                                                                                                                                              | —      |
| Source ports                           | Source port numbers.                                                                                                                                                                                                                                                                                                                          | —      |
| Ip protocol                            | IP protocol.                                                                                                                                                                                                                                                                                                                                  | —      |
| Action                                 | Action taken for a packet that matches a rule.                                                                                                                                                                                                                                                                                                | —      |
| Persistent NAT type                    | Persistent NAT type.                                                                                                                                                                                                                                                                                                                          | —      |
| Inactivity timeout                     | Inactivity timeout interval for the persistent NAT binding.                                                                                                                                                                                                                                                                                   | —      |
| Alarm threshold                        | Utilization alarm threshold.                                                                                                                                                                                                                                                                                                                  | —      |
| Max session number                     | The maximum number of sessions.                                                                                                                                                                                                                                                                                                               | —      |
| Sessions (Succ/<br>Failed/<br>Current) | Successful, failed, and current sessions. <ul style="list-style-type: none"> <li>Succ—Number of successful session installations after the NAT rule is matched.</li> <li>Failed—Number of unsuccessful session installations after the NAT rule is matched.</li> <li>Current—Number of sessions that reference the specified rule.</li> </ul> | —      |
| Translation Hits                       | Number of times a translation in the translation table is used for a source NAT rule.                                                                                                                                                                                                                                                         | —      |

Table 178: Source NAT Monitoring Page (*continued*)

| Field                                  | Description                                                                    | Action                                                        |
|----------------------------------------|--------------------------------------------------------------------------------|---------------------------------------------------------------|
| <b>Pools</b>                           |                                                                                |                                                               |
| Pool Name                              | The names of the pools.                                                        | Select all pools or a specific pool to display from the list. |
| Total Pools                            | Total pools added.                                                             | —                                                             |
| ID                                     | ID of the pool.                                                                | —                                                             |
| Name                                   | Name of the source pool.                                                       | —                                                             |
| Address range                          | IP address range in the source pool.                                           | —                                                             |
| Single/Twin ports                      | Number of allocated single and twin ports.                                     | —                                                             |
| Port                                   | Source port number in the pool.                                                | —                                                             |
| Address assignment                     | Displays the type of address assignment.                                       | —                                                             |
| Alarm threshold                        | Utilization alarm threshold.                                                   | —                                                             |
| Port overloading factor                | Port overloading capacity.                                                     | —                                                             |
| Routing instance                       | Name of the routing instance.                                                  | —                                                             |
| Total addresses                        | Total IP address, IP address set, or address book entry.                       | —                                                             |
| Host address base                      | Host base address of the original source IP address range.                     | —                                                             |
| Translation hits                       | Number of times a translation in the translation table is used for source NAT. | —                                                             |
| <b>Top 10 Translation Hits</b>         |                                                                                |                                                               |
| Graph                                  | Displays the graph of top 10 translation hits.                                 | —                                                             |
| <b>Persistent NAT</b>                  |                                                                                |                                                               |
| <b>Persistent NAT table statistics</b> |                                                                                |                                                               |
| binding total                          | Displays the total number of persistent NAT bindings for the FPC.              | —                                                             |

Table 178: Source NAT Monitoring Page (*continued*)

| Field                       | Description                                                                       | Action                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| binding in use              | Number of persistent NAT bindings that are in use for the FPC.                    | —                                                                          |
| enode total                 | Total number of persistent NAT enodes for the FPC.                                | —                                                                          |
| enode in use                | Number of persistent NAT enodes that are in use for the FPC.                      | —                                                                          |
| <b>Persistent NAT table</b> |                                                                                   |                                                                            |
| Source NAT pool             | Name of the pool.                                                                 | Select all pools or a specific pool to display from the list.              |
| Internal IP                 | Internal IP address.                                                              | Select all IP addresses or a specific IP address to display from the list. |
| Internal port               | Displays the internal ports configured in the system.                             | Select the port to display from the list.                                  |
| Internal protocol           | Internal protocols .                                                              | Select all protocols or a specific protocol to display from the list.      |
| Internal IP                 | Internal transport IP address of the outgoing session from internal to external.  | —                                                                          |
| Internal port               | Internal transport port number of the outgoing session from internal to external. | —                                                                          |
| Internal protocol           | Internal protocol of the outgoing session from internal to external.              | —                                                                          |
| Reflective IP               | Translated IP address of the source IP address.                                   | —                                                                          |
| Reflective port             | Displays the translated number of the port.                                       | —                                                                          |
| Reflective protocol         | Translated protocol.                                                              | —                                                                          |
| Source NAT pool             | Name of the source NAT pool where persistent NAT is used.                         | —                                                                          |
| Type                        | Persistent NAT type.                                                              | —                                                                          |
| Left time/Conf time         | Inactivity timeout period that remains and the configured timeout value.          | —                                                                          |

Table 178: Source NAT Monitoring Page (*continued*)

| Field                                   | Description                                                                                               | Action                                                                                                                                                                        |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Current session num/Max session num     | Number of current sessions associated with the persistent NAT binding and the maximum number of sessions. | —                                                                                                                                                                             |
| Source NAT rule                         | Name of the source NAT rule to which this persistent NAT binding applies.                                 | —                                                                                                                                                                             |
| <b>External node table</b>              |                                                                                                           |                                                                                                                                                                               |
| Internal IP                             | Internal transport IP address of the outgoing session from internal to external.                          | —                                                                                                                                                                             |
| Internal port                           | Internal port number of the outgoing session from internal to external.                                   | —                                                                                                                                                                             |
| External IP                             | External IP address of the outgoing session from internal to external.                                    | —                                                                                                                                                                             |
| External port                           | External port of the outgoing session from internal to external.                                          | —                                                                                                                                                                             |
| Zone                                    | External zone of the outgoing session from internal to external.                                          | —                                                                                                                                                                             |
| <b>Paired Address</b>                   |                                                                                                           |                                                                                                                                                                               |
| Pool name                               | Name of the pool.                                                                                         | Select all pools or a specific pool to display from the list.                                                                                                                 |
| Specified Address                       | IP address.                                                                                               | Select all addresses, or select the internal or external IP address to display, and enter the IP address.                                                                     |
| Pool name                               | Displays the selected pool or pools.                                                                      | —                                                                                                                                                                             |
| Internal address                        | Displays the internal IP address.                                                                         | —                                                                                                                                                                             |
| External address                        | Displays the external IP address.                                                                         | —                                                                                                                                                                             |

Table 178: Source NAT Monitoring Page (*continued*)

| Field | Description                                                          | Action |
|-------|----------------------------------------------------------------------|--------|
| Total | Displays the number of used and available ports.                     | —      |
| Usage | Displays the percentage of ports used during the peak date and time. | —      |

## Monitoring Destination NAT Information

**Purpose** View the destination Network Address Translation (NAT) summary table and the details of the specified NAT destination address pool information.

**Action** Select **Monitor>NAT> Destination NAT** in the J-Web user interface, or enter the following CLI commands:

- **show security nat destination summary**
- **show security nat destination pool *pool-name***

Table 179 summarizes key output fields in the destination NAT display.

Table 179: Summary of Key Destination NAT Output Fields

| Field                     | Values                                                                   | Action                                                                |
|---------------------------|--------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Rules</b>              |                                                                          |                                                                       |
| Rule-set Name             | Name of the rule set.                                                    | Select all rule sets or a specific rule set to display from the list. |
| Total rules               | Number of rules configured.                                              | —                                                                     |
| ID                        | Rule ID number.                                                          | —                                                                     |
| Name                      | Name of the rule .                                                       | —                                                                     |
| Ruleset Name              | Name of the rule set.                                                    | —                                                                     |
| From                      | Name of the routing instance/zone/interface from which the packet flows. | —                                                                     |
| Source address range      | Source IP address range in the source pool.                              | —                                                                     |
| Destination address range | Destination IP address range in the source pool.                         | —                                                                     |

## Monitoring Static NAT Information

**Purpose** View static NAT rule information.

**Action** Select **Monitor>NAT>Static NAT** in the J-Web user interface, or enter the following CLI command:

**show security nat static rule**

Table 180 summarizes key output fields in the static NAT display.

**Table 180: Summary of Key Static NAT Output Fields**

| Field                 | Values                                                                        | Action                                                                |
|-----------------------|-------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| Rule-set Name         | Name of the rule set.                                                         | Select all rule sets or a specific rule set to display from the list. |
| Total rules           | Number of rules configured.                                                   | —                                                                     |
| ID                    | Rule ID number.                                                               | —                                                                     |
| Position              | Position of the rule that indicates the order in which it applies to traffic. | —                                                                     |
| Name                  | Name of the rule.                                                             | —                                                                     |
| Ruleset Name          | Name of the rule set.                                                         | —                                                                     |
| From                  | Name of the routing instance/interface/zone from which the packet comes       | —                                                                     |
| Source addresses      | Source IP addresses.                                                          | —                                                                     |
| Source ports          | Source port numbers.                                                          | —                                                                     |
| Destination addresses | Destination IP address and subnet mask.                                       | —                                                                     |
| Destination ports     | Destination port numbers .                                                    | —                                                                     |
| Host addresses        | Name of the host addresses.                                                   | —                                                                     |
| Host ports            | Host port numbers.                                                            | —                                                                     |
| Netmask               | Subnet IP address.                                                            | —                                                                     |
| Host routing instance | Name of the routing instance from which the packet comes.                     | —                                                                     |

Table 180: Summary of Key Static NAT Output Fields (*continued*)

| Field                                     | Values                                                                                                                                                                                                                                                                                                                                        | Action |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| Alarm threshold                           | Utilization alarm threshold.                                                                                                                                                                                                                                                                                                                  | —      |
| Sessions<br>(Succ/<br>Failed/<br>Current) | Successful, failed, and current sessions. <ul style="list-style-type: none"> <li>Succ—Number of successful session installations after the NAT rule is matched.</li> <li>Failed—Number of unsuccessful session installations after the NAT rule is matched.</li> <li>Current—Number of sessions that reference the specified rule.</li> </ul> | —      |
| Translation hits                          | Number of times a translation in the translation table is used for a static NAT rule.                                                                                                                                                                                                                                                         | —      |
| <b>Top 10 Translation Hits</b>            |                                                                                                                                                                                                                                                                                                                                               |        |
| Graph                                     | Displays the graph of top 10 translation hits.                                                                                                                                                                                                                                                                                                | —      |

## Monitoring Incoming Table Information

**Purpose** View NAT table information.

**Action** Select **Monitor>NAT>Incoming Table** in the J-Web user interface, or enter the following CLI command:

```
show security nat incoming-table
```

Table 181 summarizes key output fields in the incoming table display.

Table 181: Summary of Key Incoming Table Output Fields

| Field                   | Values                                                                        |
|-------------------------|-------------------------------------------------------------------------------|
| <b>Statistics</b>       |                                                                               |
| In use                  | Number of entries in the NAT table.                                           |
| Maximum                 | Maximum number of entries possible in the NAT table.                          |
| Entry allocation failed | Number of entries failed for allocation.                                      |
| <b>Incoming Table</b>   |                                                                               |
| Clear                   |                                                                               |
| Destination             | Destination IP address and port number.                                       |
| Host                    | Host IP address and port number that the destination IP address is mapped to. |
| References              | Number of sessions referencing the entry.                                     |

Table 181: Summary of Key Incoming Table Output Fields (*continued*)

| Field       | Values                                              |
|-------------|-----------------------------------------------------|
| Timeout     | Timeout, in seconds, of the entry in the NAT table. |
| Source-pool | Name of source pool where translation is allocated. |

## Monitoring Interface NAT Port Information

**Purpose** View port usage for an interface source pool information.

**Action** Select **Monitor>Firewall/NAT>Interface NAT** in the J-Web user interface, or enter the following CLI command:

- **show security nat interface-nat-ports**

Table 182 summarizes key output fields in the interface NAT display.

Table 182: Summary of Key Interface NAT Output Fields

| Field                              | Values                                                         | Additional Information |
|------------------------------------|----------------------------------------------------------------|------------------------|
| <b>Interface NAT Summary Table</b> |                                                                |                        |
| Pool Index                         | Port pool index.                                               | —                      |
| Total Ports                        | Total number of ports in a port pool.                          | —                      |
| Single Ports Allocated             | Number of ports allocated one at a time that are in use.       | —                      |
| Single Ports Available             | Number of ports allocated one at a time that are free for use. | —                      |
| Twin Ports Allocated               | Number of ports allocated two at a time that are in use.       | —                      |
| Twin Ports Available               | Number of ports allocated two at a time that are free for use. | —                      |

## Monitoring Policy Statistics

---

**Purpose** Monitor and record traffic that Junos OS permits or denies based on previously configured policies.

**Action** To monitor traffic, enable the count and log options.

**Count**—Configurable in an individual policy. If count is enabled, statistics are collected for sessions that enter the device for a given policy, and for the number of packets and bytes that pass through the device in both directions for a given policy. For counts (only for packets and bytes), you can specify that alarms be generated whenever the traffic exceeds specified thresholds. See [count \(Security Policies\)](#).

**Log**—Logging capability can be enabled with security policies during session initialization (**session-init**) or session close (**session-close**) stage. See [log \(Security Policies\)](#).

- To view logs from denied connections, enable log on **session-init**.
- To log sessions after their conclusion/tear-down, enable log on **session-close**.

**NOTE:** Session log is enabled at real time in the flow code which impacts the user performance. If both **session-close** and **session-init** are enabled, performance is further degraded as compared to enabling **session-init** only.

---

For details about information collected for session logs, see [Information Provided in Session Log Entries for SRX Series Services Gateways](#).

- [Monitoring RIP Routing Information on page 1822](#)
- [Monitoring OSPF Routing Information on page 1823](#)
- [Monitoring BGP Routing Information on page 1825](#)

### Monitoring Route Information

**Purpose** View information about the routes in a routing table, including destination, protocol, state, and parameter information.

**Action** Select **Monitor>Routing>Route Information** in the J-Web user interface, or enter the following CLI commands:

- **show route terse**
- **show route detail**

**NOTE:** When you use an HTTPS connection in the Microsoft Internet Explorer browser to save a report from this page in the J-Web interface, the error message "Internet Explorer was not able to open the Internet site" is displayed. This problem occurs because the Cache-Control: no cache HTTP header is added on the server side and Internet Explorer does not allow you to download the encrypted file with the Cache-Control: no cache HTTP header set in the response from the server.

As a workaround, refer to Microsoft Knowledge Base article 323308, which is available at this URL: <http://support.microsoft.com/kb/323308>. Also, you can alternatively use HTTP in the Internet Explorer browser or use HTTPS in the Mozilla Firefox browser to save a file from this page.

[Table 183](#) describes the different filters, their functions, and the associated actions.

[Table 184](#) summarizes key output fields in the routing information display.

Table 183: Filtering Route Messages

| Field               | Function                                                                                                                             | Your Action                                                     |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Destination Address | Specifies the destination address of the route.                                                                                      | Enter the destination address.                                  |
| Protocol            | Specifies the protocol from which the route was learned.                                                                             | Enter the protocol name.                                        |
| Next hop address    | Specifies the network layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it. | Enter the next hop address.                                     |
| Receive protocol    | Specifies the dynamic routing protocol using which the routing information was received through a particular neighbor.               | Enter the routing protocol.                                     |
| Best route          | Specifies only the best route available.                                                                                             | Select the view details of the best route.                      |
| Inactive routes     | Specifies the inactive routes.                                                                                                       | Select the view details of inactive routes.                     |
| Exact route         | Specifies the exact route.                                                                                                           | Select the view details of the exact route.                     |
| Hidden routes       | Specifies the hidden routes.                                                                                                         | Select the view details of hidden routes.                       |
| Search              | Applies the specified filter and displays the matching messages.                                                                     | To apply the filter and display messages, click <b>Search</b> . |
| Reset               | Resets selected options to default                                                                                                   | To reset the filter, click <b>Reset</b> .                       |

Table 184: Summary of Key Routing Information Output Fields

| Field                  | Values                                                                                                                          | Additional Information                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Static Route Addresses | The list of static route addresses.                                                                                             | —                                                                    |
| Protocol               | Protocol from which the route was learned: <b>Static</b> , <b>Direct</b> , <b>Local</b> , or the name of a particular protocol. | —                                                                    |
| Preference             | The preference is the individual preference value for the route.                                                                | The route preference is used as one of the route selection criteria. |

Table 184: Summary of Key Routing Information Output Fields (*continued*)

| Field    | Values                                                                                                                                                                                                                                                                     | Additional Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Next-Hop | Network Layer address of the directly reachable neighboring system (if applicable) and the interface used to reach it.                                                                                                                                                     | <p>If a next hop is listed as <b>Discard</b>, all traffic with that destination address is discarded rather than routed. This value generally means that the route is a static route for which the <b>discard</b> attribute has been set.</p> <p>If a next hop is listed as <b>Reject</b>, all traffic with that destination address is rejected. This value generally means that the address is unreachable. For example, if the address is a configured interface address and the interface is unavailable, traffic bound for that address is rejected.</p> <p>If a next hop is listed as <b>Local</b>, the destination is an address on the host (either the loopback address or Ethernet management port 0 address, for example).</p> |
| Age      | How long the route has been active.                                                                                                                                                                                                                                        | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| State    | Flags for this route.                                                                                                                                                                                                                                                      | There are many possible flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| AS Path  | <p>AS path through which the route was learned. The letters of the AS path indicate the path origin:</p> <ul style="list-style-type: none"> <li>• <b>I</b>—IGP.</li> <li>• <b>E</b>—EGP.</li> <li>• <b>?</b>—Incomplete. Typically, the AS path was aggregated.</li> </ul> | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Monitoring RIP Routing Information

**Purpose** View RIP routing information, including a summary of RIP neighbors and statistics.

**Action** Select **Monitor>Routing>RIP Information** in the J-Web user interface, or enter the following CLI commands:

- **show rip statistics**
- **show rip neighbors**

[Table 185](#) summarizes key output fields in the RIP routing display in the J-Web user interface.

Table 185: Summary of Key RIP Routing Output Fields

| Field                 | Values                            | Additional Information |
|-----------------------|-----------------------------------|------------------------|
| <b>RIP Statistics</b> |                                   |                        |
| Protocol Name         | The RIP protocol name.            | —                      |
| Port number           | The port on which RIP is enabled. | —                      |

Table 185: Summary of Key RIP Routing Output Fields (*continued*)

| Field                    | Values                                                                                 | Additional Information                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Hold down time           | The interval during which routes are neither advertised nor updated.                   | —                                                                                                                     |
| Global routes learned    | Number of RIP routes learned on the logical interface.                                 | —                                                                                                                     |
| Global routes held down  | Number of RIP routes that are not advertised or updated during the hold-down interval. | —                                                                                                                     |
| Global request dropped   | Number of requests dropped.                                                            | —                                                                                                                     |
| Global responses dropped | Number of responses dropped.                                                           | —                                                                                                                     |
| <b>RIP Neighbors</b>     |                                                                                        |                                                                                                                       |
| Details                  | Tab used to view the details of the interface on which RIP is enabled.                 | —                                                                                                                     |
| Neighbor                 | Name of the RIP neighbor.                                                              | This value is the name of the interface on which RIP is enabled. Click the name to see the details for this neighbor. |
| State                    | State of the RIP connection: <b>Up</b> or <b>Dn</b> (Down).                            | —                                                                                                                     |
| Source Address           | Local source address.                                                                  | This value is the configured address of the interface on which RIP is enabled.                                        |
| Destination Address      | Destination address.                                                                   | This value is the configured address of the immediate RIP adjacency.                                                  |
| Send Mode                | The mode of sending RIP messages.                                                      | —                                                                                                                     |
| Receive Mode             | The mode in which messages are received.                                               | —                                                                                                                     |
| In Metric                | Value of the incoming metric configured for the RIP neighbor.                          | —                                                                                                                     |

## Monitoring OSPF Routing Information

**Purpose** View OSPF routing information, including a summary of OSPF neighbors, interfaces, and statistics.

**Action** Select **Monitor>Routing>OSPF Information** in the J-Web user interface, or enter the following CLI commands:

- **show ospf neighbors**

- **show ospf interfaces**
- **show ospf statistics**

Table 186 summarizes key output fields in the OSPF routing display in the J-Web user interface.

**Table 186: Summary of Key OSPF Routing Output Fields**

| Field                    | Values                                                                                                                            | Additional Information                                                                                                                                                                          |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OSPF Interfaces</b>   |                                                                                                                                   |                                                                                                                                                                                                 |
| Details                  | Tab used to view the details of the selected OSPF.                                                                                | —                                                                                                                                                                                               |
| Interface                | Name of the interface running OSPF.                                                                                               | —                                                                                                                                                                                               |
| State                    | State of the interface: <b>BDR</b> , <b>Down</b> , <b>DR</b> , <b>DROther</b> , <b>Loop</b> , <b>PtToPt</b> , or <b>Waiting</b> . | The <b>Down</b> state, indicating that the interface is not functioning, and <b>PtToPt</b> state, indicating that a point-to-point connection has been established, are the most common states. |
| Area                     | Number of the area that the interface is in.                                                                                      | —                                                                                                                                                                                               |
| DR ID                    | ID of the area's designated device.                                                                                               | —                                                                                                                                                                                               |

| Address                  | Address of the neighbor.                                                                                                          | —                                                                                                                                                                                               |
| Interface                | Interface through which the neighbor is reachable.                                                                                | —                                                                                                                                                                                               |

Table 186: Summary of Key OSPF Routing Output Fields (*continued*)

| Field         | Values                                                                                                                                                 | Additional Information                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| State         | State of the neighbor: <b>Attempt</b> , <b>Down</b> , <b>Exchange</b> , <b>ExStart</b> , <b>Full</b> , <b>Init</b> , <b>Loading</b> , or <b>2way</b> . | Generally, only the <b>Down</b> state, indicating a failed OSPF adjacency, and the <b>Full</b> state, indicating a functional adjacency, are maintained for more than a few seconds. The other states are transitional states that a neighbor is in only briefly while an OSPF adjacency is being established. |
| ID            | ID of the neighbor.                                                                                                                                    | –                                                                                                                                                                                                                                                                                                              |
| Priority      | Priority of the neighbor to become the designated router.                                                                                              | –                                                                                                                                                                                                                                                                                                              |
| Activity Time | The activity time.                                                                                                                                     | –                                                                                                                                                                                                                                                                                                              |
| Area          | Area that the neighbor is in.                                                                                                                          | –                                                                                                                                                                                                                                                                                                              |
| Options       | Option bits received in the hello packets from the neighbor.                                                                                           | –                                                                                                                                                                                                                                                                                                              |
| DR Address    | Address of the designated router.                                                                                                                      | –                                                                                                                                                                                                                                                                                                              |
| BDR Address   | Address of the backup designated router.                                                                                                               | –                                                                                                                                                                                                                                                                                                              |
| Uptime        | Length of time since the neighbor came up.                                                                                                             | –                                                                                                                                                                                                                                                                                                              |
| Adjacency     | Length of time since the adjacency with the neighbor was established.                                                                                  | –                                                                                                                                                                                                                                                                                                              |

## Monitoring BGP Routing Information

**Purpose** Monitor BGP routing information on the routing device, including a summary of BGP routing and neighbor information.

**Action** Select **Monitor>Routing>BGP Information** in the J-Web user interface, or enter the following CLI commands:

- **show bgp summary**
- **show bgp neighbor**

[Table 187](#) summarizes key output fields in the BGP routing display in the J-Web user interface.

Table 187: Summary of Key BGP Routing Output Fields

| Field            | Values | Additional Information |
|------------------|--------|------------------------|
| BGP Peer Summary |        |                        |

Table 187: Summary of Key BGP Routing Output Fields (*continued*)

| Field                  | Values                                                                                                                                                                 | Additional Information |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Total Groups           | Number of BGP groups.                                                                                                                                                  | —                      |
| Total Peers            | Number of BGP peers.                                                                                                                                                   | —                      |
| Down Peers             | Number of unavailable BGP peers.                                                                                                                                       | —                      |
| Unconfigured Peers     | Address of each BGP peer.                                                                                                                                              | —                      |
| <b>RIB Summary tab</b> |                                                                                                                                                                        |                        |
| RIB Name               | Name of the RIB group.                                                                                                                                                 | —                      |
| Total Prefixes         | Total number of prefixes from the peer, both active and inactive, that are in the routing table.                                                                       | —                      |
| Active Prefixes        | Number of prefixes received from the EBGp peers that are active in the routing table.                                                                                  | —                      |
| Suppressed Prefixes    | Number of routes received from EBGp peers currently inactive because of damping or other reasons.                                                                      | —                      |
| History Prefixes       | History of the routes received or suppressed.                                                                                                                          | —                      |
| Dumped Prefixes        | Number of routes currently inactive because of damping or other reasons. These routes do not appear in the forwarding table and are not exported by routing protocols. | —                      |
| Pending Prefixes       | Number of pending routes.                                                                                                                                              | —                      |
| State                  | Status of the graceful restart process for this routing table: BGP restart is complete, BGP restart in progress, VPN restart in progress, or VPN restart is complete.  | —                      |
| <b>BGP Neighbors</b>   |                                                                                                                                                                        |                        |
| Details                | Click this button to view the selected BGP neighbor details.                                                                                                           | —                      |
| Peer Address           | Address of the BGP neighbor.                                                                                                                                           | —                      |
| Autonomous System      | AS number of the peer.                                                                                                                                                 | —                      |

Table 187: Summary of Key BGP Routing Output Fields (*continued*)

| Field        | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Additional Information                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer State   | <p>Current state of the BGP session:</p> <ul style="list-style-type: none"> <li>• <b>Active</b>—BGP is initiating a TCP connection in an attempt to connect to a peer. If the connection is successful, BGP sends an open message.</li> <li>• <b>Connect</b>—BGP is waiting for the TCP connection to become complete.</li> <li>• <b>Established</b>—The BGP session has been established, and the peers are exchanging BGP update messages.</li> <li>• <b>Idle</b>—This is the first stage of a connection. BGP is waiting for a Start event.</li> <li>• <b>OpenConfirm</b>—BGP has acknowledged receipt of an open message from the peer and is waiting to receive a keepalive or notification message.</li> <li>• <b>OpenSent</b>—BGP has sent an open message and is waiting to receive an open message from the peer.</li> </ul> | Generally, the most common states are <b>Active</b> , which indicates a problem establishing the BGP connection, and <b>Established</b> , which indicates a successful session setup. The other states are transition states, and BGP sessions normally do not stay in those states for extended periods of time. |
| Elapsed Time | Elapsed time since the peering session was last reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | —                                                                                                                                                                                                                                                                                                                 |
| Description  | Description of the BGP session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | —                                                                                                                                                                                                                                                                                                                 |

## Monitoring Security Events by Policy

**Purpose** Monitor security events by policy and display logged event details with the J-Web user interface.

**Action** 1. Select **Monitor>Events and Alarms>Security Events** in the J-Web user interface. The View Policy Log pane appears. [Table 188](#) describes the content of this pane.

Table 188: View Policy Log Fields

| Field               | Value                                                        |
|---------------------|--------------------------------------------------------------|
| Log file name       | Name of the event log files to search.                       |
| Policy name         | Name of the policy of the events to be retrieved.            |
| Source address      | Source address of the traffic that triggered the event.      |
| Destination address | Destination address of the traffic that triggered the event. |

Table 188: View Policy Log Fields (*continued*)

| Field                | Value                                                         |
|----------------------|---------------------------------------------------------------|
| Event type           | Type of event that was triggered by the traffic.              |
| Application          | Application of the traffic that triggered the event.          |
| Source port          | Source port of the traffic that triggered the event.          |
| Destination port     | Destination port of the traffic that triggered the event.     |
| Source zone          | Source zone of the traffic that triggered the event.          |
| Destination zone     | Destination zone of the traffic that triggered the event.     |
| Source NAT rule      | Source NAT rule of the traffic that triggered the event.      |
| Destination NAT rule | Destination NAT rule of the traffic that triggered the event. |
| Is global policy     | Specifies that the policy is a global policy.                 |

If your device is not configured to store session log files locally, the Create log configuration button is displayed in the lower-right portion of the View Policy Log pane.

- To store session log files locally, click **Create log configuration**.

If session logs are being sent to an external log collector (stream mode has been configured for log files), a message appears indicating that event mode must be configured to view policy logs.

**NOTE:** Reverting to event mode will discontinue event logging to the external log collector.

- To reset the **mode** option to **event**, enter the **set security log** command.

2. Enter one or more search fields in the View Policy Log pane and click **Search** to display events matching your criteria.

For example, enter the event type **Session Close** and the policy **pol1** to display event details from all Session Close logs that contain the specified policy. To reduce search results further, add more criteria about the particular event or group of events that you want displayed.

The Policy Events Detail pane displays information from each matching session log. [Table 189](#) describes the contents of this pane.

Table 189: Policy Events Detail Fields

| Field                   | Value                                                                   |
|-------------------------|-------------------------------------------------------------------------|
| Timestamp               | Time when the event occurred.                                           |
| Policy name             | Policy that triggered the event.                                        |
| Record type             | Type of event log providing the data.                                   |
| Source IP/Port          | Source address (and port, if applicable) of the event traffic.          |
| Destination IP/Port     | Destination address (and port, if applicable) of the event traffic.     |
| Service name            | Service name of the event traffic.                                      |
| NAT source IP/Port      | NAT source address (and port, if applicable) of the event traffic.      |
| NAT destination IP/Port | NAT destination address (and port, if applicable) of the event traffic. |

### Monitoring Policies

- Purpose** Display, sort, and review policy activity for every activated policy configured on the device. Policies are grouped by Zone Context (the from and to zones of the traffic) to control the volume of data displayed at one time. From the policy list, select a policy to display statistics and current network activity.

**Action** To review policy activity:

1. Select **Monitor>Security>Policy>Activities** in the J-Web user interface. The Security Policies Monitoring page appears and lists the policies from the first Zone Context. See [Table 190](#) for field descriptions.
2. Select the **Zone Context** of the policy you want to monitor, and click **Filter**. All policies within the zone context appear in match sequence.
3. Select a policy, and click **Clear Statistics** to set all counters to zero for the selected policy.

