YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Guide 1

Installation and Upgrade Guide

Part 1

Junos Software and Hardware Overview

Chapter 1

Software Overview	3
Junos OS Overview	3
One Operating System	4
One Modular Software Architecture	4
Junos OS Editions	5
FIPS 140-2 Security Compliance	5
Junos OS Installation Packages	6
Junos OS Package Names for EX Series Switches	7
Software Naming Convention	9
Software Naming Convention for SRX Series Devices	10
Software Package Information Security	11
Junos OS Release Numbers	11
Installation Media	12
Installation Bundles	13
Installation Modules	14
Configuration Files	15
Configuration File Selection Sequence	15
Remote Storage of Configuration Files	16
Understanding Software Infrastructure and Processes	17
Routing Engine and Packet Forwarding Engine	17
Junos OS Processes	17
Understanding Junos OS with Upgraded FreeBSD	19
Understanding Junos OS with Upgraded FreeBSD Package Names	22
Understanding Junos OS with Upgraded FreeBSD Snapshots	23
Understanding Junos OS with Upgraded FreeBSD Disk Volumes	24

Chapter 2	Hardware Overview	27
	Hardware Architecture Overview	27
	Hardware Overview (ACX Series, M Series, MX Series, T Series, and TX Matrix Routers)	28
	System Memory	29
	Storage Media	30
	Hardware Overview of SRX Series Services Gateways	31
	SRX Series Device Overview	31
	System Memory	31
	Storage Media	31
	Routing Engines and Storage Media Names (ACX Series, M Series, MX Series, PTX Series, T Series, TX Matrix, TX Matrix Plus, and JCS 1200 Routers)	32
	Storage Media Names for SRX Series Devices	34
	Boot Sequence on M Series, MX Series, T Series, TX Matrix, TX Matrix Plus, ACX Series, and PTX Series Devices with Routing Engines	34
	Boot Sequence on SRX Series Devices	36
Part 2	Installing Junos Software	
Chapter 3	Installation Overview	41
	Installation Type Overview	41
	Standard Installation	41
	Category Change Installation	41
	Recovery Installation	42
	Installation Categories on the ACX Series, M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus Routers	42
	Installation Categories on SRX Series Devices	43
	Understanding Software Installation on EX Series Switches	44
	Overview of the Software Installation Process	44
	Software Package Security	44
	Installing Software on a Virtual Chassis	45
	Installing Software on Switches with Redundant Routing Engines	45
	Installing Software Using Automatic Software Download	45
	Autoinstalling a Configuration File on an EX2200 or EX3300 Switch from a Disk-on-Key USB Memory Stick	46
	Installing Software on an EX2300 or EX3400 Switch	46
	Troubleshooting Software Installation	46
Chapter 4	Performing a Standard or Change Category Installation	47
	Checking the Current Configuration and Candidate Software Compatibility	47
	Determining the Junos OS Version	48
	Downloading Software	48
	Downloading Software with a Browser	49
	Downloading Software Using the Command-Line Interface	49
	Downloading Software Packages from Juniper Networks	51
	Understanding Download Manager for SRX Series Devices	51
	Overview	51
	Using Download Manager to Upgrade Junos OS	52
	Handling Errors	52

	Considerations	53
	Understanding the Console Port	53
	Backing Up the Existing Installation on Routers	55
	Backing Up the Current Installation on SRX Series Devices	56
	Backing Up the Current Installation on High-End SRX Series Devices	56
	Backing Up the Current Installation on Branch SRX Series Devices	57
	Installing the Software Package on a Router with a Single Routing Engine	57
	Installing the Software Package on a Router with Redundant Routing Engines	58
	Preparing the Router for the Installation	59
	Installing Software on the Backup Routing Engine	59
	Installing Software on the Master Routing Engine	61
	Finalizing the Installation	63
	Repartitioning Routing Engine System Storage To Increase the Swap Partition	64
	Installing Software on EX Series Switches (J-Web Procedure)	64
	Installing Software Upgrades from a Server	65
	Installing Software Upgrades by Uploading Files	65
	Registering the EX Series Switch with the J-Web Interface	66
	Preparing the USB Flash Drive to Upgrade Junos OS on SRX Series Devices	66
	Installing Junos OS on SRX Series Devices Using a USB Flash Drive	68
	Upgrading the Boot Loader on SRX Series Devices	69
	Installing Junos OS on SRX Series Devices from the Boot Loader Using a TFTP Server	70
	Installing Junos OS on SRX Series Devices from the Boot Loader Using a USB Storage Device	72
Chapter 5	Configuring Zero Touch Provisioning	73
	Understanding Zero Touch Provisioning	73
	Configuring Zero Touch Provisioning	76
Chapter 6	Configuring Automatic Installation of Configuration Files	81
	Autoinstallation Overview	81
	Automatic Installation of Configuration Files	82
	Supported Autoinstallation Interfaces and Protocols	82
	Typical Autoinstallation Process on a New Device	83
	Configuring Autoinstallation on SRX Series Devices	84
	Configuring Autoinstallation on JNU Satellite Devices	87
	Autoinstallation Process on Satellite Devices in a Junos Node Unifier Group	89
	Supported Autoinstallation Interfaces and Protocols	89
	Typical Autoinstallation Process on a New Router	90
	Autoinstallation of Satellite Devices in a Junos Node Unifier Group	91
	Verifying Autoinstallation on JNU Satellite Devices	92
Chapter 7	Configuring Dual-Root Partitions for High Availability	95
	Understanding Resilient Dual-Root Partitions on Switches	95
	Resilient Dual-Root Partition Scheme (Junos OS Release 10.4R3 and Later)	96
	Automatic Fixing of Corrupted Primary Root Partition with the Automatic Snapshot Feature	96

Earlier Partition Scheme (Junos OS Release 10.4R2 and Earlier)	97
Understanding Upgrading or Downgrading Between Resilient Dual-Root Partition Releases and Earlier Releases	98
Resilient Dual-Root Partitions Frequently Asked Questions	99
How Does Upgrading to Junos OS Release 10.4R3 and Later Differ from Normal Upgrades?	99
What Happens If I Do Not Upgrade Both the Loader Software and Junos OS at the Same Time?	100
Can I Downgrade Junos OS Without Downgrading the Loader Software?	101
Can I Upgrade to a Resilient Dual-Root Partition Release by Using the CLI?	101
Will I Lose My Configuration During an Upgrade?	102
How Long Will the Upgrade Process Take?	102
What Happens to My Files If the System Detects a File System Corruption and Automatic Snapshot Is Enabled?	102
What Happens to My Files If the System Detects a File System Corruption and Automatic Snapshot Is Not Enabled?	103
How Will I Be Informed If My Switch Boots from the Alternate Slice Because of Corruption in the Root File System?	103
Can I Use Automatic Software Update and Download to Upgrade to a Resilient Dual-Root Partition Release?	104
Why Is the Message "At least one package installed on this device has limited support" Displayed When Users Log In to a Switch?	104
Where Can I Find Instructions for Upgrading?	104
Dual-Root Partitioning Scheme on SRX Series Devices	105
Boot Media and Boot Partition on SRX Series Devices	106
Important Features of the Dual-Root Partitioning Scheme	106
Understanding Automatic Recovery of the Primary Junos OS Image with Dual-Root Partitioning	106
Understanding How the Primary Junos OS Image with Dual-Root Partitioning Recovers Devices	108
Understanding How Junos OS Release 10.0 or Later Upgrades with Dual-Root Partitioning	109
Example: Installing Junos OS on SRX Series Devices Using the Partition Option	110
Chapter 8 Upgrading Software	115
Upgrading Software Packages	116
Upgrading to 64-bit Junos OS	119
Upgrading Routers Using Unified ISSU	122
Understanding Nonstop Software Upgrade on EX Series Switches	123
Requirements for Performing an NSSU	124
How an NSSU Works	125
EX3300, EX4200, EX4300, EX4500, and Mixed Virtual Chassis	125
EX6200 and EX8200 Switches	126
EX8200 Virtual Chassis	127
NSSU Limitations	128
NSSU and Junos OS Release Support	128

Overview of NSSU Configuration and Operation	129
Upgrading Software by Using Automatic Software Download	129
Verifying That Automatic Software Download Is Working Correctly	131
Verifying Junos OS and Boot Loader Software Versions on an EX Series Switch	131
Verifying the Number of Partitions and File System Mountings	132
Verifying the Loader Software Version	132
Verifying Which Root Partition Is Active	133
Verifying the Junos OS Version in Each Root Partition	134
Upgrading the Loader Software on the Line Cards in a Standalone EX8200 Switch or an EX8200 Virtual Chassis	136
Upgrading Junos OS with Upgraded FreeBSD	139
To Install Junos OS with Upgraded FreeBSD Over a Plain Junos OS	141
To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of an Earlier Release	144
To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of a Later Release	145
Understanding Junos OS Upgrades for SRX Series Devices	145
Understanding Junos OS Upgrades	146
Junos OS Upgrade Methods on the SRX Series Devices	146
Preparing Your SRX Series Device for Junos OS Upgrades	147
Secondary Storage Devices Available on SRX Series Devices	147
Verifying Available Disk Space on SRX Series Devices	148
Cleaning Up the System File Storage Space	149
Downloading Software Packages from Juniper Networks	150
Example: Installing Junos OS Upgrade Packages on SRX Series Devices	150
Installing Junos OS Upgrade Packages on SRX Series Devices from a Remote Server	152
Understanding BIOS Upgrades on SRX Series Devices	154
Understanding Manual BIOS Upgrade Using the Junos CLI	154
Understanding Auto BIOS Upgrade Methods on SRX Series Devices	155
Disabling Auto BIOS Upgrade on SRX Series Devices	155
Example: Downgrading Junos OS on SRX Series Devices	156
Chapter 9 Booting a Device Using a System Snapshot	159
Understanding System Snapshot on EX Series Switches	159
Creating a Snapshot and Using It to Boot an EX Series Switch	160
Creating a Snapshot on a USB Flash Drive and Using It to Boot the Switch	160
Verifying That a System Snapshot Was Created on an EX Series Switch	161
Booting an EX Series Switch Using a Software Package Stored on a USB Flash Drive	162

Chapter 10	Performing a Recovery Installation	165
	Creating an Emergency Boot Device	165
	Configuring Boot Devices for SRX Series Devices	166
	Example: Creating a Snapshot and Using It to Boot an SRX Series Device	166
	Understanding Integrity Check and Autorecovery of Configuration, Licenses, and Disk Information on SRX Series Devices	169
	Overview	169
	How Autorecovery Works	170
	How to Use Autorecovery	170
	Data That Is Backed Up in an Autorecovery	170
	Troubleshooting Alarms	171
	Considerations	171
	Performing a Recovery Installation	172
	Creating a New Configuration on a Single Routing Engine	173
	Log In to the Router Console	173
	Configure Administration User Accounts	174
	Add the Management Console to the Network	174
	Commit Changes	175
	Creating a New Configuration with Redundant Routing Engines	177
	Configure Administration User Accounts	178
	Set Up Routing Engine Configuration Groups	178
	Complete the Management Console Configuration	180
	Commit and Synchronize Changes	181
	Saving a Rescue Configuration File	183
	Restoring a Saved Configuration	184
	Copy Saved Files to the Router	184
	Loading and Committing the Configuration File	184
	Reverting to the Default Factory Configuration by Using the request system zeroize Command	185
	Reverting to the Rescue Configuration	186
Chapter 11	Reinstalling Software	187
	Checklist for Reinstalling Junos OS	187
	Log the Software Version Information	189
	Log the Hardware Version Information	190
	Log the Chassis Environment Information	191
	Log the System Boot-Message Information	192
	Log the Active Configuration	194
	Log the Interfaces on the Router	194
	Log the BGP, IS-IS, and OSPF Adjacency Information	195
	Log the System Storage Information	196
	Back Up the Currently Running and Active File System	197

	Reinstall Junos OS	197
	Reconfigure Junos OS	198
	Configure Host Names, Domain Names, and IP Addresses	198
	Protecting Network Security by Configuring the Root Password	200
	Check Network Connectivity	201
	Copy Backup Configurations to the Router	202
	Configure Host Names, Domain Names, and IP Addresses	202
	Protecting Network Security by Configuring the Root Password	204
	Check Network Connectivity	206
	Copy Backup Configurations to the Router	206
	After You Reinstall Junos OS	206
	Compare Information Logged Before and After the Reinstall	206
	Back Up the New Software	207
	Compare Information Logged Before and After the Reinstall	207
	Back Up the New Software	207
Chapter 12	Downgrading Software	209
	Downgrading Junos OS from Upgraded FreeBSD	209
	Downgrading from Junos OS with Upgraded FreeBSD to Junos OS	209
	Downgrading from Junos OS with Upgraded FreeBSD to an Earlier Release of Junos OS with Upgraded FreeBSD	211
Chapter 13	Rebooting or Halting Software Processes on a Device	213
	Restarting and Halting SRX Series Devices	213
	Rebooting SRX Series Devices	213
	Halting SRX Series Devices	215
	Bringing Chassis Components Online and Offline on SRX Series Devices	217
	Restarting the Chassis on SRX Series Devices	217
	Bringing Chassis Components Online and Offline on SRX Series Devices	218
	Restarting the Chassis on SRX Series Devices	218
	Rebooting or Halting the EX Series Switch (J-Web Procedure)	219
Part 3	Installing and Managing Software Licenses	
Chapter 14	Software License Overview	223
	Junos OS Feature Licenses	223
	License Enforcement	224
	Junos OS Feature License Keys	225
	Release-Tied License Keys and Upgrade Licenses on MX Series Routers	225
	Licensable Ports on MX5, MX10, and MX40 Routers	226
	Port Activation on MX104 Routers	227
	Software Feature Licenses	228
	Software Features That Require Licenses on M Series, MX Series, and T Series Routers	228
	Software Features That Require Licenses on M Series Routers Only	231
	Software Features That Require Licenses on MX Series Routers Only	232
	Software Feature Licenses for SRX Series Devices	236
	Software Features That Require Licenses on EX Series Switches	241
	Software Features That Require Licenses on the QFX Series	243

	Understanding Software Licenses for EX Series Switches	246
	Purchasing a Software Feature License	246
	Features Requiring a License on EX2200 Switches	247
	Features Requiring a License on EX2300 Switches	248
	Features Requiring a License on EX3300 Switches	248
	Features Requiring a License on EX3400 Switches	249
	Features Requiring a License on EX4300 Switches	250
	Features Requiring a License on EX4600 Switches	252
	Features Requiring a License on EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 Switches	253
	License Warning Messages	254
Chapter 15	Installing and Managing Licenses	257
	Adding New Licenses (CLI Procedure)	257
	Deleting a License (CLI Procedure)	258
	Saving License Keys	259
	Verifying Junos OS License Installation	260
	Displaying Installed Licenses	260
	Displaying License Usage	261
Part 4	Troubleshooting Information	
Chapter 16	Troubleshooting Software Installation	265
	Troubleshooting Software Installation	265
	Recovering from a Failed Software Upgrade on an EX Series Switch	265
	Rebooting from the Inactive Partition	266
	Freeing Disk Space for Software Installation	267
	Installation from the Boot Loader Generates 'cannot open package' Error	267
	Troubleshooting a Switch That Has Booted from the Backup Junos OS Image	268
	Disk Space Management for Junos OS Installation	269
	Verifying PIC Combinations	269
Part 5	Configuration Statements and Operational Commands	
Chapter 17	Configuration Statements	273
	auto-configuration	274
	auto-configuration (System)	275
	auto-image-upgrade	277
	auto-snapshot	278
	autoinstallation	279
	autoinstallation (JNU Satellite Devices)	280
	bootp	281
	commit	282
	configuration-servers	283
	delete-after-commit (JNU Satellites)	284
	interfaces (Autoinstallation)	285
	license	286
	usb	288

Chapter 18

usb-control	288
Operational Commands	289
clear system login lockout	291
request system autorecovery state	292
request system download abort	294
request system download clear	295
request system download pause	296
request system download resume	297
request system download start	298
request system firmware upgrade	299
request system halt	300
request system license add	302
request system license delete	303
request system license save	304
request system license update	305
request system partition compact-flash	306
request system power-off	307
request system reboot	309
request system reboot	314
request system reboot (Junos OS with Upgraded FreeBSD)	316
request system scripts add	319
request system scripts delete	320
request system scripts rollback	321
request system snapshot	322
request system snapshot (Junos OS with Upgraded FreeBSD)	329
request system snapshot (SRX Series)	331
request system software abort in-service-upgrade (ICU)	333
request system software add	334
request system software add (Maintenance)	344
request system software configuration-backup	345
request system software configuration-restore	346
request system software delete	347
request system software rollback	351
request system software rollback (SRX Series)	356
request system software validate	357
request system software validate on (Junos OS with Upgraded FreeBSD)	361
request system storage cleanup	364
request system storage cleanup (SRX Series)	374
request system zeroize	377
show chassis usb storage	382
show system autoinstallation status	383
show system autorecovery state	385
show system boot-messages	387
show system auto-snapshot	394
show system download	396
show system license	398
show system license (View)	406
show system login lockout	409

show system snapshot	410
show system snapshot (Junos OS with Upgraded FreeBSD)	413
show system snapshot media	414
show system storage partitions (EX Series Switches Only)	415
show system storage partitions (View SRX Series)	417

Guide 2 CLI User Guide

Chapter 19	Overview	421
	Introducing the Junos OS Command-Line Interface	421
	Key Features of the CLI	422
	Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies	423
	Junos OS CLI Command Modes	423
	CLI Command Hierarchy	424
	Configuration Statement Hierarchy	424
	Moving Among Hierarchy Levels	425
	Other Tools to Configure and Monitor Devices Running Junos OS	426
	Commands and Configuration Statements for Junos-FIPS	426
Chapter 20	Getting Started: A Quick Tour of the CLI	429
	Getting Started with the Junos OS Command-Line Interface	429
	Switching Between Junos OS CLI Operational and Configuration Modes	431
	Configuring a User Account on a Device Running Junos OS	432
	Using the CLI Editor in Configuration Mode	434
	Checking the Status of a Device Running Junos OS	436
	Example: Configuring a Routing Protocol	438
	Shortcut	439
	Longer Configuration	439
	Making Changes to a Routing Protocol Configuration	441
	Rolling Back Junos OS Configuration Changes	444
Chapter 21	Getting Online Help	447
	Getting Online Help from the Junos OS Command-Line Interface	447
	Getting Help About Commands	447
	Getting Help About a String in a Statement or Command	448
	Getting Help About Configuration Statements	449
	Getting Help About System Log Messages	449
	Junos OS CLI Online Help Features	450
	Help for Omitted Statements	450
	Using CLI Command Completion	450
	Using Command Completion in Configuration Mode	451
	Displaying Tips About CLI Commands	451
	Examples: Using Command Completion in Configuration Mode	451
	Examples: Using the Junos OS CLI Command Completion	453
	Displaying the Junos OS CLI Command and Word History	454

Chapter 22	Using Configuration Statements to Configure a Device	455
	Understanding Junos OS CLI Configuration Mode	456
	Configuration Mode Commands	457
	Configuration Statements and Identifiers	458
	Configuration Statement Hierarchy	460
	Entering and Exiting the Junos OS CLI Configuration Mode	462
	Notational Conventions Used in Junos OS Configuration Hierarchies	464
	Forms of the configure Command	465
	Using the configure exclusive Command	467
	Using the configure Command	468
	Modifying the Junos OS Configuration	468
	Adding Junos OS Configuration Statements and Identifiers	469
	Deleting a Statement from a Junos OS Configuration	470
	Example: Deleting a Statement from the Junos OS Configuration	471
	Copying a Junos OS Statement in the Configuration	473
	Example: Copying a Statement in the Junos Configuration	473
	Issuing Relative Junos OS Configuration Mode Commands	475
	Renaming an Identifier in a Junos OS Configuration	476
	Examples: Re-Using Configuration	476
	Inserting a New Identifier in a Junos OS Configuration	481
	Example: Inserting a New Identifier in a Junos Configuration	481
	Example: Using the Wildcard Command with the Range Option	485
	Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration	489
	Example: Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration	490
	Adding Comments in a Junos OS Configuration	492
	Adding Comments in the CLI	492
	Adding Comments in a File	493
	Example: Including Comments in a Junos OS Configuration by Using the CLI	494
	Updating the configure private Configuration	496
	Displaying the Current Junos OS Configuration	497
	Example: Displaying the Current Junos OS Configuration	498
	Displaying Additional Information About the Junos OS Configuration	499
	Displaying set Commands from the Junos OS Configuration	501
	Example: Displaying set Commands from the Configuration	502
	Example: Displaying Required set Commands at the Current Hierarchy Level	502
	Example: Displaying set Commands with the match Option	503
	Displaying Users Currently Editing the Junos OS Configuration	504
	Verifying a Junos OS Configuration	504
Chapter 23	Committing a Junos OS Configuration	507
	Junos OS Commit Model for Router or Switch Configuration	507
	Committing a Junos OS Configuration	508
	Committing a Junos OS Configuration and Exiting Configuration Mode	510
	Commit Operation When Multiple Users Configure the Software	511
	Activating a Junos OS Configuration but Requiring Confirmation	512
	Scheduling a Junos OS Commit Operation	513