**Table 190: Security Policies Monitoring Output Fields**

| Field                  | Value                                                                                                                                                                                                                                                                               | Additional Information                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Zone Context (Total #) | Displays a list of all from and to zone combinations for the configured policies. The total number of active policies for each context is specified in the Total # field. By default, the policies from the first Zone Context are displayed.                                       | To display policies for a different context, select a zone context and click <b>Filter</b> . Both inactive and active policies appear for each context. However, the Total # field for a context specifies the number of active policies only. |
| Default Policy action  | Specifies the action to take for traffic that does not match any of the policies in the context: <ul style="list-style-type: none"> <li>• permit-all—Permit all traffic that does not match a policy.</li> <li>• deny-all—Deny all traffic that does not match a policy.</li> </ul> | —                                                                                                                                                                                                                                              |
| From Zone              | Displays the source zone to be used as match criteria for the policy.                                                                                                                                                                                                               | —                                                                                                                                                                                                                                              |
| To Zone                | Displays the destination zone to be used as match criteria for the policy.                                                                                                                                                                                                          | —                                                                                                                                                                                                                                              |
| Name                   | Displays the name of the policy.                                                                                                                                                                                                                                                    | —                                                                                                                                                                                                                                              |
| Source Address         | Displays the source addresses to be used as match criteria for the policy. Address sets are resolved to their individual names. (In this case, only the names are given, not the IP addresses).                                                                                     | —                                                                                                                                                                                                                                              |
| Destination Address    | Displays the destination addresses (or address sets) to be used as match criteria for the policy. Addresses are entered as specified in the destination zone's address book.                                                                                                        | —                                                                                                                                                                                                                                              |
| Source Identity        | Displays the name of the source identities set for the policy.                                                                                                                                                                                                                      | To display the value of the source identities, hover the mouse on this field. Unknown source identities are also displayed.                                                                                                                    |
| Application            | Displays the name of a predefined or custom application signature to be used as match criteria for the policy.                                                                                                                                                                      | —                                                                                                                                                                                                                                              |

Table 190: Security Policies Monitoring Output Fields (*continued*)

| Field                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Additional Information                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic App               | <p>Displays the dynamic application signatures to be used as match criteria if an application firewall rule set is configured for the policy.</p> <p>For a network firewall, a dynamic application is not defined.</p>                                                                                                                                                                                                                                                                                                   | <p>The rule set appears in two lines. The first line displays the configured dynamic application signatures in the rule set. The second line displays the default dynamic application signature.</p> <p>If more than two dynamic application signatures are specified for the rule set, hover over the output field to display the full list in a tooltip.</p> |
| Action                    | <p>Displays the action portion of the rule set if an application firewall rule set is configured for the policy.</p> <ul style="list-style-type: none"> <li>• permit—Permits access to the network services controlled by the policy. A green background signifies permission.</li> <li>• deny—Denies access to the network services controlled by the policy. A red background signifies denial.</li> </ul>                                                                                                             | <p>The action portion of the rule set appears in two lines. The first line identifies the action to be taken when the traffic matches a dynamic application signature. The second line displays the default action when traffic does not match a dynamic application signature.</p>                                                                            |
| NW Services               | <p>Displays the network services permitted or denied by the policy if an application firewall rule set is configured. Network services include:</p> <ul style="list-style-type: none"> <li>• gprs-gtp-profile—Specify a GPRS Tunneling Protocol profile name.</li> <li>• idp—Perform intrusion detection and prevention.</li> <li>• redirect-wx—Set WX redirection.</li> <li>• reverse-redirect-wx—Set WX reverse redirection.</li> <li>• uac-policy—Enable unified access control enforcement of the policy.</li> </ul> | —                                                                                                                                                                                                                                                                                                                                                              |
| Policy Hit Counters Graph | <p>Provides a representation of the value over time for a specified counter. The graph is blank if Policy Counters indicates no data. As a selected counter accumulates data, the graph is updated at each refresh interval.</p>                                                                                                                                                                                                                                                                                         | <p>To toggle a graph on and off, click the counter name below the graph.</p>                                                                                                                                                                                                                                                                                   |

Table 190: Security Policies Monitoring Output Fields (*continued*)

| Field           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Additional Information                                                                                                                             |

| Policy Counters | <p>Lists statistical counters for the selected policy if Count is enabled. The following counters are available for each policy:</p> <ul style="list-style-type: none"> <li>• input-bytes</li> <li>• input-byte-rate</li> <li>• output-bytes</li> <li>• output-byte-rate</li> <li>• input-packets</li> <li>• input-packet-rate</li> <li>• output-packets</li> <li>• output-packet-rate</li> <li>• session-creations</li> <li>• session-creation-rate</li> <li>• active-sessions</li> </ul> | To graph or to remove a counter from the Policy Hit Counters Graph, toggle the counter name. The names of enabled counters appear below the graph. |

## Checking Policies

- Purpose** Enter match criteria and conduct a policy search. The search results include all policies that match the traffic criteria in the sequence in which they will be encountered.
- Because policy matches are listed in the sequence in which they would be encountered, you can determine whether a specific policy is being applied correctly or not. The first policy in the list is applied to all matching traffic. Policies listed after this one remain in the “shadow” of the first policy and are never encountered by this traffic.
- By manipulating the traffic criteria and policy sequence, you can tune policy application to suit your needs. During policy development, you can use this feature to establish the appropriate sequence of policies for optimum traffic matches. When troubleshooting, use this feature to determine if specific traffic is encountering the appropriate policy.
- Action**
1. Select **Monitor>Security>Policy>Shadow Policies** in the J-Web user interface. The Check Policies page appears. [Table 191](#) explains the content of this page.
  2. In the top pane, enter the From Zone and To Zone to supply the context for the search.
  3. Enter match criteria for the traffic, including the source address and port, the destination address and port, and the protocol of the traffic.
  4. Enter the number of matching policies to display.
  5. Click **Search** to find policies matching your criteria. The lower pane displays all policies matching the criteria up to the number of policies you specified.
    - The first policy will be applied to all traffic with this match criteria.

- Remaining policies will not be encountered by any traffic with this match criteria.
6. To manipulate the position and activation of a policy, select the policy and click the appropriate button:
- **Move**—Moves the selected policy up or down to position it at a more appropriate point in the search sequence.
  - **Move to**—Moves the selected policy by allowing you to drag and drop it to a different location on the same page.

Table 191: Check Policies Output

| Field                                   | Function                                                                                                            |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Check Policies Search Input Pane</b> |                                                                                                                     |
| From Zone                               | Name or ID of the source zone. If a From Zone is specified by name, the name is translated to its ID internally.    |
| To Zone                                 | Name or ID of the destination zone. If a To Zone is specified by name, the name is translated to its ID internally. |
| Source Address                          | Address of the source in IP notation.                                                                               |
| Source Port                             | Port number of the source.                                                                                          |
| Destination Address                     | Address of the destination in IP notation.                                                                          |
| Destination Port                        | Port number of the destination.                                                                                     |
| Source Identity                         | Name of the source identity.                                                                                        |

Table 191: Check Policies Output (*continued*)

| Field                      | Function                                                                                                                                                                                                                                              |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Result Count               | (Optional) Number of policies to display. Default value is 1. Maximum value is 16.                                                                                                                                                                    |
| <b>Check Policies List</b> |                                                                                                                                                                                                                                                       |
| From Zone                  | Name of the source zone.                                                                                                                                                                                                                              |
| To Zone                    | Name of the destination zone.                                                                                                                                                                                                                         |
| Total Policies             | Number of policies retrieved.                                                                                                                                                                                                                         |
| Default Policy action      | The action to be taken if no match occurs.                                                                                                                                                                                                            |
| Name                       | Policy name                                                                                                                                                                                                                                           |
| Source Address             | Name of the source address (not the IP address) of a policy. Address sets are resolved to their individual names.                                                                                                                                     |

Table 191: Check Policies Output (*continued*)

| Field               | Function                                                                                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Destination Address | Name of the destination address or address set. A packet's destination address must match this value for the policy to apply to it. |
| Source Identity     | Name of the source identity for the policy.                                                                                         |
| Application         | Name of a preconfigured or custom application of the policy match.                                                                  |
| Action              | Action taken when a match occurs as specified in the policy.                                                                        |
| Hit Counts          | Number of matches for this policy. This value is the same as the Policy Lookups in a policy statistics report.                      |
| Active Sessions     | Number of active sessions matching this policy.                                                                                     |

Alternatively, to list matching policies using the CLI, enter the **show security match-policies** command and include your match criteria and the number of matching policies to display.

## Monitoring Screen Counters

**Purpose** View screen statistics for a specified security zone.

**Action** Select **Monitor>Security>Screen Counters** in the J-Web user interface, or enter the following CLI command:

**show security screen statistics zone *zone-name***

Table 192 summarizes key output fields in the screen counters display.

Table 192: Summary of Key Screen Counters Output Fields

| Field        | Values                                                      | Additional Information                                                                                                                                                               |
|--------------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Zones</b> |                                                             |                                                                                                                                                                                      |
| ICMP Flood   | Internet Control Message Protocol (ICMP) flood counter.     | An ICMP flood typically occurs when ICMP echo requests use all resources in responding, such that valid network traffic can no longer be processed.                                  |
| UDP Flood    | User Datagram Protocol (UDP) flood counter.                 | UDP flooding occurs when an attacker sends IP packets containing UDP datagrams with the purpose of slowing down the resources, such that valid connections can no longer be handled. |
| TCP Winnuke  | Number of Transport Control Protocol (TCP) WinNuke attacks. | WinNuke is a denial-of-service (DoS) attack targeting any computer on the Internet running Windows.                                                                                  |

Table 192: Summary of Key Screen Counters Output Fields (*continued*)

| Field                  | Values                                                     | Additional Information                                                                                                                                     |
|------------------------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCP Port Scan          | Number of TCP port scans.                                  | The purpose of this attack is to scan the available services in the hopes that at least one port will respond, thus identifying a service to target.       |
| ICMP Address Sweep     | Number of ICMP address sweeps.                             | An IP address sweep can occur with the intent of triggering responses from active hosts.                                                                   |
| IP Tear Drop           | Number of teardrop attacks.                                | Teardrop attacks exploit the reassembly of fragmented IP packets.                                                                                          |
| TCP SYN Attack         | Number of TCP SYN attacks.                                 | —                                                                                                                                                          |
| IP Spoofing            | Number of IP spoofs.                                       | IP spoofing occurs when an invalid source address is inserted in the packet header to make the packet appear to come from a trusted source.                |
| ICMP Ping of Death     | ICMP ping of death counter.                                | Ping of death occurs when IP packets are sent that exceed the maximum legal length (65,535 bytes).                                                         |
| IP Source Route        | Number of IP source route attacks.                         | —                                                                                                                                                          |
| TCP Land Attack        | Number of land attacks.                                    | Land attacks occur when attacker sends spoofed SYN packets containing the IP address of the victim as both the destination and source IP address.          |
| TCP SYN Fragment       | Number of TCP SYN fragments.                               | —                                                                                                                                                          |
| TCP No Flag            | Number of TCP headers without flags set.                   | A normal TCP segment header has at least one control flag set.                                                                                             |
| IP Unknown Protocol    | Number of unknown Internet protocols.                      | —                                                                                                                                                          |
| IP Bad Options         | Number of invalid options.                                 | —                                                                                                                                                          |
| IP Record Route Option | Number of packets with the IP record route option enabled. | This option records the IP addresses of the network devices along the path that the IP packet travels.                                                     |
| IP Timestamp Option    | Number of IP timestamp option attacks.                     | This option records the time (in Universal Time) when each network device receives the packet during its trip from the point of origin to its destination. |
| IP Security Option     | Number of IP security option attacks.                      | —                                                                                                                                                          |

Table 192: Summary of Key Screen Counters Output Fields (*continued*)

| Field                         | Values                                                      | Additional Information                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Loose route Option         | Number of IP loose route option attacks.                    | This option specifies a partial route list for a packet to take on its journey from source to destination.                                                                                                                                                                         |
| IP Strict Source Route Option | Number of IP strict source route option attacks.            | This option specifies the complete route list for a packet to take on its journey from source to destination.                                                                                                                                                                      |
| IP Stream Option              | Number of stream option attacks.                            | This option provides a way for the 16-bit SATNET stream identifier to be carried through networks that do not support streams.                                                                                                                                                     |
| ICMP Fragment                 | Number of ICMP fragments.                                   | Because ICMP packets contain very short messages, there is no legitimate reason for ICMP packets to be fragmented. If an ICMP packet is so large that it must be fragmented, something is amiss.                                                                                   |
| ICMP Large Packet             | Number of large ICMP packets.                               | —                                                                                                                                                                                                                                                                                  |
| TCP SYN FIN Packet            | Number of TCP SYN FIN packets.                              | —                                                                                                                                                                                                                                                                                  |
| TCP FIN without ACK           | Number of TCP FIN flags without the acknowledge (ACK) flag. | —                                                                                                                                                                                                                                                                                  |
| TCP SYN-ACK-ACK Proxy         | Number of TCP flags enabled with SYN-ACK-ACK.               | To prevent flooding with SYN-ACK-ACK sessions, you can enable the SYN-ACK-ACK proxy protection screen option. After the number of connections from the same IP address reaches the SYN-ACK-ACK proxy threshold, Junos OS rejects further connection requests from that IP address. |
| IP Block Fragment             | Number of IP block fragments.                               | —                                                                                                                                                                                                                                                                                  |

## Monitoring IDP Status

**Purpose** View detailed information about the IDP Status, Memory, Counters, Policy Rulebase Statistics, and Attack table statistics.

**Action** To view Intrusion Detection and Prevention (IDP) table information, select **Monitor>Security>IDP>Status** in the J-Web user interface, or enter the following CLI commands:

- **show security idp status**
- **show security idp memory**

Table 193 summarizes key output fields in the IDP display.

Table 193: Summary of IDP Status Output Fields

| Field                            | Values                                                                                                | Additional Information |
|----------------------------------|-------------------------------------------------------------------------------------------------------|------------------------|
| <b>IDP Status</b>                |                                                                                                       |                        |
| Status of IDP                    | Displays the status of the current IDP policy.                                                        | —                      |
| Up Since                         | Displays the time from when the IDP policy first began running on the system.                         | —                      |
| Packets/Second                   | Displays the number of packets received and returned per second.                                      | —                      |
| Peak                             | Displays the maximum number of packets received per second and the time when the maximum was reached. | —                      |
| Kbits/Second                     | Displays the aggregated throughput (kilobits per second) for the system.                              | —                      |
| Peak Kbits                       | Displays the maximum kilobits per second and the time when the maximum was reached.                   | —                      |
| Latency (Microseconds)           | Displays the delay, in microseconds, for a packet to receive and return by a node .                   | —                      |
| Current Policy                   | Displays the name of the current installed IDP policy.                                                | —                      |
| <b>IDP Memory Status</b>         |                                                                                                       |                        |
| IDP Memory Statistics            | Displays the status of all IDP data plane memory.                                                     | —                      |
| PIC Name                         | Displays the name of the PIC.                                                                         | —                      |
| Total IDP Data Plane Memory (MB) | Displays the total memory space, in megabytes, allocated for the IDP data plane.                      | —                      |
| Used (MB)                        | Displays the used memory space, in megabytes, for the data plane.                                     | —                      |
| Available (MB)                   | Displays the available memory space, in megabytes, for the data plane.                                | —                      |

## Monitoring Flow Gate Information

- Purpose** View information about temporary openings known as pinholes or gates in the security firewall.
- Action** Select **Monitor>Security>Flow Gate** in the J-Web user interface, or enter the **show security flow gate** command.

Table 194 summarizes key output fields in the flow gate display.

**Table 194: Summary of Key Flow Gate Output Fields**

| Field                        | Values                                                                                                                                                                           | Additional Information |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>Flow Gate Information</b> |                                                                                                                                                                                  |                        |
| Hole                         | Range of flows permitted by the pinhole.                                                                                                                                         | —                      |
| Translated                   | Tuples used to create the session if it matches the pinhole: <ul style="list-style-type: none"> <li>• Source address and port</li> <li>• Destination address and port</li> </ul> | —                      |
| Protocol                     | Application protocol, such as UDP or TCP.                                                                                                                                        | —                      |
| Application                  | Name of the application.                                                                                                                                                         | —                      |
| Age                          | Idle timeout for the pinhole.                                                                                                                                                    | —                      |
| Flags                        | Internal debug flags for pinhole.                                                                                                                                                | —                      |
| Zone                         | Incoming zone.                                                                                                                                                                   | —                      |
| Reference count              | Number of resource manager references to the pinhole.                                                                                                                            | —                      |
| Resource                     | Resource manager information about the pinhole.                                                                                                                                  | —                      |

## Monitoring Firewall Authentication Table

**Purpose** View information about the authentication table, which divides firewall authentication user information into multiple parts.

**Action** Select **Monitor>Security>Firewall Authentication>Authentication Table** in the J-Web user interface. To view detailed information about the user with a particular identifier, select the ID on the Authentication Table page. To view detailed information about the user at a particular source IP address, select the Source IP on the Authentication Table page.

Alternatively, enter the following CLI **show** commands:

- **show security firewall-authentication users**
- **show security firewall-authentication users address *ip-address***
- **show security firewall-authentication users identifier *identifier***

Table 195 summarizes key output fields in firewall authentication table display.

Table 195: Summary of Key Firewall Authentication Table Output Fields

| Field                                             | Values                                                         | Additional Information |
|---------------------------------------------------|----------------------------------------------------------------|------------------------|
| <b>Firewall authentication users</b>              |                                                                |                        |
| Total users in table                              | Number of users in the authentication table.                   | —                      |
| <b>Authentication table</b>                       |                                                                |                        |
| ID                                                | Authentication identification number.                          | —                      |
| Source Ip                                         | IP address of the authentication source.                       | —                      |
| Age                                               | Idle timeout for the user.                                     | —                      |
| Status                                            | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| user                                              | Name of the user.                                              | —                      |
| <b>Detailed report per ID selected: <i>ID</i></b> |                                                                |                        |
| Source Zone                                       | Name of the source zone.                                       | —                      |
| Destination Zone                                  | Name of the destination zone.                                  | —                      |
| profile                                           | Name of the profile.                                           | Users information.     |
| Authentication method                             | Path chosen for authentication.                                | —                      |
| Policy Id                                         | Policy Identifier.                                             | —                      |
| Interface name                                    | Name of the interface.                                         | —                      |
| Bytes sent by this user                           | Number of packets in bytes sent by this user.                  | —                      |
| Bytes received by this user                       | Number of packets in bytes received by this user.              | —                      |
| Client-groups                                     | Name of the client group.                                      | —                      |
| <b>Detailed report per Source Ip selected</b>     |                                                                |                        |
| Entries from Source IP                            | IP address of the authentication source.                       | —                      |
| Source Zone                                       | Name of the source zone.                                       | —                      |
| Destination Zone                                  | Name of the destination zone.                                  | —                      |

| Interface name              | Name of the interface.                            | —                      |
| Bytes sent by this user     | Number of packets in bytes sent by this user.     | —                      |
| Bytes received by this user | Number of packets in bytes received by this user. | —                      |
| Client-groups               | Name of the client group.                         | —                      |

## Monitoring Firewall Authentication History

**Purpose** View information about the authentication history, which is divided into multiple parts.

**Action** Select **Monitor>Security>Firewall Authentication>Authentication History** in the J-Web user interface. To view the detailed history of the authentication with this identifier, select the ID on the Firewall Authentication History page. To view a detailed authentication history of this source IP address, select the Source IP on the Firewall Authentication History page.

Alternatively, enter the following CLI **show** commands:

- **show security firewall-authentication history**
- **show security firewall-authentication history address *ip-address***
- **show security firewall-authentication history identifier *identifier***

Table 196 summarizes key output fields in firewall authentication history display.

Table 196: Summary of Key Firewall Authentication History Output Fields

| Field                                          | Values                                   | Additional Information |
|------------------------------------------------|------------------------------------------|------------------------|
| <b>History of Firewall Authentication Data</b> |                                          |                        |
| Total authentications                          | Number of authentication.                | —                      |
| <b>History Table</b>                           |                                          |                        |
| ID                                             | Identification number.                   | —                      |
| Source Ip                                      | IP address of the authentication source. | —                      |

Table 196: Summary of Key Firewall Authentication History Output Fields (*continued*)

| Field                                                 | Values                                                         | Additional Information |
|-------------------------------------------------------|----------------------------------------------------------------|------------------------|
| Start Date                                            | Authentication date.                                           | —                      |
| Start Time                                            | Authentication time.                                           | —                      |
| Duration                                              | Authentication duration.                                       | —                      |
| Status                                                | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| User                                                  | Name of the user.                                              | —                      |
| <b>Detail history of selected Id: ID</b>              |                                                                |                        |
| Authentication method                                 | Path chosen for authentication.                                | —                      |
| Policy Id                                             | Security policy identifier.                                    | —                      |
| Source zone                                           | Name of the source zone.                                       | —                      |
| Destination Zone                                      | Name of the destination zone.                                  | —                      |
| Interface name                                        | Name of the interface.                                         | —                      |
| Bytes sent by this user                               | Number of packets in bytes sent by this user.                  | —                      |
| Bytes received by this user                           | Number of packets in bytes received by this user.              | —                      |
| Client-groups                                         | Name of the client group.                                      | —                      |
| <b>Detail history of selected Source Ip:Source Ip</b> |                                                                |                        |
| User                                                  | Name of the user.                                              | —                      |
| Start Date                                            | Authentication date.                                           | —                      |
| Start Time                                            | Authentication time.                                           | —                      |
| Duration                                              | Authentication duration.                                       | —                      |
| Status                                                | Status of authentication ( <b>success</b> or <b>failure</b> ). | —                      |
| Profile                                               | Name of the profile.                                           | —                      |
| Authentication method                                 | Path chosen for authentication.                                | —                      |
| Policy Id                                             | Security policy identifier.                                    | —                      |
| Source zone                                           | Name of the source zone.                                       | —                      |

Table 196: Summary of Key Firewall Authentication History Output Fields (*continued*)

| Field                       | Values                                            | Additional Information |
|-----------------------------|---------------------------------------------------|------------------------|
| Destination Zone            | Name of the destination zone.                     | —                      |
| Interface name              | Name of the interface.                            | —                      |
| Bytes sent by this user     | Number of packets in bytes sent by this user.     | —                      |
| Bytes received by this user | Number of packets in bytes received by this user. | —                      |
| Client-groups               | Name of the client group.                         | —                      |

## Monitoring 802.1x

**Purpose** View information about 802.1X properties.

**Action** Select **Monitor>Security>802.1x** in the J-Web user interface, or enter the following CLI commands:

- **show dot1x interfaces *interface-name***
- **show dot1x authentication-failed-users**

[Table 197](#) summarizes the Dot1X output fields.

Table 197: Summary of Dot1X Output Fields

| Field                                      | Values                                                                  | Additional Information |
|--------------------------------------------|-------------------------------------------------------------------------|------------------------|
| Select Port                                | List of ports for selection.                                            | —                      |
| Number of connected hosts                  | Total number of hosts connected to the port.                            | —                      |
| Number of authentication bypassed hosts    | Total number of authentication-bypassed hosts with respect to the port. | —                      |
| <b>Authenticated Users Summary</b>         |                                                                         |                        |
| MAC Address                                | MAC address of the connected host.                                      | —                      |
| User Name                                  | Name of the user.                                                       | —                      |
| Status                                     | Information about the host connection status.                           | —                      |
| Authentication Due                         | Information about host authentication.                                  | —                      |
| <b>Authentication Failed Users Summary</b> |                                                                         |                        |

**Table 197: Summary of Dot1X Output Fields (*continued*)**

| Field       | Values                                         | Additional Information |
|-------------|------------------------------------------------|------------------------|
| MAC Address | MAC address of the authentication-failed host. | –                      |
| User Name   | Name of the authentication-failed user.        | –                      |

# Monitoring Events, Services and System

- [Monitoring DHCP Client Bindings on page 1845](#)
- [Monitoring Events on page 1845](#)
- [Monitoring the System on page 1848](#)

## Monitoring DHCP Client Bindings

**Purpose** View information about DHCP client bindings.

**Action** Select **Monitor>Services>DHCP>Binding** in the J-Web user interface, or enter the **show system services dhcp binding** command.

[Table 198](#) summarizes the key output fields in the DHCP client binding displays.

**Table 198: Summary of Key DHCP Client Binding Output Fields**

| Field            | Values                                                                          | Additional Information |
|------------------|---------------------------------------------------------------------------------|------------------------|
| IP Address       | List of IP addresses the DHCP server has assigned to clients.                   | —                      |
| Hardware Address | Corresponding media access control (MAC) address of the client.                 | —                      |
| Type             | Type of binding assigned to the client: dynamic or static.                      | —                      |
| Lease Expires at | Date and time the lease expires, or <b>never</b> for leases that do not expire. | —                      |

## Monitoring Events

**Purpose** Use the monitoring functionality to view the events page.

**Action** To monitor events select **Monitor>Events and Alarms>View Events** in the J-Web user interface.

**NOTE:** When you use an HTTPS connection in the Microsoft Internet Explorer browser to save a report from this page in the J-Web interface, the error message "Internet Explorer was not able to open the Internet site" is displayed. This problem occurs because the Cache-Control: no cache HTTP header is added on the server side and Internet Explorer does not allow you to download the encrypted file with the Cache-Control: no cache HTTP header set in the response from the server.

As a workaround, refer to Microsoft Knowledge Base article 323308, which is available at this URL: <http://support.microsoft.com/kb/323308>. Also, you can alternatively use HTTP in the Internet Explorer browser or use HTTPS in the Mozilla Firefox browser to save a file from this page.

**Meaning** Table 199 summarizes key output fields in the events page.

**Table 199: Events Monitoring Page**

| Field                  | Value                                                                                      | Additional Information |
|------------------------|--------------------------------------------------------------------------------------------|------------------------|
| <b>Events Filter</b>   |                                                                                            |                        |
| System Log File        | Specifies the name of the system log file that records errors and events.                  | -                      |
| Process                | Specifies the system processes that generate the events to display.                        | -                      |
| Include archived files | Specifies to enable the option to include archived files.                                  | Select to enable.      |
| Date From              | Specifies the beginning date range to monitor. Set the date using the calendar pick tool.  | -                      |
| To                     | Specifies the end of the date range to monitor. Set the date using the calendar pick tool. | -                      |
| Event ID               | Specifies the specific ID of the error or event to monitor.                                | -                      |
| Description            | Enter a description for the errors or events.                                              | -                      |
| Search                 | Fetches the errors and events specified in the search criteria.                            | -                      |
| Reset                  | Clears the cache of errors and events that were previously selected.                       | -                      |

Table 199: Events Monitoring Page (*continued*)

| Field                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Additional Information |

| Generate Report      | Creates an HTML report based on the specified parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | -                      |
| <b>Events Detail</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |
| Process              | Displays the system process that generated the error or event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | -                      |
| Severity             | <p>Displays the severity level that indicates how seriously the triggering event affects routing platform functions. Only messages from the facility that are rated at that level or higher are logged. Possible severities and their corresponding color code are:</p> <ul style="list-style-type: none"> <li>• <b>Debug/Info/Notice (Green)</b>—Indicates conditions that are not errors but are of interest or might warrant special handling.</li> <li>• <b>Warning (Yellow)</b> — Indicates conditions that warrant monitoring.</li> <li>• <b>Error (Blue)</b> — Indicates standard error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels.</li> <li>• <b>Critical (Pink)</b> — Indicates critical conditions, such as hard drive errors.</li> <li>• <b>Alert (Orange)</b> — Indicates conditions that require immediate correction, such as a corrupted system database.</li> <li>• <b>Emergency (Red)</b> — Indicates system panic or other conditions that cause the routing platform to stop functioning.</li> </ul> | -                      |
| Event ID             | Displays the unique ID of the error or event. The prefix on each code identifies the generating software process. The rest of the code indicates the specific event or error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | -                      |
| Event Description    | Displays a more detailed explanation of the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | -                      |
| Time                 | Time that the error or event occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | -                      |

## Monitoring the System

---

The J-Web user interface lets you monitor a device's physical characteristics, current processing status and alarms, and ongoing resource utilization to quickly assess the condition of a device at any time.

On SRX Series devices, the **Dashboard** lets you customize your view by selecting which informational panes to include on the Dashboard.

This section contains the following topics:

- [Monitoring System Properties for SRX Series Devices on page 1848](#)
- [Monitoring Chassis Information on page 1850](#)
- [System Health Management for Branch SRX Series Devices on page 1852](#)

### Monitoring System Properties for SRX Series Devices

**Purpose** View system properties and customize the Dashboard.

When you start the J-Web user interface on an SRX Series device, the interface opens to the Dashboard. At the top and bottom of the page, the Dashboard displays an interactive representation of your device and a current log messages pane. By default, the center panes of the Dashboard display System Information, Resource Utilization, Security Resources, and System Alarms. However, you can customize the Dashboard panes to provide the best overview of your system.

**Action** To control the content and appearance of the Dashboard:

1. Click the **Preferences** icon at the top-right corner of the page. The Dashboard Preference dialog box appears.
2. Select the types of information you want to display.
3. (Optional) Specify the Automatically Refresh Data option to specify how often you want the data on the Dashboard to be refreshed.
4. Click **OK** to save the configuration or **Cancel** to clear it.
5. On the Dashboard, minimize, maximize, or drag the individual information panes to customize the display as needed.

Chassis View—Displays an image of the device chassis, including line cards, link states, errors, individual PICs, FPCs, fans, and power supplies.

You can use the Chassis View to link to corresponding configuration and monitoring pages for the device. To link to interface configuration pages for a selected port from the Chassis View, right-click the port in the device image and choose one of the following options:

- Chassis Information—Links to the Chassis page.
- Configure Port: *Port-name*—Links to the interfaces configuration page for the selected port.

- Monitor Port: *Port-name*—Links to the monitor interfaces page for the selected port.

System Identification—Displays the device's serial number, hostname, current software version, the BIOS version, the amount of time since the device was last booted, and the system's time.

NOTE:

- To view the BIOS version under system identification, delete your browser cookies.
- The hostname that appears in this pane is defined using the `set system hostname` command.

On SRX Series devices, security logs were always timestamped using the UTC time zone by running `set system time-zone utc` and `set security log utc-timestamp` CLI commands. Now, time zone can be defined using the local time zone by running the `set system time-zone time-zone` command to specify the local time zone that the system should use when timestamping the security logs.

Resource Utilization—Provides a graphic representation of resource use. Each bar represents the percentage of CPU, memory, or storage utilization for the data plane or the control plane.

Security Resources—Provides the maximum, configured, and active sessions; firewall and VPN policies; and IPsec VPNs. Click **Sessions**, **FW/VPN Policies**, or **IPsec VPNs** for detailed statistics about each category.

System Alarms—Indicates a missing rescue configuration or software license, where valid. System alarms are preset and cannot be modified.

File Usage—Displays the usage statistics for log files, temporary files, crash (core) files, and database files.

Login Sessions—Provides a list of all currently logged in sessions. The display includes user credentials, login time, and idle time for each session.

Chassis Status—Provides a snapshot of the current physical condition of the device, including temperature and fan status.

Storage Usage—Displays the storage usage report in detail.

Threat Activity—Provides information about the most current threats received on the device.

Message Logs—Displays log messages and errors. You can clear old logs from the Message Logs pane by clicking the Clear button.

To control the information that is displayed in the Chassis View, use the following options:

- To view an image of the front of the device, right-click the image and choose **View Front**.
- To view an image of the back of the device, right-click the image and choose **View Rear**.
- To enlarge or shrink the device view, use the **Zoom** bar.
- To return the device image to its original position and size, click **Reset**.

**NOTE:** To use the Chassis View, a recent version of Adobe Flash that supports ActionScript and AJAX (Version 9) must be installed. Also note that the Chassis View appears by default on the Dashboard page. You can enable or disable it using options in the Dashboard Preference dialog box. Clearing cookies in Internet Explorer also causes the Chassis View appear on the Dashboard page.

To return to the Dashboard at any time, select **Dashboard** in the J-Web user interface.

Alternatively, you can view system properties by entering the following **show** commands in the CLI:

- **show system uptime**
- **show system users**
- **show system storage**
- **show version**
- **show chassis hardware**

## Monitoring Chassis Information

**Purpose** View chassis properties, which include the status of hardware components on the device.

**Action** To view these chassis properties, select **Monitor>System View>Chassis Information** in the J-Web user interface.

**CAUTION:** Do not install a combination of Physical Interface Modules (PIMs) in a single chassis that exceeds the maximum power and heat capacity of the chassis. If power management is enabled, PIMs that exceed the maximum power and heat limits remain offline when the chassis is powered on. To check PIM power and heat status, use the **show chassis fpc** and **show chassis power-ratings** commands.

The Chassis Information page displays the following types of information:

- **Routing Engine Details**—This section of the page includes the following tabs:
  - **Master**—Master tab displays information about the routing engine, including the routing engine module, model number, version, part number, serial number, memory utilization, temperature, and start time. Additionally, this tab displays the CPU load averages for the last 1, 5, and 15 minutes.
  - **Backup**—If a backup routing engine is available, the Backup tab displays the routing engine module, model number, version, part number, serial number, memory utilization, temperature, and start time. Additionally, this tab displays the CPU load averages for the last 1, 5, and 15 minutes.

**NOTE:** If you need to contact customer support about the device chassis, supply them with the version and serial number displayed in the Routing Engine Details section of the page.

- **Power and Fan Tray Details**—This Details section of the page includes the following tabs:
  - **Power**—Power tab displays the names of the device's power supply units and their statuses.
  - **Fan**—Fan tab displays the names of the device's fans and their speeds (normal or high). (The fan speeds are adjusted automatically according to the current temperature.)
- **Chassis Component Details**—This section of the page includes the following tabs:
  - **General**—General tab displays the version number, part number, serial number, and description of the selected device component.
  - **Temperature**—Temperature tab displays the temperature of the selected device component (if applicable).
  - **Resource**—Resource tab displays the state, total CPU DRAM, and start time of the selected device component (if applicable).

**NOTE:** On some devices, you can have an FPC state as “offline.” You might want to put an FPC offline because of an error or if the FPC is not responding. You can put the FPC offline by using the CLI command `request chassis fpc slot number offline`.

- **Sub-Component**—Sub-Component tab displays information about the device's sub-components (if applicable). Details include the sub-component's version, part number, serial number, and description.

To control which component details appear, select a hardware component from the **Select component** list.

Alternatively, you can view chassis details by entering the following **show** commands in the CLI configuration editor:

- **show chassis hardware**
- **show chassis routing-engine**
- **show chassis environment**
- **show chassis redundant-power-supply**
- **show redundant-power-supply status**

## System Health Management for Branch SRX Series Devices

**Purpose** Tracking the utilization of critical resources in the system ensures that all parameters are within normal limits and the system remains functional.

In the event of a malfunction caused by abnormal resource usage, the system health management feature provides the right diagnostic information to identify the source of the problem.

When the system health management action is configured by the user, the system takes appropriate monitoring, preventive, and recovery actions to ensure that the system is accessible. The system configuration might be updated based on the information collected by system health management feature to ensure that the system stays in the normal operating environment. For example, when a system runs out of memory, then the configuration associated with applications identified to be consuming memory resources can be updated to bring down the memory resource consumption.

**Action** The system health management feature periodically monitors critical system resources against configurable thresholds. The resources that can be monitored include CPU usage, memory, storage, open-file-descriptor, process-count, and temperature. The system health management feature collects usage information for each resource at the configured interval and compares it against the three levels of thresholds: moderate, high, and critical. Based on the configurations, appropriate action is taken.

The intervals, thresholds, and action are associated with system health management and can be configured at both the resource level and the global level. Configurable and default levels are as follows:

- **Default configuration level**—Default configuration is applied when system health monitoring is enabled, and neither a global nor a resource-specific configuration is present.
- **Global configuration level**—Configuration that is applied to resources when no resource-specific configuration is available.
- **Resource-specific configuration level**—Configuration that, if available, overrides both the global and the default configurations.

Per-resource configurations take precedence over the global configuration, and a global configuration takes precedence over the defaults.

When resource usage exceeds the configured thresholds, the system collects information that can be used to find the source of the increased usage and saves it in history for analysis and action.

When resource utilization exceeds the high threshold, a minor system alarm is generated, and the alarm LED lights yellow. When resource utilization exceeds the critical threshold, a major alarm is generated, and the alarm LED lights red.

An SNMP trap is also sent to the remote monitoring server (NMS) for all events that exceed the threshold.

To enable the system health monitor, use the **set snmp health-monitor routing engine** command. You can view system properties by using CLI show commands.

## Monitoring Antivirus Scan Engine Status

---

**Purpose** Using the CLI, you can view the following scan engine status items:

Antivirus license key status

- View license expiration dates.

Scan engine status and settings

- View last action result.
- View default file extension list.

Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

Antivirus pattern database status

- View auto update status.
- View last result of database loading.
- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

**Action** In the CLI, enter the `user@host> show security utm anti-virus status` command.

Example status result:

```
AV Key Expire Date: 03/01/2010 00:00:00
Update Server: http://update.juniper-updates.net/AV/device-name
interval: 60 minutes
auto update status: next update in 12 minutes
last result: new database loaded
AV signature version: 12/21/2008 00:35 GMT, virus records: 154018
Scan Engine Info: last action result: No error(0x00000000)
```

---

## Monitoring Antivirus Scan Results

---

**Purpose** View statistics for antivirus requests, scan results, and fallback counters.

Scan requests provide

- The total number of scan request forwarded to the engine.
- The number of scan request being pre-windowed.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.
- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
- Maximum content size reached.
- Too many requests.
- Password protected file found.
- Decompress layer too large.
- Corrupt file found.

- Timeout occurred.
- Out of resources.
- Other.

**Action** To view antivirus scan results using the CLI editor, enter the **user@host> show security utm anti-virus statistics status** command.

To view antivirus scan results using J-Web:

1. Select **Monitor>Security>UTM>Anti-Virus**.

The following information becomes viewable in the right pane.

Antivirus license key status

- View license expiration dates.

Antivirus pattern update server settings

- View update URL (HTTP or HTTPS-based).
- View update interval.

Antivirus pattern database status

- View auto update status.
- View last result of database loading.
- If the download completes, view database version timestamp virus record number.
- If the download fails, view failure reason.

Antivirus statistics provide

- The number of scan request being pre-windowed.
- The total number of scan request forwarded to the engine.
- The number of scan requests using scan-all mode.
- The number of scan requests using scan-by-extension mode.

Scan code counters provide

- Number of clean files.
- Number of infected files.
- Number of password protected files.
- Number of decompress layers.
- Number of corrupt files.
- When the engine is out of resources.
- When there is an internal error.

Fallback applied status provides either a log-and-permit or block result when the following has occurred

- Scan engine not ready.
  - Password protected file found.
  - Decompress layer too large.
  - Corrupt file found.
  - Out of resources.
  - Timeout occurred.
  - Maximum content size reached.
  - Too many requests.
  - Other.
2. You can click the **Clear Anti-Virus Statistics** button to clear all current viewable statistics and begin collecting new statistics.

**Related Documentation** • [Monitoring Antivirus Session Status on page 1858](#)

---

## Monitoring Antivirus Session Status

**Purpose** Using the CLI, you can view the following session status items:

Antivirus session status displays a snapshot of current antivirus sessions. It includes

- Maximum supported antivirus session numbers.
- Total allocated antivirus session numbers.
- Total freed antivirus session numbers.
- Current active antivirus session numbers.

**Action** In the CLI, enter the **user@host> show security utm session status** command.

---

## Monitoring Content Filtering Configurations

**Purpose** View content filtering statistics.

**Action** To view content filtering statistics in the CLI, enter the **user@host > show security utm content-filtering statistics** command.

The content filtering **show statistics** command displays the following information:

```
Base on command list: # Blocked
Base on mime list: # Blocked
Base on extension list: # Blocked
ActiveX plugin: # Blocked
Java applet: # Blocked
EXE files: # Blocked
ZIP files: # Blocked
HTTP cookie: # Blocked
```

To view content filtering statistics using J-Web:

1. Select **Clear Content filtering statistics** **Monitor>Security>UTM>Content Filtering** **Monitor>Security>UTM>Content Filtering**.

The following statistics become viewable in the right pane.

```
Base on command list: # Passed # Blocked
Base on mime list: # Passed # Blocked
Base on extension list: # Passed # Blocked
ActiveX plugin: # Passed # Blocked
Java applet: # Passed # Blocked
EXE files: # Passed # Blocked
ZIP files: # Passed # Blocked
HTTP cookie: # Passed # Blocked
```

2. You can click **Clear Content filtering statistics** to clear all current viewable statistics and begin collecting new statistics.

## Monitoring Reports

On-box reporting offers a comprehensive reporting facility where your security management team can spot a security event when it occurs, immediately access and review pertinent details about the event, and quickly decide appropriate remedial action. The J-Web reporting feature provides one- or two-page reports that are equivalent to a compilation of numerous log entries.

This section contains the following topics:

- [Threats Monitoring Report on page 1859](#)
- [Traffic Monitoring Report on page 1864](#)

### Threats Monitoring Report

**Purpose** Use the Threats Report to monitor general statistics and activity reports of current threats to the network. You can analyze logging data for threat type, source and destination

details, and threat frequency information. The report calculates, displays, and refreshes the statistics, providing graphic presentations of the current state of the network.

**Action** To view the Threats Report:

1. Click **Threats Report** in the bottom right of the Dashboard, or select **Monitor>Reports>Threats** in the J-Web user interface. The Threats Report appears.
2. Select one of the following tabs:
  - **Statistics** tab. See [Table 200](#) for a description of the page content.
  - **Activities** tab. See [Table 201](#) for a description of the page content.

**Table 200: Statistics Tab Output in the Threats Report**

| Field                                     | Description                                                                                                                                                                                                                                                                                                                                                                                           |

| Destination IP/Port                    | IP address (and port number, if applicable) of the destination.                                                                                                                                                       |
| Hits in current hour                   | Number of threats encountered in the last hour.                                                                                                                                                                       |
| <b>Most Recent IDP Attacks</b>         |                                                                                                                                                                                                                       |
| Attack                                 |                                                                                                                                                                                                                       |

Table 201: Activities Tab Output in the Threats Report (*continued*)

| Field               | Function                                                                                                                                                                                                 |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Severity            | Severity of each threat: <ul style="list-style-type: none"> <li>• emerg</li> <li>• alert</li> <li>• crit</li> <li>• err</li> <li>• warning</li> <li>• notice</li> <li>• info</li> <li>• debug</li> </ul> |
| Source IP/Port      | IP address (and port number, if applicable) of the source.                                                                                                                                               |
| Destination IP/Port | IP address (and port number, if applicable) of the destination.                                                                                                                                          |
| Protocol            | Protocol name of the threat.                                                                                                                                                                             |
| Action              | Action taken in response to the threat.                                                                                                                                                                  |
| Last Send Time      | Last time the IDP threat was sent.                                                                                                                                                                       |

## Traffic Monitoring Report

**Purpose** Monitor network traffic by reviewing reports of flow sessions over the past 24 hours. You can analyze logging data for connection statistics and session usage by a transport protocol.

**Action** To view network traffic in the past 24 hours, select **Monitor>Reports>Traffic** in the J-Web user interface. See [Table 202](#) for a description of the report.

Table 202: Traffic Report Output

| Field                                         | Description                                                                                                                                                                                                                            |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sessions in Past 24 Hours per Protocol</b> |                                                                                                                                                                                                                                        |
| Protocol Name                                 | Name of the protocol. To see hourly activity by protocol, click the protocol name and review the “Protocol activities chart” in the lower pane. <ul style="list-style-type: none"> <li>• TCP</li> <li>• UDP</li> <li>• ICMP</li> </ul> |
| Total Session                                 | Total number of sessions for the protocol in the past 24 hours.                                                                                                                                                                        |
| Bytes In (KB)                                 | Total number of incoming bytes in KB.                                                                                                                                                                                                  |
| Bytes Out (KB)                                | Total number of outgoing bytes in KB.                                                                                                                                                                                                  |

Table 202: Traffic Report Output (*continued*)

| Field                                | Description                                                                                                                                                                                                                                     |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Packets In                           | Total number of incoming packets.                                                                                                                                                                                                               |
| Packets Out                          | Total number of outgoing packets.                                                                                                                                                                                                               |
| <b>Most Recently Closed Sessions</b> |                                                                                                                                                                                                                                                 |
| Source IP/Port                       | Source IP address (and port number, if applicable) of the closed session.                                                                                                                                                                       |
| Destination IP/Port                  | Destination IP address (and port number, if applicable) of the closed session.                                                                                                                                                                  |
| Protocol                             | Protocol of the closed session. <ul style="list-style-type: none"> <li>• TCP</li> <li>• UDP</li> <li>• ICMP</li> </ul>                                                                                                                          |
| Bytes In (KB)                        | Total number of incoming bytes in KB.                                                                                                                                                                                                           |
| Bytes Out (KB)                       | Total number of outgoing bytes in KB.                                                                                                                                                                                                           |
| Packets In                           | Total number of incoming packets.                                                                                                                                                                                                               |
| Packets Out                          | Total number of outgoing packets.                                                                                                                                                                                                               |
| Timestamp                            | The time the session was closed.                                                                                                                                                                                                                |
| <b>Protocol Activities Chart</b>     |                                                                                                                                                                                                                                                 |
| Bytes In/Out                         | Graphic representation of traffic as incoming and outgoing bytes per hour. The byte count is for the protocol selected in the Sessions in Past 24 Hours per Protocol pane. Changing the selection causes this chart to refresh immediately.     |
| Packets In/Out                       | Graphic representation of traffic as incoming and outgoing packets per hour. The packet count is for the protocol selected in the Sessions in Past 24 Hours per Protocol pane. Changing the selection causes this chart to refresh immediately. |
| Sessions                             | Graphic representation of traffic as the number of sessions per hour. The session count is for the protocol selected in the Sessions in Past 24 Hours per Protocol pane. Changing the selection causes this chart to refresh immediately.       |
| X Axis                               | One hour per column for 24 hours.                                                                                                                                                                                                               |
| Y Axis                               | Byte, packet, or session count.                                                                                                                                                                                                                 |
| <b>Protocol Session Chart</b>        |                                                                                                                                                                                                                                                 |
| Sessions by Protocol                 | Graphic representation of the traffic as the current session count per protocol. The protocols displayed are TCP, UDP, and ICMP.                                                                                                                |

## Monitoring Web Filtering Configurations

---

**Purpose** View Web-filtering statistics.

**Action** To view Web-filtering statistics using the CLI, enter the following commands:

```
user@host> show security utm web-filtering status
user@host> show security utm web-filtering statistics
```

To view Web-filtering statistics using J-Web:

1. Select **Clear Web Filtering Statistics**.

The following information is displayed in the right pane.

```
Total Requests: #
White List Hit: #
Black List Hit: #
Queries to Server: #
Server Reply Permit: #
Server Reply Block: #
Custom Category Permit: #
Custom Category Block: #
Cache Hit Permit: #
Cache Hit Block: #
Web Filtering Session Total: #
Web Filtering Session Inuse: #
Fall Back: Log-and-Permit Block
Default # #
Timeout # #
Server-Connectivity # #

## Monitoring VPNs

This section contains the following topics:

- [Monitoring IKE Gateway Information on page 1867](#)
- [Monitoring IPsec VPN—Phase I on page 1871](#)
- [Monitoring IPsec VPN—Phase II on page 1872](#)
- [Monitoring IPsec VPN Information on page 1873](#)

### Monitoring IKE Gateway Information

**Purpose** View information about IKE security associations (SAs).

**Action** Select **Monitor>IPSec VPN>IKE Gateway** in the J-Web user interface. To view detailed information for a particular SA, select the IKE SA index on the IKE gateway page.

Alternatively, enter the following CLI commands:

- **show security ike security-associations**
- **show security ike security-associations index *index-id* detail**

[Table 203](#) summarizes key output fields in the IKE gateway display.

Table 203: Summary of Key IKE SA Information Output Fields

| Field                     | Values                                                                     | Additional Information                                                                              |
|---------------------------|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| IKE Security Associations |                                                                            |                                                                                                     |
| IKE SA Index              | Index number of an SA.                                                     | This number is an internally generated number you can use to display information about a single SA. |
| Remote Address            | IP address of the destination peer with which the local peer communicates. | —                                                                                                   |

Table 203: Summary of Key IKE SA Information Output Fields (*continued*)

| Field                                      | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Additional Information                                                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| State                                      | State of the IKE security associations: <ul style="list-style-type: none"> <li>• <b>DOWN</b>—SA has not been negotiated with the peer.</li> <li>• <b>UP</b>—SA has been negotiated with the peer.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | —                                                                                                                                                    |
| Initiator cookie                           | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | —                                                                                                                                                    |
| Responder cookie                           | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |
| Mode                                       | Negotiation method agreed on by the two IPsec endpoints, or peers, used to exchange information between themselves. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are: <ul style="list-style-type: none"> <li>• <b>Main</b>—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>• <b>Aggressive</b>—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul> | —                                                                                                                                                    |
| <b>IKE Security Association (SA) Index</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                      |
| IKE Peer                                   | IP address of the destination peer with which the local peer communicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | —                                                                                                                                                    |
| IKE SA Index                               | Index number of an SA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | This number is an internally generated number you can use to display information about a single SA.                                                  |
| Role                                       | Part played in the IKE session. The device triggering the IKE negotiation is the initiator, and the device accepting the first IKE exchange packets is the responder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | —                                                                                                                                                    |
| State                                      | State of the IKE security associations: <ul style="list-style-type: none"> <li>• <b>DOWN</b>—SA has not been negotiated with the peer.</li> <li>• <b>UP</b>—SA has been negotiated with the peer.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | —                                                                                                                                                    |

Table 203: Summary of Key IKE SA Information Output Fields (*continued*)

| Field                 | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Additional Information                                                                                                                               |

| Initiator cookie      | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | –                                                                                                                                                    |
| Responder cookie      | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |
| Exchange Type         | <p>Negotiation method agreed on by the two IPsec endpoints, or peers, used to exchange information between themselves. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are:</p> <ul style="list-style-type: none"> <li>• <b>Main</b>—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>• <b>Aggressive</b>—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul> | –                                                                                                                                                    |
| Authentication Method | Path chosen for authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | –                                                                                                                                                    |
| Local                 | Address of the local peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | –                                                                                                                                                    |
| Remote                | Address of the remote peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | –                                                                                                                                                    |
| Lifetime              | Number of seconds remaining until the IKE SA expires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | –                                                                                                                                                    |

Table 203: Summary of Key IKE SA Information Output Fields (*continued*)

| Field                       | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Additional Information |

## Monitoring IPsec VPN—Phase I

**Purpose** View IPsec VPN Phase I information.

**Action** Select **Monitor>IPSec VPN>Phase I** in the J-Web user interface.

Table 204 describes the available options for monitoring IPsec VPN-Phase I.

Table 204: IPsec VPN—Phase I Monitoring Page

| Field                     | Values                                                                                                                                                                                     | Additional Information                                                                                                                               |

| SA Index                  | Index number of an SA.                                                                                                                                                                     | —                                                                                                                                                    |
| Remote Address            | IP address of the destination peer with which the local peer communicates.                                                                                                                 | —                                                                                                                                                    |
| State                     | State of the IKE security associations: <ul style="list-style-type: none"> <li>DOWN—SA has not been negotiated with the peer.</li> <li>UP—SA has been negotiated with the peer.</li> </ul> | —                                                                                                                                                    |
| Initiator Cookie          | Random number, called a cookie, which is sent to the remote node when the IKE negotiation is triggered.                                                                                    | —                                                                                                                                                    |
| Responder Cookie          | Random number generated by the remote node and sent back to the initiator as a verification that the packets were received.                                                                | A cookie is aimed at protecting the computing resources from attack without spending excessive CPU resources to determine the cookie's authenticity. |

Table 204: IPsec VPN—Phase I Monitoring Page (*continued*)

| Field | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Mode  | <p>Negotiation method agreed upon by the two IPsec endpoints, or peers, used to exchange information. Each exchange type determines the number of messages and the payload types that are contained in each message. The modes, or exchange types, are:</p> <ul style="list-style-type: none"> <li>• Main—The exchange is done with six messages. This mode, or exchange type, encrypts the payload, protecting the identity of the neighbor. The authentication method used is displayed: preshared keys or certificate.</li> <li>• Aggressive—The exchange is done with three messages. This mode, or exchange type, does not encrypt the payload, leaving the identity of the neighbor unprotected.</li> </ul> | —                      |

## Monitoring IPsec VPN—Phase II

**Purpose** View IPsec VPN Phase II information.

**Action** Select **Monitor>IPSec VPN>Phase II** in the J-Web user interface.

Table 205 describes the available options for monitoring IPsec VPN-Phase II.

Table 205: IPsec VPN—Phase II Monitoring Page

| Field                              | Values                                                                                                | Additional Information |
|------------------------------------|-------------------------------------------------------------------------------------------------------|------------------------|
| <b>Statistics Tab Details</b>      |                                                                                                       |                        |
| By bytes                           | Provides total number of bytes encrypted and decrypted by the local system across the IPsec tunnel.   | —                      |
| By packets                         | Provides total number of packets encrypted and decrypted by the local system across the IPsec tunnel. | —                      |
| IPsec Statistics                   | Provides details of the IPsec statistics.                                                             | —                      |
| <b>IPsec SA Tab Details</b>        |                                                                                                       |                        |
| <b>IPsec Security Associations</b> |                                                                                                       |                        |
| ID                                 | Index number of the SA.                                                                               | —                      |
| Gateway/Port                       | IP address of the remote gateway/port.                                                                | —                      |

Table 205: IPsec VPN—Phase II Monitoring Page (*continued*)

| Field      | Values                                                                                                                                                                                                                                                                                                                                                                   | Additional Information |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Algorithm  | <p>Cryptography scheme used to secure exchanges between peers during the IKE Phase II negotiations:</p> <ul style="list-style-type: none"> <li>An authentication algorithm used to authenticate exchanges between the peers. Options are hmac-md5-95 or hmac-sha1-96.</li> </ul>                                                                                         | —                      |
| SPI        | <p>Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase I and Phase II.</p> | —                      |
| Life       | The lifetime of the SA, after which it expires, expressed either in seconds or kilobytes.                                                                                                                                                                                                                                                                                | —                      |
| Monitoring | Specifies if VPN-Liveliness Monitoring has been enabled/disabled. Enabled - 'U ', Disabled- '—'                                                                                                                                                                                                                                                                          | —                      |
| Vsys       | Specifies the root system.                                                                                                                                                                                                                                                                                                                                               | —                      |

## Monitoring IPsec VPN Information

**Purpose** View information about IPsec security (SAs).

**Action** Select **Monitor>IPSec VPN>IPsec VPN** in the J-Web user interface. To view the IPsec statistics information for a particular SA, select the IPsec SA ID value on the IPsec VPN page.

Alternatively, enter the following CLI commands:

- show security ipsec security-associations**
- show security ipsec statistics**

Table 206 summarizes key output fields in the IPsec VPN display.

Table 206: Summary of Key IPsec VPN Information Output Fields

| Field                       | Values | Additional Information |
|-----------------------------|--------|------------------------|
| IPsec Security Associations |        |                        |

Table 206: Summary of Key IPsec VPN Information Output Fields (*continued*)

| Field               | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Total configured SA | Total number of IPsec security associations (SAs) configured on the device.                                                                                                                                                                                                                                                                                                                                                                                       | —                                                                                 |
| ID                  | Index number of the SA.                                                                                                                                                                                                                                                                                                                                                                                                                                           | —                                                                                 |
| Gateway             | IP address of the remote gateway.                                                                                                                                                                                                                                                                                                                                                                                                                                 | —                                                                                 |
| Port                | If Network Address Translation (NAT-T) is used, this value is 4500. Otherwise, it is the standard IKE port, 500.                                                                                                                                                                                                                                                                                                                                                  | —                                                                                 |
| Algorithm           | <p>Cryptography used to secure exchanges between peers during the IKE Phase 2 negotiations:</p> <ul style="list-style-type: none"> <li>An authentication algorithm used to authenticate exchanges between the peers. Options are <b>hmac-md5-95</b> or <b>hmac-sha1-96</b>.</li> <li>An encryption algorithm used to encrypt data traffic. Options are <b>3des-cbc</b>, <b>aes-128-cbc</b>, <b>aes-192-cbc</b>, <b>aes-256-cbc</b>, or <b>des-cbc</b>.</li> </ul> | —                                                                                 |
| SPI                 | Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase 1 and Phase 2.                                                                                                  | —                                                                                 |
| Life: sec/kb        | The lifetime of the SA, after which it expires, expressed either in seconds or kilobytes.                                                                                                                                                                                                                                                                                                                                                                         | —                                                                                 |
| State               | <p>State has two options, <b>Installed</b> and <b>Not Installed</b>.</p> <ul style="list-style-type: none"> <li><b>Installed</b>—The security association is installed in the security association database.</li> <li><b>Not Installed</b>—The security association is not installed in the security association database.</li> </ul>                                                                                                                             | For <b>transport</b> mode, the value of <b>State</b> is always <b>Installed</b> . |
| Vsys                | The root system.                                                                                                                                                                                                                                                                                                                                                                                                                                                  | —                                                                                 |

| Virtual System                        | The root system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | —                      |

Table 206: Summary of Key IPsec VPN Information Output Fields (*continued*)

| Field           | Values                                                                                                                                                                                                                                                                                                                                                                                        | Additional Information |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Local Gateway   | Gateway address of the local system.                                                                                                                                                                                                                                                                                                                                                          | —                      |
| Remote Gateway  | Gateway address of the remote system.                                                                                                                                                                                                                                                                                                                                                         | —                      |
| Local identity  | Specifies the identity of the local peer so that its partner destination gateway can communicate with it. The value is specified as any of the following: IPv4 address, fully qualified domain name, e-mail address, or distinguished name.                                                                                                                                                   | —                      |
| Remote identity | IPv4 address of the destination peer gateway.                                                                                                                                                                                                                                                                                                                                                 | —                      |
| Df bit          | State of the don't fragment bit— <b>set</b> or <b>cleared</b> .                                                                                                                                                                                                                                                                                                                               | —                      |
| Policy name     | Name of the applicable policy.                                                                                                                                                                                                                                                                                                                                                                | —                      |
| Direction       | Direction of the security association— <b>inbound</b> , or <b>outbound</b> .                                                                                                                                                                                                                                                                                                                  | —                      |
| SPI             | Security parameter index (SPI) identifier. An SA is uniquely identified by an SPI. Each entry includes the name of the VPN, the remote gateway address, the SPIs for each direction, the encryption and authentication algorithms, and keys. The peer gateways each have two SAs, one resulting from each of the two phases of negotiation: Phase 1 and Phase 2.                              | —                      |
| Mode            | Mode of the security association. Mode can be transport or tunnel. <ul style="list-style-type: none"> <li>• <b>transport</b>—Protects host-to-host connections.</li> <li>• <b>tunnel</b>—Protects connections between security gateways.</li> </ul>                                                                                                                                           | —                      |
| Type            | Type of the security association, either <b>manual</b> or <b>dynamic</b> . <ul style="list-style-type: none"> <li>• <b>manual</b>—Security parameters require no negotiation. They are static and are configured by the user.</li> <li>• <b>dynamic</b>—Security parameters are negotiated by the IKE protocol. Dynamic security associations are not supported in transport mode.</li> </ul> | —                      |

Table 206: Summary of Key IPsec VPN Information Output Fields (*continued*)

| Field                     | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Additional Information                                                                                                                                                                                                                                        |

## Resource Monitoring Usage Computation Overview

---

You can configure the resource monitoring capability using both the configuration statements in the CLI and SNMP MIB queries. You can employ this utility to provision sufficient headroom (memory space limits that are set for the application or virtual router) for monitoring the health and operating efficiency of DPCs and MPCs. To configure the resource-monitoring capability on MX80, MX104, MX240, MX480, MX960, MX2010, and MX2020 routers. You can also analyze and view the usage or consumption of memory for the jtree memory type and for contiguous pages, double words, and free memory pages. The jtree memory on all MX Series router Packet Forwarding Engines has two segments: one segment primarily stores routing tables and related information, and the other segment primarily stores firewall-filter-related information. As the allocation of more memory for routing tables or firewall filters might disrupt the forwarding operations of a Packet Forwarding Engine, the Junos OS CLI displays a warning to restart all affected FPCs when you commit a configuration that includes the memory-enhanced route statement.

The following sections describe the computation equations and the interpretation of the different memory regions for I-chip-based and Trio-based line cards:

## Resource Monitoring and Usage Computation For Trio-Based Line Cards

In Trio-based line cards, memory blocks for next-hop and firewall filters are allocated separately. Also, an expansion memory is present, which is used when the allocated memory for next-hop or firewall filter is fully consumed. Both next-hop and firewall filters can allocate memory from the expansion memory. The encapsulation memory region is specific to I-chip-based line cards and it is not applicable to Trio-based line cards. Therefore, for Trio-based line cards, the percentage of free memory space can be interpreted as follows:

$$\% \text{ Free (NH)} = (1 - (\text{Used NH memory} + \text{Used Expansion memory}) / (\text{Total NH memory} + \text{Total Expansion memory})) \times 100$$
$$\% \text{ Free (Firewall or Filter)} = (1 - (\text{Used FW memory} + \text{Used Expansion memory}) / (\text{Total FW memory} + \text{Total Expansion memory})) \times 100$$

Encapsulation memory is I-chip-specific and is not applicable for Trio-based line cards.

% Free (Encap memory) = Not applicable

## Resource Monitoring and Usage Computation For I-Chip-Based Line Cards

I-chip-based line cards contain 32 MB of static RAM (SRAM) memory associated with the route lookup block and 16 MB of SRAM memory associated with the output WAN block.

The route-lookup memory is a single pool of 32 MB memory that is divided into two segments of 16 MB each. In a standard configuration, segment 0 is used for NH and prefixes, and segment 1 is used for firewall or filter. This allocation can be modified by using the route-memory-enhanced option at the [edit chassis] hierarchy level. In a general configuration, NH application can be allocated memory from any of the two segments. Therefore, the percentage of free memory for NH is calculated on 32 MB memory. Currently, firewall applications are allotted memory only from segment 1. As a result, the percentage of free memory to be monitored for firewall starts from the available 16 MB memory in segment 1 only.

For I-chip-based line cards, the percentage of free memory space can be interpreted as follows:

$$\% \text{ Free (NH)} = (32 - (\text{Used NH memory} + \text{Used FW memory} + \text{Used Other application})) / 32 \times 100$$
$$\% \text{ Free (Firewall or Filter)} = (16 - (\text{Used NH memory} + \text{Used FW memory} + \text{Used Other application})) / 16 \times 100$$

The memory size for Output WAN (lwo) SRAM is 16 MB and stores the Layer 2 descriptors that contain the encapsulation information. This entity is a critical resource and needs to be monitored. This memory space is displayed in the output of the show command as "Encap mem". The percentage of free memory for the encapsulation region is calculated as follows:

$\% \text{ Free (Encapsulation memory)} = (16 - (\text{two memory used (L2 descriptors + other applications)})) / 16 \times 100$

The watermark level configured for next-hop memory is also effective for encapsulation memory. Therefore, if the percentage of free memory for encapsulation region falls below the configured watermark, logs are generated.

If the free memory percentage is lower than the free memory watermark of a specific memory type, the following error message is recorded in the syslog:

**“Resource Monitor: FPC <slot no> PFE <pfe inst> <“JNH memory” or “FW/ Filter memory”> is below set watermark <configured watermark>”.**

You can configure resource-monitoring tracing operations by using the **traceoptions** file **<filename> flag flag level level size bytes** statement at the **[edit system services resource-monitor]** hierarchy level. By default, messages are written to **/var/log/rsmonlog**. The error logs associated with socket communication failure (between the Routing Engine and the Packet Forwarding Engine) are useful in diagnosing the problems in the communication between the Routing Engine and the Packet Forwarding Engine.

From the Ukern perspective, MPC5E contains only one Packet Forwarding Engine instance. The **show chassis fabric plane** command output displays the state of fabric plane connections to the Packet Forwarding Engine. Because two Packet Forwarding Engines exist, you notice PFE-0 and PFE-1 in the output.