	Monitoring the Junos OS Commit Process	514
	Adding a Comment to Describe the Committed Configuration	515
	Backing Up the Committed Configuration on the Alternate Boot Drive	516
	Junos OS Batch Commits Overview	516
	Aggregation and Error Handling	517
	Example: Configuring Batch Commit Server Properties	517
Chapter 24	Managing Configurations	525
	Understanding How the Junos OS Configuration Is Stored	525
	Comparing Configuration Changes with a Prior Version	526
	Understanding the show compare display xml Command Output	528
	Adding a Statement (create Operation)	529
	Deleting a Statement (delete Operation)	529
	Changing a Statement (delete and create Operations)	530
	Changing Metadata (inactive Attribute and Operation)	531
	Adding an Annotation (comment Tag and create Operation)	532
	Changing an Annotation (comment Tag, and delete and create Operations)	532
	Adding a Statement Inside a Container (create Operation, and insert and key Attributes)	533
	Changing the Order Inside a Container (merge Operation, and insert and key Attributes)	534
	Returning to the Most Recently Committed Junos OS Configuration	534
	Returning to a Previously Committed Junos OS Configuration	535
	Returning to a Configuration Prior to the One Most Recently Committed	535
	Displaying Previous Configurations	535
	Comparing Configuration Changes with a Prior Version	536
	Creating and Returning to a Rescue Configuration	538
	Saving a Configuration to a File	539
	Saving a Configuration to a File	540
	Additional Details About Specifying Junos OS Statements and Identifiers	541
	Specifying Statements	541
	Performing CLI Type Checking	543
	Loading a Configuration from a File	544
	Examples: Loading a Configuration from a File	547
	Creating and Returning to a Rescue Configuration	549
	Compressing the Current Configuration File	549
	Example: Protecting the Junos OS Configuration from Modification or Deletion	551
	Synchronizing Routing Engines	558
	Configuring Multiple Routing Engines to Synchronize Committed Configurations Automatically	560
Chapter 25	Using Operational Commands to Monitor a Device	563
	Overview of Junos OS CLI Operational Mode Commands	563
	CLI Command Categories	563
	Commonly Used Operational Mode Commands	565
	Junos OS Operational Mode Commands That Combine Other Commands	566
	Understanding the Brief, Detail, Extensive, and Terse Options of Junos OS Operational Commands	567

Controlling the Scope of an Operational Mode Command	568
Operational Mode Commands on a TX Matrix Router or TX Matrix Plus Router	569
Examples of Routing Matrix Command Options	569
Monitoring Who Uses the Junos OS CLI	571
Interface Naming Conventions Used in the Junos OS Operational Commands	572
Physical Part of an Interface Name	572
Logical Part of an Interface Name	572
Channel Identifier Part of an Interface Name	573
Viewing Files and Directories on a Device Running Junos OS	573
Directories on the Router or Switch	573
Listing Files and Directories	574
Specifying Filenames and URLs	576
Displaying Junos OS Information	577
Managing Programs and Processes Using Junos OS Operational Mode Commands	579
Showing Software Processes	580
Restarting the Junos OS Process	581
Stopping Junos OS	582
Rebooting Junos OS	583
Using the Junos OS CLI Comment Character # for Operational Mode Commands	584
Example: Using Comments in Junos OS Operational Mode Commands	584
Chapter 26 Filtering Command Output	587
Using the Pipe () Symbol to Filter Junos OS Command Output	587
Using Regular Expressions with the Pipe () Symbol to Filter Junos OS Command Output	588
Filtering Operational Mode Command Output in a QFabric System	589
Pipe () Filter Functions in the Junos OS Command-Line Interface	590
Comparing Configurations and Displaying the Differences in Text	590
Comparing Configurations and Displaying the Differences in XML	592
Counting the Number of Lines of Output	592
Displaying Output in XML Tag Format	592
Displaying Output in JSON Format	593
Displaying the RPC tags for a Command	593
Ignoring Output That Does Not Match a Regular Expression	593
Displaying Output from the First Match of a Regular Expression	594
Retaining Output After the Last Screen	594
Displaying Output Beginning with the Last Entries	594
Displaying Output That Matches a Regular Expression	595
Preventing Output from Being Paginated	595
Sending Command Output to Other Users	595
Resolving IP Addresses	596
Saving Output to a File	596
Appending Output to a File	596
Displaying Output on Screen and Writing to a File	597
Trimming Output by Specifying the Starting Column	597

	Refreshing the Output of a Command	597
Chapter 27	Using Shortcuts, Wildcards, and Regular Expressions in the CLI	599
	Using Keyboard Sequences to Move Around and Edit the Junos OS CLI	599
	Using Wildcard Characters in Interface Names	601
	Common Regular Expressions to Use with the replace Command	602
	Using Global Replace in the Junos OS Configuration	603
	Example: Using Global Replace in a Junos OS Configuration—Using the \n Back Reference	604
	Example: Using Global Replace in a Junos OS Configuration—Replacing an Interface Name	606
	Example: Using Global Replace in a Junos OS Configuration—Using the upto Option	608
	Using Regular Expressions to Delete Related Items from a Junos OS cConfiguration	609
Chapter 28	Using Configuration Groups to Quickly Configure Devices	613
	Understanding Junos OS Configuration Groups	614
	Configuration Groups Overview	614
	Inheritance Model	614
	Configuring Configuration Groups	614
	Creating the Junos OS Configuration Group	615
	Applying the Junos OS Configuration Group	617
	Example: Configuring and Applying Junos OS Configuration Groups	618
	Example: Creating and Applying Configuration Groups on a TX Matrix Router	619
	Disabling Inheritance of a Junos OS Configuration Group	620
	Using Wildcards with Configuration Groups	622
	Example: Configuring Sets of Statements with Configuration Groups	625
	Example: Configuring Interfaces Using Junos OS Configuration Groups	626
	Example: Configuring a Consistent IP Address for the Management Interface	628
	Example: Configuring Peer Entities	630
	Establishing Regional Configurations	631
	Configuring Wildcard Configuration Group Names	633
	Example: Referencing the Preset Statement From the Junos OS defaults Group	634
	Example: Viewing Default Statements That Have Been Applied to the Configuration	635
	Using Conditions to Apply Configuration Groups Overview	636
	Example: Configuring Conditions for Applying Configuration Groups	636
	Improving Commit Time When Using Configuration Groups	638
	Example: Improving Commit Time When Using Configuration Groups	639
	Using Junos OS Defaults Groups	640
	Set Up Routing Engine Configuration Groups	642
Chapter 29	Controlling the CLI Environment	645
	Controlling the Junos OS CLI Environment	645
	Setting the Terminal Type	646
	Setting the CLI Prompt	646
	Setting the CLI Directory	646
	Setting the CLI Timestamp	646

	Setting the Idle Timeout	646
	Setting the CLI to Prompt After a Software Upgrade	646
	Setting Command Completion	647
	Displaying CLI Settings	647
	Setting the Junos OS CLI Screen Length and Width	647
	Setting the Screen Length	647
	Setting the Screen Width	648
	Example: Controlling the CLI Environment	648
	Example: Enabling Configuration Breadcrumbs	654
Chapter 30	Junos OS Configuration Statements and Commands	657
	apply-groups	658
	apply-groups-except	659
	activate	660
	annotate	661
	commit	662
	commit-interval (Batch Commits)	667
	configuration-breadcrumbs	668
	copy	669
	days-to-keep-error-logs (Batch Commits)	669
	deactivate	670
	delete	671
	edit	672
	exit	673

	update	704
	when	705
	wildcard delete	707
Chapter 31	Junos OS CLI Environment Commands	709
	set cli complete-on-space	710
	set cli directory	711
	set cli idle-timeout	712
	set cli prompt	713
	set cli restart-on-upgrade	714
	set cli screen-length	715
	set cli screen-width	716
	set cli terminal	717
	set cli timestamp	718
	set date	719
	show cli	720
	show cli	722
	show cli authorization	723
	show cli directory	724
	show cli history	725
Chapter 32	Junos OS CLI Operational Mode Commands	727
	configure	728
	file	730
	help	731
	(pipe)	732
	request	735
	request system commit server pause	737
	request system commit server queue cleanup	738
	request system commit server start	739
	restart	740
	set	751
	show system commit server queue	752
	show system commit server status	756
Guide 3	J-Web User Guide for Security Devices	
Part 6	Overview	
Chapter 33	Understanding the J-Web User Interface	761
	J-Web Overview	761
	Starting the J-Web User Interface	762
	Understanding the J-Web Interface Layout	762
	Top Pane	763
	Main Pane	764
	Side Pane	764
	Getting Help in the J-Web User Interface	765

Part 7	Configuring and Managing a Device Using J-Web	
Chapter 34	Installing J-Web	769
	J-Web Software Requirements	769
	Installing the J-Web Software	769
Chapter 35	Configuring Secure Web Access to a Device	771
	Secure Web Access Overview	771
	Generating SSL Certificates	771
	Configuring Secure Web Access	772
	Establishing J-Web Sessions	772
Chapter 36	Configuring a Device Using J-Web	775
	Configuring Basic Settings	776
	J-Web Configuration Pages Overview	778
	Editing a Configuration	779
	J-Web Commit Options Guidelines	782
	Committing a Configuration	783
Chapter 37	Managing J-Web Sessions and Users	785
	Setting J-Web Session Limits	785
	Terminating J-Web Sessions	785
Part 8	Troubleshooting	
Chapter 38	Troubleshooting the J-Web User Interface	789
	Lost Router Connectivity	789
	Unpredictable J-Web Behavior	789
	No J-Web Access	789
Guide 4	Administration Guide for Security Devices	
Part 9	User Access and Authentication	
Chapter 39	User Access and Authentication Overview	795
	Understanding Login Classes	795
	Permission Bits	796
	Denying or Allowing Individual Commands	798
	Understanding User Accounts	798
	Understanding Junos OS Access Privilege Levels	799
	Junos OS Login Class Permission Flags	799
	Allowing or Denying Individual Commands for Junos OS Login Classes	803
	Understanding User Authentication Methods	804
	Hardening Shared Secrets in Junos OS	804
	Understanding Hardening Shared Secrets	804
	Chassis Cluster Considerations	806

Chapter 40	Configuring Junos OS User Accounts	807
	Example: Configuring New Users	807
	Understanding Template Accounts	810
	Example: Creating Template Accounts	810
	Understanding Administrative Roles	813
	Example: Configuring Administrative Roles	815
	Handling Authorization Failure	822
	Example: Configuring System Retry Options	823
Chapter 41	Configuring User Access Privileges	829
	Configuring Access Privilege Levels	829
	Example: Configuring User Permissions with Access Privilege Levels	830
	Specifying Access Privileges for Junos OS Operational Mode Commands	830
	Example: Configuring User Permissions with Access Privileges for Operational Mode Commands	833
	Specifying Access Privileges for Junos OS Configuration Mode Hierarchies	834
	Example: Specifying Access Privileges Using allow/deny-configuration-regexps Statements	835
Chapter 42	Permissions Flags for User Access Privileges	839
	Access Privilege User Permission Flags Overview	840
	access	841
	access-control	842
	admin	843
	admin-control	844
	all-control	844
	clear	845
	configure	895
	control	896
	field	896
	firewall	896
	firewall-control	897
	floppy	898
	flow-tap	898
	flow-tap-control	899
	flow-tap-operation	899
	idp-profiler-operation	899
	interface	900
	interface-control	901
	maintenance	901
	network	908
	pgcp-session-mirroring	910
	pgcp-session-mirroring-control	910
	reset	911
	rollback	912
	secret	912
	secret-control	913
	security	914
	security-control	918

	shell	921
	snmp	921
	system	921
	system-control	924
	trace	925
	trace-control	930
	view	935
	view-configuration	1008
Chapter 43	Configuring Authentication Methods	1011
	Configuring RADIUS Server Authentication	1011
	Example: Configuring a RADIUS Server for System Authentication	1014
	Configuring TACACS+ Authentication	1017
	Configuring TACACS+ Server Details	1017
	Specifying a Source Address for the Junos OS to Access External TACACS+ Servers	1018
	Configuring the Same Authentication Service for Multiple TACACS+ Servers	1018
	Configuring Juniper Networks Vendor-Specific TACACS+ Attributes	1019
	Example: Configuring a TACACS+ Server for System Authentication	1019
	Example: Configuring Authentication Order	1022
Part 10	Configuring Remote Access to an SRX Series Appliances	
Chapter 44	Configuring Secure Web Access	1027
	Secure Web Access Overview	1027
	Generating an SSL Certificate Using the openssl Command	1028
	Generating a Self-Signed SSL Certificate	1028
	Manually Generating Self-Signed SSL Certificates	1029
	Configuring Device Addresses	1029
	Enabling Access Services	1030
	Example: Configuring Secure Web Access	1031
	Adding, Editing, and Deleting Certificates on the Device	1033
Chapter 45	Setting up USB Modems for Remote Management	1035
	USB Modem Interface Overview	1035
	USB Modem Interfaces	1036
	Dialer Interface Rules	1036
	How the Device Initializes USB Modems	1037
	USB Modem Configuration Overview	1038
	Example: Configuring a USB Modem Interface	1040
	Example: Configuring a Dialer Interface	1042
	Example: Configuring a Dialer Interface for USB Modem Dial-In	1046
	Configuring a Dial-Up Modem Connection Remotely	1048
	Connecting to the Device Remotely	1049
	Modifying USB Modem Initialization Commands	1049
	Resetting USB Modems	1050

Chapter 46	Configuring Telnet and SSH Access to an SRX Series Appliance	1051
	Securing the Console Port Configuration Overview	1051
	Configuring Password Retry Limits for Telnet and SSH Access	1052
	Configuring Reverse Telnet and Reverse SSH	1053
	Example: Controlling Management Access on SRX Series Devices	1054
	Example: Configuring a Filter to Block Telnet and SSH Access	1057
	The telnet Command	1062
	The ssh Command	1063
	Configuring Outbound SSH Service	1064
	Configuring the Device Identifier for Outbound SSH Connections	1064
	Sending the Public SSH Host Key to the Outbound SSH Client	1065
	Configuring Keepalive Messages for Outbound SSH Connections	1066
	Configuring a New Outbound SSH Connection	1066
	Configuring the Outbound SSH Client to Accept NETCONF as an Available Service	1066
	Configuring Outbound SSH Clients	1067
Part 11	Configuring DNS	
Chapter 47	Configuring DNS Server Caching, DNSSEC, and DNS Proxy	1071
	DNS Overview	1071
	DNS Components	1071
	DNS Server Caching	1072
	Example: Configuring the TTL Value for DNS Server Caching	1072
	DNSSEC Overview	1073
	Example: Configuring DNSSEC	1073
	Example: Configuring Keys for DNSSEC	1074
	Example: Configuring Secure Domains and Trusted Keys for DNSSEC	1074
	DNS Proxy Overview	1076
	DNS Proxy Cache	1076
	DNS Proxy with Split DNS	1076
	Dynamic Domain Name System Client	1078
	Configuring the Device as a DNS Proxy	1080
Part 12	Configuring DHCP Access Service for IP Address Management	
Chapter 48	Understanding DHCP Services	1085
	DHCP Overview	1085
	DHCP Local Server	1085
	DHCP Client, DHCP Local Server, and Address-Assignment Pool Interaction	1085
	DHCP Local Server and Address-Assignment Pools	1086
	DHCP Client	1086
	DHCP Relay Agent	1086
	DHCP Client, DHCP Relay Agent, and DHCP Local Servers	1087
	Considerations	1087
	DHCP Server, Client, and Relay Agent Overview	1088

	DHCP Settings and Restrictions Overview	1089
	Propagation of TCP/IP Settings for DHCP	1089
	DHCP Conflict Detection and Resolution	1089
	DHCP Interface Restrictions	1090
Chapter 49	Configuring a DHCP Local Server	1091
	Understanding DHCP Server Operation	1091
	DHCP Options	1091
	Compatibility with Autoinstallation	1092
	Chassis Cluster Support	1092
	DHCP Server Configuration Overview	1092
	Minimum DHCP Local Server Configuration	1093
	Configuring Address-Assignment Pools	1094
	Configuring an Address-Assignment Pool Name and Addresses	1095
	Configuring a Named Address Range for Dynamic Address Assignment	1095
	Configuring Static Address Assignments	1096
	Enabling TCP/IP Propagation on a DHCP Local Server	1096
	Verifying and Managing DHCP Local Server Configuration	1097
Chapter 50	Configuring a DHCP Client	1099
	Understanding DHCP Client Operation	1099
	Minimum DHCP Client Configuration	1099
	Configuring DHCP Client-Specific Attributes for Address-Assignment Pools	1100
	Configuring Optional DHCP Client Attributes	1101
	Verifying and Managing DHCP Client Configuration	1101
Chapter 51	Configuring a DHCP Relay Agent	1103
	Understanding DHCP Relay Agent Operation	1103
	Minimum DHCP Relay Agent Configuration	1104
	Verifying and Managing DHCP Relay Configuration	1104
Chapter 52	Configuring a DHCPv6 Local Server	1107
	DHCPv6 Server Overview	1107
	Creating a Security Policy for DHCPv6	1108
	Example: Configuring DHCPv6 Server Options	1109
	Example: Configuring an Address-Assignment Pool	1111
	Configuring a Named Address Range for Dynamic Address Assignment	1114
	Configuring Address-Assignment Pool Linking	1114
	Configuring DHCP Client-Specific Attributes	1115
	Configuring an Address-Assignment Pool for Router Advertisement	1116
	Understanding DHCPv6 Client and Server Identification	1116
Chapter 53	Configuring a DHCPv6 Client	1119
	DHCPv6 Client Overview	1120
	Minimum DHCPv6 Client Configuration	1121
	Configuring Optional DHCPv6 Client Attributes	1122
	Configuring Nontemporary Address Assignment	1123
	Configuring Identity Associations for Nontemporary Addresses and Prefix Delegation	1124
	Configuring Auto-Prefix Delegation	1124
	Configuring the DHCPv6 Client Rapid Commit Option	1125

	Configuring a DHCPv6 Client in Autoconfig Mode	1126
	Configuring TCP/IP Propagation on a DHCPv6 Client	1126
Part 13	Managing System Files	
Chapter 54	Performing File Management Tasks	1131
	File Management Overview	1131
	Decrypting Configuration Files	1132
	Encrypting Configuration Files	1132
	Modifying the Encryption Key	1134
	Cleaning Up Files in J-Web	1134
	Cleaning Up Files with the CLI	1135
	Deleting Files	1136
	Deleting the Backup Software Image	1137
	Downloading Files	1137
	Configuring RADIUS System Accounting	1138
	Configuring Auditing of User Events on a RADIUS Server	1138
	Specifying RADIUS Server Accounting and Auditing Events	1139
	Configuring RADIUS Server Accounting	1139
	Managing Accounting Files	1141
Part 14	Working with Junos OS Licenses	
Chapter 55	Managing Junos OS Licenses	1145
	Junos OS Feature License Keys	1145
	License Key Components	1145
	License Management Fields Summary	1146
	Software Feature Licenses for SRX Series Devices	1147
	Displaying License Keys in J-Web	1152
	Downloading License Keys	1152
	Generating a License Key	1152
	Saving License Keys	1153
	Updating License Keys	1154
	Example: Adding a New License Key	1154
	Example: Deleting a License Key	1157
Part 15	Configuration Statements and Operational Commands	
Chapter 56	Configuration Statements	1161
	[edit security certificates] Hierarchy Level	1163
	[edit security ssh-known-hosts] Hierarchy Level	1164
	Groups Configuration Statement Hierarchy	1164
	System Configuration Statement Hierarchy	1165
	address-assignment (Access)	1196
	address-pool (Access)	1199

Guide 5 Network Management Administration Guide for Routing Devices

Part 16	Overview
Chapter 58	Network Management Overview 1393
	Understanding Device Management Functions in Junos OS 1393
	Understanding the Integrated Local Management Interface 1396
Chapter 59	Introduction to Network Monitoring 1397
	Monitoring Overview 1397
	Diagnostic Tools Overview 1398
	J-Web Diagnostic Tools 1398
	CLI Diagnostic Commands 1399
Part 17	Network Monitoring Using SNMP
Chapter 60	SNMP Overview 1403
	Understanding SNMP Implementation in Junos OS 1403
	SNMPv3 Overview 1406
Chapter 61	SNMP MIBs and Traps Supported by Junos OS 1409
	Standard SNMP MIBs Supported by Junos OS 1409
	Enterprise-Specific SNMP MIBs Supported by Junos OS 1427
	Enterprise-Specific MIBs and Supported Devices 1439
	SNMP MIB Objects Supported by Junos OS for the SNMP Set Operation . . . 1449
	Standard SNMP Traps Supported on Devices Running Junos OS 1456
	Juniper Networks Enterprise-Specific SNMP Traps 1456
Chapter 62	Loading MIB Files to a Network Management System 1459
	Loading MIB Files to a Network Management System 1459
Chapter 63	Configuring SNMP 1463
	Configuration Statements at the [edit snmp] Hierarchy Level 1464
	Optimizing the Network Management System Configuration for the Best
	Results 1467
	Changing the Polling Method from Column-by-Column to Row-by-Row . . 1467
	Reducing the Number of Variable Bindings per PDU 1468
	Increasing Timeout Values in Polling and Discovery Intervals 1468
	Reducing Incoming Packet Rate at the snmpd 1468
	Configuring Options on Managed Devices for Better SNMP Response Time . . 1469
	Enabling the stats-cache-lifetime Option 1469
	Filtering Out Duplicate SNMP Requests 1469
	Excluding Interfaces That Are Slow in Responding to SNMP Queries . . . 1470
	Configuring SNMP on Devices Running Junos OS 1471
	Configuring Basic Settings for SNMPv1 and SNMPv2 1471
	Configuring Basic Settings for SNMPv3 1471