```
user@host# run show chassis fabric plane
Fabric management PLANE state
Plane 0
 Plane state: ACTIVE
 FPC 0
 PFE 0 :Links ok
 PFE 1 :Links ok
```

Because only one Packet Forwarding Engine instance for MPC5E exists, the output of the **show system resource-monitor fpc** command displays only one row corresponding to Packet Forwarding Engine instance 0.

```
user@host# run show system resource-monitor fpc
FPC Resource Usage Summary
```

```
Free Heap Mem Watermark : 20 %
Free NH Mem Watermark : 20 %
Free Filter Mem Watermark : 20 %
```

\* - Watermark reached

|        | Heap   |       | ENCAP mem | NH mem | FW     |
|--------|--------|-------|-----------|--------|--------|
| mem    |        |       |           |        |        |
| Slot # | % Free | PFE # | % Free    | % Free | % Free |
| 0      | 94     | 0     |           | NA     | 83     |
| 99     |        |       |           |        |        |

The configured watermark is retained across GRES and unified ISSU procedures.

## Resource Monitoring Mechanism on MX Series Routers Overview

---

Junos OS supports a resource monitoring capability using both the configuration statements in the CLI interface and SNMP MIB queries. You can employ this utility to provision sufficient headroom (memory space limits that are set for the application or virtual router) for ensuring system stability, especially the health and operating efficiency of I-chip-based line cards and Trio-based FPCs on MX Series routers. When the memory utilization, either the ukernel memory or ASIC memory reaches a certain threshold, the system operations compromise on the health and traffic-handling stability of the line card and such a trade-off on the system performance can be detrimental for supporting live traffic and protocols. Besides the ability to configure a threshold to raise error logs when a specific threshold value of resources is exceeded, you can also monitor the threshold values and resource utilization using SNMP MIB queries. You can configure watermark or checkpoint values for the line card resources, such as ukern memory (heap), next-hop (NH) memory, and firewall or filter memory, to be uniform for both Trio-based and I-chip-based line cards. The NH memory watermark is applicable only for encapsulation memory (output WAN static RAM memory). Encapsulation memory is specific to I-chips and not applicable for Trio-based chips. When the configured watermark is exceeded, error logs are triggered. If the resource has been used above a certain threshold, warning system log messages are generated to notify about the threshold value having exceeded. Based on your network needs, you can then determine whether you want to terminate any existing subscribers and services to prevent the system from being overloaded and resulting in a breakdown. This feature gathers input from each of the line cards and transfers this statistical detail to the Routing Engine process using a well-known internal port. This information is scanned by the daemon on the Routine Engine and using the shared memory space built into the session database, warning messages are generated for exceeded threshold conditions.

The capability to configure resource monitoring is supported on the MX80, MX104 routers and on the following line cards on MX240, MX480, MX960, MX2010, and MX2020 routers:

- MX-MPC1-3D
- MX-MPC1-3D-Q
- MX-MPC2-3D
- MX-MPC2-3D-Q
- MX-MPC2-3D-EQ
- MPC-3D-16XGE-SFPP
- MPC3E
- MPC4E-3D-2CGE-8XGE
- MPC4E-3D-32XGE
- MPC5EQ-40G10G

- MPC5EQ-100G10G
- MPC5E-100G10G
- MPC5E-40G10G
- MX2K-MPC6E
- DPCE
- MS-DPC
- MX Series Flexible PIC Concentrators (MX-FPCs)

You can configure the following parameters at the **[edit system services]** hierarchy level to specify the high threshold value that is common for all the memory spaces or regions and the watermark values for the different memory blocks on DPCs and MPCs:

- High threshold value, exceeding which warnings or error logs are generated, for all the regions of memory, such as heap or ukernel, next-hop and encapsulation, and firewall filter memory, by using the **set resource-monitor high-threshold value** statement.
- Percentage of free memory space used for next-hops to be monitored with a watermark value by using the **set resource-monitor free-nh-memory-watermark percentage** statement.
- Percentage of free memory space used for ukernel or heap memory to be monitored with a watermark value by using the **set resource-monitor free-heap-memory-watermark percentage** statement.
- Percentage of free memory space used for firewall and filter memory to be monitored with a watermark value by using the **set resource-monitor free-filter-memory-watermark percentage** statement. This feature is enabled by default and you cannot disable it manually. The default value and the configured value of the watermark value for the percentage of free next-hop memory also applies to encapsulation memory.

The default watermark values for the percentage of free ukernel or heap memory, next-hop memory, and firewall filter memory are as follows:

- free-heap-memory-watermark—20
- free-nh-memory-watermark—20
- free-filter-memory-watermark—20

## Examining the Utilization of Memory Resource Regions Using show Commands

You can use the **show system resource-monitor fpc** command to monitor the utilization of memory resources on the Packet Forwarding Engines of an FPC. The filter memory denotes the filter counter memory used for firewall filter counters. The asterisk (\*) displayed next to each of the memory regions denotes the ones for which the configured threshold is being currently exceeded. Resource monitoring commands display the configured values of watermark for memories for different line card applications to be monitored. The displayed statistical metrics are based on the computation performed of the current memory utilization of the individual line cards. The ukern memory is generic across the different types of line cards and signifies the heap memory buffers. Because

a line card or an FPC in a particular slot can contain multiple Packet Forwarding Engine complexes, the memory utilized on the application-specific integrated circuits (ASICs) are specific to a particular PFE complex. Owing to different architecture models for different variants of line cards supported, the ASIC-specific memory (next-hop and firewall or filter memory) utilization percentage can be interpreted differently.

## Diagnosing and Debugging System Performance By Configuring Memory Resource Usage Monitoring on MX Series Routers

---

Junos OS supports a resource monitoring capability using both the configuration statements in the CLI interface and SNMP MIB queries. You can employ this utility to provision sufficient headroom (memory space limits that are set for the application or virtual router) for ensuring system stability, especially the health and operating efficiency of I-chip-based line cards and Trio-based FPCs on MX Series routers. When the memory utilization, either the ukernel memory or ASIC memory reaches a certain threshold, the system operations compromise on the health and traffic-handling stability of the line card and such a trade-off on the system performance can be detrimental for supporting live traffic and protocols. You can configure the resource-monitoring capability on MX80, MX104, MX240, MX480, MX960, MX2010, and MX2020 routers,

To configure the properties of the memory resource-utilization functionality:

1. Specify that you want to configure the monitoring mechanism for utilization of different memory resource regions.

```
[edit]
user@host# edit system services resource-monitor
```

This feature is enabled by default and you cannot disable it manually.

2. Specify the high threshold value, exceeding which warnings or error logs are generated, for all the regions of memory, such as heap or ukernel, next-hop and encapsulation, and firewall filter memory.

```
[edit system services resource-monitor]
user@host# set high-threshold value
```

3. Specify the percentage of free memory space used for next-hops to be monitored with a watermark value.

```
[edit system services resource-monitor]
user@host# set free-nh-memory-watermark percentage
```

4. Specify the percentage of free memory space used for ukernel or heap memory to be monitored with a watermark value.

```
[edit system services resource-monitor]
user@host# set free-heap-memory- watermark percentage
```

5. Specify the percentage of free memory space used for firewall and filter memory to be monitored with a watermark value.

```
[edit system services resource-monitor]
```

```
user@host# set free-filter-memory-memory- watermark percentage
```

**NOTE:**

The default value and the configured value of the watermark value for the percentage of free next-hop memory also applies to encapsulation memory. The default watermark values for the percentage of free ukernel or heap memory, next-hop memory, and firewall filter memory are 20 percent.

6. Disable the generation of error log messages when the utilization of memory resources exceeds the threshold or checkpoint levels. By default, messages are written to `/var/log/rsmonlog`.

```
[edit system services resource-monitor]
user@host# set no-logging
```

7. Define the resource category that you want to monitor and analyze for ensuring system stability, especially the health and operating efficiency of I-chip-based line cards and Trio-based FPCs on MX Series routers. The resource category includes detailed CPU utilization, session rate, and session count statistics. You use the resource category statistics to understand the extent to which new attack objects or applications affect performance.

```
[edit system services resource-monitor]
user@host# edit resource-category jtree
```

**NOTE:** The jtree memory on all MX Series router Packet Forwarding Engines has two segments: one segment primarily stores routing tables and related information, and the other segment primarily stores firewall-filter-related information. The Junos OS provides the memory-enhanced statement to reallocate the jtree memory for routes, firewall filters, and Layer 3 VPNs.

8. Configure the type of resource as contiguous pages for which you want to enable the monitoring mechanism to provide sufficient headroom for ensuring effective system performance and traffic-handling capacity. Specify the high and low threshold value, exceeding which warnings or error logs are generated, for the specified type or region of memory, which is contiguous page in this case.

```
[edit system services resource-monitor resource-category jtree]
user@host# set resource-type contiguous-pages high-threshold percentage
user@host# set resource-type contiguous-pages low-threshold percentage
```

9. Configure the type of resource as free double words (dwords) for which you want to enable the monitoring mechanism to provide sufficient headroom for ensuring effective system performance and traffic-handling capacity. Specify the high and low threshold value, exceeding which warnings or error logs are generated, for the specified type or region of memory, which is free dwords in this case.

```
[edit system services resource-monitor resource-category jtree]
```

```

user@host# set resource-type free-dwords high-threshold percentage
user@host# set resource-type free-dwords low-threshold percentage

```

10. Configure the type of resource as free memory pages for which you want to enable the monitoring mechanism to provide sufficient headroom for ensuring effective system performance and traffic-handling capacity. Specify the high and low threshold value, exceeding which warnings or error logs are generated, for the specified type or region of memory, which is free memory pages in this case.

```

[edit system services resource-monitor resource-category jtree]
user@host# set resource-type free-pages high-threshold percentage
user@host# set resource-type free-pages low-threshold percentage

```

11. View the utilization of memory resources on the Packet Forwarding Engines of an FPC by using the **show system resource-monitor fpc** command. The filter memory denotes the filter counter memory used for firewall filter counters. The asterisk (\*) displayed next to each of the memory regions denotes the ones for which the configured threshold is being currently exceeded.

```

user@host# run show system resource-monitor fpc
FPC Resource Usage Summary

```

```

Free Heap Mem Watermark : 20 %
Free NH Mem Watermark : 20 %
Free Filter Mem Watermark : 20 %

```

```
* - Watermark reached
```

| FW mem |        | Heap  |        | ENCAP mem |        | NH mem |  |
|--------|--------|-------|--------|-----------|--------|--------|--|
| Slot # | % Free | PFE # | % Free | % Free    | % Free | %      |  |
| Free   |        |       |        |           |        |        |  |
| 0      | 94     | 0     |        | NA        | 83     |        |  |
| 99     |        |       |        |           |        |        |  |

**Table 208: jnxPfeMemory Table**

| Object                             | Object ID             | Description                                                                                                                                                                                                       |
|------------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>jnxPfeMemoryUkernTable</b>      | <b>jnxPfeMemory 1</b> | Provides global ukern memory statistics for the specified Packet Forwarding Engine slot.                                                                                                                          |
| <b>jnxPfeMemoryForwardingTable</b> | <b>jnxPfeMemory 2</b> | Provides global next-hop (for Trio-based line cards) or Jtree (for I-chip-based line cards) memory utilization and firewall filter memory utilization statistics for the specified Packet Forwarding Engine slot. |

## Managed Objects for Next-Hop, Jtree, and Firewall Filter Memory for a Packet Forwarding Engine in an FPC Slot

The **jnxPfeMemoryForwardingTable**, whose object identifier is **{jnxPfeMemory 2}**, contains **JnxPfeMemoryForwardingEntry** that retrieves the next-hop memory for Trio-based line cards, jtree memory for I-chip-based line cards, and firewall or filter memory statistics for the specified Packet Forwarding Engine slot for both I-chip and Trio-based line cards. Each **jnxPfeMemoryForwardingEntry**, whose object identifier is **{jnxPfeMemoryForwardingTable 1}**, contains the objects listed in the following table.

The **jnxPfeMemoryForwardingEntry** represents the ASIC instance, ASIC memory used, and ASIC free memory. The jtree memory on all MX Series router Packet Forwarding Engines has two segments: one segment primarily stores routing tables and related information, and the other segment primarily stores firewall-filter-related information. As the allocation of more memory for routing tables or firewall filters might disrupt the forwarding operations of a Packet Forwarding Engine, the Junos OS CLI displays a warning to restart all affected FPCs when you commit a configuration that includes the memory-enhanced route statement. The configuration does not become effective until you restart the FPC or DPC (on MX Series routers).

**Table 209: jnxPfeMemoryForwardingTable**

| Object                                   | Object ID                            | Description                                                                          |
|------------------------------------------|--------------------------------------|--------------------------------------------------------------------------------------|
| <b>jnxPfeMemoryForwardingChipSlot</b>    | <b>jnxPfeMemoryForwardingEntry 1</b> | Indicates the ASIC instance number in the Packet Forwarding Engine complex.          |
| <b>jnxPfeMemoryType</b>                  | <b>jnxPfeMemoryForwardingEntry 2</b> | Indicates the Packet Forwarding Engine memory type, where nh = 1, fw = 2, encap = 3. |
| <b>jnxPfeMemoryForwardingPercentFree</b> | <b>jnxPfeMemoryForwardingEntry 3</b> | Indicates the percentage of memory free for each memory type.                        |

## jnxPfeMemoryErrorsTable

The Juniper Networks enterprise-specific Packet Forwarding Engine MIB, whose object ID is **{jnxPfeMibRoot 1}**, supports a new MIB table, **jnxPfeMemoryErrorsTable**, to display Packet Forwarding Engine memory error counters. The **jnxPfeMemoryErrorsTable**, whose object identifier is **jnxPfeNotification 3**, contains the **JnxPfeMemoryErrorsEntry**. Each **JnxPfeMemoryErrorsEntry**, whose object identifier is **{jnxPfeMemoryErrorsTable 1}**, contains the objects listed in the following table.

Table 210: jnxPfeMemoryErrorsTable

| Object             | Object ID                 | Description                                                    |
|--------------------|---------------------------|----------------------------------------------------------------|
| jnxPfeFpcSlot      | jnxPfeMemoryErrorsEntry 1 | Signifies the FPC slot number for this set of PFE notification |
| jnxPfeSlot         | jnxPfeMemoryErrorsEntry 2 | Signifies the PFE slot number for this set of errors           |
| jnxPfeParityErrors | jnxPfeMemoryErrorsEntry 3 | Signifies the parity error count                               |
| jnxPfeEccErrors    | jnxPfeMemoryErrorsEntry 4 | Signifies the error-checking code (ECC) error count            |

## pfeMemoryErrors

The **pfeMemoryErrorsNotificationPrefix**, whose object identifier is **{jnxPfeNotification 0}**, contains the **pfeMemoryErrors** attribute. The **pfeMemoryErrors** object, whose identifier is **{pfeMemoryErrorsNotificationPrefix 1}** contains the **jnxPfeParityErrors** and **jnxPfeEccErrors** objects.

Table 211: pfeMemoryErrors

| Object          | Object ID                           | Description                                                                                               |
|-----------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------|
| pfeMemoryErrors | pfeMemoryErrorsNotificationPrefix 1 | A pfeMemoryErrors notification is sent when the value of jnxPfeParityErrors or jnxPfeEccErrors increases. |

## Understanding Data Path Debugging for SRX Series Devices

---

Data path debugging, or end-to-end debugging, support provides tracing and debugging at multiple processing units along the packet-processing path. The packet filter can be executed with minimal impact to the production system.

On a high-end SRX Series device, a packet goes through series of events involving different components from ingress to egress processing.

With the data path debugging feature, you can trace and debug (capture packets) at different data points along the processing path. The events available in the packet-processing path are: NP ingress, load-balancing thread (LBT), jexec, packet-ordering thread (POT), and NP egress. You can also enable flow module trace if the security flow trace flag for a certain module is set.

At each event, you can specify any of the four actions (count, packet dump, packet summary, and trace). Data path debugging provides filters to define what packets to

capture, and only the matched packets are traced. The packet filter can filter out packets based on logical interface, protocol, source IP address prefix, source port, destination IP address prefix, and destination port.

To enable end-to-end debugging, you must perform the following steps:

1. Define the capture file and specify the maximum capture size.
2. Define the packet filter to trace only a certain type of traffic based on the requirement.
3. Define the action profile specifying the location on the processing path from where to capture the packets (for example, LBT or NP ingress).
4. Enable the data path debugging.
5. Capture traffic.
6. Disable data path debugging.
7. View or analyze the report.

**NOTE:**

The packet-filtering behavior for the port and interface options is as follows:

- The packet filter traces both IPv4 and IPv6 traffic if only **port** is specified.
  - The packet filter traces IPv4, IPV6, and non-IP traffic if only **interface** is specified.
-

---

## Debugging the Data Path (CLI Procedure)

---

To configure the device for data path debugging:

1. Specify the following request command to set the data path debugging for the multiple processing units along the packet-processing path:

```
[edit]
user@host# set security datapath-debug
```

2. Specify the trace options for data path-debug using the following command:

```
[edit]
user@host# set security datapath-debug traceoptions
```

- Using the request security packet-filter command, you can set the packet filter to specify the related packets to perform data path-debug action. A maximum of four filters are supported at the same time. For example, the following command sets the first packet-filter:

```
[edit]
user@host# set security datapath-debug packet-filter name
```

- Using the request security action-profile command, you can set the action for the packet match for a specified filter. Only the default action profile is supported, which is the trace option for network processor ezchip ingress, ezchip egress, spu.lbt, and spu.pot:

```
[edit]
user@host# set security datapath-debug packet-filter name action-profile
```

## Example: Configuring End-to-End Debugging on a High-End SRX Series Device

This example shows how to configure end-to-end debugging on an SRX Series device with an SRX5K-MPC.

- [Requirements on page 1895](#)
- [Overview on page 1895](#)
- [Configuration on page 1896](#)
- [Enabling Data Path Debugging on page 1898](#)
- [Verification on page 1898](#)

### Requirements

This example uses the following hardware and software components:

- SRX5600 device with an SRX5K-MPC installed with 100-Gigabit Ethernet CFP installed
- Junos OS Release 12.1X47-D15 or later for SRX Series devices

Before you begin:

- See *Understanding Data Path Debugging for SRX Series Devices*.

No special configuration beyond device initialization is required before configuring this feature.

### Overview

Data path debugging enhances troubleshooting capabilities by providing tracing and debugging at multiple processing units along the packet-processing path. With the data

path debugging feature, you can trace and debug (capture packets) at different data points along the processing path. At each event, you can specify an action (count, packet dump, packet summary, and trace) and you can set filters to define what packets to capture.

In this example, you define a traffic filter, then you apply an action profile. The action profile specifies a variety of actions on the processing unit. The NP ingress and NP egress are specified as location on the processing path to capture the data for incoming and outgoing traffic.

Next, you enable data path debugging in operational mode, and finally you view the data capture report.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security datapath-debug traceoptions file e2e.trace size 10m
set security datapath-debug capture-file datapcap format pcap
set security datapath-debug maximum-capture-size 1500
set security datapath-debug action-profile profile-1 preserve-trace-order
set security datapath-debug action-profile profile-1 record-pic-history
set security datapath-debug action-profile profile-1 event np-ingress trace
set security datapath-debug action-profile profile-1 event np-ingress count
set security datapath-debug action-profile profile-1 event np-ingress packet-summary
set security datapath-debug action-profile profile-1 event np-ingress packet-count
set security datapath-debug action-profile profile-1 event np-egress trace
set security datapath-debug action-profile profile-1 event np-egress count
set security datapath-debug action-profile profile-1 event np-egress packet-summary
set security datapath-debug action-profile profile-1 event np-egress packet-count
set security datapath-debug packet-filter filter-1
set security datapath-debug packet-filter filter-1 action-profile profile-1
set security datapath-debug packet-filter filter-1 protocol tcp
set security datapath-debug packet-filter filter-1 source-prefix 200.7.6.0/24
set security datapath-debug packet-filter filter-1 destination-prefix 200.8.6.0/24
set security datapath-debug packet-filter filter-1 source-port 1000
set security datapath-debug packet-filter filter-1 destination-port 80
set security datapath-debug packet-filter filter-1 interface xe-2/2/0.0
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure data path debugging:

1. Edit the security datapath-debug option for the multiple processing units along the packet-processing path:  

```
[edit]
user@host# edit security datapath-debug
```
2. Enable the capture file, file format, file size, and the number of files.

```
[edit security datapath-debug]
user@host# set traceoptions file e2e.trace size 10m
user@host# set capture-file datapcap format pcap;
user@host# set maximum-capture-size 1500
```

3. Configure action profile, event type, and actions for the action profile.

```
[edit security datapath-debug]
user@host# set action-profile profile-1 preserve-trace-order
user@host# set action-profile profile-1 record-pic-history
user@host# set action-profile profile-1 event np-ingress trace
user@host# set action-profile profile-1 event np-ingress count
user@host# set action-profile profile-1 event np-ingress packet-summary
user@host# set action-profile profile-1 event np-ingress packet-count
user@host# set action-profile profile-1 event np-egress trace
user@host# set action-profile profile-1 event np-egress count
user@host# set action-profile profile-1 event np-egress packet-summary
user@host# set action-profile profile-1 event np-egress packet-count
```

4. Configure packet filter, action, and filter options.

```
[edit security datapath-debug]
user@host# set packet-filter filter-1
user@host# set packet-filter filter-1 action-profile profile-1
user@host# set packet-filter filter-1 protocol tcp
user@host# set packet-filter filter-1 source-prefix 200.7.6.0/24
user@host# set packet-filter filter-1 destination-prefix 200.8.6.0/24
user@host# set packet-filter filter-1 source-port 1000
user@host# set packet-filter filter-1 destination-port 80
user@host# set packet-filter filter-1 interface xe-2/2/0.0
```

**Results** From configuration mode, confirm your configuration by entering the **show security datapath-debug** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
traceoptions {
 file e2e.trace size 10m;
}
capture-file datapcap format pcap;
maximum-capture-size 1500;
action-profile {
 profile-1 {
 preserve-trace-order;
 record-pic-history;
 event np-ingress {
 trace;
 count;
 packet-summary;
 packet-dump;
 }
 event np-egress {
 trace;
 count;
 packet-summary;
 packet-dump;
 }
 }
}
```

```
}
}
packet-filter filter-1 {
 action-profile profile-1;
 protocol tcp;
 source-prefix 200.7.6.0/24;
 destination-prefix 200.8.6.0/24;
 source-port 1000;
 destination-port 80;
 interface xe-2/2/0.0;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Enabling Data Path Debugging

- Step-by-Step Procedure** After configuring data path debugging, you must start the process on the device from operational mode.
1. Enable data path debugging.  

```
user@host> request security datapath-debug capture start
```

datapath-debug capture started on file datapcap
  2. Once you are done, you must disable data path debugging before you verify the configuration and view the reports.  

```
user@host> request security datapath-debug capture stop
```

datapath-debug capture successfully stopped, use show security datapath-debug capture to view

## Verification

Confirm that the configuration is working properly.

### Verifying Data Path Debug Packet Capture Details

---

**Purpose** Verify the data captured by enabling the data path debugging configuration.

**Action** From operational mode, enter the **show security datapath-debug capture** command.

```
Packet 8, len 152: (C2/F2/P0/SEQ:57935:np-ingress)
00 10 db ff 10 02 00 30 48 83 8d 4f 08 00 45 00
00 54 00 00 40 00 40 01 9f c7 c8 07 05 69 c8 08
05 69 08 00 91 1f 8f 03 2a a2 ae 66 85 53 8c 7d
02 00 08 09 0a 0b 0c 0d 0e 0f 10 11 12 13 14 15
16 17 18 19 1a 1b 1c 1d 1e 1f 20 21 22 23 24 25
26 27 28 29 2a 2b 2c 2d 2e 2f 30 31 32 33 34 35
36 37
Packet 9, len 152: (C2/F2/P0/SEQ:57935:np-egress)
00 30 48 8d 1a bf 00 10 db ff 10 03 08 00 45 00
00 54 00 00 40 00 3f 01 a0 c7 c8 07 05 69 c8 08
05 69 08 00 91 1f 8f 03 2a a2 ae 66 85 53 8c 7d
02 00 08 09 0a 0b 0c 0d 0e 0f 10 11 12 13 14 15
16 17 18 19 1a 1b 1c 1d 1e 1f 20 21 22 23 24 25
```

```
26 27 28 29 2a 2b 2c 2d 2e 2f 30 31 32 33 34 35
36 37....
```

For brevity, the **show** command output is truncated to display only a few samples. Additional samples have been replaced with ellipses (...).

To view the results, from CLI operational mode, access the local UNIX shell and navigate to the directory `/var/log/<file-name>`. The result can be read by using the **tcpdump** utility.

## Understanding Security Debugging Using Trace Options

The Junos OS trace function allows applications to write security debugging information to a file. The information that appears in this file is based on criteria you set. You can use this information to analyze security application issues.

The trace function operates in a distributed manner, with each thread writing to its own trace buffer. These trace buffers are then collected at one point, sorted, and written to trace files. Trace messages are delivered using the InterProcess Communications (IPC) protocol. A trace message has a lower priority than that of control protocol packets such as BGP, OSPF, and IKE, and therefore delivery is not considered to be as reliable.

## Setting Security Trace Options (CLI Procedure)

Use the following configuration statements to configure security trace options in the CLI configuration editor.

- To disable remote tracing, enter the following statement:

```
[edit]
user@host# set security traceoptions no-remote-trace
```

- To write trace messages to a local file, enter the following statement. The system saves the trace file in the `/var/log/` directory.

```
[edit]
user@host# set security traceoptions use-local-files
```

- To specify a name for the trace file, enter the following statement. Valid values range from 1 and 1024 characters. The name cannot include spaces, /, or % characters. The default filename is security.

```
[edit]
```

**user@host# set security traceoptions file *filename***

- To specify the maximum number of trace files that can accumulate, enter the following statement. Valid values range from 2 to 1000. The default value is 3.

**[edit]**

**user@host# set security traceoptions file files 3**

- To specify the match criteria that you want the system to use when logging information to the file, enter the following statement. Enter a regular expression. Wildcard (\*) characters are accepted.

**[edit]**

**user@host# set security traceoptions file match \*thread**

- To allow any user to read the trace file, enter the **world-readable** statement. Otherwise, enter the **no-world-readable** statement.

**[edit]**

**user@host# set security traceoptions file world-readable**

**user@host# set security traceoptions file no-world-readable**

- To specify the maximum size to which the trace file can grow, enter the following statement. Once the file reaches the specified size, it is compressed and renamed *filename0.gz*, the next file is named *filename1.gz*, and so on. Valid values range from 10240 to 1,073,741,824.

**[edit]**

**user@host# set security traceoptions file size 10240**

- To turn on trace options and to perform more than one tracing operation, set the following flags.

**[edit]**

**user@host# set security traceoptions flag all**

**user@host# set security traceoptions flag compilation**

**user@host# set security traceoptions flag configuration**

**user@host# set security traceoptions flag routing-socket**

- To specify the groups that these trace option settings do or do not apply to, enter the following statements:

**[edit]**

**user@host# set security traceoptions apply-groups *value***

**user@host# set security traceoptions apply-groups-except *value***

---

## Displaying Log and Trace Files

Enter the **monitor start** command to display real-time additions to system logs and trace files:

**user@host> monitor start *filename***

When the device adds a record to the file specified by *filename*, the record displays on the screen. For example, if you have configured a system log file named **system-log** (by including the **syslog** statement at the [edit system] hierarchy level), you can enter the **monitor start system-log** command to display the records added to the system log.

To display a list of files that are being monitored, enter the **monitor list** command. To stop the display of records for a specified file, enter the **monitor stop filename** command.

- Related Documentation**
- [Displaying a List of Devices on page 1906](#)
  - [Displaying Real-Time Monitoring Information on page 1757](#)

## Displaying Output for Security Trace Options

**Purpose** Display output for security trace options.

**Action** Use the **show security traceoptions** command to display the output of your trace files. For example:

```
[edit]
user@host # show security traceoptions file usp_trace
user@host # show security traceoptions flag all
user@host # show security traceoptions rate-limit 888
```

The output for this example is as follows:

```
Apr 11 16:06:42 21:13:15.750395:CID-906489336:FPC-01:PIC-01:THREAD_ID-01:PFE:now

## Displaying Multicast Trace Operations

To monitor and display multicast trace operations, enter the **mtrace monitor** command:

```
user@host> mtrace monitor
```

```
Mtrace query at Apr 21 16:00:54 by 192.1.30.2, resp to 224.0.1.32, qid 2a83aa
packet from 192.1.30.2 to 224.0.0.2 from 192.1.30.2 to 192.1.4.1 via group
224.1.1.1 (mxhop=60) Mtrace query at Apr 21 16:00:57 by 192.1.30.2, resp to
224.0.1.32, qid 25dc17 packet from 192.1.30.2 to 224.0.0.2 from 192.1.30.2 to
192.1.4.1 via group 224.1.1.1 (mxhop=60) Mtrace query at Apr 21 16:01:00 by
192.1.30.2, resp to same, qid 20e046 packet from 192.1.30.2 to 224.0.0.2 from
192.1.30.2 to 192.1.4.1 via group 224.1.1.1 (mxhop=60) Mtrace query at Apr 21
16:01:10 by 192.1.30.2, resp to same, qid 1d25ad packet from 192.1.30.2 to
224.0.0.2 from 192.1.30.2 to 192.1.4.1 via group 224.1.1.1 (mxhop=60)
```

This example displays only **mtrace** queries. However, when the device captures an **mtrace** response, the display is similar, but the complete **mtrace** response also appears (exactly as it is appears in the **mtrace from-source** command output).