Configuring System Name, Location, Description, and Contact Information	1473
Configuring the System Contact on a Device Running Junos OS	1474
Configuring the System Location for a Device Running Junos OS	1475
Configuring the System Description on a Device Running Junos OS	1475
Configuring SNMP Details	1476
Configuring a Different System Name	1477
Configuring the Commit Delay Timer	1478
Filtering Duplicate SNMP Requests	1478
Configuring SNMP Communities	1479
Examples: Configuring the SNMP Community String	1482
Adding a Group of Clients to an SNMP Community	1482
Configuring a Proxy SNMP Agent	1484
Configuring SNMP Traps	1485
Configuring SNMP Trap Options and Groups on a Device Running Junos OS	1487
Configuring SNMP Trap Options	1487
Configuring the Source Address for SNMP Traps	1488
Configuring the Agent Address for SNMP Traps	1490
Adding snmpTrapEnterprise Object Identifier to Standard SNMP Traps	1491
Configuring SNMP Trap Groups	1491
Example: Configuring SNMP Trap Groups	1493
Configuring the Interfaces on Which SNMP Requests Can Be Accepted	1494
Example: Configuring Secured Access List Checking	1494
Filtering Interface Information Out of SNMP Get and GetNext Output	1495
Configuring MIB Views	1496
Example: Ping Proxy MIB	1497
Chapter 64	
Configuring SNMPv3	1499
Complete SNMPv3 Configuration Statements	1500
Minimum SNMPv3 Configuration on a Device Running Junos OS	1502
Example: SNMPv3 Configuration	1503
Configuring the Local Engine ID	1506
Creating SNMPv3 Users	1507
Example: Creating SNMPv3 Users	1508
Configuring the SNMPv3 Authentication Type	1509
Configuring MD5 Authentication	1509
Configuring SHA Authentication	1509
Configuring No Authentication	1510
Configuring the SNMPv3 Encryption Type	1510
Configuring the Advanced Encryption Standard Algorithm	1510
Configuring the Data Encryption Algorithm	1511
Configuring Triple DES	1511
Configuring No Encryption	1511
Defining Access Privileges for an SNMP Group	1512
Configuring the Access Privileges Granted to a Group	1513
Configuring the Group	1513
Configuring the Security Model	1514

Configuring the Security Level	1514
Associating MIB Views with an SNMP User Group	1514
Configuring the Notify View	1515
Configuring the Read View	1515
Configuring the Write View	1516
Example: Configuring the Access Privileges Granted to a Group	1516
Assigning Security Model and Security Name to a Group	1517
Configuring the Security Model	1517
Assigning Security Names to Groups	1518
Configuring the Group	1518
Example: Security Group Configuration	1519
Configuring SNMPv3 Traps on a Device Running Junos OS	1519
Configuring the SNMPv3 Trap Notification	1520
Example: Configuring SNMPv3 Trap Notification	1521
Configuring the Trap Notification Filter	1522
Configuring the Trap Target Address	1522
Configuring the Address	1523
Configuring the Address Mask	1523
Configuring the Port	1524
Configuring the Routing Instance	1524
Configuring the Trap Target Address	1524
Applying Target Parameters	1525
Example: Configuring the Tag List	1525
Defining and Configuring the Trap Target Parameters	1526
Applying the Trap Notification Filter	1527
Configuring the Target Parameters	1527
Configuring the Message Processing Model	1527
Configuring the Security Model	1528
Configuring the Security Level	1528
Configuring the Security Name	1528
Configuring SNMP Informs	1529
Configuring the Remote Engine and Remote User	1530
Example: Configuring the Remote Engine ID and Remote User	1531
Configuring the Inform Notification Type and Target Address	1534
Example: Configuring the Inform Notification Type and Target Address	1536
Configuring the SNMPv3 Community	1536
Configuring the Community Name	1537
Configuring the Context	1538
Configuring the Security Names	1538
Configuring the Tag	1538
Example: Configuring an SNMPv3 Community	1539
Chapter 65	
Configuring SNMP for Routing Instances	1541
Understanding SNMP Support for Routing Instances	1541
SNMP MIBs Supported for Routing Instances	1542
Support Classes for MIB Objects	1552
SNMP Traps Supported for Routing Instances	1553

	Identifying a Routing Instance	1554
	Enabling SNMP Access over Routing Instances	1555
	Specifying a Routing Instance in an SNMPv1 or SNMPv2c Community	1555
	Example: Configuring Interface Settings for a Routing Instance	1556
	Configuring Access Lists for SNMP Access over Routing Instances	1557
Chapter 66	Configuring SNMP Remote Operations	1559
	SNMP Remote Operations Overview	1559
	SNMP Remote Operation Requirements	1560
	Setting SNMP Views	1560
	Example: Setting SNMP Views	1560
	Setting Trap Notification for Remote Operations	1561
	Example: Setting Trap Notification for Remote Operations	1561
	Using Variable-Length String Indexes	1561
	Example: Set Variable-Length String Indexes	1561
	Enabling Logging	1562
	Using the Ping MIB for Remote Monitoring Devices Running Junos OS	1562
	Starting a Ping Test	1562
	Using Multiple Set Protocol Data Units (PDUs)	1563
	Using a Single Set PDU	1563
	Monitoring a Running Ping Test	1564
	pingResultsTable	1564
	pingProbeHistoryTable	1565
	Generating Traps	1566
	Gathering Ping Test Results	1567
	Stopping a Ping Test	1568
	Interpreting Ping Variables	1568
	Using the Traceroute MIB for Remote Monitoring Devices Running Junos OS	1569
	Starting a Traceroute Test	1570
	Using Multiple Set PDUs	1570
	Using a Single Set PDU	1570
	Monitoring a Running Traceroute Test	1571
	traceRouteResultsTable	1571
	traceRouteProbeResultsTable	1572
	traceRouteHopsTable	1573
	Generating Traps	1574
	Monitoring Traceroute Test Completion	1575
	Gathering Traceroute Test Results	1576
	Stopping a Traceroute Test	1577
	Interpreting Traceroute Variables	1578
Chapter 67	Tracing SNMP Activity	1579
	Monitoring SNMP Activity and Tracking Problems That Affect SNMP Performance on a Device Running Junos OS	1579
	Checking for MIB Objects Registered with the snmpd	1579
	Tracking SNMP Activity	1580
	Monitoring SNMP Statistics	1582
	Checking CPU Utilization	1583

	Checking Kernel and Packet Forwarding Engine Response	1584
	Tracing SNMP Activity on a Device Running Junos OS	1585
	Configuring the Number and Size of SNMP Log Files	1586
	Configuring Access to the Log File	1586
	Configuring a Regular Expression for Lines to Be Logged	1587
	Configuring the Trace Operations	1587
	Example: Tracing SNMP Activity	1588
Chapter 68	SNMP FAQs	1591
	Junos OS SNMP FAQ Overview	1591
	Junos OS SNMP FAQs	1592
	Junos OS SNMP Support FAQs	1592
	Junos OS MIBs FAQs	1593
	Junos OS SNMP Configuration FAQs	1600
	SNMPv3 FAQs	1604
	SNMP Interaction with Juniper Networks Devices FAQs	1606
	SNMP Traps and Informs FAQs	1608
	Junos OS Dual Routing Engine Configuration FAQs	1614
	SNMP Support for Routing Instances FAQs	1615
	SNMP Counters FAQs	1616
Part 18	Remote Monitoring (RMON) with SNMP	
Chapter 69	RMON Overview	1621
	Understanding RMON Alarms	1621
	alarmTable	1621
	jnxRmonAlarmTable	1622
	Understanding RMON Events	1623
	eventTable	1623
Chapter 70	Configuring RMON Alarms and Events	1625
	Understanding RMON Alarms and Events Configuration	1625
	Minimum RMON Alarm and Event Entry Configuration	1626
	Configuring an Alarm Entry and Its Attributes	1626
	Configuring the Alarm Entry	1627
	Configuring the Description	1627
	Configuring the Falling Event Index or Rising Event Index	1627
	Configuring the Falling Threshold or Rising Threshold	1627
	Configuring the Interval	1628
	Configuring the Falling Threshold Interval	1628
	Configuring the Request Type	1629
	Configuring the Sample Type	1629
	Configuring the Startup Alarm	1629
	Configuring the System Log Tag	1630
	Configuring the Variable	1630
	Configuring an Event Entry and Its Attributes	1630
	Example: Configuring an RMON Alarm and Event Entry	1631

Chapter 71	Monitoring RMON Alarms and Events	1633
	Using alarmTable to Monitor MIB Objects	1633
	Creating an Alarm Entry	1633
	Configuring the Alarm MIB Objects	1633
	alarmInterval	1634
	alarmVariable	1634
	alarmSampleType	1634
	alarmValue	1634
	alarmStartupAlarm	1634
	alarmRisingThreshold	1635
	alarmFallingThreshold	1635
	alarmOwner	1635
	alarmRisingEventIndex	1635
	alarmFallingEventIndex	1635
	Activating a New Row in alarmTable	1636
	Modifying an Active Row in alarmTable	1636
	Deactivating a Row in alarmTable	1636
	Using eventTable to Log Alarms	1636
	Creating an Event Entry	1636
	Configuring the MIB Objects	1637
	eventType	1637
	eventCommunity	1637
	eventOwner	1637
	eventDescription	1638
	Activating a New Row in eventTable	1638
	Deactivating a Row in eventTable	1638
Chapter 72	Using RMON to Monitor Network Service Quality	1639
	Understanding RMON for Monitoring Service Quality	1639
	Setting Thresholds	1639
	RMON Command-Line Interface	1640
	RMON Event Table	1641
	RMON Alarm Table	1641
	Troubleshooting RMON	1642
	Understanding Measurement Points, Key Performance Indicators, and Baseline Values	1643
	Measurement Points	1643
	Basic Key Performance Indicators	1644
	Setting Baselines	1644
	Defining and Measuring Network Availability	1644
	Defining Network Availability	1645
	Monitoring the SLA and the Required Bandwidth	1646
	Measuring Availability	1647
	Real-Time Performance Monitoring	1647
	Measuring Health	1650
	Measuring Performance	1656
	Measuring Class of Service	1659
	Inbound Firewall Filter Counters per Class	1660
	Monitoring Output Bytes per Queue	1661

	Dropped Traffic	1662
Part 19	Health Monitoring with SNMP	
Chapter 73	Configuring Health Monitoring	1667
	Configuring Health Monitoring on Devices Running Junos OS	1667
	Monitored Objects	1668
	Minimum Health Monitoring Configuration	1669
	Configuring the Falling Threshold or Rising Threshold	1669
	Configuring the Interval	1669
	Log Entries and Traps	1670
	Example: Configuring Health Monitoring	1670
Part 20	Gathering Statistics for Accounting Purposes Using Accounting Options, Source Class Usage and Destination Class Usage Options	
Chapter 74	Accounting Options, Source Class Usage and Destination Class Usage Options Overview	1673
	Accounting Options Overview	1673
	Understanding Source Class Usage and Destination Class Usage Options . . .	1674
Chapter 75	Configuring Accounting Options, Source Class Usage and Destination Class Usage Options	1677
	Configuration Statements at the [edit accounting-options] Hierarchy Level . .	1677
	Accounting Options Configuration	1678
	Accounting Options—Full Configuration	1679
	Minimum Accounting Options Configuration	1680
	Configuring Accounting-Data Log Files	1682
	Configuring the Storage Location of the File	1682
	Configuring the Maximum Size of the File	1683
	Configuring the Maximum Number of Files	1683
	Configuring the Start Time for File Transfer	1683
	Configuring the Transfer Interval of the File	1683
	Configuring Archive Sites	1684
	Configuring the Interface Profile	1685
	Configuring Fields	1685
	Configuring the File Information	1685
	Configuring the Interval	1686
	Example: Configuring the Interface Profile	1686
	Configuring the Filter Profile	1687
	Configuring the Counters	1688
	Configuring the File Information	1688
	Configuring the Interval	1689
	Example: Configuring a Filter Profile	1689
	Example: Configuring Interface-Specific Firewall Counters and Filter Profiles . .	1690
	Configuring SCU or DCU	1691
	Creating Prefix Route Filters in a Policy Statement	1692
	Applying the Policy to the Forwarding Table	1692
	Enabling Accounting on Inbound and Outbound Interfaces	1692

	Configuring SCU on a Virtual Loopback Tunnel Interface	1693
	Example: Configuring a Virtual Loopback Tunnel Interface on a Provider Edge Router Equipped with a Tunnel PIC	1693
	Example: Mapping the VRF Instance Type to the Virtual Loopback Tunnel Interface	1694
	Example: Sending Traffic Received from the Virtual Loopback Interface Out the Source Class Output Interface	1694
	Configuring Class Usage Profiles	1695
	Configuring a Class Usage Profile	1695
	Configuring the File Information	1695
	Configuring the Interval	1696
	Creating a Class Usage Profile to Collect Source Class Usage Statistics . .	1696
	Creating a Class Usage Profile to Collect Destination Class Usage Statistics	1696
	Configuring the MIB Profile	1697
	Configuring the File Information	1697
	Configuring the Interval	1698
	Configuring the MIB Operation	1698
	Configuring MIB Object Names	1698
	Example: Configuring a MIB Profile	1698
	Configuring the Routing Engine Profile	1699
	Configuring Fields	1699
	Configuring the File Information	1700
	Configuring the Interval	1700
	Example: Configuring a Routing Engine Profile	1700
Part 21	Configuring Monitoring Options	
Chapter 76	Configuring Interface Alarms	1703
	Alarm Overview	1703
	Alarm Types	1703
	Alarm Severity	1704
	Alarm Conditions	1704
	Interface Alarm Conditions	1705
	System Alarm Conditions	1708
	Example: Configuring Interface Alarms	1709
	Monitoring Active Alarms on a Device	1711
	Monitoring Alarms	1712
Chapter 77	Using RPM to Measure Network Performance	1715
	RPM Overview	1715
	RPM Probes	1716
	RPM Tests	1716
	Probe and Test Intervals	1716
	Jitter Measurement with Hardware Timestamping	1717
	RPM Statistics	1717
	RPM Thresholds and Traps	1718
	RPM for BGP Monitoring	1719
	IPv6 RPM Probes	1719
	Guidelines for Configuring RPM Probes for IPv6	1719

	RPM Support for VPN Routing and Forwarding	1721
	Example: Configuring Basic RPM Probes	1721
	Example: Configuring RPM Using TCP and UDP Probes	1725
	Example: Configuring RPM Probes for BGP Monitoring	1728
	Directing RPM Probes to Select BGP Devices	1730
	Configuring IPv6 RPM Probes	1731
	Tuning RPM Probes	1732
	RPM Configuration Options	1732
	Monitoring RPM Probes	1736
Chapter 78	Configuring IP Monitoring	1741
	IP Monitoring Overview	1741
	Understanding IP Monitoring Test Parameters	1742
	Example: Configuring IP Monitoring on Branch SRX Series Devices	1743
	Understanding IP Monitoring Through Redundant Ethernet Interface Link Aggregation Groups	1745
	Example: Configuring IP Monitoring on High-End SRX Series Devices	1746
	Example: Configuring Chassis Cluster Redundancy Group IP Address Monitoring	1751
Part 22	Monitoring Common Security Features	
Chapter 79	Displaying Real-Time Information from Device to Host	1757
	Displaying Real-Time Monitoring Information	1757
	Displaying Multicast Path Information	1759
Chapter 80	Monitoring Application Layer Gateways Features	1763
	Monitoring H.323 ALG Information	1763
	Monitoring MGCP ALGs	1764
	Monitoring MGCP ALG Calls	1764
	Monitoring MGCP ALG Counters	1765
	Monitoring MGCP ALG Endpoints	1766
	Monitoring SCCP ALGs	1767
	Monitoring SCCP ALG Calls	1767
	Monitoring SCCP ALG Counters	1768
	Monitoring SIP ALGs	1769
	Monitoring SIP ALG Calls	1770
	Monitoring SIP ALG Counters	1770
	Monitoring SIP ALG Rate Information	1772
	Monitoring SIP ALG Transactions	1773
	Monitoring Voice ALG H.323	1774
	Monitoring Voice ALG MGCP	1776
	Monitoring Voice ALG SCCP	1779
	Monitoring Voice ALG SIP	1782
	Monitoring Voice ALG Summary	1787
Chapter 81	Monitoring Interfaces and Switching Functions	1789
	Displaying Real-Time Interface Information	1789
	Monitoring Address Pools	1791
	Monitoring Ethernet Switching	1792

	Monitoring GVRP	1793
	Monitoring Interfaces	1794
	Monitoring MPLS Traffic Engineering Information	1795
	Monitoring MPLS Interfaces	1796
	Monitoring MPLS LSP Information	1796
	Monitoring MPLS LSP Statistics	1797
	Monitoring RSVP Session Information	1798
	Monitoring MPLS RSVP Interfaces Information	1799
	Monitoring PPP	1800
	Monitoring PPPoE	1801
	Monitoring Spanning Tree	1805
	Monitoring the WAN Acceleration Interface	1806
Chapter 82	Monitoring NAT	1807
	Monitoring NAT	1807
	Monitoring Source NAT Information	1807
	Monitoring Destination NAT Information	1813
	Monitoring Static NAT Information	1815
	Monitoring Incoming Table Information	1816
	Monitoring Interface NAT Port Information	1817
Chapter 83	Monitoring Security Policies	1819
	Monitoring Policy Statistics	1819
	Monitoring Routing Information	1820
	Monitoring Route Information	1820
	Monitoring RIP Routing Information	1822
	Monitoring OSPF Routing Information	1823
	Monitoring BGP Routing Information	1825
	Monitoring Security Events by Policy	1827
	Monitoring Security Features	1829
	Monitoring Policies	1829
	Checking Policies	1832
	Monitoring Screen Counters	1835
	Monitoring IDP Status	1837
	Monitoring Flow Gate Information	1838
	Monitoring Firewall Authentication Table	1839
	Monitoring Firewall Authentication History	1841
	Monitoring 802.1x	1843
Chapter 84	Monitoring Events, Services and System	1845
	Monitoring DHCP Client Bindings	1845
	Monitoring Events	1845
	Monitoring the System	1848
	Monitoring System Properties for SRX Series Devices	1848
	Monitoring Chassis Information	1850
	System Health Management for Branch SRX Series Devices	1852
Chapter 85	Monitoring Unified Threat Management Features	1855
	Monitoring Antivirus Scan Engine Status	1855
	Monitoring Antivirus Scan Results	1856

	Monitoring Antivirus Session Status	1858
	Monitoring Content Filtering Configurations	1858
	Monitoring Reports	1859
	Threats Monitoring Report	1859
	Traffic Monitoring Report	1864
	Monitoring Web Filtering Configurations	1866
Chapter 86	Monitoring VPNs	1867
	Monitoring VPNs	1867
	Monitoring IKE Gateway Information	1867
	Monitoring IPsec VPN—Phase I	1871
	Monitoring IPsec VPN—Phase II	1872
	Monitoring IPsec VPN Information	1873
Part 23	Resource Monitoring of Memory Regions and Types Using CLI and SNMP Queries	
Chapter 87	Effective Troubleshooting of System Performance With Resource Monitoring Methodology	1881
	Resource Monitoring Usage Computation Overview	1881
	Resource Monitoring and Usage Computation For Trio-Based Line Cards	1882
	Resource Monitoring and Usage Computation For I-Chip-Based Line Cards	1882
	Resource Monitoring Mechanism on MX Series Routers Overview	1884
	Examining the Utilization of Memory Resource Regions Using show Commands	1885
	Diagnosing and Debugging System Performance By Configuring Memory Resource Usage Monitoring on MX Series Routers	1886
	Managed Objects for Ukernl Memory for a Packet Forwarding Engine in an FPC Slot	1888
	Managed Objects for Packet Forwarding Engine Memory Statistics Data	1889
	Managed Objects for Next-Hop, Jtree, and Firewall Filter Memory for a Packet Forwarding Engine in an FPC Slot	1889
	jnxPfeMemoryErrorsTable	1890
	pfeMemoryErrors	1890
Part 24	Troubleshooting	
Chapter 88	Configuring Data Path Debugging and Trace Options	1893
	Understanding Data Path Debugging for SRX Series Devices	1893
	Debugging the Data Path (CLI Procedure)	1894
	Example: Configuring End-to-End Debugging on a High-End SRX Series Device	1895
	Understanding Security Debugging Using Trace Options	1899
	Setting Security Trace Options (CLI Procedure)	1899
	Displaying Log and Trace Files	1900
	Displaying Output for Security Trace Options	1901
	Displaying Multicast Trace Operations	1901

	Using the J-Web Traceroute Tool	1902
	J-Web Traceroute Results and Output Summary	1904
	Understanding Flow Debugging Using Trace Options	1905
	Setting Flow Debugging Trace Options (CLI Procedure)	1905
	Displaying a List of Devices	1906
Chapter 89	Using MPLS to Diagnose LSPs, VPNs, and Layer 2 Circuits	1909
	MPLS Connection Checking Overview	1909
	Configuring Ping MPLS	1911
	Using the ping Command	1912
	Using the J-Web Ping Host Tool	1914
	J-Web Ping Host Results and Output Summary	1916
	Using the J-Web Ping MPLS Tool	1917
	J-Web Ping MPLS Results and Output Summary	1920
	Pinging Layer 2 Circuits	1921
	Pinging Layer 2 VPNs	1922
	Pinging Layer 3 VPNs	1923
	Pinging RSVP-Signaled LSPs and LDP-Signaled LSPs	1924
Chapter 90	Using Packet Capture to Analyze Network Traffic	1927
	Packet Capture Overview	1927
	Packet Capture on Device Interfaces	1928
	Firewall Filters for Packet Capture	1929
	Packet Capture Files	1929
	Analysis of Packet Capture Files	1929
	Example: Enabling Packet Capture on a Device	1930
	Example: Configuring Packet Capture on an Interface	1933
	Example: Configuring a Firewall Filter for Packet Capture	1935
	Example: Configuring Packet Capture for Datapath Debugging	1937
	Disabling Packet Capture	1940
	Deleting Packet Capture Files	1941
	Changing Encapsulation on Interfaces with Packet Capture Configured	1941
	Displaying Packet Headers	1943
	Using the J-Web Packet Capture Tool	1947
	J-Web Packet Capture Results and Output Summary	1950
Chapter 91	Troubleshooting Security Devices	1953
	Recovering the Root Password for SRX Series Devices	1953
	Troubleshooting DNS Name Resolution in Logical System Security Policies (Master Administrators Only)	1954
	Troubleshooting the Link Services Interface	1955
	Determine Which CoS Components Are Applied to the Constituent Links	1955
	Determine What Causes Jitter and Latency on the Multilink Bundle	1957
	Determine If LFI and Load Balancing Are Working Correctly	1957
	Determine Why Packets Are Dropped on a PVC Between a Juniper Networks Device and a Third-Party Device	1964
	Troubleshooting Security Policies	1964
	Checking a Security Policy Commit Failure	1964
	Verifying a Security Policy Commit	1965

	Debugging Policy Lookup	1965
	Understanding Log Error Messages for Troubleshooting ISSU-Related Problems	1966
	Chassisd Process Errors	1966
	Kernel State Synchronization	1966
	Installation Related Errors	1966
	ISSU Support Related Errors	1967
	Redundancy Group Failover Errors	1967
	Initial Validation Checks Fail	1967
Part 25	Configuration Statements and Operational Commands	
Chapter 92	Configuration Statements: Accounting Options, Source Class Usage and Destination Class Usage Options	1971
	accounting-options	1972
	archive-sites	1972
	class-usage-profile	1973
	counters	1974
	destination-classes	1974
	fields (for Interface Profiles)	1975
	fields (for Routing Engine Profiles)	1976
	file (Associating with a Profile)	1977
	file (Configuring a Log File)	1978
	files	1979
	filter-profile	1980
	interface-profile	1981
	interval	1982
	mib-profile	1983
	mpls (Security Forwarding Options)	1984
	nonpersistent	1985
	object-names	1985
	operation	1986
	packet-capture	1987
	packet-filter	1988
	redundancy-group (Chassis Cluster)	1989
	retry-interval (Chassis Cluster)	1990
	routing-engine-profile	1991
	size	1992
	source-classes	1992
	start-time	1993
	traceoptions (System Accounting)	1994
	transfer-interval	1995
Chapter 93	Configuration Statements: Chassis Cluster	1997
	cluster (Chassis)	1998
	global-threshold	1999
	global-weight	2000
	ip-monitoring	2001
	ip-monitoring (Services)	2002
	next-hop	2003

Chapter 94	Configuration Statements: Datapath Debug	2005
	action-profile	2006
	capture-file (Security)	2007
	datapath-debug	2008
	flow (Security Flow)	2010
	icmp	2012
	maximum-capture-size (Datapath Debug)	2012
	traceoptions (Security Datapath Debug)	2013
Chapter 95	Configuration Statements: Health Monitoring	2015
	falling-threshold	2015
	health-monitor	2016
	interval	2016
	rising-threshold	2017
Chapter 96	Configuration Statements: Remote Monitoring (RMON)	2019
	alarm (SNMP RMON)	2020
	community	2021
	description	2021
	event	2022
	falling-event-index	2022
	falling-threshold	2023
	falling-threshold-interval	2024
	interval	2024
	request-type	2025
	rising-event-index	2026
	rising-threshold	2026

	Accessing Standards Documents on the Internet	2227
Part 27	Supported Standards	
Chapter 103	Chassis and System Standards	2231
	Supported BFD Standards	2231
	Supported BOOTP and DHCP Standards	2232
	Supported Mobile IP Standards	2233
	Supported Network Management Standards	2233
	Supported RADIUS and TACACS+ Standards for User Authentication	2244

	Supported System Access Standards	2244
	Supported Time Synchronization Standard	2245
Chapter 104	Interface Standards	2247
	Supported ATM Interface Standards	2247
	Supported Ethernet Interface Standards	2248
	Supported Frame Relay Interface Standards	2249
	Supported GRE and IP-IP Interface Standards	2249
	Supported PPP Interface Standards	2250
	Supported SDH and SONET Interface Standards	2251
	Supported Serial Interface Standards	2252
	Supported T3 Interface Standard	2252
Chapter 105	Layer 2 Standards	2253
	Supported Layer 2 Networking Standards	2253
	Supported L2TP Standards	2254
	Supported VPWS Standards	2254
	Supported Layer 2 VPN Standards	2255
	Supported Security Standards	2256
Chapter 106	MPLS Applications Standards	2257
	Supported GMPLS Standards	2257
	Supported LDP Standards	2258
	Supported MPLS Standards	2259
	Supported RSVP Standards	2262
Chapter 107	Open Standards	2265
	Supported Open Standards	2265
Chapter 108	Packet Processing Standards	2269
	Supported CoS Standards	2269
	Supported Packet Filtering Standards	2270
	Supported Policing Standard	2270
Chapter 109	Routing Protocol Standards	2273
	Supported Standards for BGP	2273
	Supported ES-IS Standards	2275
	Supported ICMP Router Discovery and IPv6 Neighbor Discovery Standards	2276
	Supported IP Multicast Protocol Standards	2276
	Supported IPv4, TCP, and UDP Standards	2278
	Supported IPv6 Standards	2280
	Supported Standards for IS-IS	2283
	Supported OSPF and OSPFv3 Standards	2284
	Supported RIP and RIPvng Standards	2286
Chapter 110	Services PIC and DPC Standards	2287
	Supported DTCP Standard	2287
	Supported Flow Monitoring and Discard Accounting Standards	2287
	Supported IPsec and IKE Standards	2288
	Supported L2TP Standards	2290
	Supported Link Services Standards	2290
	Supported NAT and SIP Standards	2291

	Supported RPM Standard	2291
	Supported Voice Services Standards	2292
Chapter 111	VPLS and VPN Standards	2293
	Supported Carrier-of-Carriers and Interprovider VPN Standards	2293
	Supported EVPN Standards	2294
	Supported Layer 2 VPN Standards	2294
	Supported Layer 3 VPN Standards	2295
	Supported Multicast VPN Standards	2296
	Supported VPLS Standards	2296

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

Documentation Conventions

[Table 1](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

[Table 2](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
<i>Italic text like this</i>	<ul style="list-style-type: none">Introduces or emphasizes important new terms.Identifies guide names.Identifies RFC and Internet draft titles.	<ul style="list-style-type: none">A policy <i>term</i> is a named structure that defines match conditions and actions.<i>Junos OS CLI User Guide</i>RFC 1997, <i>BGP Communities Attribute</i>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none">To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level.The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (<i>string1</i> <i>string2</i> <i>string3</i>)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [<i>community-ids</i>]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none">In the Logical Interfaces box, select All Interfaces.To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page of the Juniper Networks TechLibrary site at <http://www.juniper.net/techpubs/index.html>, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at <http://www.juniper.net/techpubs/feedback/>.
- E-mail—Send your comments to techpubs-comments@juniper.net. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <http://kb.juniper.net/InfoCenter/>

- Join and participate in the Juniper Networks Community Forum:
<http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

Junos OS Overview

Juniper Networks provides high-performance network devices that create a responsive and trusted environment for accelerating the deployment of services and applications over a single network. The Junos[®] operating system (Junos OS) is the foundation of these high-performance networks.

Starting with Junos OS Release 15.1, certain hardware platforms run Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD. Basing Junos OS on the newer kernel (referred to as Junos OS with upgraded FreeBSD) provides Junos OS with sophisticated processing, efficiency, and security features which do not have to be reproduced in Junos OS.

Unlike other complex, monolithic software architectures, Junos OS incorporates key design and developmental differences to deliver increased network availability, operational efficiency, and flexibility. The key advantages to this approach are:

- [One Operating System on page 4](#)
- [One Modular Software Architecture on page 4](#)

One Operating System

Unlike other network operating systems that share a common name but splinter into many different programs, Junos OS is a single, cohesive operating system that is shared across all network devices and product lines. This allows Juniper Networks engineers to develop software features once and share these features across all product lines simultaneously. Because features are common to a single source, they generally are implemented the same way for all product lines, thus reducing the training required to learn different tools and methods for each product. Because all Juniper Networks products use the same code base, interoperability between products is not an issue.

One Modular Software Architecture

Although individual modules of Junos OS communicate through well-defined interfaces, each module runs in its own protected memory space, preventing one module from disrupting another. This separation enables the independent restart of each module as necessary. This is in contrast to monolithic operating systems where a malfunction in one module can ripple to other modules and cause a full system crash or restart. This modular architecture then provides for high performance, high availability, security, and device scalability not found in other operating systems.

The Junos OS is preinstalled on your Juniper Networks device when you receive it from the factory. Thus, when you first power on the device, all software starts automatically. You simply need to configure the software so that the device can participate in the network.

You can upgrade the device software as new features are added or software problems are fixed. You normally obtain new software by downloading the software installation packages from the Juniper Networks Support Web page onto your device or onto another system on your local network. You then install the software upgrade onto the device.

Juniper Networks routing platforms run only binaries supplied by Juniper Networks, and currently do not support third-party binaries. Each Junos OS image includes a digitally signed manifest of executables that are registered with the system only if the signature can be validated. Junos OS will not execute any binary without a registered signature. This feature protects the system against unauthorized software and activity that might compromise the integrity of your device.

Related Documentation

- [Junos OS Editions on page 5](#)
- [Junos OS Installation Packages on page 6](#)

Junos OS Editions

NOTE: Hardware platforms running Junos OS with the upgraded FreeBSD kernel employ a new naming scheme for software packages that does not recognize different major software package categories, such as domestic, world-wide, or Federal Information Processing Standard (FIPS). For more information, see [“Understanding Junos OS with Upgraded FreeBSD Package Names” on page 22](#).

Junos OS is released in the following editions:

- Domestic—Junos OS for customers in the United States and Canada, and for all other customers with a valid encryption agreement. This edition includes high-encryption capabilities such as ipsec and ssh for data leaving the router or switch.
- Export—Junos OS for all other customers. This edition does not include any high-encryption capabilities for data leaving the router or switch.
- Junos-FIPS—Junos OS that provides advanced network security for customers who need software tools to configure a network of Juniper Networks routers and switches in a Federal Information Processing Standards (FIPS) 140-2 environment. For more information about Junos-FIPS, see [“FIPS 140-2 Security Compliance” on page 5](#).

Related Documentation

- [Understanding Junos OS with Upgraded FreeBSD Package Names on page 22](#)

FIPS 140-2 Security Compliance

NOTE: Hardware platforms running Junos OS with the upgraded FreeBSD kernel employ a new naming scheme for software packages that does not recognize different major software package categories, such as domestic, world-wide, or Federal Information Processing Standard (FIPS). For more information, see [“Understanding Junos OS with Upgraded FreeBSD Package Names” on page 22](#).

For advanced network security, a special version of Junos OS, called Junos-FIPS 140-2, is available. Junos-FIPS 140-2 provides customers with software tools to configure a network of Juniper Networks devices in a FIPS environment. FIPS support includes:

- Upgrade package to convert Junos OS to Junos-FIPS 140-2
- Revised installation and configuration procedures
- Enforced security for remote access
- FIPS user roles (Crypto Officer, User, and Maintenance)
- FIPS-specific system logging and error messages

- IPsec configuration for Routing Engine–to–Routing Engine communication
- Enhanced password creation and encryption

Junos-FIPS has special installation and configuration requirements. Installation procedures include downloading the FIPS software package from www.juniper.net. For detailed guidelines on how installation and configuration procedures differ between Junos OS and Junos-FIPS 140-2, see the [Secure Configuration Guide for Common Criteria and Junos-FIPS](#).

NOTE: Junos-FIPS has special password requirements. FIPS passwords must be between 10 and 20 characters in length. Passwords must use at least three of the five defined character sets (uppercase letters, lowercase letters, digits, punctuation marks, and other special characters). If Junos-FIPS is installed on the device, you cannot configure passwords unless they meet this standard.

Related Documentation

Junos OS Installation Packages

The installation package is used to upgrade and downgrade from one release to another. When installed, the installation package completely reinstalls the software, rebuilds the Junos OS file system, and may erase system logs and other auxiliary information from the previous installation. The installation package does, however, retain the configuration files from the previous installation.

The following installation packages are available for download:

NOTE: Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD. Junos OS with upgraded FreeBSD has a different, simplified package naming convention. For more information, see [“Understanding Junos OS with Upgraded FreeBSD Package Names”](#) on page 22.

Installation Package	Description
jinstall*	Junos OS for M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus routers.
jinstall-ppc*	Junos OS for the ACX Series, MX80, and MX104 routers.
jinstall-ex*	Junos OS for the EX Series Ethernet Switch portfolio.

junos-juniper*	Junos-FIPS for the M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus routers. Once the package is installed on a device, you cannot revert back to the standard Junos OS installation without performing a software recovery procedure.
jinstall64*	64-bit Junos OS for the JCS1200 Route Reflector, TX Matrix Plus routers with 3D SIBs, and PTX Series Packet Transport Routers.
junos-srxsme*	Junos OS for all the branch SRX Series.
junos-srxentedge*	Junos OS for SRX1500
junos-srx5000*	Junos OS for SRX5400, SRX5600 and SRX5800.

Junos OS Package Names for EX Series Switches

You upgrade the Juniper Networks Junos operating system (Junos OS) on a Juniper Networks EX Series Ethernet Switch by copying a software package to your switch or another system on your local network, then install the new software package on the switch.

Two versions of a Junos OS image—a controlled version that supports Media Access Control Security (MACsec) and a domestic version that does not support MACsec—are available for EX Series switches. A domestic version of Junos OS is available for all EX Series switches; a controlled version of Junos OS is only available for EX Series switches on Junos OS releases that support MACsec. The domestic version of Junos OS on EX Series switches can be used on any switch in any geography. The controlled version of Junos OS contains encryption and is not available to customers in all geographies.

NOTE: The controlled version of Junos OS contains encryption and is, therefore, not available to customers in all geographies. The export and re-export of the controlled version of Junos OS is strictly controlled under United States export laws. The export, import, and use of the controlled version of Junos OS is also subject to controls imposed under the laws of other countries.

If you have questions about acquiring the controlled version of Junos OS in your country, contact the Juniper Networks Trade Compliance group at compliance_helpdesk@juniper.net.

NOTE: The domestic version of Junos OS on EX Series switches is intended for use on any switch in any worldwide location.

For most Junos packages on other Juniper Networks products, the domestic package is used for products installed in the United States and Canada only while an export package is used for products installed in any worldwide location.

domestic-signed indicates the domestic software package.

A domestic software package name is in the following format:

package-name-m.nZx.y-domestic-signed.tgz

A controlled software package name is in the following format:

package-name-m.nZx.y-controlled-signed.tgz

where:

- ***package-name*** is the name of the package—for example, ***jinstall-ex-4200***.
- ***m.n*** is the software release, with ***m*** representing the major release number and ***n*** representing the minor release number—for example, ***9.5***.
- ***Z*** indicates the type of software release, where ***R*** indicates released software and ***B*** indicates beta-level software.
- ***x.y*** represents the version of the major software release (***x***) and an internal tracking number (***y***)—for example, ***1.6***.
- ***domestic-signed*** indicates the domestic software package.
- ***controlled-signed*** indicates the controlled software package.

A sample EX Series software domestic package name is:

jinstall-ex-4200-9.5R1.6-domestic-signed.tgz

A sample EX Series controlled package name is:

jinstall-ex-4200-13.2X50-D15.3-controlled-signed.tgz

Software Naming Convention

All Junos OS conforms to the following naming convention:

package-release-edition-cfxxx-signed.comp

For example:

jinstall-9.2R1.8-domestic-signed.tgz

where:

- **package** is the name of the Junos OS package. For 64-bit Junos OS, the package name is **package64**.
- **cfxxx** designates the CompactFlash card size to use with the software. This value is optional.
- **signed** means that the software includes a digital signature for verification purposes. This value is not used with all software packages.

All SRX Series packages conform to the following naming convention:

junos-product-release-edition

For example:

junos-srxentedge-15.1X49-D30.3-domestic.tgz (for SRX1500)

junos-vsr-x-15.1X49-D30.3-domestic.tgz (for vSRX)

junos-srx5000-15.1X49-D30.3-domestic.tgz (for SRX5400, SRX5600, SRX5800)

junos-srxsme-15.1X49-D30.3-domestic.tgz (for SRX550M)

where:

- **product** means SRX Series product line.
- **edition** means Junos OS for customers in the United States and Canada, and for all other customers with a valid encryption agreement. This edition includes high-encryption capabilities such as IPsec and SSH for data leaving the device.

NOTE: Starting with Junos OS Release 15.1, certain hardware platforms run Junos OS based on an upgraded FreeBSD kernel (hereafter called Junos OS with upgraded FreeBSD). Junos OS with upgraded FreeBSD has a new naming convention. For more information on this new naming convention, see [“Understanding Junos OS with Upgraded FreeBSD Package Names” on page 22](#).

Related Documentation

- [Software Naming Convention for SRX Series Devices on page 10](#)

- [Junos OS Editions on page 5](#)

Software Naming Convention for SRX Series Devices

Typically, you upgrade your device software by downloading a software image to your device from another system on your local network. Using the J-Web user interface or the CLI to upgrade, the device downloads the software image, decompresses the image, and installs the decompressed software. Finally, you reboot the device, at which time it boots from the upgraded software. Junos OS is delivered in signed packages that contain digital signatures to ensure official Juniper Networks software.

An upgrade software package name for an SRX Series device is in the following format:

package-name-m.nZx-distribution.tgz

- **package-name**—Name of the package; for example, junos-srxsme.
- **m.n**—Junos OS release, with m representing the major release number and n representing the minor release number; for example, 10.0.
- **Z**—Type of Junos OS release; for example, R indicates released software, and B indicates beta-level software.

For more information, see “Junos OS Release Numbers” on page 11.

NOTE: Starting with Junos OS Release 12.1X44-D10, SRX Series devices follow a special naming convention for Junos OS releases. For more information, refer to the Knowledge Base article KB30092 at <http://kb.juniper.net/InfoCenter/index?page=home>.

- **x.y**—Junos OS build number and spin number; for example, 1.8.
- **distribution**—Area for which the Junos OS package is provided. It is domestic for the United States and Canada, and it is export for worldwide distribution.

The following package name is an example of an SRX Series device upgrade Junos OS package:

junos-srxentedge-15.1X49-D30.3-domestic.tgz

Related Documentation

- [FIPS 140-2 Security Compliance on page 5](#)
- [Junos OS Release Numbers on page 11](#)
- [Downloading Software Packages from Juniper Networks on page 150](#)
- [Understanding Junos OS Upgrades for SRX Series Devices on page 145](#)

Software Package Information Security

Junos OS software is delivered in signed packages that contain digital signatures, Secure Hash Algorithm (SHA-1), and Message Digest 5 (MD5) checksums. A package is installed only if the checksum within it matches the hash recorded in its corresponding file. Which checksum is used depends on the software version:

- Digital signatures are used when you upgrade or downgrade between Junos OS Release 7.0 and a later version.
- The SHA-1 checksum is used when you upgrade or downgrade between Junos OS Release 6.4 and a later version.
- The MD5 checksum is used when you upgrade or downgrade between Junos OS Release 6.3 or earlier and a later version.