Table 212 summarizes the output fields of the display.

Table 212: CLI mtrace monitor Command Output Summary

| Field                                       | Description                                                                                                                                                                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mtrace operation-type at time-of-day</b> | <ul style="list-style-type: none"> <li><b>operation-type</b>—Type of multicast trace operation: <b>query</b> or <b>response</b>.</li> <li><b>time-of-day</b>—Date and time the multicast trace query or response was captured.</li> </ul> |
| <b>by</b>                                   | IP address of the host issuing the query.                                                                                                                                                                                                 |
| <b>resp to address</b>                      | <b>address</b> —Response destination address.                                                                                                                                                                                             |
| <b>qid qid</b>                              | <b>qid</b> —Query ID number.                                                                                                                                                                                                              |
| <b>packet from source to destination</b>    | <ul style="list-style-type: none"> <li><b>source</b>—IP address of the source of the query or response.</li> <li><b>destination</b>—IP address of the destination of the query or response.</li> </ul>                                    |
| <b>from source to destination</b>           | <ul style="list-style-type: none"> <li><b>source</b>—IP address of the multicast source.</li> <li><b>destination</b>—IP address of the multicast destination.</li> </ul>                                                                  |
| <b>via group address</b>                    | <b>address</b> —Group address being traced.                                                                                                                                                                                               |
| <b>mxhop=number</b>                         | <b>number</b> —Maximum hop setting.                                                                                                                                                                                                       |

## Using the J-Web Traceroute Tool

You can use the traceroute diagnostic tool to display a list of devices between the device and a specified destination host. The output is useful for diagnosing a point of failure in the path from the device to the destination host, and addressing network traffic latency and throughput problems.

The device generates the list of devices by sending a series of ICMP traceroute packets in which the time-to-live (TTL) value in the messages sent to each successive device is incremented by 1. (The TTL value of the first traceroute packet is set to 1.) In this manner, each device along the path to the destination host replies with a Time Exceeded packet from which the source IP address can be obtained.

To use the traceroute tool:

1. Select **Troubleshoot>Traceroute**.
2. Next to Advanced options, click the expand icon.
3. Enter information into the Traceroute page (see [Table 213](#)).

**Table 213: Traceroute Field Summary**

| Field                   | Function                                                                                                                                                                                                                                                                                     | Your Action                                                                                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote Host             | Identifies the destination host of the traceroute.<br><br>The <b>Remote Host</b> field is the only required field.                                                                                                                                                                           | Type the hostname or IP address of the destination host.                                                                                                                                                                                                                           |
| <b>Advanced Options</b> |                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                    |
| Don't Resolve Addresses | Determines whether hostnames of the hops along the path are displayed, in addition to IP addresses.                                                                                                                                                                                          | <ul style="list-style-type: none"> <li>• Suppress the display of the hop hostnames by selecting the check box.</li> <li>• Display the hop hostnames by clearing the check box.</li> </ul>                                                                                          |
| Gateway                 | Specifies the IP address of the gateway to route through.                                                                                                                                                                                                                                    | Type the gateway IP address.                                                                                                                                                                                                                                                       |
| Source Address          | Specifies the source address of the outgoing traceroute packets.                                                                                                                                                                                                                             | Type the source IP address.                                                                                                                                                                                                                                                        |
| Bypass Routing          | Determines whether traceroute packets are routed by means of the routing table.<br><br>If the routing table is not used, traceroute packets are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, traceroute responses are not sent. | <ul style="list-style-type: none"> <li>• Bypass the routing table and send the traceroute packets to hosts on the specified interface only by selecting the check box.</li> <li>• Route the traceroute packets by means of the routing table by clearing the check box.</li> </ul> |
| Interface               | Specifies the interface on which the traceroute packets are sent.                                                                                                                                                                                                                            | Select the interface on which traceroute packets are sent from the list. If you select <b>any</b> , the traceroute requests are sent on all interfaces.                                                                                                                            |
| Time-to-Live            | Specifies the maximum time-to-live (TTL) hop count for the traceroute request packet.                                                                                                                                                                                                        | Select the TTL from the list.                                                                                                                                                                                                                                                      |
| Type-of-Service         | Specifies the type-of-service (TOS) value to include in the IP header of the traceroute request packet.                                                                                                                                                                                      | Select the decimal value of the TOS field from the list.                                                                                                                                                                                                                           |
| Resolve AS Numbers      | Determines whether the autonomous system (AS) number of each intermediate hop between the device and the destination host is displayed.                                                                                                                                                      | <ul style="list-style-type: none"> <li>• Display the AS numbers by selecting the check box.</li> <li>• Suppress the display of the AS numbers by clearing the check box.</li> </ul>                                                                                                |

4. Click **Start**.

The results of the traceroute operation are displayed in the main pane. If no options are specified, each line of the traceroute display is in the following format:

*hop-number host (ip-address) [as-number]time1 time2 time3*

The device sends a total of three traceroute packets to each router along the path and the round-trip time for each traceroute operation appears. If the device times out before receiving a **Time Exceeded** message, an asterisk (\*) appears for that round-trip time.

5. You can stop the traceroute operation before it is complete by clicking **OK** while the results of the traceroute operation appear.

## J-Web Traceroute Results and Output Summary

Table 214 summarizes the output in the traceroute display.

Table 214: J-Web Traceroute Results and Output Summary

| Field             | Description                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hop-number</i> | Number of the hop (device) along the path.                                                                                                                   |
| <i>host</i>       | Hostname, if available, or IP address of the device. If the Don't Resolve Addresses check box is selected, the hostname does not appear.                     |
| <i>ip-address</i> | IP address of the device.                                                                                                                                    |
| <i>as-number</i>  | AS number of the device.                                                                                                                                     |
| <i>time1</i>      | Round-trip time between the sending of the first traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device.  |
| <i>time2</i>      | Round-trip time between the sending of the second traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device. |
| <i>time3</i>      | Round-trip time between the sending of the third traceroute packet and the receiving of the corresponding Time Exceeded packet from that particular device.  |

If the device does not display the complete path to the destination host, one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host, or a router along the path, might be configured to ignore ICMP traceroute messages.
- The host, or a device along the path, might be configured with a firewall filter that blocks ICMP traceroute requests or ICMP time exceeded responses.
- The value you selected in the Time Exceeded box was less than the number of hops in the path to the host. In this case, the host might reply with an ICMP error message.

## Understanding Flow Debugging Using Trace Options

For flow trace options, you can define a packet filter using combinations of **destination-port**, **destination-prefix**, **interface**, **protocol**, **source-port**, and **source-prefix**. If the security flow trace flag for a certain module is set, the packet matching the specific packet filter triggers flow tracing and writes debugging information to the trace file.

## Setting Flow Debugging Trace Options (CLI Procedure)

The following examples display the options you can set by using **security flow traceoptions**.

- To match the imap destination port for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 destination-port imap
```

- To set the 1.2.3.4 destination IPv4 prefix address for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 destination-prefix 1.2.3.4
```

- To set the fxp0 logical interface for the filter1 packet filter, use the following statement:

```
[edit]
```

```
user@host# set security flow traceoptions packet-filter filter1 interface fxp0
```

- To match the TCP IP protocol for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 protocol tcp
```

- To match the HTTP source port for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 source-port http
```

- To set the 5.6.7.8 IPv4 prefix address for the filter1 packet filter, use the following statement:

```
[edit]
user@host# set security flow traceoptions packet-filter filter1 source-prefix 5.6.7.8
```

## Displaying a List of Devices

To display a list of devices between the device and a specified destination host, enter the **traceroute** command with the following syntax:

```
user@host> traceroute host <interface interface-name> <as-number-lookup>
<bypass-routing> <gateway address> <inet | inet6> <no-resolve>
<routing-instance routing-instance-name> <source source-address> <tos number>
<tll number> <wait seconds>
```

[Table 215](#) describes the **traceroute** command options.

**Table 215: CLI traceroute Command Options**

| Option                          | Description                                                                                                                                                                                                                                                                                                              |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>                     | Sends traceroute packets to the hostname or IP address you specify.                                                                                                                                                                                                                                                      |
| <i>interface interface-name</i> | (Optional) Sends the traceroute packets on the interface you specify. If you do not include this option, traceroute packets are sent on all interfaces.                                                                                                                                                                  |
| <i>as-number-lookup</i>         | (Optional) Displays the autonomous system (AS) number of each intermediate hop between the device and the destination host.                                                                                                                                                                                              |
| <i>bypass-routing</i>           | (Optional) Bypasses the routing tables and sends the traceroute packets only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.<br><br>Use this option to display a route to a local system through an interface that has no route through it. |
| <i>gateway address</i>          | (Optional) Uses the gateway you specify to route through.                                                                                                                                                                                                                                                                |
| <i>inet</i>                     | (Optional) Forces the traceroute packets to an IPv4 destination.                                                                                                                                                                                                                                                         |
| <i>inet6</i>                    | (Optional) Forces the traceroute packets to an IPv6 destination.                                                                                                                                                                                                                                                         |

Table 215: CLI traceroute Command Options (*continued*)

| Option                                                  | Description                                                                                                                    |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>no-resolve</b>                                       | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                 |
| <b>routing-instance</b><br><i>routing-instance-name</i> | (Optional) Uses the routing instance you specify for the traceroute.                                                           |
| <b>source address</b>                                   | (Optional) Uses the source address that you specify, in the traceroute packet.                                                 |
| <b>tos number</b>                                       | (Optional) Sets the type-of-service (TOS) value in the IP header of the traceroute packet. Specify a value from 0 through 255. |
| <b>ttl number</b>                                       | (Optional) Sets the time-to-live (TTL) value for the traceroute packet. Specify a hop count from 0 through 128.                |
| <b>wait seconds</b>                                     | (Optional) Sets the maximum time to wait for a response.                                                                       |

To quit the **traceroute** command, press Ctrl-C.

The following is sample output from a **traceroute** command:

```

user@host> traceroute host2

traceroute to 173.24.232.66 (172.24.230.41), 30 hops max, 40 byte packets 1
173.18.42.253 (173.18.42.253) 0.482 ms 0.346 ms 0.318 ms 2 host4.site1.net
(173.18.253.5) 0.401 ms 0.435 ms 0.359 ms 3 host5.site1.net (173.18.253.5)
0.401 ms 0.360 ms 0.357 ms 4 173.24.232.65 (173.24.232.65) 0.420 ms 0.456
ms 0.378 ms 5 173.24.232.66 (173.24.232.66) 0.830 ms 0.779 ms 0.834 ms

```

The fields in the display are the same as those displayed by the J-Web traceroute diagnostic tool.

## MPLS Connection Checking Overview

---

Use either the J-Web ping MPLS diagnostic tool or the CLI commands **ping mpls**, **ping mpls l2circuit**, **ping mpls l2vpn**, and **ping mpls l3vpn** to diagnose the state of label-switched paths (LSPs), Layer 2 and Layer 3 virtual private networks (VPNs), and Layer 2 circuits.

Based on how the LSP or VPN outbound (egress) node at the remote endpoint of the connection replies to the probes, you can determine the connectivity of the LSP or VPN.

Each probe is an echo request sent to the LSP or VPN exit point as an MPLS packet with a UDP payload. If the outbound node receives the echo request, it checks the contents of the probe and returns a value in the UDP payload of the response packet. If the device receives the response packet, it reports a successful ping response.

Responses that take longer than 2 seconds are identified as failed probes.

[Table 216](#) summarizes the options for using either the J-Web ping MPLS diagnostic tool or the CLI **ping mpls** command to display information about MPLS connections in VPNs and LSPs.

Table 216: Options for Checking MPLS Connections

| J-Web Ping MPLS Tool                        | ping mpls Command                   | Purpose                                                                                                                                                                                                                                                                                                                                 | Additional Information                                                                                                                                                                            |
|---------------------------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ping RSVP-signaled LSP                      | ping mpls rsvp                      | Checks the operability of an LSP that has been set up by the Resource Reservation Protocol (RSVP). The device pings a particular LSP using the configured LSP name.                                                                                                                                                                     | When an RSVP-signaled LSP has several paths, the device sends the ping requests on the path that is currently active.                                                                             |
| Ping LDP-signaled LSP                       | ping mpls ldp                       | Checks the operability of an LSP that has been set up by the Label Distribution Protocol (LDP). The device pings a particular LSP using the forwarding equivalence class (FEC) prefix and length.                                                                                                                                       | When an LDP-signaled LSP has several gateways, the device sends the ping requests through the first gateway.<br><br>Ping requests sent to LDP-signaled LSPs use only the master routing instance. |
| Ping LSP to Layer 3 VPN prefix              | ping mpls l3vpn                     | Checks the operability of the connections related to a Layer 3 VPN. The device tests whether a prefix is present in a provider edge (PE) device's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix.                                                                                                 | The device does not test the connection between a PE device and a customer edge (CE) router.                                                                                                      |
| Locate LSP using interface name             | ping mpls l2vpn interface           | Checks the operability of the connections related to a Layer 2 VPN. The device directs outgoing request probes out the specified interface.                                                                                                                                                                                             | —                                                                                                                                                                                                 |
| Instance to which this connection belongs   | ping mpls l2vpn instance            | Checks the operability of the connections related to a Layer 2 VPN. The device pings on a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, to test the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the inbound and outbound PE routers. | —                                                                                                                                                                                                 |
| Locate LSP from interface name              | ping mpls l2circuit interface       | Checks the operability of the Layer 2 circuit connections. The device directs outgoing request probes out the specified interface.                                                                                                                                                                                                      | —                                                                                                                                                                                                 |
| Locate LSP from virtual circuit information | ping mpls l2circuit virtual-circuit | Checks the operability of the Layer 2 circuit connections. The device pings on a combination of the IPv4 prefix and the virtual circuit identifier on the outbound PE router, testing the integrity of the Layer 2 circuit between the inbound and outbound PE routers.                                                                 | —                                                                                                                                                                                                 |

Table 216: Options for Checking MPLS Connections (*continued*)

| J-Web Ping MPLS Tool  | ping mpls Command       | Purpose                                                                                                                                     | Additional Information |
|-----------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Ping end point of LSP | ping mpls lsp-end-point | Checks the operability of an LSP endpoint. The device pings an LSP endpoint using either an LDP FEC prefix or an RSVP LSP endpoint address. | —                      |

## Configuring Ping MPLS

Before using the ping MPLS feature, make sure that the receiving interface on the VPN or LSP remote endpoint has MPLS enabled, and that the loopback interface on the outbound node is configured as **127.0.0.1**. The source address for MPLS probes must be a valid address on the device.

- **MPLS Enabled**—To process ping MPLS requests, the remote endpoint of the VPN or LSP must be configured appropriately. You must enable MPLS on the receiving interface of the outbound node for the VPN or LSP. If MPLS is not enabled, the remote endpoint drops the incoming request packets and returns an “ICMP host unreachable” message to the device.
- **Loopback Address**—The loopback address (**lo0**) on the outbound node must be configured as **127.0.0.1**. If this interface address is not configured correctly, the outbound node does not have this forwarding entry. It drops the incoming request packets and returns a “host unreachable” message to the device.
- **Source Address for Probes**—The source IP address you specify for a set of probes must be an address configured on one of the device interfaces. If it is not a valid device address, the ping request fails with the error message “Can’t assign requested address.”

## Using the ping Command

You can perform certain tasks only through the CLI. Use the CLI **ping** command to verify that a host can be reached over the network. This command is useful for diagnosing host and network connectivity problems. The device sends a series of ICMP echo (ping) requests to a specified host and receives ICMP echo responses.

Enter the **ping** command with the following syntax:

```
user@host> ping host <interface source-interface> <bypass-routing> <count number>
<do-not-fragment> <inet | inet6> <interval seconds> <loose-source [hosts]>
<no-resolve> <pattern string> <rapid> <record-route>
<routing-instance routing-instance-name> <size bytes> <source source-address> <strict>
<strict-source [hosts]> <tos number> <tll number> <wait seconds> <detail> <verbose>
```

Table 217 describes the **ping** command options.

To quit the **ping** command, press Ctrl-C.

**Table 217: CLI ping Command Options**

| Option                            | Description                                                                                                                                                                                                                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i>                       | Pings the hostname or IP address you specify.                                                                                                                                                                                                                                                         |
| <i>interface source-interface</i> | (Optional) Sends the ping requests on the interface you specify. If you do not include this option, ping requests are sent on all interfaces.                                                                                                                                                         |
| <i>bypass-routing</i>             | (Optional) Bypasses the routing tables and sends the ping requests only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.<br><br>Use this option to ping a local system through an interface that has no route through it. |
| <i>count number</i>               | (Optional) Limits the number of ping requests to send. Specify a count from 1 through 2,000,000,000. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.                                                                                                       |
| <i>do-not-fragment</i>            | (Optional) Sets the Don't Fragment (DF) bit in the IP header of the ping request packet.                                                                                                                                                                                                              |
| <i>inet</i>                       | (Optional) Forces the ping requests to an IPv4 destination.                                                                                                                                                                                                                                           |
| <i>inet6</i>                      | (Optional) Forces the ping requests to an IPv6 destination.                                                                                                                                                                                                                                           |
| <i>interval seconds</i>           | (Optional) Sets the interval between ping requests, in seconds. Specify an interval from 0.1 through 10,000. The default value is 1 second.                                                                                                                                                           |
| <i>loose-source [hosts]</i>       | (Optional) For IPv4, sets the loose source routing option in the IP header of the ping request packet.                                                                                                                                                                                                |
| <i>no-resolve</i>                 | (Optional) Suppresses the display of the hostnames of the hops along the path.                                                                                                                                                                                                                        |
| <i>pattern string</i>             | (Optional) Includes the hexadecimal string you specify, in the ping request packet.                                                                                                                                                                                                                   |

Table 217: CLI ping Command Options (*continued*)

| Option                                                  | Description                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rapid</b>                                            | (Optional) Sends ping requests rapidly. The results are reported in a single message, not in individual messages for each ping request. By default, five ping requests are sent before the results are reported. To change the number of requests, include the <b>count</b> option. |
| <b>record-route</b>                                     | (Optional) For IPv4, sets the record route option in the IP header of the ping request packet. The path of the ping request packet is recorded within the packet and displayed on the screen.                                                                                       |
| <b>routing-instance</b><br><b>routing-instance-name</b> | (Optional) Uses the routing instance you specify for the ping request.                                                                                                                                                                                                              |
| <b>size bytes</b>                                       | (Optional) Sets the size of the ping request packet. Specify a size from <b>0</b> through <b>65,468</b> . The default value is <b>56</b> bytes, which is effectively 64 bytes because 8 bytes of ICMP header data are added to the packet.                                          |
| <b>source source-address</b>                            | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                                                                                    |
| <b>strict</b>                                           | (Optional) For IPv4, sets the strict source routing option in the IP header of the ping request packet.                                                                                                                                                                             |
| <b>strict-source [hosts]</b>                            | (Optional) For IPv4, sets the strict source routing option in the IP header of the ping request packet, and uses the list of hosts you specify for routing the packet.                                                                                                              |
| <b>tos number</b>                                       | (Optional) Sets the type-of-service (TOS) value in the IP header of the ping request packet. Specify a value from <b>0</b> through <b>255</b> .                                                                                                                                     |
| <b>ttl number</b>                                       | (Optional) Sets the time-to-live (TTL) value for the ping request packet. Specify a value from <b>0</b> through <b>255</b> .                                                                                                                                                        |
| <b>wait seconds</b>                                     | (Optional) Sets the maximum time to wait after sending the last ping request packet. If you do not specify this option, the default delay is <b>10</b> seconds. If you use this option without the <b>count</b> option, the device uses a default count of <b>5</b> packets.        |
| <b>detail</b>                                           | (Optional) Displays the interface on which the ping response was received.                                                                                                                                                                                                          |
| <b>verbose</b>                                          | (Optional) Displays detailed output.                                                                                                                                                                                                                                                |

The following is sample output from a **ping** command:

```

user@host> ping host3 count 4

PING host3.site.net (176.26.232.111): 56 data bytes 64 bytes from 176.26.232.111:
icmp_seq=0 ttl=122 time=0.661 ms 64 bytes from 176.26.232.111: icmp_seq=1 ttl=122
time=0.619 ms 64 bytes from 176.26.232.111: icmp_seq=2 ttl=122 time=0.621 ms 64
bytes from 176.26.232.111: icmp_seq=3 ttl=122 time=0.634 ms --- host3.site.net
ping statistics --- 4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.619/0.634/0.661/0.017 ms

```

The fields in the display are the same as those displayed by the J-Web ping host diagnostic tool.

## Using the J-Web Ping Host Tool

You can ping a host to verify that the host can be reached over the network. The output is useful for diagnosing host and network connectivity problems. The device sends a series of ICMP echo (ping) requests to a specified host and receives ICMP echo responses.

Alternatively, you can use the CLI **ping** command. (See [“Using the ping Command” on page 1912.](#))

To use the ping host tool:

1. Select **Troubleshoot>Ping Host** from the task bar.
2. Next to Advanced options, click the expand icon.
3. Enter information into the Ping Host page (see [Table 218](#)).

**Table 218: J-Web Ping Host Field Summary**

| Field                   | Function                                                                           | Your Action                                                                                                                                                                               |
|-------------------------|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote Host             | Identifies the host to ping.<br><br>This is the only required field.               | Type the hostname or IP address of the host to ping.                                                                                                                                      |
| <b>Advanced Options</b> |                                                                                    |                                                                                                                                                                                           |
| Don't Resolve Addresses | Determines whether to display hostnames of the hops along the path.                | <ul style="list-style-type: none"> <li>• Suppress the display of the hop hostnames by selecting the check box.</li> <li>• Display the hop hostnames by clearing the check box.</li> </ul> |
| Interface               | Specifies the interface on which the ping requests are sent.                       | Select the interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces.                                              |
| Count                   | Specifies the number of ping requests to send.                                     | Select the number of ping requests to send from the list.                                                                                                                                 |
| Don't Fragment          | Specifies the Don't Fragment (DF) bit in the IP header of the ping request packet. | <ul style="list-style-type: none"> <li>• Set the DF bit by selecting the check box.</li> <li>• Clear the DF bit by clearing the check box.</li> </ul>                                     |

Table 218: J-Web Ping Host Field Summary (*continued*)

| Field            | Function                                                                                                                                                                                                                                                                            | Your Action                                                                                                                                                                                                                                                    |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Record Route     | Sets the record route option in the IP header of the ping request packet. The path of the ping request packet is recorded within the packet and displayed in the main pane.                                                                                                         | <ul style="list-style-type: none"> <li>Record and display the path of the packet by selecting the check box.</li> <li>Suppress the recording and display of the path of the packet by clearing the check box.</li> </ul>                                       |
| Type-of-Service  | Specifies the type-of-service (TOS) value in the IP header of the ping request packet.                                                                                                                                                                                              | Select the decimal value of the TOS field from the list.                                                                                                                                                                                                       |
| Routing Instance | Names the routing instance for the ping attempt.                                                                                                                                                                                                                                    | Select the routing instance name from the list.                                                                                                                                                                                                                |
| Interval         | Specifies the interval, in seconds, between the transmission of each ping request.                                                                                                                                                                                                  | Select the interval from the list.                                                                                                                                                                                                                             |
| Packet Size      | Specifies the size of the ping request packet.                                                                                                                                                                                                                                      | Type the size, in bytes, of the packet. The size can be from 0 through 65,468. The device adds 8 bytes of ICMP header to the size.                                                                                                                             |
| Source Address   | Specifies the source address of the ping request packet.                                                                                                                                                                                                                            | Type the source IP address.                                                                                                                                                                                                                                    |
| Time-to-Live     | Specifies the time-to-live (TTL) hop count for the ping request packet.                                                                                                                                                                                                             | Select the TTL from the list.                                                                                                                                                                                                                                  |
| Bypass Routing   | <p>Determines whether ping requests are routed by means of the routing table.</p> <p>If the routing table is not used, ping requests are sent only to hosts on the interface specified in the Interface box. If the host is not on that interface, ping responses are not sent.</p> | <ul style="list-style-type: none"> <li>Bypass the routing table and send the ping requests to hosts on the specified interface only by selecting the check box.</li> <li>Route the ping requests using the routing table by clearing the check box.</li> </ul> |

4. Click **Start**.

The results of the ping operation appear in the main pane. If no options are specified, each ping response is in the following format:

*bytes bytes from ip-address: icmp\_seq=number ttl=number time=time*

5. You can stop the ping operation before it is complete by clicking **OK**.

## J-Web Ping Host Results and Output Summary

Table 219 summarizes the output in the ping host display.

Table 219: Ping Host Results and Output

| Ping Host Result                                                                       | Description                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bytes bytes from ip-address</i>                                                     | <ul style="list-style-type: none"> <li><b>bytes</b>—Size of ping response packet, which is equal to the value you entered in the Packet Size box, plus 8.</li> <li><b>ip-address</b>—IP address of destination host that sent the ping response packet.</li> </ul>                                            |
| <i>icmp_seq=0</i><br><i>icmp_seq=number</i>                                            | <b>number</b> —Sequence Number field of the ping response packet. You can use this value to match the ping response to the corresponding ping request.                                                                                                                                                        |
| <i>ttl=number</i>                                                                      | <b>number</b> —Time-to-live hop-count value of the ping response packet.                                                                                                                                                                                                                                      |
| <i>number packets transmitted</i>                                                      | <b>number</b> —Number of ping requests (probes) sent to host.                                                                                                                                                                                                                                                 |
| <i>percentage packet loss</i>                                                          | <b>percentage</b> —Number of ping responses divided by the number of ping requests, specified as a percentage.                                                                                                                                                                                                |
| <i>round-trip min/avg/max/stddev =</i><br><i>min-time/avg-time/max-time/std-dev ms</i> | <ul style="list-style-type: none"> <li><b>min-time</b>—Minimum round-trip time (see <b>time=time</b> field in this table).</li> <li><b>avg-time</b>—Average round-trip time.</li> <li><b>max-time</b>—Maximum round-trip time.</li> <li><b>std-dev</b>—Standard deviation of the round-trip times.</li> </ul> |

If the device does not receive ping responses from the destination host (the output shows a packet loss of 100 percent), one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host might be configured to ignore ICMP echo requests.
- The host might be configured with a firewall filter that blocks ICMP echo requests or ICMP echo responses.
- The size of the ICMP echo request packet exceeds the MTU of a host along the path.
- The value you selected in the Time-to-Live box was less than the number of hops in the path to the host, in which case the host might reply with an ICMP error message.

## Using the J-Web Ping MPLS Tool

Before using the ping MPLS feature, make sure that the receiving interface on the VPN or LSP remote endpoint has MPLS enabled, and that the loopback interface on the outbound node is configured as **127.0.0.1**. The source address for MPLS probes must be a valid address on the device.

To use the ping MPLS tool:

1. Select **Troubleshoot>Ping MPLS** from the task bar.
2. Next to the ping MPLS option you want to use, click the expand icon.
3. Enter information into the Ping MPLS page (see [Table 220](#)).

**Table 220: J-Web Ping MPLS Field Summary**

| Field                                 | Function                                                         | Your Action                                                                          |
|---------------------------------------|------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>Ping RSVP-signaled LSP</b>         |                                                                  |                                                                                      |
| LSP Name                              | Identifies the LSP to ping.                                      | Type the name of the LSP to ping.                                                    |
| Source Address                        | Specifies the source address of the ping request packet.         | Type the source IP address—a valid address configured on a device interface.         |
| Count                                 | Specifies the number of ping requests to send.                   | Select the number of ping requests to send from the list. The default is 5 requests. |
| Detailed Output                       | Requests the display of extensive rather than brief ping output. | Select the check box to display detailed output.                                     |
| <b>Ping LDP-signaled LSP</b>          |                                                                  |                                                                                      |
| FEC Prefix                            | Identifies the LSP to ping.                                      | Type the forwarding equivalence class (FEC) prefix and length of the LSP to ping.    |
| Source Address                        | Specifies the source address of the ping request packet.         | Type the source IP address—a valid address configured on a device interface.         |
| Count                                 | Specifies the number of ping requests to send.                   | Select the number of ping requests to send from the list. The default is 5 requests. |
| Detailed Output                       | Requests the display of extensive rather than brief ping output. | Select the check box to display detailed output.                                     |
| <b>Ping LSP to Layer 3 VPN prefix</b> |                                                                  |                                                                                      |
| Layer 3 VPN Name                      | Identifies the Layer 3 VPN to ping.                              | Type the name of the VPN to ping.                                                    |
| Count                                 | Specifies the number of ping requests to send.                   | Select the number of ping requests to send from the list. The default is 5 requests. |

Table 220: J-Web Ping MPLS Field Summary (*continued*)

| Field                                            | Function                                                                | Your Action                                                                                                                                         |
|--------------------------------------------------|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Detailed Output                                  | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| VPN Prefix                                       | Identifies the IP address prefix and length of the Layer 3 VPN to ping. | Type the IP address prefix and length of the VPN to ping.                                                                                           |
| Source Address                                   | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| <b>Locate LSP using interface name</b>           |                                                                         |                                                                                                                                                     |
| Interface                                        | Specifies the interface on which the ping requests are sent.            | Select the device interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces. |
| Source Address                                   | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Count                                            | Specifies the number of ping requests to send.                          | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                                  | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| <b>Instance to which this connection belongs</b> |                                                                         |                                                                                                                                                     |
| Layer 2VPN Name                                  | Identifies the Layer 2 VPN to ping.                                     | Type the name of the VPN to ping.                                                                                                                   |
| Remote Site Identifier                           | Specifies the remote site identifier of the Layer 2 VPN to ping.        | Type the remote site identifier for the VPN.                                                                                                        |
| Source Address                                   | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |
| Local Site Identifier                            | Specifies the local site identifier of the Layer 2 VPN to ping.         | Type the local site identifier for the VPN.                                                                                                         |
| Count                                            | Specifies the number of ping requests to send.                          | Select the number of ping requests to send from the list. The default is 5 requests.                                                                |
| Detailed Output                                  | Requests the display of extensive rather than brief ping output.        | Select the check box to display detailed output.                                                                                                    |
| <b>Locate LSP from interface name</b>            |                                                                         |                                                                                                                                                     |
| Interface                                        | Specifies the interface on which the ping requests are sent.            | Select the device interface on which ping requests are sent from the list. If you select <b>any</b> , the ping requests are sent on all interfaces. |
| Source Address                                   | Specifies the source address of the ping request packet.                | Type the source IP address—a valid address configured on a device interface.                                                                        |

Table 220: J-Web Ping MPLS Field Summary (*continued*)

| Field                                              | Function                                                                       | Your Action                                                                                     |
|----------------------------------------------------|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list. The default is 5 requests.            |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                |
| <b>Locate LSP from virtual circuit information</b> |                                                                                |                                                                                                 |
| Remote Neighbor                                    | Identifies the remote neighbor (PE device) within the virtual circuit to ping. | Type the IP address of the remote neighbor within the virtual circuit.                          |
| Circuit Identifier                                 | Specifies the virtual circuit identifier for the Layer 2 circuit to ping.      | Type the virtual circuit identifier for the Layer 2 circuit.                                    |
| Source Address                                     | Specifies the source address of the ping request packet.                       | Type the source IP address—a valid address configured on a device interface.                    |
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list.                                       |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                |
| <b>Ping end point of LSP</b>                       |                                                                                |                                                                                                 |
| VPN Prefix                                         | Identifies the LSP endpoint to ping.                                           | Type either the LDP FEC prefix and length or the RSVP LSP endpoint address for the LSP to ping. |
| Source Address                                     | Specifies the source address of the ping request packet.                       | Type the source IP address—a valid address configured on a device interface.                    |
| Count                                              | Specifies the number of ping requests to send.                                 | Select the number of ping requests to send from the list.                                       |
| Detailed Output                                    | Requests the display of extensive rather than brief ping output.               | Select the check box to display detailed output.                                                |

4. Click **Start**.
5. You can stop the ping operation before it is complete by clicking **OK**.

## J-Web Ping MPLS Results and Output Summary

Table 221 summarizes the output in the ping MPLS display.