Related Documentation

Junos OS Release Numbers

The Junos OS release number represents a particular revision of the software that runs on a Juniper Networks routing platform, for example, Junos OS Release 14.1, 14.2, or 15.1. Each Junos OS release has certain new features that complement the software processes that support Internet routing protocols, control the device's interfaces and the device chassis itself, and allow device system management. On the Juniper Networks Support webpage, you download Junos OS for a particular Junos OS release number.

The following example shows how the software release number is formatted:

m.nZb.s

For example:

14.2R3.2

Where:

- *m* is the main release number of the product
- *n* is the minor release number of the product
- *Z* is the type of software release. The following release types are used:
 - *R*—FRS/Maintenance release software
 - *F*—Feature Velocity release software

NOTE: Feature velocity release was introduced in Junos OS Release 15.1.

- *B*—Beta release software

- *I*—Internal release software: Private software release for verifying fixes
- *S*—Service release software: Released to customers to solve a specific problem—this release will be maintained along with the life span of the underlying release
- *X*—Special (eXception) release software: Releases that follow a numbering system that differs from the standard Junos OS release numbering.

Starting with Junos OS Release 12.1X44-D10, SRX Series devices follow a special naming convention for Junos OS releases. For more information, refer to the Knowledge Base article KB30092 at

<http://kb.juniper.net/InfoCenter/index?page=home>.

- *b* is the build number of the product
 - if *b*=1: Software is the FRS release
 - if *b*>1: Software is a maintenance release

s is the spin number of the product

- For Service release software, the release number is added at the end. For example, 14.2R3-S4.4. Here S4 represents the 4th service release on top of 14.2R3 and is the 4th respin.

NOTE: Prior to Junos OS Release 11.4, the software release number format for service releases was same as other releases. For example, 10.4S4.2 represented the 4th service release and 2nd respin of 10.4.

NOTE: Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel (hereafter called Junos OS with upgraded FreeBSD). Junos OS with upgraded FreeBSD has a new naming convention. For more information on this new naming convention, see “[Understanding Junos OS with Upgraded FreeBSD Package Names](#)” on [page 22](#).

Related Documentation

- [Software Naming Convention for SRX Series Devices on page 10](#)
- [Junos OS Editions on page 5](#)

Installation Media

The installation media is used to recover a device from a software failure. The installation media repartitions the media and completely reinstalls Junos OS. No information from previous installations is retained during this installation. Thus, an initial configuration is required before the device can be put back into service. For more information about creating an initial configuration, see the *Getting Started Guide* for your device.

NOTE: Once you have rebuilt a device using the installation media, access to the device is restricted to the console port until the management port is configured during the initial configuration.

The following installation media files are available for download:

Installation Media	Description
floppy1-<release>*	Junos OS for the M40 router when you use the LS-120 external drive.
floppy2-<release>*	
install-media*	Junos OS for the ACX Series, M Series, MX Series, T Series, PTX Series Packet Transport Routers, TX Matrix, and TX Matrix Plus routers.

NOTE: Branch SRX Series Services Gateways are upgraded from loader prompt using USB or TFTP. For more details, see [“Installing Junos OS on SRX Series Devices Using a USB Flash Drive” on page 68](#) and [“Installing Junos OS on SRX Series Devices from the Boot Loader Using a TFTP Server” on page 70](#).

Installation Bundles

The installation bundle can be used to downgrade or upgrade Junos OS between minor revisions (from Release 9.1 to Release 9.2, for example). When used, the installation bundle modifies only the files required for the upgrade or downgrade between versions.

NOTE: You should only use the installation bundle under direction of a Juniper Networks support representative.

The following installation bundle files are available for download:

Installation Bundle	Description
jbundle*	Junos OS for the ACX series, M Series, MX Series, T Series, PTX Series Packet Transport Routers, TX Matrix, and TX Matrix Plus routers.

NOTE: Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel (hereafter called Junos OS with upgraded FreeBSD). Junos OS with upgraded FreeBSD has a new naming convention. For more information on this new naming convention, see [“Understanding Junos OS with Upgraded FreeBSD Package Names” on page 22](#).

Installation Modules

Installation modules are used to upgrade individual software modules in Junos OS. For example, you can upgrade only the Routing Engine software by installing the **jroute*** installation module.

NOTE: You should only use installation module files under the direction of a Juniper Networks support representative.

The following installation module files are available for download:

Installation Module	Description
jkernel*	The kernel and network tools package. This package contains the basic operating system files.
jbase*	The base package for Junos OS. This package contains additions to the operating system.
jroute*	The Routing Engine package. This package contains the Routing Engine software.
jpfe*	The Packet Forwarding Engine package. This package contains the PFE software.
jdocs*	The documentation package. This package contains the documentation set for the software.
jcrypto*	The encryption package. This package contains the domestic version of the security software.
jweb*	The J-Web package. This package contains the graphical user interface software for M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus routers.

NOTE: Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel (hereafter called Junos OS with upgraded FreeBSD). Junos OS with upgraded FreeBSD has a new naming convention. For more information on this new naming convention, see [“Understanding Junos OS with Upgraded FreeBSD Package Names”](#) on page 22.

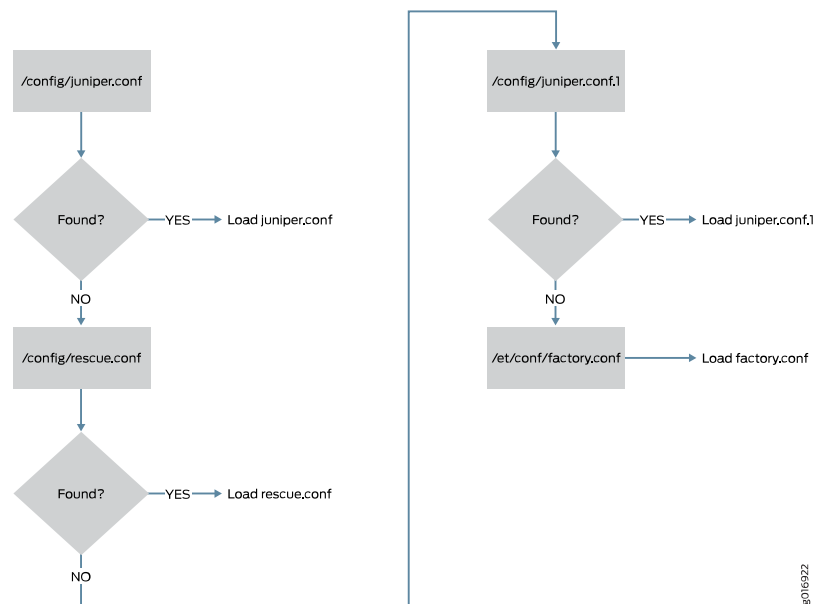

Configuration Files

All configuration settings for the device are handled in the configuration files on the device. These files are saved in the **/config** directory on the device.

Configuration File Selection Sequence

During the boot process, the device is configured based on a predefined configuration file. The device selects the configuration file based on the sequence shown in Figure 1.

Figure 1: Configuration Selection Sequence

1. **/config/juniper.conf**—Active configuration file.
2. **/config/rescue.conf**—Rescue configuration file. This file is created by the router or switch administrator.
3. **/config/juniper.conf.1**—First rollback configuration.
4. **/etc/config/factory.conf**—Default factory configuration file.

The **factory.conf** file is the initial device configuration file shipped with the system. All configuration settings are returned to the factory default, and access to the device is restricted to the console. For more information about setting up your device from the factory default configuration, see the specific hardware guide for your device.

For SRX Series Services Gateways running Junos Release 10.0 or later, the current operational Junos Software configuration is stored in a file named **juniper.conf**, and the last five committed configurations are stored in the files **juniper.conf.1** through **juniper.conf.5**. The rescue configuration is stored in a file named **rescue.conf**. These files

are located in the **/config** directory available on the flash drive of the SRX Series Services Gateway.

To list the configuration files, use the **file list /config** operational mode command.

```
user@host>file list / config
/config:
.snap/
idp-dfa-status.db
juniper.conf+.gz
juniper.conf.1.gz
juniper.conf.2.gz
juniper.conf.3.gz
juniper.conf.4.gz
juniper.conf.5.gz
juniper.conf.gz
juniper.conf.md5*
jwxd_initialized
license/
license-status.db
rescue.conf.gz
usage.db
usage.db.1344499761
```

Remote Storage of Configuration Files

Configuration files can be stored off the device. This can be helpful if the device encounters a software failure or other problem that forces you to restore the device's software. Once the software is restored, you can then reload the saved configuration file. For more information about restoring Junos OS, see [“Loading and Committing the Configuration File” on page 184](#).

When the configuration file is stored off the device, you can encrypt the configuration files using the Data Encryption Standard (DES) encryption algorithm.

Understanding Software Infrastructure and Processes

Each switch runs the Juniper Networks Junos operating system (Junos OS) for Juniper Networks EX Series Ethernet Switches on its general-purpose processors. Junos OS includes processes for Internet Protocol (IP) routing and for managing interfaces, networks, and the chassis.

The Junos OS runs on the Routing Engine. The Routing Engine kernel coordinates communication among the Junos OS processes and provides a link to the Packet Forwarding Engine.

With the J-Web interface and the command-line interface (CLI) to the Junos OS, you configure switching features and routing protocols and set the properties of network interfaces on your switch. After activating a software configuration, use either the J-Web or CLI user interface to monitor the switch, manage operations, and diagnose protocol and network connectivity problems.

- [Routing Engine and Packet Forwarding Engine on page 17](#)
- [Junos OS Processes on page 17](#)

Routing Engine and Packet Forwarding Engine

A switch has two primary software processing components:

- Packet Forwarding Engine—Processes packets; applies filters, routing policies, and other features; and forwards packets to the next hop along the route to their final destination.
- Routing Engine—Provides three main functions:
 - Creates the packet forwarding switch fabric for the switch, providing route lookup, filtering, and switching on incoming data packets, then directing outbound packets to the appropriate interface for transmission to the network
 - Maintains the routing tables used by the switch and controls the routing protocols that run on the switch.
 - Provides control and monitoring functions for the switch, including controlling power and monitoring system status.

Junos OS Processes

The Junos OS running on the Routing Engine and Packet Forwarding Engine consists of multiple processes that are responsible for individual functions.

The separation of functions provides operational stability, because each process accesses its own protected memory space. In addition, because each process is a separate software package, you can selectively upgrade all or part of the Junos OS, for added flexibility.

[Table 3](#) describes the primary Junos OS processes.

Table 3: Junos OS Processes

Process	Name	Description
Chassis process	chassisd	<p>Detects hardware on the system that is used to configure network interfaces.</p> <p>Monitors the physical status of hardware components and field-replaceable units (FRUs), detecting when environment sensors such as temperature sensors are triggered.</p> <p>Relays signals and interrupts—for example, when devices are taken offline, so that the system can close sessions and shut down gracefully.</p>
Ethernet switching process	eswd	<p>Handles Layer 2 switching functionality such as MAC address learning, Spanning Tree protocol and access port security. The process is also responsible for managing Ethernet switching interfaces, VLANs, and VLAN interfaces.</p> <p>Manages Ethernet switching interfaces, VLANs, and VLAN interfaces.</p>
Forwarding process	pfem	<p>Defines how routing protocols operate on the switch. The overall performance of the switch is largely determined by the effectiveness of the forwarding process.</p>
Interface process	dcd	<p>Configures and monitors network interfaces by defining physical characteristics such as link encapsulation, hold times, and keepalive timers.</p>
Management process	mgd	<p>Provides communication between the other processes and an interface to the configuration database.</p> <p>Populates the configuration database with configuration information and retrieves the information when queried by other processes to ensure that the system operates as configured.</p> <p>Interacts with the other processes when commands are issued through one of the user interfaces on the switch.</p> <p>If a process terminates or fails to start when called, the management process attempts to restart it a limited number of times to prevent thrashing and logs any failure information for further investigation.</p>
Routing protocol process	rpd	<p>Defines how routing protocols such as RIP, OSPF, and BGP operate on the device, including selecting routes and maintaining forwarding tables.</p>

Related Documentation

Understanding Junos OS with Upgraded FreeBSD

Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD. Basing Junos OS on the newer kernel provides Junos OS with sophisticated processing, efficiency, and security features which do not then have to be reproduced in Junos OS.

NOTE: Upgrading to Junos OS Release 15.1 reformats the file system. Only specific files and directories are preserved unless precautions are taken. For details, see [“Upgrading Junos OS with Upgraded FreeBSD” on page 139](#).

Junos OS with an upgraded FreeBSD kernel provides a clean-slate implementation of Junos OS on top of a pristine (minimally modified) and current version of the FreeBSD OS.

NOTE: In Junos OS releases earlier than 15.1, the partition swap pages were counted as part of the memory file system partition. Using this method leaves 4 GB of memory as the maximum that is theoretically accessible when you are using a 32-bit image. However, when Junos OS with upgraded FreeBSD is run, the system only counts the actual partition size, which leaves around 3.4 GB of available physical address space, or only 3 GB of usable RAM. Therefore, we recommend you use a 64-bit image with Junos OS with upgraded FreeBSD.

The platforms currently running Junos OS with upgraded FreeBSD are listed in [Table 4](#).

Table 4: Upgraded FreeBSD Kernel Support by Hardware Platform

Platforms	CPU Type	Release Introduced
MX240, MX460, MX960, MX2010, MX2020	Intel	15.1
EX9200	Intel	15.1
QFX5200	Intel	15.1X53-D30
QFX10000 switches	Intel	15.1X53-D60

The major processing changes are as follows:

- Interactions between Junos OS and the upgraded FreeBSD kernel use well-established interfaces because Junos OS is now layered on a minimally modified and current version of FreeBSD.
- Symmetric multiprocessing (SMP) is enabled by default.

- FreeBSD provides a consistent runtime environment for all Junos OS platforms.

There are also major changes in file structures and software packages. These changes are as follows:

- New packages use XML description files instead of scripts.
- Hybrid packages are used to install legacy or replacement build images in the general form **junos-upgrade-x.tgz** where *x* is a variable such as **mx-x86-64-15.1-20150114** (the whole package name is **junos-upgrade-mx-x86-64-15.1-20150114.tgz**).
- Multiple package sets (a collection of installed packages) are stored on the router at the same time. Sets can be either active (the currently used set), pending (the set that should be used at the next reboot), or previous (a formerly active set). Non-recovery snapshots (but not recoverable image snapshots) are available for the package sets to preserve package content lists.

There is now a separate Operations, Administration, and Maintenance (OAM) volume (**oam**) distinct from the Junos OS volume (**junos**). This provides support for downgrades from replacement build images (that is, those using the upgraded FreeBSD kernel) to the legacy Junos OS with a different kernel. The OAM volume allows you to recover the Junos OS volume using recovery snapshots.

One major change is the distinction between recovery snapshots and non-recovery snapshots.

The major characteristics of the recovery snapshots are as follows:

- Recovery snapshots are full copies of the packages and configuration taken at the time the snapshot command is issued.
- Recovery snapshots reside on the OAM volume or USB medium.

The major characteristics of the non-recovery snapshots are as follows:

- Non-recovery snapshots are snapshots residing on the Junos OS volume that refer to the current running set of packages and a copy of the configuration at the time the snapshot command is issued.
- Non-recovery snapshots do not need to copy the whole Junos OS installation and so are very fast.
- Non-recovery snapshots can be requested as the boot image for the next reboot.

The upgraded FreeBSD kernel requires changes to several commands and statements and their related parameters. The new and changed actions are summarized in [Table 5](#). For details on the changes, see the topics covering the specific command or statement.

Table 5: New and Changed Commands and Statements for Junos OS with Upgraded FreeBSD

Command or Statement	Release Introduced	Change
request system snapshot delete <i>snapshot</i>	15.1	New action

Table 5: New and Changed Commands and Statements for Junos OS with Upgraded FreeBSD (continued)

Command or Statement	Release Introduced	Change
<code>request system snapshot recovery</code>	15.1	New action
<code>request system snapshot load <i>snapshot</i></code>	15.1	New action
<code>request system recover <i>volume</i></code>	15.1	New action: <i>volume</i> is either <code>/junos-volume</code> or <code>/oam-volume</code>
<code>request system snapshot</code>	15.1	Changed action
<code>show system snapshot</code>	15.1	Changed action
<code>request system reboot <i>media</i></code>	15.1	Changed action with new media options

The new FreeBSD kernel also requires that several commands and statements are now deprecated. In some cases, these commands and statements generate an error, and, in other cases, the result is appropriate for the new kernel. The deprecated commands and statements are summarized in [Table 6](#). For details, see the topics covering the specific command or statement.

Table 6: Deprecated Commands and Statements for Junos OS with Upgraded FreeBSD

Deprecated Command or Configuration Statement	Release Deprecated
Deprecated Command	
<code>request system partition abort</code>	15.1
<code>request system partition compact-flash</code>	15.1
<code>request system partition hard-disk</code>	15.1
<code>request system snapshot <config-partition></code>	15.1
<code>request system snapshot <root-partition></code>	15.1
<code>request system snapshot <slice></code>	15.1
<code>request system software delete-backup</code>	15.1
<code>request system software rollback <force></code>	15.1
<code>show system processes providers</code>	15.1
<code>show system snapshot <slice></code>	15.1
Deprecated Configuration Statement	

Table 6: Deprecated Commands and Statements for Junos OS with Upgraded FreeBSD (*continued*)

Deprecated Command or Configuration Statement	Release Deprecated
<code>set system mirror-flash-on-disk</code>	15.1

Understanding Junos OS with Upgraded FreeBSD Package Names

Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel (hereafter called Junos OS with upgraded FreeBSD). In releases earlier than Junos OS Release 15.1, software packages came in several major software package categories, such as domestic, worldwide, or Federal Information Processing Standard (FIPS). However, Junos OS with upgraded FreeBSD has a new naming convention: There is only one category, and FIPS, instead of being a separate category, is an option you select on installation. This topic describes the simplified naming convention for Junos OS with upgraded FreeBSD.

If your hardware platform is listed in the table in [“Understanding Junos OS with Upgraded FreeBSD” on page 19](#), then you must use the new package names for download and installation.

The components of the new package naming conventions are as follows:

- **Prefix**—This is **junos-install**. This prefix takes the place of the prefix **jinstall** and the bundle **bundle**. We still use the term *bundle* in the new package-naming convention.
- **Media keyword**—Added to the prefix, a media keyword is only used when the image is not for use with the **request system software add** command. Values for the **media** keyword include **usb** for images installed from a USB drive or **net** for images installed over a network; for example, the entire prefix of your package might be **junos-install-usb-**.
- **Platform**—This field indicates the major product group, such as **mx** or **qfx**.
- **Architecture**—This field indicates the CPU architecture of the platforms. Values include **x86** for Intel and **arm** for Advanced RISC Machines CPUs.
- **Application Binary Interface (ABI)**—This field indicates the “word length” of the CPU architecture. Values include **32** for 32-bit architectures and **64** for 64-bit architectures.
- **Release**—This field indicates the release number, such as **15.1R1.9**.
- **Edition**—The edition field is null (empty) for the standard (domestic) images. For jurisdictions with limits on dataplane encryption, this field is set to **limited**.

As before, all images are in tarred and gzipped (.tgz) format.

NOTE: There are no longer “export” worldwide images or separate FIPS images. The keyword “signed” no longer appears because all Junos OS images are signed for validation.

Examples of valid Junos OS software package names include the following:

- **junos-install-mx-x86-32-15.1R1.9.tgz**—An image for a supported MX Series platform outside the RTZ.
- **junos-install-mx-x86-32-15.1R1.9-limited.tgz**—An image for a supported MX Series platform used in the RTZ.
- **junos-install-usb-mx-x86-32-15.1R1.9.tgz**—An image stored on and installed from a USB drive for a supported MX Series platform outside the RTZ.

Because an upgrade to Junos OS with upgraded FreeBSD from a release earlier than Junos OS 15.1 restructures the disk file system, you can lose many configuration and log files that you might want to keep. Items that are essential can be preserved by moving or copying them to the **/var/preserve** directory.

- [Upgrading Junos OS with Upgraded FreeBSD on page 139](#)

Understanding Junos OS with Upgraded FreeBSD Snapshots

Starting with Junos OS Release 15.1, certain hardware platforms have two types of snapshots. These platforms run a Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD. The two types of snapshots have different content, locations, and purposes, so it is important that they are created and maintained properly. One major change is the distinction between recovery snapshots and non-recovery snapshots. The hardware platforms listed in the table in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19 have these two different types of snapshots.

Recovery snapshots are full copies of the packages and configuration taken at the time the snapshot command is issued. Recovery snapshots reside on the OAM volume or USB medium. Recovery snapshots take some time to complete because of the level of detail captured. Recovery snapshots can be used to recover the Junos OS volume. There is only ever one recovery snapshot on the system.