**Table 221: J-Web Ping MPLS Results and Output Summary**

| Field                             | Description                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Exclamation point (!)             | Echo reply was received.                                                                                                                                                                    |
| Period (.)                        | Echo reply was not received within the timeout period.                                                                                                                                      |
| x                                 | Echo reply was received with an error code. Errored packets are not counted in the received packets count and are accounted for separately.                                                 |
| <i>number packets transmitted</i> | <i>number</i> —Number of ping requests (probes) sent to a host.                                                                                                                             |
| <i>number packets received</i>    | <i>number</i> —Number of ping responses received from a host.                                                                                                                               |
| <i>percentage packet loss</i>     | <i>percentage</i> —Number of ping responses divided by the number of ping requests, specified as a percentage.                                                                              |
| <i>time</i>                       | For Layer 2 circuits only, the number of milliseconds required for the ping packet to reach the destination. This value is approximate, because the packet has to reach the Routing Engine. |

If the device does not receive ping responses from the destination host (the output shows a packet loss of 100 percent), one of the following explanations might apply:

- The host is not operational.
- There are network connectivity problems between the device and the host.
- The host might be configured to ignore echo requests.
- The host might be configured with a firewall filter that blocks echo requests or echo responses.
- The size of the echo request packet exceeds the MTU of a host along the path.
- The outbound node at the remote endpoint is not configured to handle MPLS packets.
- The remote endpoint's loopback address is not configured to 127.0.0.1.

## Pinging Layer 2 Circuits

Enter the **ping mpls l2circuit** command with the following syntax:

```
user@host> ping mpls l2circuit (interface interface-name | virtual-circuit neighbor
 prefix-name virtual-circuit-id) <exp forwarding-class> <count number>
 <source source-address> <detail>
```

Table 222 describes the **ping mpls l2circuit** command options.

Table 222: CLI ping mpls l2circuit Command Options

| Option                                                                                              | Description                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l2circuit interface</b><br><i>interface-name</i>                                                 | Sends ping requests out the specified interface configured for the Layer 2 circuit on the outbound PE device.                                                                                                       |
| <b>l2circuit virtual-circuit</b><br><b>neighbor</b> <i>prefix-name</i><br><i>virtual-circuit-id</i> | Pings on a combination of the IPv4 prefix and the virtual circuit identifier on the outbound PE device, testing the integrity of the Layer 2 circuit between the inbound and outbound PE devices.                   |
| <b>exp forwarding-class</b>                                                                         | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                         |
| <b>count</b> <i>number</i>                                                                          | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C. |
| <b>source</b> <i>source-address</i>                                                                 | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                    |
| <b>detail</b>                                                                                       | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                |

To quit the **ping mpls l2circuit** command, press Ctrl-C.

The following is sample output from a **ping mpls l2circuit** command:

```
user@host> ping mpls l2circuit interface fe-1/0/0.0
```

```
Request for seq 1, to interface 69, labels <100000, 100208>
```

```
Reply for seq 1, return code: Egress-ok, time: 0.439 ms
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

## Pinging Layer 2 VPNs

Enter the **ping mpls l2vpn** command with the following syntax:

```
user@host> ping mpls l2vpn interface interface-name | instance l2vpn-instance-name
local-site-id local-site-id-number remote-site-id remote-site-id-number
<bottom-label-ttl> <exp forwarding-class> <count number> <source source-address>
<detail>
```

Table 223 describes the **ping mpls l2vpn** command options.

**Table 223: CLI ping mpls l2vpn Command Options**

| Option                                                                                                                                                              | Description                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l2vpn interface</b><br><i>interface-name</i>                                                                                                                     | Sends ping requests out the specified interface configured for the Layer 2 VPN on the outbound (egress) PE device.                                                                                                                                                 |
| <b>l2vpn instance</b><br><i>l2vpn-instance-name</i><br><i>local-site-id</i><br><i>local-site-id-number</i><br><i>remote-site-id</i><br><i>remote-site-id-number</i> | Pings on a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier, testing the integrity of the Layer 2 VPN circuit (specified by the identifiers) between the inbound (ingress) and outbound PE devices. |
| <b>bottom-label-ttl</b>                                                                                                                                             | (Optional) Displays the time-to-live (TTL) value for the bottom label in the MPLS label stack.                                                                                                                                                                     |
| <b>exp forwarding-class</b>                                                                                                                                         | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                                                                        |
| <b>countnumber</b>                                                                                                                                                  | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.                                                |
| <b>source source-address</b>                                                                                                                                        | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                                                                   |
| <b>detail</b>                                                                                                                                                       | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                                                               |

To quit the **ping mpls l2vpn** command, press Ctrl-C.

The following is sample output from a **ping mpls l2vpn** command:

```
user@host> ping mpls l2vpn instance vpn1 remote-site-id 1 local-site-id 2 detail
Request for seq 1, to interface 68, labels <800001, 100176>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <800001, 100176>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <800001, 100176>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <800001, 100176>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <800001, 100176>
Reply for seq 5, return code: Egress-ok
```

```
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

## Pinging Layer 3 VPNs

Enter the **ping mpls l3vpn** command with the following syntax:

```
user@host> ping mpls l3vpn prefix prefix-name <l3vpn-name> <bottom-label-ttl>
<exp forwarding-class> <count number> <source source-address> <detail>
```

[Table 224](#) describes the **ping mpls l3vpn** command options.

**Table 224: CLI ping mpls l3vpn Command Options**

| Option                                 | Description                                                                                                                                                                                                                   |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l3vpn prefix <i>prefix-name</i></b> | Pings the remote host specified by the prefix to verify that the prefix is present in the PE device's VPN routing and forwarding (VRF) table. This option does not test the connectivity between a PE device and a CE device. |
| <b><i>l3vpn-name</i></b>               | (Optional) Layer 3 VPN name.                                                                                                                                                                                                  |
| <b>bottom-label-ttl</b>                | (Optional) Displays the time-to-live (TTL) value for the bottom label in the MPLS label stack.                                                                                                                                |
| <b>exp <i>forwarding-class</i></b>     | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                                   |
| <b>count<i>number</i></b>              | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C.           |
| <b>source <i>source-address</i></b>    | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                              |
| <b>detail</b>                          | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                          |

To quit the **ping mpls l3vpn** command, press Ctrl-C.

The following is sample output from a **ping mpls l3vpn** command:

```

user@host> ping mpls l3vpn vpn1 prefix 10.255.245.122/32
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

## Pinging RSVP-Signaled LSPs and LDP-Signaled LSPs

Enter the **ping mpls** command with the following syntax:

```

user@host> ping mpls (ldp fec | lsp-end-point prefix-name | rsvp lsp-name)
<exp forwarding-class> <count number> <source source-address> <detail>

```

[Table 225](#) describes the **ping mpls** command options.

**Table 225: CLI ping mpls ldp and ping mpls lsp-end-point Command Options**

| Option                           | Description                                                                                                                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ldp fec</b>                   | Pings an LDP-signaled LSP identified by the forwarding equivalence class (FEC) prefix and length.                                                                                                                   |
| <b>lsp-end-point prefix-name</b> | Pings an LSP endpoint using either an LDP FEC or a RSVP LSP endpoint address.                                                                                                                                       |
| <b>rsvp lsp-name</b>             | Pings an RSVP-signaled LSP identified by the specified LSP name.                                                                                                                                                    |
| <b>exp forwarding-class</b>      | (Optional) Specifies the value of the forwarding class to be used in the MPLS ping packets.                                                                                                                         |
| <b>countnumber</b>               | (Optional) Limits the number of ping requests to send. Specify a count from 0 through 1,000,000. The default value is 5. If you do not specify a count, ping requests are continuously sent until you press Ctrl-C. |
| <b>source source-address</b>     | (Optional) Uses the source address that you specify, in the ping request packet.                                                                                                                                    |
| <b>detail</b>                    | (Optional) Displays detailed output about the echo requests sent and received. Detailed output includes the MPLS labels used for each request and the return codes for each request.                                |

To quit the **ping mpls** command, press Ctrl-C.

The following is sample output from a **ping mpls** command:

```
user@host> ping mpls rsvp count 5
```

```
!!xxx
```

```
--- lsping statistics ---
```

```
5 packets transmitted, 2 packets received, 60% packet loss
```

```
3 packets received with error status, not counted as received.
```

The fields in the display are the same as those displayed by the J-Web ping MPLS diagnostic tool.

## Packet Capture Overview

---

Packet capture is a tool that helps you to analyze network traffic and troubleshoot network problems. The packet capture tool captures real-time data packets traveling over the network for monitoring and logging.

**NOTE:** Packet capture is supported on physical interfaces, reth interfaces, and tunnel interfaces, such as gr, ip, st0, and lsq-/ls.

Packets are captured as binary data, without modification. You can read the packet information offline with a packet analyzer such as Ethereal or tcpdump. If you need to quickly capture packets destined for, or originating from, the Routing Engine and analyze them online, you can use the J-Web packet capture diagnostic tool.

**NOTE:** The packet capture tool does not support IPv6 packet capture.

You can use either the J-Web configuration editor or CLI configuration editor to configure packet capture.

Network administrators and security engineers use packet capture to perform the following tasks:

- Monitor network traffic and analyze traffic patterns.
- Identify and troubleshoot network problems.
- Detect security breaches in the network, such as unauthorized intrusions, spyware activity, or ping scans.

Packet capture operates like traffic sampling on the device, except that it captures entire packets including the Layer 2 header and saves the contents to a file in libpcap format. Packet capture also captures IP fragments. You cannot enable packet capture and traffic sampling on the device at the same time. Unlike traffic sampling, there are no tracing operations for packet capture.

**NOTE:** You can enable packet capture and port mirroring simultaneously on a device.

This section contains the following topics:

- [Packet Capture on Device Interfaces on page 1928](#)
- [Firewall Filters for Packet Capture on page 1929](#)
- [Packet Capture Files on page 1929](#)
- [Analysis of Packet Capture Files on page 1929](#)

## Packet Capture on Device Interfaces

Packet capture is supported on the T1, T3, E1, E3, serial, Fast Ethernet, ADSL, G.SHDSL, PPPoE, and ISDN interfaces.

To capture packets on an ISDN interface, configure packet capture on the dialer interface. To capture packets on a PPPoE interface, configure packet capture on the PPPoE logical interface.

Packet capture supports PPP, Cisco HDLC, Frame Relay, and other ATM encapsulations. Packet capture also supports Multilink PPP (MLPPP), Multilink Frame Relay end-to-end (MLFR), and Multilink Frame Relay UNI/NNI (MFR) encapsulations.

You can capture all IPv4 packets flowing on an interface in the inbound or outbound direction. However, on traffic that bypasses the flow software module (protocol packets such as ARP, OSPF, and PIM), packets generated by the Routing Engine are not captured unless you have configured and applied a firewall filter on the interface in the outbound direction.

Tunnel interfaces can support packet capture in the outbound direction only.

Use the J-Web configuration editor or CLI configuration editor to specify the maximum packet size, the filename to be used for storing the captured packets, the maximum file size, the maximum number of packet capture files, and the file permissions.

**NOTE:** For packets captured on T1, T3, E1, E3, serial, and ISDN interfaces in the outbound (egress) direction, the size of the packet captured might be 1 byte less than the maximum packet size configured because of the packet loss priority (PLP) bit.

To modify encapsulation on an interface that has packet capture configured, you must first disable packet capture.

## Firewall Filters for Packet Capture

When you enable packet capture on a device, all packets flowing in the direction specified in packet capture configuration (inbound, outbound, or both) are captured and stored. Configuring an interface to capture all packets might degrade the performance of the device. You can control the number of packets captured on an interface with firewall filters and specify various criteria to capture packets for specific traffic flows.

You must also configure and apply appropriate firewall filters on the interface if you need to capture packets generated by the host device, because interface sampling does not capture packets originating from the host device.

## Packet Capture Files

When packet capture is enabled on an interface, the entire packet including the Layer 2 header is captured and stored in a file. You can specify the maximum size of the packet to be captured, up to 1500 bytes. Packet capture creates one file for each physical interface. You can specify the target filename, the maximum size of the file, and the maximum number of files.

File creation and storage take place in the following way. Suppose you name the packet capture file **pcap-file**. Packet capture creates multiple files (one per physical interface), suffixing each file with the name of the physical interface; for example, **pcap-file.fe-0.0.1** for the Fast Ethernet interface **fe-0.0.1**. When the file named **pcap-file.fe-0.0.1** reaches the maximum size, the file is renamed **pcap-file.fe-0.0.1.0**. When the file named **pcap-file.fe-0.0.1** reaches the maximum size again, the file named **pcap-file.fe-0.0.1.0** is renamed **pcap-file.fe-0.0.1.1** and **pcap-file.fe-0.0.1** is renamed **pcap-file.fe-0.0.1.0**. This process continues until the maximum number of files is exceeded and the oldest file is overwritten. The **pcap-file.fe-0.0.1** file is always the latest file.

Packet capture files are not removed even after you disable packet capture on an interface.

## Analysis of Packet Capture Files

Packet capture files are stored in libpcap format in the **/var/tmp** directory. You can specify user or administrator privileges for the files.

Packet capture files can be opened and analyzed offline with tcpdump or any packet analyzer that recognizes the libpcap format. You can also use FTP or the Session Control Protocol (SCP) to transfer the packet capture files to an external device.

**NOTE:** Disable packet capture before opening the file for analysis or transferring the file to an external device with FTP or SCP. Disabling packet capture ensures that the internal file buffer is flushed and all the captured packets are written to the file.

---

## Example: Enabling Packet Capture on a Device

---

This example shows how to enable packet capture on a device, allowing you to analyze network traffic and troubleshoot network problems

- [Requirements on page 1930](#)
- [Overview on page 1930](#)
- [Configuration on page 1930](#)
- [Verification on page 1932](#)

### Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

### Overview

In this example, you set the maximum packet capture size in each file as 500 bytes. The range is from 68 through 1500, and the default is 68 bytes. You specify the target filename for the packet capture file as pcap-file. You then specify the maximum number of files to capture as 100. The range is from 2 through 10,000, and the default is 10 files. You set the maximum size of each file to 1024 bytes. The range is from 1,024 through 104,857,600, and the default is 512,000 bytes. Finally, you specify that all users have permission to read the packet capture files.

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set forwarding-options packet-capture maximum-capture-size 500
set forwarding-options packet-capture file filename pcap-file files 100 size 1024
world-readable
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To enable packet capture on a device:

1. Set the maximum packet capture size.  

```
[edit]
user@host# edit forwarding-options
user@host# set packet-capture maximum-capture-size 500
```
2. Specify the target filename.  

```
[edit forwarding-options]
user@host# set packet-capture file filename pcap-file
```
3. Specify the maximum number of files to capture.  

```
[edit forwarding-options]
user@host# set packet-capture file files 100
```
4. Specify the maximum size of each file.  

```
[edit forwarding-options]
user@host# set packet-capture file size 1024
```
5. Specify that all users have permission to read the file.  

```
[edit forwarding-options]
user@host# set packet-capture file world-readable
```

**Results** From configuration mode, confirm your configuration by entering the **show forwarding-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show forwarding-options
packet-capture {
 file filename pcap-file files 100 size 1k world-readable;
 maximum-capture-size 500;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Packet Capture Configuration on page 1932](#)
- [Verifying Captured Packets on page 1932](#)

### Verifying the Packet Capture Configuration

**Purpose** Verify that the packet capture is configured on the device.

**Action** From configuration mode, enter the **show forwarding-options** command. Verify that the output shows the intended file configuration for capturing packets.

### Verifying Captured Packets

**Purpose** Verify that the packet capture file is stored under the **/var/tmp** directory and the packets can be analyzed offline.

**Action** 1. Disable packet capture.

Using FTP, transfer a packet capture file (for example, **126b.fe-0.0.1**), to a server where you have installed packet analyzer tools (for example, **tools-server**).

a. From configuration mode, connect to **tools-server** using FTP.

```
[edit]
user@host# run ftp tools-server
Connected to tools-server.mydomain.net
220 tools-server.mydomain.net FTP server (Version 6.00LS) ready
Name (tools-server:user):remoteuser
331 Password required for remoteuser.
Password:
230 User remoteuser logged in.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp>
```

b. Navigate to the directory where packet capture files are stored on the device.

```
ftp> lcd /var/tmp
Local directory now /cf/var/tmp
```

c. Copy the packet capture file that you want to analyze to the server, for example **126b.fe-0.0.1**.

```
ftp> put 126b.fe-0.0.1
local: 126b.fe-0.0.1 remote: 126b.fe-0.0.1
200 PORT command successful.
150 Opening BINARY mode data connection for '126b.fe-0.0.1'.
100% 1476 00:00 ETA
226 Transfer complete.
1476 bytes sent in 0.01 seconds (142.42 KB/s)
```

d. Return to configuration mode.

```
ftp> bye
221 Goodbye.
[edit]
user@host#
```

2. Open the packet capture file on the server with tcpdump or any packet analyzer that supports libpcap format and review the output.

```
root@server% tcpdump -r 126b.fe-0.0.1 -xvvvv

01:12:36.279769 Out 0:5:85:c4:e3:d1 > 0:5:85:c8:f6:d1, ethertype IPv4 (0x0800),

- [Disabling Packet Capture on page 1940](#)

## Example: Configuring Packet Capture on an Interface

This example shows how to configure packet capture on an interface to analyze traffic.

- [Requirements on page 1934](#)
- [Overview on page 1934](#)
- [Configuration on page 1934](#)
- [Verification on page 1935](#)

## Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

## Overview

In this example, you create an interface called fe-0/0/1. You then configure the direction of the traffic for which you are enabling packet capture on the logical interface as inbound and outbound.

**NOTE:** On traffic that bypasses the flow software module (protocol packets such as ARP, OSPF, and PIM), packets generated by the Routing Engine are not captured unless you have configured and applied a firewall filter on the interface in the output direction.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
edit interfaces fe-0/0/1
set unit 0 family inet sampling input output
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To configure packet capture on an interface:

1. Create an interface.

```
[edit]
user@host# edit interfaces fe-0/0/1
```

2. Configure the direction of the traffic.

```
[edit interfaces fe-0/0/1]
user@host# set unit 0 family inet sampling input output
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

## Verification

### Verifying the Packet Capture Configuration

---

|                              |                                                                                                    |

## Example: Configuring a Firewall Filter for Packet Capture

---

This example shows how to configure a firewall filter for packet capture and apply it to a logical interface.

- [Requirements on page 1935](#)
- [Overview on page 1935](#)
- [Configuration on page 1936](#)
- [Verification on page 1937](#)

## Requirements

Before you begin:

- Establish basic connectivity.
- Configure network interfaces. See *Interfaces Feature Guide for Security Devices*.

## Overview

In this example, you set a firewall filter called dest-all and a term name called dest-term to capture packets from a specific destination address, which is 192.168.1.1/32. You define the match condition to accept the sampled packets. Finally, you apply the dest-all filter to all of the outgoing packets on interface fe-0/0/1.

**NOTE:** If you apply a firewall filter on the loopback interface, it affects all traffic to and from the Routing Engine. If the firewall filter has a `sample` action, packets to and from the Routing Engine are sampled. If packet capture is enabled, then packets to and from the Routing Engine are captured in the files created for the input and output interfaces.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall filter dest-all term dest-term from destination-address 192.168.1.1/32
set firewall filter dest-all term dest-term then sample accept
edit interfaces
set interfaces fe-0/0/1 unit 0 family inet filter output dest-all
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure a firewall filter for packet capture and apply it to a logical interface:

1. Specify the firewall filter and its destination address.

```
[edit]
user@host# edit firewall
user@host# set filter dest-all term dest-term from destination-address 192.168.1.1/32
```

2. Define the match condition and its action.

```
[edit firewall]
user@host# set filter dest-all term dest-term then sample accept
```

3. Apply the filter to all the outgoing packets.

```
[edit interfaces]
user@host# set interfaces fe-0/0/1 unit 0 family inet filter output dest-all
```

**Results** From configuration mode, confirm your configuration by entering the **show firewall filter dest-all** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show firewall filter dest-all
term dest-term {
 from {
 destination-address 192.168.1.1/32;
 }
 then {
 sample;
 accept;
 }
}
```

```
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

### Verifying the Firewall Filter for Packet Capture Configuration

**Purpose** Confirm that the configuration is working properly.

Verify that the firewall filter for packet capture is configured.

**Action** From configuration mode, enter the **show firewall filter dest-all** command. Verify that the output shows the intended configuration of the firewall filter for capturing packets sent to the destination address.

#### Related Documentation

- [Packet Capture Overview on page 1927](#)
- [Example: Configuring Packet Capture on an Interface on page 1933](#)
- [Example: Enabling Packet Capture on a Device on page 1930](#)
- [Deleting Packet Capture Files on page 1941](#)
- [Disabling Packet Capture on page 1940](#)

## Example: Configuring Packet Capture for Datapath Debugging

This example shows how to configure packet capture to monitor traffic that passes through the device. Packet capture then dumps the packets into a PCAP file format that can be later examined by the tcpdump utility.

- [Requirements on page 1937](#)
- [Overview on page 1937](#)
- [Configuration on page 1938](#)
- [Verification on page 1939](#)

## Requirements

Before you begin, see “[Debugging the Data Path \(CLI Procedure\)](#)” on page 1894.

## Overview

A filter is defined to filter traffic; then an action profile is applied to the filtered traffic. The action profile specifies a variety of actions on the processing unit. One of the supported actions is packet dump, which sends the packet to the Routing Engine and stores it in proprietary form to be read using the **show security datapath-debug capture** command.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security datapath-debug capture-file my-capture
set security datapath-debug capture-file format pcap
set security datapath-debug capture-file size 1m
set security datapath-debug capture-file files 5
set security datapath-debug maximum-capture-size 400
set security datapath-debug action-profile do-capture event np-ingress packet-dump
set security datapath-debug packet-filter my-filter action-profile do-capture
set security datapath-debug packet-filter my-filter source-prefix 1.2.3.4/32
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure packet capture:

1. Edit the security datapath-debug option for the multiple processing units along the packet-processing path:

```
[edit]
user@host# edit security datapath-debug
```

2. Enable the capture file, the file format, the file size, and the number of files. Size number limits the size of the capture file. After the limit size is reached, if the file number is specified, then the capture file will be rotated to filename *x*, where *x* is auto-incremented until it reaches the specified index and then returns to zero. If no files index is specified, the packets will be discarded after the size limit is reached. The default size is 512 kilobytes.

```
[edit security datapath-debug]
user@host# set capture-file my-capture format pcap size 1m files 5
[edit security datapath-debug]
user@host# set maximum-capture-size 400
```

3. Enable action profile and set the event. Set the action profile as do-capture and the event type as np-ingress:

```
[edit security datapath-debug]
user@host# edit action-profile do-capture
[edit security datapath-debug action-profile do-capture]
user@host# edit event np-ingress
```

4. Enable packet dump for the action profile:

```
[edit security datapath-debug action-profile do-capture event np-ingress]
user@host# set packet-dump
```

5. Enable packet filter, action, and filter options. The packet filter is set to my-filter, the action profile is set to do-capture, and filter option is set to source-prefix 1.2.3.4/32.

```
[edit security datapath-debug]
user@host# set security datapath-debug packet-filter my-filter action-profile
do-capture

[edit security datapath-debug]
user@host# set security datapath-debug packet-filter my-filter source-prefix
1.2.3.4/32
```

**Results** From configuration mode, confirm your configuration by entering the **show security datapath-debug** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it. The following is **show security datapath-debug** output from the **show security datapath-debug** command:

```
security {
 datapath-debug {
 capture-file {
 my-capture
 format pcap
 size 1m
 files 5;
 }
 }
 maximum-capture-size 100;
 action-profile do-capture {
 event np-ingress {
 packet-dump
 }
 }
 packet-filter my-filter {
 source-prefix 1.2.3.4/32
 action-profile do-capture
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying Packet Capture on page 1939](#)
- [Verifying Data Path Debugging Capture on page 1940](#)
- [Verifying Data Path Debugging Counter on page 1940](#)

### Verifying Packet Capture

**Purpose** Verify if the packet capture is working.

**Action** From operational mode, enter the **request security datapath-debug capture start** command to start packet capture and enter the **request security datapath-debug capture stop** command to stop packet capture.

To view the results, from CLI operational mode, access the local UNIX shell and navigate to the directory `/var/log/my-capture`. The result can be read by using the `tcpdump` utility.

---

### Verifying Data Path Debugging Capture

---

**Purpose** Verify the details of data path debugging capture file.

**Action** From operational mode, enter the `show security datapath-debug capture` command.

```
user@host>show security datapath-debug capture
```

**WARNING:** When you are done troubleshooting, make sure to remove or deactivate all the traceoptions configurations (not limited to flow traceoptions) and the complete security datapath-debug configuration stanza. If any debugging configurations remain active, they will continue to use the device's CPU and memory resources.

---

---

### Verifying Data Path Debugging Counter

---

**Purpose** Verify the details of the data path debugging counter.

**Action** From operational mode, enter the `show security datapath-debug counter` command.

**Related Documentation**

- [Packet Capture Overview on page 1927](#)
- [Understanding Data Path Debugging for SRX Series Devices on page 1893](#)
- [Debugging the Data Path \(CLI Procedure\) on page 1894](#)

---

## Disabling Packet Capture

---

You must disable packet capture before opening the packet capture file for analysis or transferring the file to an external device. Disabling packet capture ensures that the internal file buffer is flushed and all the captured packets are written to the file.

To disable packet capture, enter from configuration mode:

```
[edit forwarding-options]
user@host# set packet-capture disable
```

If you are done configuring the device, enter **commit** from configuration mode.

**Related Documentation**

- [Packet Capture Overview on page 1927](#)
- [Example: Configuring Packet Capture on an Interface on page 1933](#)
- [Example: Configuring a Firewall Filter for Packet Capture on page 1935](#)
- [Example: Enabling Packet Capture on a Device on page 1930](#)

- [Deleting Packet Capture Files on page 1941](#)

## Deleting Packet Capture Files

Deleting packet capture files from the `/var/tmp` directory only temporarily removes the packet capture files. Packet capture files for the interface are automatically created again the next time a packet capture configuration change is committed or as part of a packet capture file rotation.

To delete a packet capture file:

1. Disable packet capture (see [“Disabling Packet Capture” on page 1940](#)).
2. Delete the packet capture file for the interface.
  - a. From operational mode, access the local UNIX shell.
 

```
user@host> start shell
%
```
  - b. Navigate to the directory where packet capture files are stored.
 

```
% cd /var/tmp
%
```
  - c. Delete the packet capture file for the interface; for example `pcap-file.fe.0.0.0`.
 

```
% rm pcap-file.fe.0.0.0
%
```
  - d. Return to operational mode.
 

```
% exit
user@host>
```
3. Reenable packet capture (see [“Example: Enabling Packet Capture on a Device” on page 1930](#)).
4. If you are done configuring the device, enter **commit** from configuration mode.

## Changing Encapsulation on Interfaces with Packet Capture Configured

Before modifying the encapsulation on a device interface that is configured for packet capture, you must disable packet capture and rename the latest packet capture file.

Otherwise, packet capture saves the packets with different encapsulations in the same packet capture file. Packet files containing packets with different encapsulations are not useful, because packet analyzer tools like tcpdump cannot analyze such files.

After modifying the encapsulation, you can safely reenabling packet capture on the device.

To change the encapsulation on interfaces with packet capture configured:

1. Disable packet capture (see [“Disabling Packet Capture” on page 1940](#)).
2. Enter **commit** from configuration mode.
3. Rename the latest packet capture file on which you are changing the encapsulation with the **.chdsl** extension.
  - a. From operational mode, access the local UNIX shell.

```
user@host> start shell
%
```
  - b. Navigate to the directory where packet capture files are stored.

```
% cd /var/tmp
%
```
  - c. Rename the latest packet capture file for the interface on which you are changing the encapsulation; for example **fe.0.0.0**.

```
% mv pcap-file.fe.0.0.0 pcap-file.fe.0.0.0.chdsl
%
```
  - d. Return to operational mode.

```
% exit
user@host>
```
4. Change the encapsulation on the interface using the J-Web user interface or CLI configuration editor.
5. If you are done configuring the device, enter **commit** from configuration mode.
6. Reenable packet capture (see [“Example: Enabling Packet Capture on a Device” on page 1930](#)).
7. If you are done configuring the device, enter **commit** from configuration mode.

## Displaying Packet Headers

Enter the **monitor traffic** command to display packet headers transmitted through network interfaces with the following syntax:

**NOTE:** Using the **monitor traffic** command can degrade system performance. We recommend that you use filtering options—such as **count** and **matching**—to minimize the impact to packet throughput on the system.

```
user@host> monitor traffic <absolute-sequence> <count number>
<interface interface-name> <layer2-headers> <matching "expression">
<no-domain-names> <no-promiscuous> <no-resolve> <no-timestamp> <print-ascii>
<print-hex> <size bytes> <brief | detail | extensive>
```

Table 226 describes the **monitor traffic** command options.

**Table 226: CLI monitor traffic Command Options**

| Option                          | Description                                                                                                                                                                                                                                          |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>absolute-sequence</b>        | (Optional) Displays the absolute TCP sequence numbers.                                                                                                                                                                                               |
| <b>count number</b>             | (Optional) Displays the specified number of packet headers. Specify a value from 0 through 100,000. The command quits and exits to the command prompt after this number is reached.                                                                  |
| <b>interface interface-name</b> | (Optional) Displays packet headers for traffic on the specified interface. If an interface is not specified, the lowest numbered interface is monitored.                                                                                             |
| <b>layer2-headers</b>           | (Optional) Displays the link-layer packet header on each line.                                                                                                                                                                                       |
| <b>matching "expression"</b>    | (Optional) Displays packet headers that match an expression enclosed in quotation marks (" "). Table 227 through Table 229 list match conditions, logical operators, and arithmetic, binary, and relational operators you can use in the expression. |
| <b>no-domain-names</b>          | (Optional) Suppresses the display of the domain name portion of the hostname.                                                                                                                                                                        |
| <b>no-promiscuous</b>           | (Optional) Specifies <i>not</i> to place the monitored interface in promiscuous mode.<br><br>In promiscuous mode, the interface reads every packet that reaches it. In nonpromiscuous mode, the interface reads only the packets addressed to it.    |
| <b>no-resolve</b>               | (Optional) Suppresses the display of hostnames.                                                                                                                                                                                                      |
| <b>no-timestamp</b>             | (Optional) Suppresses the display of packet header timestamps.                                                                                                                                                                                       |
| <b>print-ascii</b>              | (Optional) Displays each packet header in ASCII format.                                                                                                                                                                                              |

Table 226: CLI monitor traffic Command Options (*continued*)

| Option            | Description                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>print-hex</b>  | (Optional) Displays each packet header, except link-layer headers, in hexadecimal format.                                                                                                  |
| <b>size bytes</b> | (Optional) Displays the number of bytes for each packet that you specify. If a packet header exceeds this size, the displayed packet header is truncated. The default value is <b>96</b> . |
| <b>brief</b>      | (Optional) Displays minimum packet header information. This is the default.                                                                                                                |
| <b>detail</b>     | (Optional) Displays packet header information in moderate detail. For some protocols, you must also use the <b>size</b> option to see detailed information.                                |
| <b>extensive</b>  | (Optional) Displays the most extensive level of packet header information. For some protocols, you must also use the <b>size</b> option to see extensive information.                      |

To quit the **monitor traffic** command and return to the command prompt, press Ctrl-C.

To limit the packet header information displayed by the **monitor traffic** command, include the **matching "expression"** option. An expression consists of one or more match conditions listed in [Table 227](#), enclosed in quotation marks ( " "). You can combine match conditions by using the logical operators listed in [Table 228](#) (shown in order of highest to lowest precedence).

For example, to display TCP or UDP packet headers, enter:

```
user@host> monitor traffic matching "tcp || udp"
```

To compare the following types of expressions, use the relational operators listed in [Table 229](#) (listed from highest to lowest precedence):

- Arithmetic—Expressions that use the arithmetic operators listed in [Table 229](#).
- Binary—Expressions that use the binary operators listed in [Table 229](#).
- Packet data accessor—Expressions that use the following syntax:

```
protocol [byte-offset <size>]
```

Replace **protocol** with any protocol in [Table 227](#). Replace **byte-offset** with the byte offset, from the beginning of the packet header, to use for the comparison. The optional **size** parameter represents the number of bytes examined in the packet header—1, 2, or 4 bytes.

For example, the following command displays all multicast traffic:

```
user@host> monitor traffic matching "ether[0] & 1 != 0"
```

Table 227: CLI monitor traffic Match Conditions

| Match Condition                                                                       | Description                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Entity Type</b>                                                                    |                                                                                                                                                                                                                                                                          |
| <b>host</b> [ <i>address</i>   <i>hostname</i> ]                                      | Matches packet headers that contain the specified address or hostname. You can prepend any of the following protocol match conditions, followed by a space, to <b>host</b> : <b>arp</b> , <b>ip</b> , <b>rarp</b> , or any of the Directional match conditions.          |
| <b>network</b> <i>address</i>                                                         | Matches packet headers with source or destination addresses containing the specified network address.                                                                                                                                                                    |
| <b>network</b> <i>address</i> mask <i>mask</i>                                        | Matches packet headers containing the specified network address and subnet mask.                                                                                                                                                                                         |
| <b>port</b> [ <i>port-number</i>   <i>port-name</i> ]                                 | Matches packet headers containing the specified source or destination TCP or UDP port number or port name.                                                                                                                                                               |
| <b>Directional</b>                                                                    |                                                                                                                                                                                                                                                                          |
| <b>destination</b>                                                                    | Matches packet headers containing the specified destination. Directional match conditions can be prepended to any Entity Type match conditions, followed by a space.                                                                                                     |
| <b>source</b>                                                                         | Matches packet headers containing the specified source.                                                                                                                                                                                                                  |
| <b>source and destination</b>                                                         | Matches packet headers containing the specified source <i>and</i> destination.                                                                                                                                                                                           |
| <b>source or destination</b>                                                          | Matches packet headers containing the specified source <i>or</i> destination.                                                                                                                                                                                            |
| <b>Packet Length</b>                                                                  |                                                                                                                                                                                                                                                                          |
| <b>less</b> <i>bytes</i>                                                              | Matches packets with lengths less than or equal to the specified value, in bytes.                                                                                                                                                                                        |
| <b>greater</b> <i>bytes</i>                                                           | Matches packets with lengths greater than or equal to the specified value, in bytes.                                                                                                                                                                                     |
| <b>Protocol</b>                                                                       |                                                                                                                                                                                                                                                                          |
| <b>arp</b>                                                                            | Matches all ARP packets.                                                                                                                                                                                                                                                 |
| <b>ether</b>                                                                          | Matches all Ethernet frames.                                                                                                                                                                                                                                             |
| <b>ether</b> [ <b>broadcast</b>   <b>multicast</b> ]                                  | Matches broadcast or multicast Ethernet frames. This match condition can be prepended with <b>source</b> or <b>destination</b> .                                                                                                                                         |
| <b>ether protocol</b> [ <i>address</i>   ( <b>\arp</b>   <b>\ip</b>   <b>\rarp</b> )] | Matches Ethernet frames with the specified address or protocol type. The arguments <b>arp</b> , <b>ip</b> , and <b>rarp</b> are also independent match conditions, so they must be preceded with a backslash (\) when used in the <b>ether protocol</b> match condition. |
| <b>icmp</b>                                                                           | Matches all ICMP packets.                                                                                                                                                                                                                                                |
| <b>ip</b>                                                                             | Matches all IP packets.                                                                                                                                                                                                                                                  |
| <b>ip</b> [ <b>broadcast</b>   <b>multicast</b> ]                                     | Matches broadcast or multicast IP packets.                                                                                                                                                                                                                               |

Table 227: CLI monitor traffic Match Conditions (*continued*)

| Match Condition                                                     | Description                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip protocol</b> [ <i>address</i>   (\icmp   igrp   \tcp   \udp)] | Matches IP packets with the specified address or protocol type. The arguments <b>icmp</b> , <b>tcp</b> , and <b>udp</b> are also independent match conditions, so they must be preceded with a backslash (\) when used in the <b>ip protocol</b> match condition. |
| <b>isis</b>                                                         | Matches all IS-IS routing messages.                                                                                                                                                                                                                               |
| <b>rarp</b>                                                         | Matches all RARP packets.                                                                                                                                                                                                                                         |
| <b>tcp</b>                                                          | Matches all TCP packets.                                                                                                                                                                                                                                          |
| <b>udp</b>                                                          | Matches all UDP packets.                                                                                                                                                                                                                                          |

Table 228: CLI monitor traffic Logical Operators

| Logical Operator  | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>!</b>          | Logical NOT. If the first condition does not match, the next condition is evaluated.                                                                |
| <b>&amp;&amp;</b> | Logical AND. If the first condition matches, the next condition is evaluated. If the first condition does not match, the next condition is skipped. |
| <b>  </b>         | Logical OR. If the first condition matches, the next condition is skipped. If the first condition does not match, the next condition is evaluated.  |
| <b>()</b>         | Group operators to override default precedence order. Parentheses are special characters, each of which must be preceded by a backslash (\).        |

Table 229: CLI monitor traffic Arithmetic, Binary, and Relational Operators

| Operator                   | Description           |
|----------------------------|-----------------------|
| <b>Arithmetic Operator</b> |                       |
| <b>+</b>                   | Addition operator.    |
| <b>–</b>                   | Subtraction operator. |
| <b>/</b>                   | Division operator.    |
| <b>Binary Operator</b>     |                       |
| <b>&amp;</b>               | Bitwise AND.          |
| <b>*</b>                   | Bitwise exclusive OR. |
| <b> </b>                   | Bitwise inclusive OR. |

**Table 229: CLI monitor traffic Arithmetic, Binary, and Relational Operators** (*continued*)

| Operator                   | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| <b>Relational Operator</b> |                                                                                |
| <b>&lt;=</b>               | A match occurs if the first expression is less than or equal to the second.    |
| <b>&gt;=</b>               | A match occurs if the first expression is greater than or equal to the second. |
| <b>&lt;</b>                | A match occurs if the first expression is less than the second.                |
| <b>&gt;</b>                | A match occurs if the first expression is greater than the second.             |
| <b>=</b>                   | A match occurs if the first expression is equal to the second.                 |
| <b>!=</b>                  | A match occurs if the first expression is not equal to the second.             |

The following is sample output from the **monitor traffic** command:

```
user@host> monitor traffic count 4 matching "arp" detail
```

```
Listening on fe-0/0/0, capture size 96 bytes 15:04:16.276780 In arp who-has
193.1.1.1 tell host1.site2.net 15:04:16.376848 In arp who-has host2.site2.net
tell host1.site2.net 15:04:16.376887 In arp who-has 193.1.1.2 tell host1.site2.net
15:04:16.601923 In arp who-has 193.1.1.3 tell host1.site2.net
```

## Using the J-Web Packet Capture Tool

You can use the J-Web packet capture diagnostic tool when you need to quickly capture and analyze router control traffic on a device. Packet capture on the J-Web user interface allows you to capture traffic destined for, or originating from, the Routing Engine. You can use the J-Web packet capture tool to compose expressions with various matching criteria to specify the packets that you want to capture. You can either choose to decode and view the captured packets in the J-Web user interface as they are captured, or save the captured packets to a file and analyze them offline using packet analyzers such as Ethereal. The J-Web packet capture tool does not capture transient traffic.

To capture transient traffic and entire IPv4 data packets for offline analysis, you must configure packet capture with the J-Web user interface or CLI configuration editor.

To use J-Web packet capture:

1. Select **Troubleshoot>Packet Capture**.
2. Enter information into the Packet Capture page (see [Table 230](#)). The sample configuration captures the next 10 TCP packets originating from the IP address **10.1.40.48** on port 23 and passing through the Gigabit Ethernet interface **ge-0/0/0**.
3. Save the captured packets to a file, or specify other advanced options by clicking the expand icon next to Advanced options.
4. Click **Start**.

The captured packet headers are decoded and appear in the Packet Capture display.

5. Do one of the following:
  - To stop capturing the packets and stay on the same page while the decoded packet headers are being displayed, click **Stop Capturing**.
  - To stop capturing packets and return to the Packet Capture page, click **OK**.

**Table 230: Packet Capture Field Summary**

| Field        | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Your Action                                                                                                                                                                                                                                                                                         |

| Interface    | <p>Specifies the interface on which the packets are captured.</p> <p>If you select <b>default</b>, packets on the Ethernet management port 0 are captured.</p>                                                                                                                                                                                                                                                                                                                 | Select an interface from the list—for example, <b>ge-0/0/0</b> .                                                                                                                                                                                                                                    |
| Detail level | <p>Specifies the extent of details to be displayed for the packet headers.</p> <ul style="list-style-type: none"> <li>• Brief—Displays the minimum packet header information. This is the default.</li> <li>• Detail—Displays packet header information in moderate detail.</li> <li>• Extensive—Displays the maximum packet header information.</li> </ul>                                                                                                                    | Select <b>Detail</b> from the list.                                                                                                                                                                                                                                                                 |
| Packets      | <p>Specifies the number of packets to be captured. Values range from 1 to <b>1000</b>. Default is <b>10</b>. Packet capture stops capturing packets after this number is reached.</p>                                                                                                                                                                                                                                                                                          | Select the number of packets to be captured from the list—for example, <b>10</b> .                                                                                                                                                                                                                  |
| Addresses    | <p>Specifies the addresses to be matched for capturing the packets using a combination of the following parameters:</p> <ul style="list-style-type: none"> <li>• Direction—Matches the packet headers for IP address, hostname, or network address of the source, destination or both.</li> <li>• Type—Specifies if packet headers are matched for host address or network address.</li> </ul> <p>You can add multiple entries to refine the match criteria for addresses.</p> | <p>Select address-matching criteria. For example:</p> <ol style="list-style-type: none"> <li>1. From the Direction list, select <b>source</b>.</li> <li>2. From the Type list, select <b>host</b>.</li> <li>3. In the Address box, type <b>10.1.40.48</b>.</li> <li>4. Click <b>Add</b>.</li> </ol> |

Table 230: Packet Capture Field Summary (*continued*)

| Field                   | Function                                                                                                                                                                                                 | Your Action                                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocols               | Matches the protocol for which packets are captured. You can choose to capture TCP, UDP, or ICMP packets or a combination of TCP, UDP, and ICMP packets.                                                 | Select a protocol from the list—for example, <b>tcp</b> .                                                                                                                                                                                                                                                                |
| Ports                   | Matches packet headers containing the specified source or destination TCP or UDP port number or port name.                                                                                               | Select a direction and a port. For example:<br><br>1. From the Type list, select <b>src</b> .<br><br>2. In the Port box, type <b>23</b> .                                                                                                                                                                                |
| <b>Advanced Options</b> |                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                          |
| Absolute TCP Sequence   | Specifies that absolute TCP sequence numbers are to be displayed for the packet headers.                                                                                                                 | <ul style="list-style-type: none"> <li>Display absolute TCP sequence numbers in the packet headers by selecting this check box.</li> <li>Stop displaying absolute TCP sequence numbers in the packet headers by clearing this check box.</li> </ul>                                                                      |
| Layer 2 Headers         | Specifies that link-layer packet headers to display.                                                                                                                                                     | <ul style="list-style-type: none"> <li>Include link-layer packet headers while capturing packets, by selecting this check box.</li> <li>Exclude link-layer packet headers while capturing packets by clearing this check box.</li> </ul>                                                                                 |
| Non-Promiscuous         | <p>Specifies not to place the interface in promiscuous mode, so that the interface reads only packets addressed to it.</p> <p>In promiscuous mode, the interface reads every packet that reaches it.</p> | <ul style="list-style-type: none"> <li>Read all packets that reach the interface by selecting this check box.</li> <li>Read only packets addressed to the interface by clearing this check box.</li> </ul>                                                                                                               |
| Display Hex             | Specifies that packet headers, except link-layer headers, are to be displayed in hexadecimal format.                                                                                                     | <ul style="list-style-type: none"> <li>Display the packet headers in hexadecimal format by selecting this check box.</li> <li>Stop displaying the packet headers in hexadecimal format by clearing this check box.</li> </ul>                                                                                            |
| Display ASCII and Hex   | Specifies that packet headers are to be displayed in hexadecimal and ASCII format.                                                                                                                       | <ul style="list-style-type: none"> <li>Display the packet headers in ASCII and hexadecimal formats by selecting this check box.</li> <li>Stop displaying the packet headers in ASCII and hexadecimal formats by clearing this check box.</li> </ul>                                                                      |
| Header Expression       | <p>Specifies the match condition for the packets to capture.</p> <p>The match conditions you specify for Addresses, Protocols, and Ports appear in expression format in this field.</p>                  | Enter match conditions in expression format or modify the expression composed from the match conditions you specified for Addresses, Protocols, and Ports. If you change the match conditions specified for Addresses, Protocols, and Ports again, packet capture overwrites your changes with the new match conditions. |
| Packet Size             | Specifies the number of bytes to be displayed for each packet. If a packet header exceeds this size, the display is truncated for the packet header. The default value is 96 bytes.                      | Type the number of bytes you want to capture for each packet header—for example, <b>256</b> .                                                                                                                                                                                                                            |

Table 230: Packet Capture Field Summary (*continued*)

| Field                     | Function                                                                                                                                                                                                                                                                                      | Your Action                                                                                                                                                                                                                        |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Don't Resolve Addresses   | Specifies that IP addresses are not to be resolved into hostnames in the packet headers displayed.                                                                                                                                                                                            | <ul style="list-style-type: none"> <li>Prevent packet capture from resolving IP addresses to hostnames by selecting this check box.</li> <li>Resolve IP addresses into hostnames by clearing this check box.</li> </ul>            |
| No Timestamp              | Suppresses the display of packet header timestamps.                                                                                                                                                                                                                                           | <ul style="list-style-type: none"> <li>Stop displaying timestamps in the captured packet headers by selecting this check box.</li> <li>Display the timestamp in the captured packet headers by clearing this check box.</li> </ul> |
| Write Packet Capture File | <p>Writes the captured packets to a file in PCAP format in <code>/var/tmp</code>. The files are named with the prefix <code>jweb-pcap</code> and the extension <code>.pcap</code>.</p> <p>If you select this option, the decoded packet headers do not appear on the packet capture page.</p> | <ul style="list-style-type: none"> <li>Save the captured packet headers to a file by selecting this check box.</li> <li>Decode and display the packet headers on the J-Web page by clearing this check box.</li> </ul>             |

## J-Web Packet Capture Results and Output Summary

Table 231 summarizes the output in the packet capture display.

Table 231: J-Web Packet Capture Results and Output Summary

| Field                   | Description                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>timestamp</i></b> | <p>Time when the packet was captured. The timestamp <code>00:45:40.823971</code> means 00 hours (12.00 a.m.), 45 minutes, and 40.823971 seconds.</p> <p><b>NOTE:</b> The time displayed is local time.</p> |
| <b><i>direction</i></b> | Direction of the packet. Specifies whether the packet originated from the Routing Engine ( <b>Out</b> ), or was destined for the Routing Engine ( <b>In</b> ).                                             |
| <b><i>protocol</i></b>  | <p>Protocol for the packet.</p> <p>In the sample output, <b>IP</b> indicates the Layer 3 protocol.</p>                                                                                                     |

Table 231: J-Web Packet Capture Results and Output Summary (*continued*)

| Field                      | Description                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>source address</i>      | <p>Hostname, if available, or IP address and the port number of the packet's origin. If the Don't Resolve Addresses check box is selected, only the IP address of the source displays.</p> <p><b>NOTE:</b> When a string is defined for the port, the packet capture output displays the string instead of the port number.</p>                       |
| <i>destination address</i> | <p>Hostname, if available, or IP address of the packet's destination with the port number. If the Don't Resolve Addresses check box is selected, only the IP address of the destination and the port appear.</p> <p><b>NOTE:</b> When a string is defined for the port, the packet capture output displays the string instead of the port number.</p> |
| <i>protocol</i>            | <p>Protocol for the packet.</p> <p>In the sample output, <b>TCP</b> indicates the Layer 4 protocol.</p>                                                                                                                                                                                                                                               |
| <i>data size</i>           | Size of the packet (in bytes).                                                                                                                                                                                                                                                                                                                        |

## Recovering the Root Password for SRX Series Devices

---

If you forget the root password for an SRX Series device, you can use the password recovery procedure to reset the root password. This procedure also involves disabling the watchdog functionality to allow the system to properly boot into single-user mode (KB article 17565).

**NOTE:** You need console access to recover the root password

To recover the root password for an SRX Series device:

1. Power on the device by pressing the power button on the front panel. Verify that the **POWER** LED on the front panel turns green.

The device's boot sequence on your management device appears on the terminal emulation screen.

2. When the autoboot completes, press the Spacebar a few times to access the bootstrap loader prompt.
3. In operational mode, disable the watchdog functionality and enter **boot -s** to start up the system in single-user mode.

```
loader>boot -s
```

The SRX Series device will start up in single-user mode.

4. Enter **recovery** to start the root password recovery procedure.

System watchdog timer disabled.

Enter full pathname of shell or 'recovery' for root password recovery or RETURN for /bin/sh: **recovery**

5. Enter configuration mode in the CLI.

6. Set the root password.

```
[edit]
user@host# set system root-authentication plain-text-password
```

7. Enter the new root password.

```
New password: juniper1
Retype new password:
```

8. At the second prompt, reenter the new root password.

9. If you are finished configuring the network, commit the configuration.

```
root@host# commit
commit complete
```

10. Exit from configuration mode.

11. Exit from operational mode.

12. Enter **y** to reboot the device.

```
Reboot the system? [y/n] y
```

The start up messages display on the screen.

13. Once again, press the Spacebar a few times to access the bootstrap loader prompt.

14. In operational mode, enable the watchdog functionality and enter **boot** to start up the system.

```
loader>watchdog enable
loader>boot
```

15. The SRX Series device starts up again and prompts you to enter a user name and password. Enter the newly configured password:

```
Wed Jul 12 14:20:21 UTC 2011
Deviceabc (ttyu0)
login: root
Password: juniper1
```

## Troubleshooting DNS Name Resolution in Logical System Security Policies (Master Administrators Only)

---

**Problem**    **Description:** The address of a hostname in an address book entry that is used in a security policy might fail to resolve correctly.

**Cause**      Normally, address book entries that contain dynamic hostnames refresh automatically for SRX Series devices. The TTL field associated with a DNS entry indicates the time after

which the entry should be refreshed in the policy cache. Once the TTL value expires, the SRX Series device automatically refreshes the DNS entry for an address book entry.

However, if the SRX Series device is unable to obtain a response from the DNS server (for example, the DNS request or response packet is lost in the network or the DNS server cannot send a response), the address of a hostname in an address book entry might fail to resolve correctly. This can cause traffic to drop as no security policy or session match is found.

**Solution** The master administrator can use the **show security dns-cache** command to display DNS cache information on the SRX Series device. If the DNS cache information needs to be refreshed, the master administrator can use the **clear security dns-cache** command.

**NOTE:** These commands are only available to the master administrator on devices that are configured for logical systems. This command is not available in user logical systems or on devices that are not configured for logical systems.

## Troubleshooting the Link Services Interface

To solve configuration problems on a link services interface:

- [Determine Which CoS Components Are Applied to the Constituent Links on page 1955](#)
- [Determine What Causes Jitter and Latency on the Multilink Bundle on page 1957](#)
- [Determine If LFI and Load Balancing Are Working Correctly on page 1957](#)
- [Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device on page 1964](#)

### Determine Which CoS Components Are Applied to the Constituent Links

**Problem** **Description:** You are configuring a multilink bundle, but you also have traffic without MLPPP encapsulation passing through constituent links of the multilink bundle. Do you apply all CoS components to the constituent links, or is applying them to the multilink bundle enough?

**Solution** You can apply a scheduler map to the multilink bundle and its constituent links. Although you can apply several CoS components with the scheduler map, configure only the ones that are required. We recommend that you keep the configuration on the constituent links simple to avoid unnecessary delay in transmission.

[Table 232](#) shows the CoS components to be applied on a multilink bundle and its constituent links.

Table 232: CoS Components Applied on Multilink Bundles and Constituent Links

| Cos Component                                                         | Multilink Bundle | Constituent Links | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------|------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Classifier                                                            | Yes              | No                | CoS classification takes place on the incoming side of the interface, not on the transmitting side, so no classifiers are needed on constituent links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Forwarding class                                                      | Yes              | No                | Forwarding class is associated with a queue, and the queue is applied to the interface by a scheduler map. The queue assignment is predetermined on the constituent links. All packets from Q2 of the multilink bundle are assigned to Q2 of the constituent link, and packets from all the other queues are queued to Q0 of the constituent link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Scheduler map                                                         | Yes              | Yes               | <p>Apply scheduler maps on the multilink bundle and the constituent link as follows:</p> <ul style="list-style-type: none"> <li>• Transmit rate—Make sure that the relative order of the transmit rate configured on Q0 and Q2 is the same on the constituent links as on the multilink bundle.</li> <li>• Scheduler priority—Make sure that the relative order of the scheduler priority configured on Q0 and Q2 is the same on the constituent links as on the multilink bundle.</li> <li>• Buffer size—Because all non-LFI packets from the multilink bundle transit on Q0 of the constituent links, make sure that the buffer size on Q0 of the constituent links is large enough.</li> <li>• RED drop profile—Configure a RED drop profile on the multilink bundle only. Configuring the RED drop profile on the constituent links applies a back pressure mechanism that changes the buffer size and introduces variation. Because this behavior might cause fragment drops on the constituent links, make sure to leave the RED drop profile at the default settings on the constituent links.</li> </ul> |
| Shaping rate for a per-unit scheduler or an interface-level scheduler | No               | Yes               | Because per-unit scheduling is applied only at the end point, apply this shaping rate to the constituent links only. Any configuration applied earlier is overwritten by the constituent link configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Transmit-rate exact or queue-level shaping                            | Yes              | No                | The interface-level shaping applied on the constituent links overrides any shaping on the queue. Thus apply transmit-rate exact shaping on the multilink bundle only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Rewrite rules                                                         | Yes              | No                | Rewrite bits are copied from the packet into the fragments automatically during fragmentation. Thus what you configure on the multilink bundle is carried on the fragments to the constituent links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 232: CoS Components Applied on Multilink Bundles and Constituent Links (*continued*)

| Cos Component         | Multilink Bundle | Constituent Links | Explanation                                                                                                                                                                                                                       |
|-----------------------|------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual channel group | Yes              | No                | Virtual channel groups are identified through firewall filter rules that are applied on packets only before the multilink bundle. Thus you do not need to apply the virtual channel group configuration to the constituent links. |

### Determine What Causes Jitter and Latency on the Multilink Bundle

**Problem** **Description:** To test jitter and latency, you send three streams of IP packets. All packets have the same IP precedence settings. After configuring LFI and CRTP, the latency increased even over a noncongested link. How can you reduce jitter and latency?

**Solution** To reduce jitter and latency, do the following:

1. Make sure that you have configured a shaping rate on each constituent link.
2. Make sure that you have not configured a shaping rate on the link services interface.
3. Make sure that the configured shaping rate value is equal to the physical interface bandwidth.
4. If shaping rates are configured correctly, and jitter still persists, contact the Juniper Networks Technical Assistance Center (JTAC).

### Determine If LFI and Load Balancing Are Working Correctly

**Problem** **Description:** In this case, you have a single network that supports multiple services. The network transmits data and delay-sensitive voice traffic. After configuring MLPPP and LFI, make sure that voice packets are transmitted across the network with very little delay and jitter. How can you find out if voice packets are being treated as LFI packets and load balancing is performed correctly?

**Solution** When LFI is enabled, data (non-LFI) packets are encapsulated with an MLPPP header and fragmented to packets of a specified size. The delay-sensitive, voice (LFI) packets are PPP-encapsulated and interleaved between data packet fragments. Queuing and load balancing are performed differently for LFI and non-LFI packets.

To verify that LFI is performed correctly, determine that packets are fragmented and encapsulated as configured. After you know whether a packet is treated as an LFI packet or a non-LFI packet, you can confirm whether the load balancing is performed correctly.

**Solution Scenario**—Suppose two Juniper Networks devices, R0 and R1, are connected by a multilink bundle `lsq-0/0/0.0` that aggregates two serial links, `se-1/0/0` and `se-1/0/1`. On R0 and R1, MLPPP and LFI are enabled on the link services interface and the fragmentation threshold is set to 128 bytes.

In this example, we used a packet generator to generate voice and data streams. You can use the packet capture feature to capture and analyze the packets on the incoming interface.

The following two data streams were sent on the multilink bundle:

- 100 data packets of 200 bytes (larger than the fragmentation threshold)
- 500 data packets of 60 bytes (smaller than the fragmentation threshold)

The following two voice streams were sent on the multilink bundle:

- 100 voice packets of 200 bytes from source port 100
- 300 voice packets of 200 bytes from source port 200

To confirm that LFI and load balancing are performed correctly:

**NOTE:** Only the significant portions of command output are displayed and described in this example.

1. Verify packet fragmentation. From operational mode, enter the **show interfaces lsq-0/0/0** command to check that large packets are fragmented correctly.

```

user@R0#> show interfaces lsq-0/0/0
Physical interface: lsq-0/0/0, Enabled, Physical link is Up
 Interface index: 136, SNMP ifIndex: 29
 Link-level type: LinkService, MTU: 1504
 Device flags : Present Running
 Interface flags: Point-To-Point SNMP-Traps
 Last flapped : 2006-08-01 10:45:13 PDT (2w0d 06:06 ago)
 Input rate : 0 bps (0 pps)
 Output rate : 0 bps (0 pps)

Logical interface lsq-0/0/0.0 (Index 69) (SNMP ifIndex 42)
 Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: Multilink-PPP
 Bandwidth: 16mbps
 Statistics
 Bundle:
 Fragments:
 Input : 0 0 0 0
 Output: 1100 0 118800 0
 Packets:
 Input : 0 0 0 0
 Output: 1000 0 112000 0
 ...
 Protocol inet, MTU: 1500
 Flags: None
 Addresses, Flags: Is-Preferred Is-Primary
 Destination: 9.9.9/24, Local: 9.9.9.10

```

**Meaning**—The output shows a summary of packets transiting the device on the multilink bundle. Verify the following information on the multilink bundle:

- The total number of transiting packets = 1000
- The total number of transiting fragments=1100
- The number of data packets that were fragmented =100

The total number of packets sent (600 + 400) on the multilink bundle match the number of transiting packets (1000), indicating that no packets were dropped.

The number of transiting fragments exceeds the number of transiting packets by 100, indicating that 100 large data packets were correctly fragmented.

**Corrective Action**—If the packets are not fragmented correctly, check your fragmentation threshold configuration. Packets smaller than the specified fragmentation threshold are not fragmented.

2. Verify packet encapsulation. To find out whether a packet is treated as an LFI or non-LFI packet, determine its encapsulation type. LFI packets are PPP encapsulated,

and non-LFI packets are encapsulated with both PPP and MLPPP. PPP and MLPPP encapsulations have different overheads resulting in different-sized packets. You can compare packet sizes to determine the encapsulation type.