On the other hand, non-recovery snapshots are snapshots residing on the Junos OS volume that refer to the current running set of packages and a copy of the configuration at the time the snapshot command is issued. Non-recovery snapshots do not need to copy the whole Junos OS installation and so are very fast. They also consume little space, except for the **config.tgz** file. Non-recovery snapshots can be requested as the boot image for the next reboot. You can rename non-recovery snapshots and retain more than one. You rename the non-recovery snapshots with the same procedure used to rename any other file on the system.

NOTE: We recommend that you generate both a non-recovery and a recovery snapshot after you successfully upgrade to Junos OS with upgraded FreeBSD. These snapshots should be refreshed periodically.

Package sets relate to non-recovery and recovery snapshots. The **/active**, **/pending**, and **/previous** sets are all package sets. A non-recovery snapshot is also a package set in a sense, with the addition of a copy of the configuration at the time that the non-recovery snapshot is taken.

Packages that are no longer referenced by any package set or non-recovery snapshot are automatically deleted. We recommend deleting any old non-recovery snapshots after an upgrade so that old packages can be deleted and space recovered.

Some helpful commands for non-recovery snapshots are:

- **request system snapshot**—Use this command to create a non-recovery snapshot.
- **show system snapshot**—Use this command to list all the available non-recovery snapshots.
- **request system snapshot delete**—Use this command to delete a non-recovery snapshot.
- **request system snapshot recovery**—Use this command to create a recovery snapshot. You can use other parameters to determine the details of the recovery snapshot created. There is only ever one recovery snapshot on the system.

Understanding Junos OS with Upgraded FreeBSD Disk Volumes

Starting with Junos OS Release 15.1, certain hardware platforms have a new disk naming convention. These platforms run a Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD.

The hardware platforms listed in the table in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19 have two volumes. The main device is the **/junos** volume and contains all of the software and files needed for the day-to-day running of the device. The compact flash drive is the **/oam** volume and stores recovery snapshot backup

information. In case of failure of the main drive (that is, the **/junos** volume), the **/oam** volume can be used to boot the system.

Because the **/junos** and **/oam** volumes have very different purposes, their content is different. Technically, these volumes are **dev/gpt/oam** and **dev/gpt/junos**, but the short forms (**/junos** and **/oam**) are used in this topic. Essentially, the **/junos** volume is used for the running device software and holds configuration information and logs, whereas the **/oam** volume is used for backup copies of everything needed in the event that the **/junos** volume fails.

The **/junos** volume contains a directory named **/packages/db** that has all the components present on the device, such as **os-kernel-123**, **os-kernel-456**, and so on. A sibling directory named **/package-sets** is also present. Package sets are an important concept in Junos OS with upgraded FreeBSD.

The **/package-sets** directory contains a package listing that gathers all the components of the running Junos OS into an XML format in the **/active** subdirectory. So **os-kernel-123** could be a component in the **/package-sets/active** subdirectory, but then **os-kernel-456** could not be in the same XML package. Package sets do not contain the kernel software itself (for example), but tell the device where to find the kernel component needed for the software package. The same kernel can be present in several package listings, but only one package can be active and running on the device at any given time.

There are several directories on the **/junos** volume where a particular software package listing can be found:

- **/previous**—The package set in this directory contains the list of all the components that ran on the device before the last upgrade.
- **/active**—The package set in this directory contains the list of all the software components currently running on the device.
- **/pending**—The package set in this directory contains the list of all the software components on the device that will run after the next reboot.

NOTE: After a successful reboot, the package set in the **/pending** directory becomes the active package set, and the package set in the **/active** directory becomes the previous set.

The **/junos** volume also contains non-recovery snapshots taken with the **request system snapshot** command. These types of snapshots are new to Junos OS with upgraded FreeBSD and cannot be used for recovery of a failed system. Non-recovery snapshots are a special type of package set that includes a copy of the configuration. There can be many non-recovery snapshots on the device, and the files can be renamed. Multiple non-recovery snapshots, essentially lists of software components and configuration files, can be helpful when major software or configuration changes are occurring and establishment of a known stable system baseline is required.

On the other hand, a recovery snapshot, created with the **request system snapshot recovery** command, is stored on the **/oam** volume and is always replaced when a new recovery snapshot is taken.

The **/oam** volume should contain all the information needed to reboot the system if there is a failure of the **/junos** volume and restore the system to the state running at the time of the failure. In order to perform this reboot, the **/oam** volume needs to have all of the information required to provide the system with a running configuration. This information is provided by the recovery snapshot, created with the **request system snapshot recovery** command. Although it can take a while to perform, the recovery snapshot establishes an **.izo** or **.iso** image of the running Junos OS.

In the case of a total failure of the **/junos** volume, the system can be booted from the **/oam** volume. The recovery snapshot can then restore the repaired system.

Hardware Architecture Overview

Juniper Network routing platforms are made up of two basic routing components:

- **Routing Engine**—The Routing Engine controls the routing updates and system management.
- **Packet Forwarding Engine (PFE)**—The Packet Forwarding Engine performs Layer 2 and Layer 3 packet switching, route lookups, and packet forwarding.

From a system administration perspective, you install the software onto the Routing Engine and during the installation, the appropriate software is forwarded to other components as necessary. Most Routing Engines include a CompactFlash card that stores Junos OS. On M Series Multiservice Edge Routers, MX240, MX480, and MX960 3D Universal Edge Routers, T Series Core Routers, and TX Matrix routers, the system also includes a hard disk or solid-state drive (SSD) that acts as a backup boot drive. PTX Series Packet Transport Routers and the TX Matrix Plus router include a solid state drive as a backup boot drive.

NOTE: The MX80 router is a single-board router with a built-in Routing Engine and single Packet Forwarding Engine. On an MX80 router, Junos OS is stored on dual, internal NAND flash devices. These devices provide the same functionality as a CompactFlash card and hard disk or solid-state drive (SSD).

NOTE: The ACX Series router is a single board router with a built-in Routing Engine and one Packet Forwarding Engine. The ACX router supports dual-root partitioning, which means that the primary and backup Junos OS images are kept in two independently bootable root partitions. If the primary partition becomes corrupted, the system remains fully functional by booting from the backup Junos OS image located in the other root partition.

On routing platforms with dual Routing Engines, each Routing Engine is independent with regard to upgrading the software. To install new software on both Routing Engines, you need to install the new software on each Routing Engine. On platforms with dual Routing Engines configured for high availability, you can use the unified in-service software upgrade procedure to upgrade the software. For more information about this procedure, see the [High Availability Feature Guide for Routing Devices](#).

[Hardware Overview \(ACX Series, M Series, MX Series, T Series, and TX Matrix Routers\)](#)

[Figure 2](#) shows examples of Routing Engines.

Figure 2: Routing Engines

The ACX Series, M Series, MX Series, PTX Series, T Series, TX Matrix, and TX Matrix Plus routers include the following:

- [System Memory on page 29](#)
- [Storage Media on page 30](#)

System Memory

Starting with Junos OS Release 9.0, all routing platforms require a minimum of 512 MB of system memory on each Routing Engine. All M7i and M10i routers delivered before December 7, 2007, had 256 MB of memory. These routers require a system memory upgrade before you install Junos OS Release 9.0 or a later release. To determine the amount of memory currently installed on your system, use the **show chassis routing-engine** command in the command-line interface (CLI).

For more information about upgrading your M7i or M10i router, see the Customer Support Center JTAC Technical Bulletin PSN-2007-10-001:

<https://www.juniper.net/alerts/viewalert.jsp?txtAlertNumber=PSN-2007-10-001&actionBtn=Search>.

ACX2000 routers are shipped with 2 GB of memory and ACX1000 routers with 1 GB of memory.

Storage Media

Except for the ACX Series, MX80 routers, MX104 routers, the M Series, MX Series, PTX Series, T Series, TX Matrix, and TX Matrix Plus routers use the following media storage devices:

- CompactFlash card—The CompactFlash card is typically the primary storage device for most routers.

NOTE: M7i and M10i routers using RE-400 are not delivered from the factory with the CompactFlash card installed. In this case, the hard disk is the primary and only boot device. The M7i and M10i routers with RE-400 can be upgraded to include the CompactFlash card.

- Hard disk or solid-state drive—For most routers,, a hard disk or solid-state drive is the secondary boot device. When the CompactFlash card is not installed on the router, the hard disk or the solid-state drive becomes the primary boot device. The hard disk or solid-state drive is also used to store system log files and diagnostic dump files.
- Emergency boot device—Depending on the router, the emergency boot device can be a PC card, a USB storage device, or an LS-120 floppy disk.

On MX80 routers, the internal NAND flash devices (first *da0*, then *da1*) act as the primary and secondary boot devices.

On ACX Series routers, the internal NAND flash devices (first *da0s1*, then *da0s2*) act as the primary and secondary boot devices.

Emergency boot devices can be used to revive a routing platform that has a damaged Junos OS. When an emergency boot device is attached to the router, the router attempts to boot from that device before it boots from the CompactFlash card, solid-state drive (SSD), or hard disk.

On an ACX Series router, the emergency boot device is a USB storage device.

On MX104 routers, the internal NAND flash device (**da0**) mounted on the internal eUSB card acts as the primary boot and storage device. On MX104 routers, the emergency boot device is a USB storage device that is plugged into one of the USB ports in the front plate.

When booting from an emergency boot device, the router requests a boot acknowledgment on the console interface. If you enter yes, the emergency boot device repartitions the primary boot device and reloads Junos OS onto the primary boot device. After the loading is complete, the routing platform requests that you remove the

emergency boot device and reboot the system. After the reboot is complete, you must perform an initial configuration of the router before it can be used on your network.

Hardware Overview of SRX Series Services Gateways

SRX Series Device Overview

Figure 3 shows an example of an SRX345 device.

Figure 3: SRX345 Device Front Panel

Figure 4 shows an example of an SRX1500 device.

Figure 4: SRX1500 Device Front Panel

Figure 5 shows an example of an SRX5800 device Routing Engine.

Figure 5: SRX5800 Device Routing Engine

System Memory

The amount of free disk space necessary to upgrade a device with a new version of Junos OS can vary from one release to another for different SRX Series devices. Check the Junos OS software version you are installing to determine the free disk space requirements.

To determine the amount of free disk space on the device, issue the **show system storage detail** command. The command output displays statistics about the amount of free disk space in the device file systems.

Storage Media

The SRX300, SRX320, SRX340, 345 Services Gateway can boot from the following storage media (in the order of priority):

- Internal NAND flash device mounted on the internal eUSB card (default; always present)
- USB storage key (alternate)

The SRX550M Services Gateway can boot from the following storage media (in the order of priority):

- CompactFlash (default; always present)
- USB storage key (alternate)

SRX1500 device use the following media storage devices:

- Internal eSATA flash disk (default; always present)
- SSD Card

SRX5400, SRX5600, SRX5800 devices use the following media storage devices:

- The CompactFlash card in the Routing Engine
- The hard disk in the Routing Engine

NOTE: You can also use a Junos OS image stored on a USB flash drive that you insert into the Routing Engine faceplate.

Routing Engines and Storage Media Names (ACX Series, M Series, MX Series, PTX Series, T Series, TX Matrix, TX Matrix Plus, and JCS 1200 Routers)

Table 7 specifies the storage media names by Routing Engine. The storage media device names are displayed when the router boots.

Table 7: Routing Engines and Storage Media Names (ACX Series, M Series, MX Series, T Series, TX Matrix, TX Matrix Plus, and JCS 1200 Routers)

Routing Engine	CompactFlash Card	Hard Disk	Solid State Drive	Removable Media Emergency Boot Device
RE-400-768 (RE5)	ad0	ad1	No	ad3
RE-600-2048 (RE3)	ad0	ad1	No	ad3
RE-850-1536 (RE-850)	ad0	ad1	No	ad3
RE-A-1000-2048 (RE-A-1000)	ad0	ad2	No	da0

Table 7: Routing Engines and Storage Media Names (ACX Series, M Series, MX Series, T Series, TX Matrix, TX Matrix Plus, and JCS 1200 Routers) (continued)

Routing Engine	CompactFlash Card	Hard Disk	Solid State Drive	Removable Media Emergency Boot Device
RE-A-1800x2 (RE-A-1800)	ad0	No	Yes SSD1: ad1 SSD2: ad2	da0
RE-S-1300-2048 (RE-S-1300)	ad0	ad2	No	da0
RE-S-1800x2 RE-S-1800x4 (RE-S-1800)	ad0	No	Yes SSD1: ad1 SSD2: ad2	da0
RE-B-1800X1-4G-S	ad0	No	Yes SSD1: ad1	da0
RE-1600-2048 (RE4)	ad0	ad1	No	ad3 and ad4
RE-A-2000-4096 (RE-A-2000)	ad0	ad2	No	da0
RE-S-2000-4096 (RE-S-2000)	ad0	ad2	No	da0
RE-MX-104	No	da0	No	da1 and da2
RE-DUO-C2600-16G (RE-DUO-2600)	ad0	No	ad1	da0
RE-DUO-C1800-8G- (RE-DUO-1800)	ad0	No	ad1	da0
RE-DUO-C1800-16G	ad0	No	ad1	da0
RE-JCS1200-1x2330	da0	da1	No	da2

NOTE: On MX80 routers, the Routing Engine is a built-in device and has no model number. The dual internal NAND flash devices are *da0* and *da1*. The USB storage device is *da2*.

NOTE: On ACX Series routers, the Routing Engine is a built-in device, which does not have a model number. The dual internal NAND flash devices are da0s1 and da0s2. The USB storage device is da0s2a. Use the `show chassis hardware models` command to obtain the field-replaceable unit (FRU) model number—for example, ACX2000BASE-DC for the ACX2000 router.

To view the storage media currently available on your system, use the CLI **show system storage** command. For more information about this command, see the *CLI User Guide*.

- [Boot Sequence on SRX Series Devices on page 36](#)

Boot Sequence on M Series, MX Series, T Series, TX Matrix, TX Matrix Plus, ACX Series, and PTX Series Devices with Routing Engines

NOTE: For information about which Routing Engines are supported by each device, see http://www.juniper.net/techpubs/en_US/release-independent/junos/topics/reference/general/routing-engine-m-mx-t-series-support-by-chassis.html.

The M Series, MX Series (except for the MX80 routers and the MX104 routers), T Series, and TX Matrix routers with a Routing Engine that has a hard disk attempt to boot from the storage media in the following order:

1. Removable media emergency boot device, such as a PC Card (if present)
2. CompactFlash card (if present)
3. Hard disk

The M Series and MX Series with a Routing Engine that has a solid-state drive (SSD) attempt to boot from the storage media in the following order:

1. USB media emergency boot device (if present)
2. CompactFlash card
3. Solid-state drive (SSD) in the SSD slot 1 or SSD slot 2 (if present)

MX80 routers attempt to boot from the storage media in the following order:

1. USB media emergency boot device
2. Dual, internal NAND flash device (first *da0*, then *da1*)

MX104 routers attempt to boot from the storage media in the following order:

1. USB storage media device
2. Internal NAND flash device (**da0**)

The T series routers with a Routing Engine that has a solid-state drive (SSD), and TX Matrix Plus routers attempt to boot from the storage media in the following order:

1. USB media emergency boot device
2. CompactFlash card (if present)
3. Solid-state drive (SSD) in the Disk 1 slot (if present)

NOTE: The Disk 2 slot is not currently supported.

4. Storage media available on the LAN

The ACX Series routers attempt to boot from the storage media in the following order:

1. USB storage media device
2. Dual, internal NAND flash device (first **da0s1**, then **da0s2**)

The PTX Series Packet Transport Routers attempt to boot from the storage media in the following order:

1. USB media emergency boot device
2. CompactFlash card

3. Solid-state drive (SSD) in the Disk 1 slot (if present)
4. Storage media available on the LAN

NOTE: Do not insert an emergency boot device during normal operations. The router does not operate normally when it is booted from an emergency boot device.

If the router boots from an alternate boot device, Junos OS displays a message indicating this when you log in to the router. For example, the following message shows that the software booted from the hard disk (`/dev/ad1s1a`):

```
login: username
Password: password
Last login: date on terminal
```

```
--- Junos 8.0 R1 built date
```

```
---
```

```
--- NOTICE: System is running on alternate media device (/dev/ad2s1a).
```

This situation results when the router detects a problem with the primary boot device—usually the CompactFlash card—that prevents it from booting, and consequently boots from the alternate boot device (the hard disk drive). When this happens, the primary boot device is removed from the list of candidate boot devices. The problem is usually a serious hardware error. We recommend you contact the Juniper Networks Technical Assistance Center (JTAC).

NOTE: On MX104 routers, if the router boots from an alternate boot device, Junos OS does not display any message indicating this when you log in to the router.

When the router boots from the alternate boot device, the software and configuration are only as current as the most recent **request system snapshot** command. However, if the **mirror-flash-on-disk** command was enabled, then the hard disk drive contains a synchronized, mirror image of the compact flash drive and therefore the current software and configuration.

CHAPTER 3

Installation Overview

- [Installation Type Overview on page 41](#)
- [Installation Categories on the ACX Series, M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus Routers on page 42](#)
- [Installation Categories on SRX Series Devices on page 43](#)
- [Understanding Software Installation on EX Series Switches on page 44](#)

Installation Type Overview

The three types of installations used to upgrade or downgrade your routing platform are standard installation, category change, and recovery. The standard installation is the standard method of upgrading and downgrading the software. Use a category change installation when you are moving from one software category to another; for example, if you are changing the device from using the standard Junos OS to the Junos-FIPS category. Perform a recovery installation when the software on the device is damaged or otherwise unable to accommodate a software upgrade or downgrade.

Standard Installation

A standard installation is the typical method used to upgrade or downgrade software on the server. This method uses the installation package that matches the installation package already installed on the system.

For information on the different installation packages available, see [“Junos OS Installation Packages” on page 6](#).

Category Change Installation

The category change installation process is used to move from one category of Junos OS to another on the same router; for example, moving from a Junos OS standard installation to a Junos-FIPS installation. When moving from one installation category to another, you need to be aware of the restrictions regarding this change.

NOTE: Juniper Networks does not support using the `request system software rollback` command to restore a different installation category on the device. When installing a different Junos OS category on a device, once the installation is complete, you should execute a `request system snapshot` command to delete the backup installation from the system.

Recovery Installation

A recovery installation is performed to repair a device with damaged software or a condition that prevents the upgrade, downgrade, or change in installation category of the software.

For example, you may need to perform a recovery installation to change a device's software category from Junos-FIPS to standard Junos OS.

Installation Categories on the ACX Series, M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus Routers

The following installation categories are available with the ACX Series, M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus routers:

- Standard Junos OS, domestic—`jinstall-<release>-domestic-signed.tgz`

This software includes high-encryption capabilities for data leaving the router. Because of U.S. government export restrictions, this software can only be installed on systems within the United States and Canada. For all other customers, a valid encryption agreement is required to use this software edition. Furthermore, no router can be shipped out of the United States or Canada without the domestic edition first being overwritten by the export edition. There are no current system-enforced restrictions when you install this software category.

- Standard Junos OS, export—`jinstall-<release>-export-signed.tgz`

This software does not include high-encryption capabilities. It can be installed on any system worldwide. There are no current system-enforced restrictions when you install this software category.

- Junos-FIPS—`junos-juniper-<release>-domestic-signed.tgz` and `junos-juniper-<release>-fips-signed.tgz`

The Junos-FIPS OS base provides customers with the software tools to configure the router for use within a Federal Information Processing Standards (FIPS) environment. Once you have installed this software category onto a router, you cannot install a different software category on the router using the `request system software add` command. When attempting to install a different Junos OS category package on the router, you receive the following warning message:

WARNING: Package `jinstall-<release>-<edition>-signed` is not compatible with this system.

WARNING: Please install a supported package (`junos-juniper-*.tgz`).

To return to a standard Junos OS category installation, you must perform a system recovery installation of the software. All configuration files, logs, and other data files on the server are overwritten during a recovery installation.

For more information about Junos-FIPS OS base, see [“FIPS 140-2 Security Compliance” on page 5](#).

NOTE: When you install a Junos OS installation package, the previous installation is maintained as a backup installation. You should issue a `request system software snapshot` command to overwrite the backup files any time you change software categories on a router. This is mandatory if the router is to be shipped outside of the United States or Canada after the Export edition of Junos OS has been installed. There are no current system-enforced restrictions when you install this software category.

Installation Categories on SRX Series Devices

The following installation categories are available with the SRX Series devices:

- Junos OS, domestic—`junos-srxsme-<release>-domestic.tgz` for SRX Series devices. .

This software includes high-encryption capabilities for data leaving the router. Because of U.S. government export restrictions, this software can only be installed on systems within the United States and Canada. For all other customers, a valid encryption agreement is required to use this software edition. Furthermore, no router can be shipped out of the United States or Canada without the domestic edition first being overwritten by the export edition. There are no current system-enforced restrictions when you install this software category.

- Junos OS, export—`junos-srxsme-<release>-export.tgz` for SRX Series devices.

This software does not include high-encryption capabilities. It can be installed on any system worldwide. There are no current system-enforced restrictions when you install this software category.