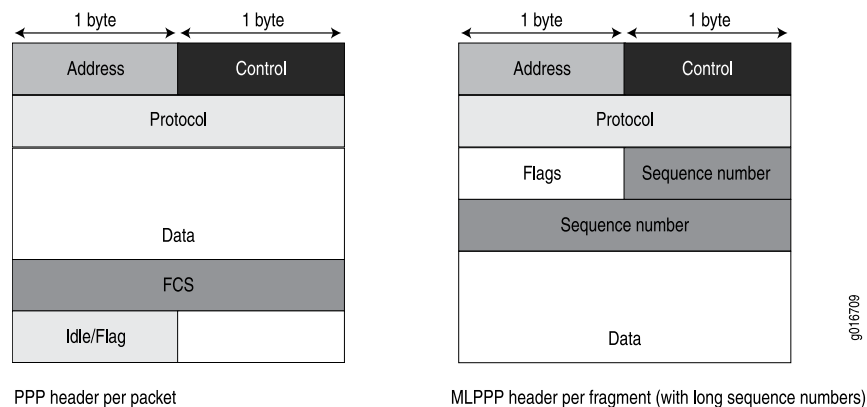

A small unfragmented data packet contains a PPP header and a single MLPPP header. In a large fragmented data packet, the first fragment contains a PPP header and an MLPPP header, but the consecutive fragments contain only an MLPPP header.

PPP and MLPPP encapsulations add the following number of bytes to a packet:

- PPP encapsulation adds 7 bytes:  
4 bytes of header+2 bytes of frame check sequence (FCS)+1 byte that is idle or contains a flag
- MLPPP encapsulation adds between 6 and 8 bytes:  
4 bytes of PPP header+2 to 4 bytes of multilink header

Figure 42 shows the overhead added to PPP and MLPPP headers.

**Figure 42: PPP and MLPPP Headers**

For CRTP packets, the encapsulation overhead and packet size are even smaller than for an LFI packet. For more information, see [Example: Configuring the Compressed Real-Time Transport Protocol](#).

Table 233 shows the encapsulation overhead for a data packet and a voice packet of 70 bytes each. After encapsulation, the size of the data packet is larger than the size of the voice packet.

**Table 233: PPP and MLPPP Encapsulation Overhead**

| Packet Type                                 | Encapsulation | Initial Packet Size | Encapsulation Overhead       | Packet Size after Encapsulation |
|---------------------------------------------|---------------|---------------------|------------------------------|---------------------------------|
| Voice packet (LFI)                          | PPP           | 70 bytes            | 4 + 2 + 1 = 7 bytes          | 77 bytes                        |
| Data fragment (non-LFI) with short sequence | MLPPP         | 70 bytes            | 4 + 2 + 1 + 4 + 2 = 13 bytes | 83 bytes                        |

Table 233: PPP and MLPPP Encapsulation Overhead (*continued*)

| Packet Type                                | Encapsulation | Initial Packet Size | Encapsulation Overhead       | Packet Size after Encapsulation |
|--------------------------------------------|---------------|---------------------|------------------------------|---------------------------------|
| Data fragment (non-LFI) with long sequence | MLPPP         | 70 bytes            | 4 + 2 + 1 + 4 + 4 = 15 bytes | 85 bytes                        |

From operational mode, enter the **show interfaces queue** command to display the size of transmitted packet on each queue. Divide the number of bytes transmitted by the number of packets to obtain the size of the packets and determine the encapsulation type.

3. Verify load balancing. From operational mode, enter the **show interfaces queue** command on the multilink bundle and its constituent links to confirm whether load balancing is performed accordingly on the packets.

```

user@R0> show interfaces queue lsq-0/0/0
Physical interface: lsq-0/0/0, Enabled, Physical link is Up

```

**Meaning**—The output from these commands shows the packets transmitted and queued on each queue of the link services interface and its constituent links. [Table 234](#) shows a summary of these values. (Because the number of transmitted packets equaled the number of queued packets on all the links, this table shows only the queued packets.)

**Table 234: Number of Packets Transmitted on a Queue**

| Packets Queued | Bundle<br>lsq-0/0/0.0 | Constituent Link<br>se-1/0/0 | Constituent Link<br>se-1/0/1 | Explanation                                                                                                                                                          |
|----------------|-----------------------|------------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Packets on Q0  | 600                   | 350                          | 350                          | The total number of packets transiting the constituent links (350+350 = 700) exceeded the number of packets queued (600) on the multilink bundle.                    |
| Packets on Q2  | 400                   | 100                          | 300                          | The total number of packets transiting the constituent links equaled the number of packets on the bundle.                                                            |
| Packets on Q3  | 0                     | 19                           | 18                           | The packets transiting Q3 of the constituent links are for keepalive messages exchanged between constituent links. Thus no packets were counted on Q3 of the bundle. |

On the multilink bundle, verify the following:

- The number of packets queued matches the number transmitted. If the numbers match, no packets were dropped. If more packets were queued than were transmitted, packets were dropped because the buffer was too small. The buffer size on the constituent links controls congestion at the output stage. To correct this problem, increase the buffer size on the constituent links.
- The number of packets transiting Q0 (600) matches the number of large and small data packets received (100+500) on the multilink bundle. If the numbers match, all data packets correctly transited Q0.
- The number of packets transiting Q2 on the multilink bundle (400) matches the number of voice packets received on the multilink bundle. If the numbers match, all voice LFI packets correctly transited Q2.

On the constituent links, verify the following:

- The total number of packets transiting Q0 (350+350) matches the number of data packets and data fragments (500+200). If the numbers match, all the data packets after fragmentation correctly transited Q0 of the constituent links.

Packets transited both constituent links, indicating that load balancing was correctly performed on non-LFI packets.

- The total number of packets transiting Q2 (300+100) on constituent links matches the number of voice packets received (400) on the multilink bundle. If the numbers match, all voice LFI packets correctly transited Q2.

LFI packets from source port **100** transited **se-1/0/0**, and LFI packets from source port **200** transited **se-1/0/1**. Thus all LFI (Q2) packets were hashed based on the source port and correctly transited both constituent links.

**Corrective Action**—If the packets transited only one link, take the following steps to resolve the problem:

- a. Determine whether the physical link is **up** (operational) or **down** (unavailable). An unavailable link indicates a problem with the PIM, interface port, or physical connection (link-layer errors). If the link is operational, move to the next step.
  - b. Verify that the classifiers are correctly defined for non-LFI packets. Make sure that non-LFI packets are not configured to be queued to Q2. All packets queued to Q2 are treated as LFI packets.
  - c. Verify that at least one of the following values is different in the LFI packets: source address, destination address, IP protocol, source port, or destination port. If the same values are configured for all LFI packets, the packets are all hashed to the same flow and transit the same link.
4. Use the results to verify load balancing.

## Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device

**Problem**    **Description:** You are configuring a permanent virtual circuit (PVC) between T1, E1, T3, or E3 interfaces on a Juniper Networks device and a third-party device, and packets are being dropped and ping fails.

**Solution**    If the third-party device does not have the same FRF.12 support as the Juniper Networks device or supports FRF.12 in a different way, the Juniper Networks device interface on the PVC might discard a fragmented packet containing FRF.12 headers and count it as a "Policed Discard."

As a workaround, configure multilink bundles on both peers, and configure fragmentation thresholds on the multilink bundles.

## Troubleshooting Security Policies

- [Checking a Security Policy Commit Failure on page 1964](#)
- [Verifying a Security Policy Commit on page 1965](#)
- [Debugging Policy Lookup on page 1965](#)

### Checking a Security Policy Commit Failure

**Problem**    **Description:** Most policy configuration failures occur during a commit or runtime. Commit failures are reported directly on the CLI when you execute the CLI command **commit-check** in configuration mode. These errors are configuration errors, and you cannot commit the configuration without fixing these errors.

**Solution** To fix these errors, do the following:

1. Review your configuration data.
2. Open the file `/var/log/nsd_chk_only`. This file is overwritten each time you perform a commit check and contains detailed failure information.

## Verifying a Security Policy Commit

**Problem** **Description:** Upon performing a policy configuration commit, if you notice that the system behavior is incorrect, use the following steps to troubleshoot this problem:

- Solution**
1. Operational **show** Commands—Execute the operational commands for security policies and verify that the information shown in the output is consistent with what you expected. If not, the configuration needs to be changed appropriately.
  2. Traceoptions—Set the **traceoptions** command in your policy configuration. The flags under this hierarchy can be selected as per user analysis of the **show** command output. If you cannot determine what flag to use, the flag option **all** can be used to capture all trace logs.

```
user@host# set security policies traceoptions <flag all>
```

You can also configure an optional filename to capture the logs.

```
user@host# set security policies traceoptions <filename>
```

If you specified a filename in the trace options, you can look in the `/var/log/<filename>` for the log file to ascertain if any errors were reported in the file. (If you did not specify a filename, the default filename is `eventd`.) The error messages indicate the place of failure and the appropriate reason.

After configuring the trace options, you must recommit the configuration change that caused the incorrect system behavior.

## Debugging Policy Lookup

**Problem** **Description:** When you have the correct configuration, but some traffic was incorrectly dropped or permitted, you can enable the **lookup** flag in the security policies traceoptions. The **lookup** flag logs the lookup related traces in the trace file.

**Solution** `user@host# set security policies traceoptions <flag lookup>`

## Understanding Log Error Messages for Troubleshooting ISSU-Related Problems

---

The following problems might occur during an ISSU upgrade. You can identify the errors by using the details in the logs. You can also see the details of the error messages in the *Junos OS System Log Reference*.

- [Chassisd Process Errors on page 1966](#)
- [Kernel State Synchronization on page 1966](#)
- [Installation Related Errors on page 1966](#)
- [ISSU Support Related Errors on page 1967](#)
- [Redundancy Group Failover Errors on page 1967](#)
- [Initial Validation Checks Fail on page 1967](#)

### Chassisd Process Errors

**Problem**    **Description:** Errors related to chassisd.

**Solution**    Use the error messages to understand the issues related to chassisd.

When ISSU starts, a request is sent to chassisd to check whether there are any problems related to ISSU from a chassis perspective. If there is a problem, a log message is created.

### Kernel State Synchronization

**Problem**    **Description:** Errors related to ksyncd.

**Solution**    Use the following error messages to understand the issues related to ksyncd:

Failed to get kernel-replication error information from Standby Routing Engine.  
mgd\_slave\_peer\_has\_errors() returns error at line 4414 in mgd\_package\_issu.

ISSU checks whether there are any ksyncd errors on the secondary node (node 1) and displays the error message if there are any problems and aborts the ISSU.

### Installation Related Errors

**Problem**    **Description:** The install image file does not exist or the remote site is inaccessible.

**Solution**    Use the following error messages to understand the installation related problems:

error: File does not exist: /var/tmp/junos-srx5000-11.4X3.2-domest  
error: Couldn't retrieve package /var/tmp/junos-srx5000-11.4X3.2-domest

ISSU downloads the install image as specified in the ISSU command as an argument. The image file can be a local file or located at a remote site. If the file does not exist or the remote site is inaccessible, an error is reported.

## ISSU Support Related Errors

**Problem**    **Description:** Installation failure because of unsupported software and unsupported feature configuration.

**Solution**    Use the following error messages to understand the compatibility-related problems:

```
WARNING: Current configuration not compatible with
/var/tmp/junos-srx5000-11.4X3.2-domestic.tgz
Exiting in-service-upgrade window
Exiting in-service-upgrade window
```

## Redundancy Group Failover Errors

**Problem**    **Description:** Problem with automatic redundancy group (RG) failure.

**Solution**    Use the following error messages to understand the problem:

```
failover all RG 1+ groups to node 0
error: Command failed. None of the redundancy-groupss has been failed over.
Some redundancy-groups on node1 are already in manual failover mode.
Please execute 'failover reset all' first..
```

## Initial Validation Checks Fail

**Problem**    **Description:** The initial validation checks fail.

**Solution**    The following error messages are displayed when initial validation checks fail when the image is not present and ISSU is aborted:

### When Image is Not Present

```
user@host> ...0120914_srx_12q1_major2.2-539764-domestic.tgz reboot
Chassis ISSU Started
Chassis ISSU Started
ISSU: Validating Image
Initiating in-service-upgrade
Initiating in-service-upgrade
Fetching package...
error: File does not exist:
/var/tmp/junos-srx1k3k-12.1I20120914_srx_12q1_major2.2-539764-domestic.tgz
error: Couldn't retrieve package
/var/tmp/junos-srx1k3k-12.1I20120914_srx_12q1_major2.2-539764-domestic.tgz
Exiting in-service-upgrade window
Exiting in-service-upgrade window
Chassis ISSU Aborted
Chassis ISSU Aborted
Chassis ISSU Aborted
ISSU: IDLE
ISSU aborted; exiting ISSU window.
```

### When Image File is Corrupted

```
user@host> ...junos-srx1k3k-11.4X9-domestic.tgz_1 reboot
```

```
Chassis ISSU Started
node1:

Chassis ISSU Started
ISSU: Validating Image
Initiating in-service-upgrade

node1:

Initiating in-service-upgrade
ERROR: Cannot use /var/tmp/junos-srx1k3k-11.4X9-domestic.tgz_1:
gzip: stdin: invalid compressed data--format violated
tar: Child returned status 1
tar: Error exit delayed from previous errors
ERROR: It may have been corrupted during download.
ERROR: Please try again, making sure to use a binary transfer.
Exiting in-service-upgrade window

node1:

Exiting in-service-upgrade window

Chassis ISSU Aborted

node1:

Chassis ISSU Aborted
ISSU: IDLE
ISSU aborted; exiting ISSU window.

{primary:node0}
```

The primary node validates the device configuration to ensure that it can be committed using the new software version. If anything goes wrong, ISSU aborts and error messages are displayed.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Configure an archive site. If more than one site name is configured, an ordered list of archive sites for the accounting-data log files is created. When a file is archived, the router or switch attempts to transfer the file to the first URL in the list, moving to the next site only if the transfer does not succeed. The log file is stored at the archive site with a filename of the format <i>router-name_log-filename_timestamp</i> . |
| <b>Options</b>                  | <i>site-name</i> —Any valid FTP/SCP URL to a destination.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Required Privilege Level</b> | snmp—To view this statement in the configuration.<br>snmp-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                     |

| Release Information      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description              | <p>Create a class usage profile, which is used to log class usage statistics to a file in the <code>/var/log</code> directory. The class usage profile logs class usage statistics for the configured source classes on every interface that has <b>destination-class-usage</b> configured.</p> <p>For information about configuring source classes, see the <a href="#">Junos Routing Protocols Configuration Guide</a>. For information about configuring source class usage, see the <a href="#">Junos Network Management Configuration Guide</a>.</p> |
| Options                  | <p><b>profile-name</b>—Name of the destination class profile.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                          |
| <b>Description</b>              | Specify the maximum number of log files to be used for accounting data.                                                                                                                                                                                                                                                                                            |
| <b>Options</b>                  | <i>number</i> —The maximum number of files. When a log file (for example, <b>profilelog</b> ) reaches its maximum size, it is renamed <b>profilelog.0</b> , then <b>profilelog.1</b> , and so on, until the maximum number of log files is reached. Then the oldest log file is overwritten. The minimum value for <i>number</i> is 3 and the default value is 10. |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                                                            |

## mib-profile

---

**Syntax**    `mib-profile profile-name {  
                  file filename;  
                  interval minutes;  
                  object-names {  
                      mib-object-name;  
                  }  
                  operation operation-name;  
                  }`

**Hierarchy Level**    [edit accounting-options]

**Release Information**    Statement introduced in Junos OS Release 8.2.  
                              Statement introduced in Junos OS Release 9.0 for EX Series switches.

**Description**    Create a MIB profile to collect selected MIB statistics and write them to a file in the `/var/log` directory.

**NOTE:** Do not configure MIB objects related to interface octets or packets for a MIB profile, because it can cause the SNMP walk or a CLI show command to time out.

---

**Options**    *profile-name*—Name of the MIB statistics profile.  
  
                  The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

## mpls (Security Forwarding Options)

---

|                            |                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>              | <pre>mpls {<br/>  mode packet-based;<br/>}</pre>                                  |
| <b>Hierarchy Level</b>     | [edit security forwarding-options family]                                         |
| <b>Release Information</b> | Statement introduced in Junos OS Release 9.0.                                     |
| <b>Description</b>         | Enable the forwarding of MPLS traffic. By default, the device drops MPLS traffic. |

**CAUTION:** Because MPLS operates in packet mode, security services are not available.

---

**NOTE:** Packet-based processing is not supported on the following SRX Series devices: SRX1500, SRX5600, and SRX5800.

## redundancy-group (Chassis Cluster)

**Syntax**

```

redundancy-group group-number {
 gratuitous-arp-count number;
 hold-down-interval number;
 interface-monitor interface-name {
 weight number;
 }
 ip-monitoring {
 family {
 inet {
 ipv4-address {
 interface {
 logical-interface-name;
 secondary-ip-address ip-address;
 }
 weight number;
 }
 }
 }
 global-threshold number;
 global-weight number;
 retry-count number;
 retry-interval seconds;
 }
 node (0 | 1) {
 priority number;
 }
 preempt;
}

```

**Hierarchy Level** [edit chassis cluster]

**Release Information** Statement introduced in Junos OS Release 9.0.

**Description** Define a redundancy group. Except for redundancy group 0, a redundancy group is a logical interface consisting of two physical Ethernet interfaces, one on each chassis. One interface is active, and the other is on standby. When the active interface fails, the standby interface becomes active. The logical interface is called a redundant Ethernet interface (**reth**).

Redundancy group 0 consists of the two Routing Engines in the chassis cluster and controls which Routing Engine is primary. You must define redundancy group 0 in the chassis cluster configuration.

**Options** *group-number* —Redundancy group identification number.

**Range:** 0 through 128

**NOTE:** The maximum number of redundancy groups is equal to the number of redundant Ethernet interfaces that you configure.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

**Related Documentation** • [ip-monitoring on page 2001](#)

---

## retry-interval (Chassis Cluster)

---

**Syntax** `retry-interval interval;`

**Hierarchy Level** [edit chassis cluster redundancy-group *group-number* ip-monitoring ]

**Release Information** Statement introduced in Junos OS Release 10.1.

**Description** Specify the ping packet send frequency (in seconds) for each IP address monitored by the redundancy group. (See **retry-count** for a related IP address monitoring configuration variable.)

**Options** *interval*—Pause time between each ping sent to each IP address monitored by the redundancy group.

**Range:** 1 to 30 seconds

**Default:** 1 second

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Specify attributes of an accounting-data log file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Options</b>                  | <b>bytes</b> —Maximum size of each log file, in bytes, kilobytes (KB), megabytes (MB), or gigabytes (GB). When a log file (for example, <b>profilelog</b> ) reaches its maximum size, it is renamed <b>profilelog.0</b> , then <b>profilelog.1</b> , and so on, until the maximum number of log files is reached. Then the oldest log file is overwritten. If you do not specify a size, the file is closed, archived, and renamed when the time specified for the transfer interval is exceeded.<br><br><b>Syntax:</b> <i>x</i> to specify bytes, <i>xk</i> to specify KB, <i>xm</i> to specify MB, <i>xg</i> to specify GB<br><b>Range:</b> 256 KB through 1 GB |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>         | Define tracing operations for System Accounting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>             | Trace options are not enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—Name of the file in which Junos OS stores the accounting logs. By default, this is created under the /var/log directory.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file reaches the size specified by the size option, the filename is appended with 0 and compressed. For example, when trace file named trace-file-log reaches size &lt;<i>size</i>&gt;, it is renamed and compressed to trace-file-log.0.gz. When trace-file-log reaches size &lt;<i>size</i>&gt; or the second time, the trace-file-log.0.gz is renamed to trace-file-log.1.gz and trace-file-log is renamed and compressed to trace-file-log.0.gz. This renaming scheme ensures that the older logs to have a greater index number. When number of trace files reach &lt;<i>number</i>&gt; then the oldest file is deleted.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 10</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. You can include one or more of the following flags:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—Trace all operations.</li> <li>• <b>config</b>—Trace configuration processing.</li> <li>• <b>events</b>—Trace accounting events and their processing.</li> <li>• <b>radius</b>—Trace RADIUS processing.</li> <li>• <b>tacplus</b>—Trace TACPLUS processing.</li> </ul> <p><b>no-remote-trace</b>—(Optional) Disable tracing and logging operations that track normal operations, error conditions, and packets that are generated by or passed through the Juniper Networks device.</p> <p><b>no-world-readable</b>—Restrict access to the trace files to the owner.</p> |

**Default:** no-world-readable

**size *size***—(Optional) Maximum size of each trace file in bytes, kilobytes (KB), megabytes (MB), or gigabytes (GB). If you do not specify a unit, the default is bytes. If you specify a maximum file size, you also must specify a maximum number of trace files by using the **files** option and a filename by using the **file** option.

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

**Syntax:** size to specify bytes, sizek to specify KB, sizem to specify MB, or sizeg to specify GB.

**Range:** 10 KB through 1 MB

**Default:** 128 KB

**world-readable**—Enable any user to access the trace files.

| <b>Description</b>              | <p>Specify the relative importance of all IP address monitored objects to the operation of the redundancy group. Every monitored IP address is assigned a weight. If the monitored address becomes unreachable, the weight of the object is deducted from the global-threshold of IP monitoring objects in its redundancy group. When the global-threshold reaches 0, the global-weight is deducted from the redundancy group. Every redundancy group has a default threshold of 255. If the threshold reaches 0, a failover is triggered. Failover is triggered even if the redundancy group is in manual failover mode and preemption is not enabled.</p> |
| <b>Options</b>                  | <p><i>number</i> —Combined weight assigned to all monitored IP addresses. A higher weight value indicates a greater importance.</p> <p><b>Range:</b> 0 through 255</p> <p><b>Default:</b> 255</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## ip-monitoring

```
Syntax ip-monitoring {
 family {
 inet {
 ipv4-address {
 interface {
 logical-interface-name;
 secondary-ip-address ip-address;
 }
 weight number;
 }
 }
 }
 global-threshold number;
 global-weight number;
 retry-count number;
 retry-interval seconds;
 }
```

**Hierarchy Level** [edit chassis cluster redundancy-group *group-number* ]

**Release Information** Statement updated in Junos OS Release 10.1.

**Description** Specify a global IP address monitoring threshold and weight, and the interval between pings (**retry-interval**) and the number of consecutive ping failures (**retry-count**) permitted before an IP address is considered unreachable for all IP addresses monitored by the redundancy group. Also specify IP addresses, a monitoring weight, a redundant Ethernet interface number, and a secondary IP monitoring ping source for each IP address, for the redundancy group to monitor.

**Options** **family inet *IPv4 address***—The address to be continually monitored for reachability.

**NOTE:** All monitored object failures, including IP monitoring, are deducted from the redundancy group threshold priority. Other monitored objects include interface monitor, SPU monitor, cold-sync monitor, and NPC monitor (on supported platforms).

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## ip-monitoring (Services)

```
Syntax ip-monitoring {
 policy policy-name {
 match {
 rpm-probe [probe-name];
 }
 no-preempt ;
 then {
 interface interface-name (disable | enable);
 preferred-route {
 route destination-address {
 next hop next-hop;
 preferred-metric metric;
 }
 }
 routing-instances name;
 }
 }
 }
 traceoptions {
 file {
 filename;
 files number;
 match regular-expression;
 size maximum-file-size;
 (world-readable | no-world-readable);
 }
 flag flag;
 no-remote-trace;
 }
}
```

**Hierarchy Level** [edit services]

**Release Information** Statement introduced in Junos OS Release 10.4.

**Description** Configure IP monitoring.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** services—To view this statement in the configuration.  
services-control—To add this statement to the configuration.

## action-profile

---

**Syntax**    `action-profile profile-name {  
                  event (jexec | lbt | lt-enter | lt-leave | mac-egress | mac-ingress | np-egress | np-ingress |  
                  pot) {  
                  count;  
                  packet-dump;  
                  packet-summary;  
                  trace;  
                  }  
                  module {  
                  flow {  
                  flag {  
                  all;  
                  }  
                  }  
                  }  
                  }  
                  preserve-trace-order;  
                  record-pic-history;  
                  }`

**Hierarchy Level**    [edit security datapath-debug]

**Release Information**    Command introduced in Junos OS Release 10.0.

**Description**    Configure the action profile options for data path debugging.

- Options**
- ***action-profile name*** — Name of the action profile.
  - **event**—Enable the events to trace the packet when the packet hit the events (jexec, lbt, lt-enter, lt-leave, mac-egress, mac-ingress, np-egress, np-ingress, pot)
    - **count**—Number of times a packet hits the specified event.
    - **packet-dump**—Capture the packet that hits the specified event.
    - **packet-summary**—Print the source/destination IP address details with protocol number and IP length details along with trace message for the specified event.
    - **trace**—Print the standard trace message when the packet hits the specified event.
  - **module**—Turn on the flow session related trace messages.
    - **flow**—Trace flow session related messages.
    - **flag**—Specify which flow message needs to be traced.
    - **all**—Trace all possible flow trace messages.
    - **trace**—Print the standard trace message when the packet hits the specified event.
  - **preserve-trace-order**—Preserve trace order.
  - **record-pic-history**—Record the PICs in which the packet has been processed.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

**Related Documentation** • [Example: Configuring Packet Capture for Datapath Debugging on page 1937](#)

## capture-file (Security)

**Syntax** `capture-file {  
    filename;  
    files number;  
    format pcap-format;  
    size maximum-file-size;  
    (world-readable | no-world-readable);  
}`

**Hierarchy Level** [edit security datapath-debug]

**Release Information** Statement introduced in Junos OS Release 10.4.

**Description** Sets packet capture for performing the datapath-debug action.

- Options**
- **filename**—Name of the file to receive the output of the packet capturing operation.
  - **files**—Maximum number of capture files.  
  
If you specify a maximum number of files, you also must specify a maximum file size with the **size** option and a filename.  
  
Range: 1 through 10 files
  - **format**—Describes the format of the capture file. The default format file is pcap. You can also set it as private (binary) format.
  - **size**—Describes the size limit of the capture file.  
  
If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option and a filename.  
  
Range: 10 KB through 100 MB
  - **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

 source-port port-identifier;
 source-prefix address;
 }
 rate-limit messages-per-second;
}

```

**Hierarchy Level** [edit security]

**Release Information** Statement modified in Junos OS Release 9.5.

**Description** Determine how the device manages packet flow. The device can regulate packet flow in the following ways:

- Enable or disable DNS replies when there is no matching DNS request.
- Set the initial session-timeout values.

**Options** The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** security—To view this statement in the configuration.  
security-control—To add this statement to the configuration.

| <b>Release Information</b> | Command introduced in Junos OS Release 9.6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>         | Sets the trace options for datapath-debug.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>             | <ul style="list-style-type: none"> <li><b>file</b>—Configure the trace file options. <ul style="list-style-type: none"> <li><b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <code>/var/log</code>. By default, the name of the file is the name of the process being traced.</li> <li><b>files number</b>—Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed to <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.</li> </ul> <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> </li> <li><b>match regular-expression</b>—Refine the output to include lines that contain the regular expression.</li> <li><b>size maximum-file-size</b>—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named <b>trace-file</b> reaches this size, it is renamed <b>trace-file.0</b>. When the trace-file again reaches its maximum size, <b>trace-file.0</b> is renamed <b>trace-file.1</b> and <b>trace-file</b> is renamed <b>trace-file.0</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</li> </ul> <p>If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.</p> <p>Syntax: x K to specify KB, x m to specify MB, or x g to specify GB</p> <p>Range: 10 KB through 1 GB</p> <p>Default: 128 KB</p> |

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option
- **no-remote-trace**—Set remote tracing as disabled.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.0.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>              | The lower threshold is expressed as a percentage of the maximum possible value for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the <b>rising-threshold</b> . |
| <b>Options</b>                  | <b><i>percentage</i></b> —The lower threshold for the alarm entry.<br><b>Range:</b> 1 through 100<br><b>Default:</b> 70 percent of the maximum possible value                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## alarm (SNMP RMON)

---

**Syntax**    `alarm index {  
                  description description;  
                  falling-event-index index;  
                  falling-threshold integer;  
                  falling-threshold-interval seconds;  
                  interval seconds;  
                  request-type (get-next-request | get-request | walk-request);  
                  rising-event-index index;  
                  rising-threshold integer;  
                  sample-type (absolute-value | delta-value);  
                  startup-alarm (falling-alarm | rising-alarm | rising-or-falling alarm);  
                  syslog-subtag syslog-subtag;  
                  variable oid-variable;  
                  }`

**Hierarchy Level**    [edit snmp rmon]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.1 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description**    Configure RMON alarm entries.

**Options**    *index*—Identifies this alarm entry as an integer.  
  
The remaining statements are explained separately.

**Required Privilege Level**    snmp—To view this statement in the configuration.  
snmp-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | The trap group that is used when generating a trap (if <b>eventType</b> is configured to send traps). If that trap group has the <b>rmon-alarm</b> trap category configured, a trap is sent to all the targets configured for that trap group. The community string in the trap matches the name of the trap group (and hence, the value of <b>eventCommunity</b> ). If nothing is configured, traps are sent to each group with the <b>rmon-alarm</b> category set. |
| <b>Options</b>                  | <b>community-name</b> —Identifies the trap group that is used when generating a trap if the event is configured to send traps.                                                                                                                                                                                                                                                                                                                                       |
| <b>Required Privilege Level</b> | <b>snmp</b> —To view this statement in the configuration.<br><b>snmp-control</b> —To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | The lower threshold for the sampled variable. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval is greater than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is less than or equal to this threshold, and the associated startup-alarm value is equal to falling-alarm value or rising-or-falling-alarm value. After a falling event is generated, another falling event cannot be generated until the sampled value rises above this threshold and reaches the <b>rising-threshold</b> . |
| <b>Options</b>                  | <b>integer</b> —The lower threshold for the alarm entry.<br><b>Range:</b> -2,147,483,648 through 2,147,483,647<br><b>Default:</b> 20 percent less than <b>rising-threshold</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b>              | Upper threshold for the sampled variable. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval is less than this threshold, a single event is generated. A single event is also generated if the first sample after this entry becomes valid is greater than or equal to this threshold, and the associated startup alarm value is equal to the falling alarm or rising or falling alarm value. After a rising event is generated, another rising event cannot be generated until the sampled value falls below this threshold and reaches the falling threshold. |
| <b>Options</b>                  | <i>integer</i> —The lower threshold for the alarm entry.<br><b>Range:</b> -2,147,483,648 through 2,147,483,647                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                                 |                                                                                                                                                                                                                |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | <code>variable oid-variable;</code>                                                                                                                                                                            |
| <b>Hierarchy Level</b>          | [edit snmp rmon <a href="#">alarm index</a> ]                                                                                                                                                                  |
| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                      |
| <b>Description</b>              | Object identifier (OID) of MIB variable to be monitored.                                                                                                                                                       |
| <b>Options</b>                  | <b>oid-variable</b> —OID of the MIB variable that is being monitored. The OID can be a dotted decimal (for example, 1.3.6.1.2.1.2.1.10.1). Alternatively, use the MIB object name (for example, ifInOctets.1). |