Understanding Software Installation on EX Series Switches

A Juniper Networks EX Series Ethernet Switch is delivered with the Juniper Networks Junos operating system (Junos OS) preinstalled. As new features and software fixes become available, you must upgrade your software to use them. You can also downgrade Junos OS to a previous release.

This topic covers:

- [Overview of the Software Installation Process on page 44](#)
- [Software Package Security on page 44](#)
- [Installing Software on a Virtual Chassis on page 45](#)
- [Installing Software on Switches with Redundant Routing Engines on page 45](#)
- [Installing Software Using Automatic Software Download on page 45](#)
- [Autoinstalling a Configuration File on an EX2200 or EX3300 Switch from a Disk-on-Key USB Memory Stick on page 46](#)
- [Installing Software on an EX2300 or EX3400 Switch on page 46](#)
- [Troubleshooting Software Installation on page 46](#)

Overview of the Software Installation Process

An EX Series switch is delivered with a domestic version of Junos OS preinstalled. When you connect power to the switch, it starts (boots) from the installed software.

You upgrade Junos OS on an EX Series switch by copying a software package to your switch or another system on your local network, then use either the J-Web interface or the command-line interface (CLI) to install the new software package on the switch. Finally, you reboot the switch; it boots from the upgraded software. After a successful upgrade, you should back up the new current configuration to a secondary device. You should follow this procedure regardless of whether you are installing a domestic or controlled Junos OS package.

During a successful upgrade, the upgrade package removes all files from `/var/tmp` and completely reinstalls the existing software. It retains configuration files, and similar information, such as secure shell and host keys, from the previous version. The previous software package is preserved in a separate disk partition, and you can manually revert back to it if necessary. If the software installation fails for any reason, such as loss of power during the installation process, the system returns to the originally active installation when you reboot.

Software Package Security

All Junos OS releases are delivered in signed packages that contain digital signatures to ensure official Juniper Networks software. For more information about signed software packages, see the [Junos OS Installation and Upgrade Guide](#).

Installing Software on a Virtual Chassis

You can connect individual EX Series switches together to form one unit and manage the unit as a single device, called a Virtual Chassis. The Virtual Chassis operates as a single network entity composed of member switches. Each member switch in a Virtual Chassis must be running the same version of Junos OS. See *EX Series Virtual Chassis Software Features Overview* for a list of switches that can be used in a Virtual Chassis.

For ease of management, a Virtual Chassis provides flexible methods to upgrade software releases. You can deploy a new software release to all member switches of a Virtual Chassis or to only a particular member switch.

You can also upgrade the software on an EX4200, EX4500, mixed EX4200 and EX4500, and EX8200 Virtual Chassis using nonstop software upgrade (NSSU). NSSU takes advantage of graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) to ensure no disruption to the control plane during the upgrade. You can minimize disruption to network traffic by defining link aggregation groups (LAGs) such that the member links of each LAG reside on different line cards (on EX8200 Virtual Chassis) or on different members (on EX4200, EX4500, mixed EX4200 and EX4500 Virtual Chassis). During an NSSU, the line cards and Virtual Chassis members are upgraded one at a time, so that traffic continues to flow through the other line cards or members while that line card or member is being upgraded.

Installing Software on Switches with Redundant Routing Engines

You can install software on a switch with redundant Routing Engines in one of two ways:

- Perform an NSSU—An NSSU upgrades both Routing Engines with a single command and with a minimum of network disruption. An NSSU takes advantage of GRES and NSR to ensure no disruption to the control plane. You can minimize disruption to network traffic by defining LAGs such that the member links of each LAG reside on different line cards. The line cards are upgraded one at a time, so that traffic continues to flow through the other line cards while a line card is being upgraded.

You cannot use NSSU to downgrade the software running on a switch.

For more information about NSSU, see [“Understanding Nonstop Software Upgrade on EX Series Switches” on page 123](#). See *EX Series Switch Software Features Overview* for a list of switches that support NSSU.

- Upgrade each Routing Engine manually—You can perform a Junos OS installation on each Routing Engine separately, starting with the backup Routing Engine. You can use this procedure to downgrade the software running on a switch. See *Installing Software on an EX Series Switch with Redundant Routing Engines (CLI Procedure)*.

Installing Software Using Automatic Software Download

The automatic software download feature uses the DHCP message exchange process to download and install software packages. Users can define a path to a software package on the DHCP server and then the DHCP server communicates this path to EX Series switches acting as DHCP clients as part of the DHCP message exchange process. The DHCP clients that have been configured for automatic software download receive these

messages and, when the software package name in the DHCP server message is different from that of the software package that booted the DHCP client switch, download and install the software package. See [“Upgrading Software by Using Automatic Software Download”](#) on page 129.

Autoinstalling a Configuration File on an EX2200 or EX3300 Switch from a Disk-on-Key USB Memory Stick

You can use an autoinstallation process to configure the software on an EX2200 or EX3300 switch. You can use a configuration file that is in either text format or XML format. If you want to use an XML-formatted file, you use a Junos Space platform to create the configuration file. You place the configuration file on a Disk-on-Key USB memory stick.

Installing Software on an EX2300 or EX3400 Switch

Before installing software on an EX2300 or EX3400 switch:

- Ensure that at least 620 MB of disk space is available in the system before downloading the software installation package to the `/var/tmp` directory. Use the command **show system storage** to get details of the available space.
- If the space available is inadequate, use the command **request system storage cleanup**. Additionally, you can manually delete any other log or unwanted files from the `/var/tmp` or `/var/log` directories.

You can now follow the procedure in *Installing Software on an EX Series Switch with a Single Routing Engine (CLI Procedure)* to complete the software installation.

Troubleshooting Software Installation

If Junos OS loads but the CLI is not working for any reason, or if the switch has no software installed, you can use the recovery installation procedure to install the software on the switch. See [“Troubleshooting Software Installation”](#) on page 265.

NOTE: You can also use this procedure to load two versions of Junos OS in separate partitions on the switch.

Checking the Current Configuration and Candidate Software Compatibility

When you upgrade or downgrade Junos OS, we recommend that you include the **validate** option with the **request system software add** command to check that the candidate software is compatible with the current configuration. By default, when you add a package with a different release number, the validation check is done automatically.

NOTE: On an ACX Series router, you must ensure that the primary and backup partitions are synchronized after an upgrade by issuing the `request system snapshot` command.

- [request system snapshot \(SRX Series\) on page 331](#)
- [request system software add \(Maintenance\) on page 344](#)

Determining the Junos OS Version

To determine which software packages are running on the device and to get information about these packages, use the **show version** operational mode command at the top level of the command-line interface (CLI).

NOTE: The `show version` command does not show the software category installed, only the release number of the software.

**Related
Documentation**

- [Preparing Your SRX Series Device for Junos OS Upgrades on page 147](#)

- [Example: Installing Junos OS Upgrade Packages on SRX Series Devices on page 150](#)
- [Installing Junos OS Upgrade Packages on SRX Series Devices from a Remote Server on page 152](#)

Downloading Software

You can download the software in one of two ways:

- [Downloading Software with a Browser on page 49](#)
- [Downloading Software Using the Command-Line Interface on page 49](#)

Downloading Software with a Browser

You download the software package you need from the Juniper Networks Support website at <http://www.juniper.net/support/>.

NOTE: To access the download section, you must have a service contract and an access account. If you need help obtaining an account, complete the registration form at the Juniper Networks website: <https://www.juniper.net/registration/Register.jsp>.

To download the software:

1. In a browser, go to <http://www.juniper.net/support/>.
The Support page opens.
2. In the Download Software section, select the software version to download.
Depending on your location, select Junos Canada and US, or Junos Worldwide.
3. Select the current release to download.
4. Click the Software tab and select the Junos OS installation package to download.
A dialog box opens.
5. Save the file to your system. If you are placing the file on a remote system, you must make sure that the file can be accessible by the router or switch using HTTP, FTP, or scp.

Downloading Software Using the Command-Line Interface

Download the software package you need from the Juniper Networks Support website at <http://www.juniper.net/support/>, and place the package on a local system. You can then transfer the downloaded package to the device using either the router or switch command-line interface, or the local system command-line interface.

NOTE: To access the download section, you must have a service contract and an access account. If you need help obtaining an account, complete the registration form at the Juniper Networks website: <https://www.juniper.net/registration/Register.jsp>.

Before you transfer the software package, ensure that the FTP service is enabled on the device.

Enable the FTP service using the **set system services ftp** command:

```
user@host# set system services ftp
```

To transfer the software package using the device command-line interface:

1. From the router or switch command line, initiate an FTP session with the local system (host) where the package is located using the **ftp** command:

```
user@host> ftp host
```

host is the Hostname or address of the local system.

2. Log in with your customer support–supplied username and password:

```
User Name: username
331 Password required for username.
Password: password
```

Once your credentials have been validated, the FTP session opens.

3. Navigate to the software package location on the local system, and transfer the package using the **get** command:

```
user@host> get installation-package
```

Following is an example of an *installation-package* name:

jinstall-9.2R1.8–domestic-signed.tgz

4. Close the FTP session using the **bye** command:

```
user@host> bye
Goodbye
```

To transfer the package using the local system command-line interface:

1. From the local system command line, initiate an FTP session with the device using the **ftp** command:

```
user@host> ftp host
```

host is the Hostname or address of the router or switch.

2. Log in with your customer support–supplied username and password:

```
User Name: username
331 Password required for username.
Password: password
```

Once your credentials have been validated, the FTP session opens.

3. Navigate to the software package location on the local system, and transfer the package using the **put** command:

```
user@host> put installation-package
```

Following is an example of an *installation-package* name:

jinstall-9.2R1.8–domestic-signed.tgz

4. Close the FTP session using the **bye** command:

```
user@host> bye
Goodbye
```

Downloading Software Packages from Juniper Networks

You can download Junos OS packages from the Juniper Networks website to upgrade software on your EX Series switch.

Before you begin to download software upgrades, ensure that you have a Juniper Networks Web account and a valid support contract. To obtain an account, complete the registration form at the Juniper Networks website: <https://www.juniper.net/registration/Register.jsp>.

To download software upgrades from Juniper Networks:

1. Using a Web browser, follow the links to the download URL on the Juniper Networks webpage. For EX Series, there are not separate software packages for Canada the U.S. and other locations. Therefore, select **Canada and U.S. Version** regardless of your location:
 - <https://www.juniper.net/support/downloads/junos.html>
2. Log in to the Juniper Networks authentication system using the username (generally your e-mail address) and password supplied by Juniper Networks representatives.
3. Using the J-Web interface or the CLI, select the appropriate software package for your application. See “[Junos OS Package Names for EX Series Switches](#)” on page 7.
4. Download the software to a local host or to an internal software distribution site.

Understanding Download Manager for SRX Series Devices

This topic includes the following sections:

- [Overview on page 51](#)
- [Using Download Manager to Upgrade Junos OS on page 52](#)
- [Handling Errors on page 52](#)
- [Considerations on page 53](#)

Overview

This download manager feature facilitates download of large files over low-bandwidth links. It enables you to download large Junos OS packages over low-bandwidth/flaky links so that the system can be upgraded. This feature allows you to download multiple

files while monitoring their status and progress individually. It takes automatic action when required and displays status information when requested.

This feature provides the following functions:

- Bandwidth-limited downloads
- Scheduled downloads
- Automatic resume on error
- Automatic resume on reboot

NOTE: This feature supports only the FTP and HTTP protocols.

Using Download Manager to Upgrade Junos OS

The download manager acts as a substitute for the FTP utility. You can use the download manager CLI commands for all the functions where you previously used the FTP utility.

The download manager requires the following:

- FTP or HTTP server with a Junos OS image
- Server that is reachable from the device being upgraded

The download manager consists of the following CLI commands:

1. To download the Junos OS image to your device, use the **request system download start** command (set a bandwidth limit, if required). The file is saved to the **/var/tmp** directory on your device.

You can continue to use the device while the download runs in the background.
2. Use the **show system download** command to verify that the file has been downloaded. The command displays the state as "completed" when the downloaded file is ready to be installed.
3. Use the **request system software add** command to install the downloaded image file from the **/var/tmp** directory.

Handling Errors

If you encounter any problem with a download, use the **show system download id** command to obtain details about the download.

Table 9 lists the output fields for the **show system download** command. Use this information to diagnose problems. Output fields are listed in the approximate order in which they appear.

Table 9: show system download Output Fields

Output Field	Description
Status	State of the download.
Creation Time	Time the start command was issued.
Scheduled Time	Time the download was scheduled to start.
Start Time	Time the download actually started (if it has already started).
Retry Time	Time for next retry (if the download is in the error state).
Error Count	Number of times an error was encountered by this download.
Retries Left	Number of times the system will retry the download automatically before stopping.
Most Recent Error	Message indicating the cause of the most recent error.

Considerations

- When no download limit is specified for a specific download or for all downloads, a download uses all available network bandwidth.
- Because the download limit that you set indicates an average bandwidth limit, it is possible that certain bursts might exceed the specified limit.
- When a download from an HTTP server fails, the server returns an HTML page. Occasionally, the error page is not recognized as an error page and is downloaded in place of the Junos image file.
- Remote server logins and passwords are stored by the download manager for the duration of a download. To encrypt these credentials provided along with the login keyword, define an encryption key with the **request system set-encryption-key** command. Any changes to encryption settings while download is in progress can cause the download to fail.
- A download command issued on a particular node in a chassis cluster takes place only on that node and is not propagated to the other nodes in the cluster. Downloads on different nodes are completely independent of each other. In the event of a failover, a download continues only if the server remains reachable from the node from which the command was issued. If the server is no longer reachable on that node, the download stops and returns an error.

Related Documentation

- [Installation Type Overview on page 41](#)

Understanding the Console Port

Console ports allow root access to the Junos operating system (Junos OS) devices through a terminal or laptop interface, regardless of the state of the Junos OS device,

unless it is completely powered off. By connecting to the console port, you can access the root level of the Junos OS device without using the network to which the device might or might not be connected. This creates a secondary path to the Junos OS device without relying on the network.

Using the terminal interface provides a technician sitting in a Network Operations Center a long distance away the ability to restore a Junos OS device or perform an initialization configuration securely, using a modem, even if the primary network has failed. Without a connection to the console port, a technician would have to visit the site to perform repairs or initialization. A remote connection to the Junos OS device through a modem requires the cable and connector (provided in the device accessory box), plus a DB-9 male to DB-25 male (or similar) adapter for your modem, which you must purchase separately. For more information about connecting to the console port, see the administration guide for your particular router or switch.

To configure the device initially, you must connect a terminal or laptop computer to the device through the console port, as shown in [Figure 6](#).

Figure 6: Connecting to the Console Port on a Junos OS Device

Related Documentation

- *Accessing a Junos OS Device the First Time*

Backing Up the Existing Installation on Routers

The installation process removes some files stored on the router. In the case of Junos OS, all stored files except the **juniper.conf** and SSH files are removed. Therefore, you must back up your existing installation in case you need to return to it. This topic describes how to back up the existing Junos OS installation on routers.

As of Junos OS Release 15.1, certain platforms run Junos OS based on an upgraded FreeBSD kernel (Junos OS with upgraded FreeBSD). For information about backing up Junos OS with upgraded FreeBSD, see [“Upgrading Junos OS with Upgraded FreeBSD” on page 139](#). For the platforms using Junos OS with upgraded FreeBSD, see [“Understanding Junos OS with Upgraded FreeBSD” on page 19](#).

For information about backing up the existing installation on SRX Series Services Gateways, see [“Backing Up the Current Installation on SRX Series Devices” on page 56](#).

On routers, you should back up the current installation so that you can return to it if needed.

In a dual Routing Engine system, you need to back up both Routing Engines.

To back up files to the router’s hard disk or solid-state drive (SSD):

- Issue the **request system snapshot** CLI operational command.

```
user@host> request system snapshot
```

When the **request system snapshot** command is issued, the **/root** file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The **/root** and **/config** file systems are on the router’s CompactFlash card, and the **/altroot** and **/altconfig** file systems are on the router’s hard disk or SSD. When the backup is completed, the current and backup software installations are identical.

NOTE: On routers without a CompactFlash card, where the hard disk is the primary boot device, you cannot back up your software installation. On MX104 routers, which do not have a CompactFlash card, you can back up your software installation on an external USB storage media device.

To back up files on an MX104 to a specified external storage media device:

- Issue the **request system snapshot media** CLI operational command. For example:

```
user@host > request system snapshot media usb1
```

On MX104 routers, when you issue the **request system snapshot** operational command to back up the current software installation, the backup is done on the first USB storage media device.

To back up files to the router's NAND flash device on ACX Series routers:

- Issue the **request system snapshot slice alternate** CLI operational command.

```
user@host > request system snapshot slice alternate
```

When this command is issued, the **/root** file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig** on the router's NAND flash device.

To back up files from the NAND flash device to a USB storage media device:

- Issue the **request system snapshot** CLI operational command.

```
user@host> request system snapshot
```

When you issue the **request system snapshot** operational command to back up the NAND flash device, the backup is done on the first USB storage media device.

**Related
Documentation**

- [Routing Matrix with a TX Matrix Plus Router Solutions Page](#)
- [Upgrading Junos OS with Upgraded FreeBSD on page 139](#)
- [Backing Up the Current Installation on SRX Series Devices on page 56](#)

Backing Up the Current Installation on SRX Series Devices

This topic includes the following sections:

- [Backing Up the Current Installation on High-End SRX Series Devices on page 56](#)
- [Backing Up the Current Installation on Branch SRX Series Devices on page 57](#)

Backing Up the Current Installation on High-End SRX Series Devices

You should back up the current installation so that you can return to the current software installation. The installation process using the installation package (`jinstall*`, for example) removes all stored files on the device except the `juniper.conf` and SSH files. Therefore, you should back up your current configuration in case you need to return to the current software installation after running the installation program.

To back up Junos OS on the SRX Series devices, issue the **request system snapshot** CLI operational command. This command saves the current software installation on the hard disk, external USB storage media device, or solid-state drive (SSD).

When the **request system snapshot** command is issued, the **/root** file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The **/root** and **/config** file systems are on the device's CompactFlash card, and the **/altroot** and **/altconfig** file systems are on the device's hard disk or solid-state drive (SSD). When the backup is completed, the current and backup software installations are identical.

To copy the files to the device's hard disk or solid-state drive (SSD), use the following command:

```
user@host> request system snapshot media
```

Backing Up the Current Installation on Branch SRX Series Devices

On SRX Series devices, you can backup the current Junos OS image and configuration files onto a media (such as a USB or CompactFlash) so that you can retrieve it back if something goes wrong.

To back up the currently running and active file system partitions on the device, use the following command:

```
user@host> request system snapshot media
```

Following options are supported:

- **internal**— Copies the snapshot to internal media.
- **usb**— Copies the snapshot to the USB storage device. This is the default option for Branch SRX Series devices.

Related Documentation

- [Example: Creating a Snapshot and Using It to Boot an SRX Series Device on page 166](#)
- [Installing Junos OS on SRX Series Devices from the Boot Loader Using a TFTP Server on page 70](#)
- [Installing Junos OS on SRX Series Devices from the Boot Loader Using a USB Storage Device on page 72](#)

Installing the Software Package on a Router with a Single Routing Engine

To upgrade the router or switch software, follow these steps:

1. Install the new software package using the **request system software add** command:

```
user@host> request system software add /var/tmp/installation-package
```

installation-package is the name of the installation package; for example **jinstall-9.2R1.8-domestic-signed.tgz**

For M Series, MX Series, and T Series routers and Branch SRX Series firewall filters running Junos OS Release 12.2 and above, you can use the **request system software add set** command to install multiple software packages at one time:

```
user@host> request system software add set /var/tmp/installation-package
```

installation-package can either be a list of installation packages, each separated by a blank space, or the full URL to the directory or tar file containing the list of installation packages.

WARNING: Do not include the *re0* | *re1* option when you install a package using the **request system software add** command, if the Routing Engine on which the package is located and the Routing Engine on which you want

to install the package are the same. In such cases, the package gets deleted after a successful upgrade.

For more information about the **request system software add** command, see the [CLI Explorer](#).

2. Reboot the device to start the new software using the **request system reboot** command:

```
user@host> request system reboot
Reboot the system? [yes, no] (no) yes
```

NOTE: You must reboot the device to load the new installation of Junos OS on the device.

To abort the installation, do not reboot the device. Instead, finish the installation and then issue the **request system software delete jinstall** command. This is your last chance to stop the installation.

The software is loaded when you reboot the system. Installation can take between 5 and 10 minutes. The device then reboots from the boot device on which the software was just installed. When the reboot is complete, the device displays the login prompt.

While the software is being upgraded, the Routing Engine on which you are performing the installation does not route traffic.

3. Log in and issue the **show version** command to verify the version of the software installed.
4. (Optional) Add the **jweb** package using the **request system software add** command. Before you can add this package, you must first download the software as you did the installation package. For more information about downloading the **jweb** package, see [“Downloading Software” on page 48](#).

The **jweb** installation module adds a device management graphical user interface that you can use to view and configure your device. For more information about the **jweb** package, see [“Installation Modules” on page 14](#).

5. After you have upgraded or downgraded the software and are satisfied that the new software is successfully running, issue the **request system snapshot** command to back up the new software.

**Related
Documentation**

- [Repartitioning Routing Engine System Storage To Increase the Swap Partition on page 64](#)

Installing the Software Package on a Router with Redundant Routing Engines

If the router has two Routing Engines, perform a Junos OS installation on each Routing Engine separately to avoid disrupting network operation.

WARNING: If graceful Routing Engine switchover (GRES), or nonstop active routing (NSR) is enabled when you initiate a software installation, the software does not install properly. Make sure you issue the CLI `delete chassis redundancy` command when prompted. If GRES is enabled, it will be removed with the `redundancy` command. By default, NSR is disabled. If NSR is enabled, remove the nonstop-routing statement from the [edit routing-options] hierarchy level to disable it.

To upgrade the router software, perform the following tasks:

1. [Preparing the Router for the Installation on page 59](#)
2. [Installing Software on the Backup Routing Engine on page 59](#)
3. [Installing Software on the Master Routing Engine on page 61](#)
4. [Finalizing the Installation on page 63](#)

Preparing the Router for the Installation

Perform the following steps before installing the software:

1. Log in to the master Routing Engine's console.

For more information about logging in to the Routing Engine through the console port, see the specific hardware guide for your router.

2. From the router command line, enter configuration mode:

```
a. user@host#> configure
   Entering configuration mode

   [edit]
   user@host#
```

3. Disable Routing Engine redundancy:

```
[edit]
user@host# delete chassis redundancy
```

4. Save the configuration change on both Routing Engines:

```
[edit]
user@host# commit synchronize
```

5. Exit out of the CLI configuration mode:

```
[edit]
user@host# exit
```

Installing Software on the Backup Routing Engine

After the router has been prepared, you first install the new Junos OS release on the backup Routing Engine while keeping the currently running software version on the master Routing Engine. This enables the master Routing Engine to continue operations, minimizing disruption to your network.

After making sure that the new software version is running correctly on the backup Routing Engine, you are ready to switch routing control to the backup Routing Engine and then upgrade or downgrade the software version on the other Routing Engine.

1. Log in to the console port on the other Routing Engine (currently the master).

For more information about logging in to the Routing Engine through the console port, see the specific hardware guide for your router.

2. Install the new software package using the **request system software add** command:

```
user@host> request system software add validate
/var/tmp/jinstall-9.2R1.8-domestic-signed.tgz
```

For M Series, MX Series, and T Series routers and Branch SRX Series firewall filters running Junos OS Release 12.2 and above, you can use the **request system software add set** command to install multiple software packages at the same time:

```
user@host> request system software add set /var/tmp/installation-package
```

installation-package can either be a list of installation packages, each separated by a blank space, or the full URL to the directory or tar file containing the list of installation packages.

Use the **request system software add set** command to retain any SDK configuration by installing the SDK add-on packages along with the core Junos OS installation package.

WARNING: Do not include the *re0* | *re1* option when you install a package using the **request system software add** command, if the Routing Engine on which the package is located and the Routing Engine on which you want to install the package are the same. In such cases, the package gets deleted after a successful upgrade.

For more information about the **request system software add** command, see the [CLI Explorer](#).

3. Reboot the router to start the new software using the **request system reboot** command:

```
user@host> request system reboot
Reboot the system? [yes, no] (no) yes
```

NOTE: You must reboot the device to load the new installation of Junos OS on the router.

To abort the installation, do not reboot your device. Instead, finish the installation and then issue the **request system software delete jinstall** command. This is your last chance to stop the installation.

All the software is loaded when you reboot the device. Installation can take between 5 and 10 minutes. The router then reboots from the boot device on which the software was just installed. When the reboot is complete, the router displays the login prompt.

While the software is being upgraded, the Routing Engine on which you are performing the installation is not routing traffic.

4. Log in and issue the **show version** command to verify the version of the software installed.
5. (Optional) Add the **jweb** package using the **request system software add** command. Before you can add this package, you must first download the software as you did the installation package. For more information about downloading the **jweb** package, see [“Downloading Software” on page 48](#).

The **jweb** installation module adds a router management graphical user interface that you can use to view and configure your router. For more information about the **jweb** package, see [“Installation Modules” on page 14](#).

Installing Software on the Master Routing Engine

Once the software is installed on the backup Routing Engine, you are ready to switch routing control to the backup Routing Engine and then upgrade or downgrade the master Routing Engine software:

1. Log in to the master Routing Engine console port.

For more information about logging in to the Routing Engine through the console port, see the specific hardware guide for your router.

2. Transfer routing control to the backup Routing Engine:

```
user@host> request chassis routing-engine master switch
```

For more information about the **request chassis routing-engine master** command, see the [CLI Explorer](#).

3. Verify that the backup Routing Engine (slot 1) is the master Routing Engine:

```
user@host> show chassis routing-engine
Routing Engine status:
Slot 0:
  Current state           Backup
  Election priority       Master (default)
Routing Engine status:
Slot 1:
  Current state           Master
  Election priority       Backup (default)
```

4. Install the new software package using the **request system software add** command:

```
user@host> request system software add validate
/var/tmp/jinstall-9.2R1.8-domestic-signed.tgz
```

For M Series, MX Series, and T Series routers and Branch SRX Series firewall filters running Junos OS Release 12.2 and above, you can use the **request system software add set** command to install multiple software packages at the same time:

```
user@host> request system software add set /var/tmp/installation-package
```

installation-package can either be a list of installation packages, each separated by a blank space, or the full URL to the directory or tar file containing the list of installation packages.

Use the **request system software add set** command to retain any SDK configuration by installing the SDK add-on packages along with the core Junos OS installation package.

WARNING: Do not include the *re0* | *re1* option when you install a package using the **request system software add** command, if the Routing Engine on which the package is located and the Routing Engine on which you want to install the package are the same. In such cases, the package gets deleted after a successful upgrade.

For more information about the **request system software add** command, see the [CLI Explorer](#).

5. Reboot the Routing Engine using the **request system reboot** command:

```
user@host> request system reboot
Reboot the system? [yes, no] (no) yes
```

NOTE: You must reboot to load the new installation of Junos OS on the router.

To abort the installation, do not reboot your system. Instead, finish the installation and then issue the **request system software delete jinstall** command. This is your last chance to stop the installation.

The software is loaded when you reboot the system. Installation can take between 5 and 10 minutes. The router then reboots from the boot device on which the software was just installed. When the reboot is complete, the router displays the login prompt.

While the software is being upgraded, the Routing Engine on which you are performing the installation does not route traffic.

6. Log in and issue the **show version** command to verify the version of the software installed.
7. (Optional) Add the **jweb** package using the **request system software add** command. Before you can add this package, you must first download the software as you did the installation package. For more information about downloading the **jweb** package, see [“Downloading Software” on page 48](#).

The **jweb** installation module adds a router management graphical user interface that you can use to view and configure your router. For more information about the **jweb** package, see [“Installation Modules” on page 14](#).

8. Transfer routing control back to the master Routing Engine:

```
user@host> request chassis routing-engine master switch
```

For more information about the **request chassis routing-engine master** command, see the [CLI Explorer](#).

9. Verify the master Routing Engine (slot 0) is indeed the master Routing Engine:

```

user@host> show chassis routing-engine
Routing Engine status:
  Slot 0:
    Current state           Master
    Election priority       Master (default)
Routing Engine status:
  Slot 1:
    Current state           Backup
    Election priority       Backup (default)

```

Finalizing the Installation

Once the software is installed on both Routing Engines, you return the router back to its original configuration and back up the new installation.

1. Restore the configuration that existed before you deleted it at the start of this procedure:

```

{backup}
user@host-re0> configure
[edit]
user@host-re0# rollback 1

```

2. Save the configuration change on both Routing Engines:

```

[edit]
user@host-re0> commit synchronize and-quit

```

3. After you have installed the new software and are satisfied that it is successfully running, issue the **request system snapshot** command to back up the new software on both master and backup Routing Engines:

```

{master}
user@host-re0> request system snapshot
{master}
user@host-re0> request routing-engine login other routing-engine
{backup}
user@host-re1> request system snapshot
{backup}

```

The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's CompactFlash card, and the **/altroot** and **/altconfig** file systems are on the router's hard disk or solid-state drive (SSD).

For more information about the **request routing-engine login** command, see the [CLI Explorer](#).

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running copy and backup copy of the software are identical.

Related Documentation • [Repartitioning Routing Engine System Storage To Increase the Swap Partition on page 64](#)

Repartitioning Routing Engine System Storage To Increase the Swap Partition

You can increase the size of the swap partition by repartitioning the drive (hard disk or solid-state drive (SSD)) on the Routing Engine. This feature is first available in Junos OS Release 10.4R5, 11.1R3, and 11.2R1; in earlier Junos OS releases, the swap partition is not increased by the methods described here.

This behavior applies only to Routing Engines with more than 2 GB of RAM. The new size of the swap partition depends on the size of the drive and the amount of Routing Engine RAM.

- When the drive is 32 GB or less, the swap partition is limited to 8 GB.
- When the drive is larger than 32 GB, the swap partition matches the size of the Routing Engine RAM.

To repartition the drive, perform one of the following actions:

- During the installation of a Junos OS software package (**jinstall***), issue the **request system reboot media disk** command to boot from the drive instead of issuing the **request system reboot** command. The drive is automatically repartitioned. The **request system reboot media disk** command repartitions the drive only during a software upgrade.
- Manually partition the drive by issuing the **request system partition hard-disk** command, and then reboot the router when the command completes.

CAUTION: Repartitioning the drive re-creates the `/config` and `/var` directories in the router file system. Although the contents of `/config` and `/var/db` are preserved, the remaining contents of `/var` are lost. For this reason, we recommend that you back up the `/var` directory before you repartition the SSD on a router with this configuration.

Installing Software on EX Series Switches (J-Web Procedure)

You can upgrade software packages on a single fixed-configuration switch, on an individual member of a Virtual Chassis, or for all members of a Virtual Chassis.

You can use the J-Web interface to install software upgrades from a server using FTP or HTTP, or by copying the file to the EX Series switch.

This topic describes:

1. [Installing Software Upgrades from a Server on page 65](#)
2. [Installing Software Upgrades by Uploading Files on page 65](#)

Installing Software Upgrades from a Server

To install software upgrades from a remote server by using FTP or HTTP:

1. Download the software package as described in “[Downloading Software Packages from Juniper Networks](#)” on page 51.
2. Log in to the Juniper Networks authentication system using the username (generally your e-mail address) and password supplied by Juniper Networks representatives.
3. In the J-Web interface, select **Maintain > Software > Install Package**.
4. On the Install Remote page, enter information into the fields described in [Table 10](#).
5. Click **Fetch and Install Package**. The software is activated after the switch has rebooted.

Table 10: Install Remote Summary

Field	Function	Your Action
Package Location (required)	Specifies the FTP or HTTP server, file path, and software package name.	Type the full address of the software package location on the FTP or HTTP server—one of the following: <i>ftp://hostname/pathname/package-name</i> <i>http://hostname/pathname/package-name</i>
User	Specifies the username, if the server requires one.	Type the username.
Password	Specifies the password, if the server requires one.	Type the password.
Reboot If Required	<p>NOTE: The Reboot check box will be disabled if you enter a J-Web Application package name in the Package Location text box. To enable the Reboot check box, enter a Junos package name in the Package Location text box.</p> <p>If this box is checked, the switching platform will automatically reboot when the upgrade is complete.</p>	Check the box if you want the switching platform to reboot automatically when the upgrade is complete.

Installing Software Upgrades by Uploading Files

To install software upgrades by uploading files:

1. Download the software package.
2. In the J-Web interface, select **Maintain>Software>Upload Package**.

3. On the Upload Package page, enter information into the fields described in [Table 11](#).
4. Click **Upload and Install Package**. The software is activated after the switching platform completes the installation procedure.

Table 11: Upload Package Summary

Field	Function	Your Action
File to Upload (required)	Specifies the location of the software package.	Type the location of the software package, or click Browse to navigate to the location.
Reboot If Required	Specifies that the switching platform is automatically rebooted when the upgrade is complete.	Select the check box if you want the switching platform to reboot automatically when the upgrade is complete.

Registering the EX Series Switch with the J-Web Interface

NOTE: This topic applies only to the J-Web Application package.

You can register your EX Series switch with the J-Web interface so that you can request technical assistance as and when required. To register an EX Series switch:

1. In the J-Web interface, select **Maintain > Customer Support > Product Registration**. For an EX8200 Virtual Chassis configuration, select the member from the list.
Note the serial number that is displayed.
2. Click **Register**. Enter the serial number in the page that is displayed.

- [EX Series Switch Software Features Overview](#)

Preparing the USB Flash Drive to Upgrade Junos OS on SRX Series Devices

This feature simplifies the upgrading of Junos OS images in cases where there is no console access to an SRX Series device located at a remote site. This functionality allows you to upgrade the Junos OS image with minimum configuration effort by simply copying the image onto a USB flash drive, inserting it into the USB port of the SRX Series device, and performing a few simple steps. You can also use this feature to reformat a boot device and recover an SRX Series device after boot media corruption.

All USB flash drives used on SRX Series devices must have the following features:

- USB 2.0 or later.
- Formatted with a FAT/FAT 32 or MS-DOS file system

NOTE: The Junos OS package on a USB device is commonly stored in the root drive as the only file; for example, `junos-srxsme-15.1X49-D30.3-domestic.tgz`.

CAUTION: Any USB memory product not listed as supported for SRX Series devices has not been tested by Juniper Networks. The use of any unsupported USB memory product could expose your SRX Series device to unpredictable behavior. Juniper Networks Technical Assistance Center (JTAC) can provide only limited support for issues related to unsupported hardware. We strongly recommend that you use only supported USB flash drives.

NOTE: This feature is not supported on chassis clusters.

Before you begin:

- Copy the Junos OS upgrade image and its `autoinstall.conf` file to the USB device.
- Ensure that adequate space is available on the SRX Series device to install the software image.

To prepare the USB flash drive and copy the Junos OS image onto the USB flash drive:

1. Insert the USB flash drive into the USB port of a PC or laptop computer running Windows.
2. From My Computer, right-click the drive Devices with Removable Storage.
3. Format the drive with the FAT/FAT32 file system.
4. Copy the Junos OS image onto the USB device.

For the installation process to succeed, copy only one image onto the USB device. Only images named `junos-srxsme*` are recognized by the system.

5. Check the drive name detected in My Computer for the USB device. Open the command prompt window and type:

```
echo " " > <drive-name>:\autoinstall.conf
```

For example, if the drive detected is drive F, type `echo " " > F:\autoinstall.conf` at the command prompt. This empty file indicates to the system that the automatic installation of the Junos OS image from the USB device is supported.

6. (Optional) Create a text file named `junos-config.conf` and copy the file to the USB device. For example, the following file supports an automatic configuration update during the installation process:

```
system {
  host-name host-1;
  domain-name example.net;
  domain-search [ abc.exmaple.net example.net device1.example.net];
  root-authentication {
    encrypted-password "$ABC123"; ## SECRET-DATA
  }
}
...
routing-options {
  static {
    route 0.0.0.0/0 next-hop 10.207.31.254;
  }
}
```

NOTE: The `junos-config.conf` file is optional, and it is not necessary for the automatic installation of the Junos OS image from the USB device. You can use the `junos-config.conf` file for a backup configuration for recovery or if the existing configuration is accidentally deleted.

Installing Junos OS on SRX Series Devices Using a USB Flash Drive

To install the Junos OS image on an SRX Series device using a USB flash drive:

1. Insert the USB flash drive into the USB port of the SRX Series device and wait for the LEDs to blink amber indicating that the SRX Series device detects the Junos OS image.

If the LEDs do not change to amber, press the Power button or turn the device off and then on again and wait for the LEDs to blink amber.

2. Press the **Reset Config** button on the SRX Series device to start the installation and wait for the LEDs to glow steadily amber.

When the LEDs glow green, the Junos OS upgrade image has been successfully installed.

If the USB device is plugged in, the **Reset Config** button always performs as an image upgrade button. Any other functionality of this button is overridden until you remove the USB flash drive.

3. Remove the USB flash drive.

The SRX Series device restarts automatically and loads the new Junos OS version.

NOTE: If an installation error occurs, the LEDs turn red, which might indicate that the Junos OS image on the USB flash drive is corrupted. An installation error can also occur if the current configuration on the SRX Series device is not compatible with the new Junos OS version on the USB or if there is not enough space on the SRX Series device to install the image. You must have console access to the SRX Series device to troubleshoot an installation error.

NOTE: You can use the `set system autoinstallation usb disable` command to prevent the automatic installation from the USB device. After using this command, if you insert the USB device into the USB port of the SRX Series device, the installation process does not work.

Upgrading the Boot Loader on SRX Series Devices

To upgrade the boot loader to the latest version:

1. Upgrade to Junos OS Release 10.0 or later (with or without dual-root support enabled).

The Junos OS 10.0 image contains the latest boot loader binaries in this path:
/boot/uboot, /boot/loader.

2. Enter the shell prompt using the **start shell** command.
3. Run the following command from the shell prompt:

```
bootupgrade -u /boot/uboot -l /boot/loader
```

NOTE: For the new version to take effect, you should reboot the system after upgrading the boot loader.

To verify the boot loader version on the SRX Series device, enter the **show chassis routing-engine bios** command.

```
user@host> show chassis routing-engine bios  
Routing Engine BIOS Version: 1.5
```

The command output displays the boot loader version.

NOTE: You can use the following commands to upgrade U-Boot or perform cyclic redundancy check (CRC):

- `bootupgrade -s -u` – To upgrade the secondary boot loader.
- `bootupgrade -c u-boot` – To check CRC of the boot loader.
- `bootupgrade -s -c u-boot` – To check CRC for the secondary boot loader.
- `bootupgrade -c loader` – To check CRC for the loader on boot loader.

Installing Junos OS on SRX Series Devices from the Boot Loader Using a TFTP Server

You can install Junos OS using the Trivial File Transfer Protocol (TFTP) method. The device is shipped with Junos OS loaded on the primary boot device. During Junos OS installation from the loader, the device retrieves the Junos OS package from a TFTP server. The internal media is then formatted, and the Junos OS image is installed.

From the loader installation, you can:

- Install Junos OS on the device for the first time.
- Recover the system from a file system corruption.

NOTE: Installation from a TFTP server can only be performed using the first onboard Ethernet interface.

Installation from the loader-over-TFTP method does not work reliably over slow speeds or large latency networks.

Before you begin, verify that:

- You have access to the TFTP server with the Junos OS package to be installed.
- That the TFTP server supports BOOTP or DHCP. If the TFTP server does not support BOOTP or DHCP, you must set the environment variables before performing the installation from the TFTP server.
- Functional network connectivity exists between the device and the TFTP server over the first onboard Ethernet interface.

To install the Junos OS image on the internal media of the device:

1. To access the U-boot prompt, use the console connection to connect to the device.
2. Reboot the device.

The following messages appear:

Clearing DRAM..... done BIST check passed. Net: pic init done (err = 0)octeth0 POST Passed

After this message appears, you see the following prompt:

Press SPACE to abort autoboot in 3 seconds

3. Press the space bar to stop the autoboot process.

The => U-boot prompt appears.

4. From the U-boot prompt, configure the environment variables listed in [Table 12](#).

Table 12: Environment Variables Settings

Environment Variables	Description
gatewayip	IP address of the gateway device
ipaddr	IP address of the SRX Series device
netmask	network mask
serverip	IP address of the TFTP server

This example shows you how to configure the environment variables:

```

Clearing DRAM..... done
BIST check passed.
Net: pic init done (err = 0)octeth0
POST Passed
Press SPACE to abort autoboot in 3 seconds
=>
=> setenv ipaddr 10.157.70.170
=> setenv netmask 255.255.255.0
=> setenv gatewayip 10.157.64.1
=> setenv serverip 10.157.60.1
=> saveenv

```

5. Reboot the system using the **reset** command.
6. To access the loader prompt, enter use the console connection to connect to the device.
7. Reboot the device.

The following message appears:

Loading /boot/defaults/loader.conf

After this message appears, you see the following prompt:

Hit [Enter] to boot immediately, or space bar for command prompt.

8. Press the space bar to access the loader prompt.

The **loader>** prompt appears. Enter:

```
loader> install tftp://10.77.25.12/junos-srxsme-10.0R2-domestic.tgz
```

NOTE: The URL path is relative to the TFTP server's TFTP root directory, where the URL is *tftp://tftp-server-ipaddress/package*.

When this command is executed:

- The Junos OS package is downloaded from the TFTP server.
- The internal media on the system is formatted.
- The Junos OS package is installed on the internal media.

After Junos OS is installed, the device boots from the internal media. Once the system boots up with Junos OS Release 10.0 or later, you should upgrade the U-boot and boot loader immediately.

CAUTION: When you install Junos OS using the loader-over-TFTP method, the media is formatted. The process attempts to save the current configuration. We recommend that you back up all important information on the device before using this process.

Installing Junos OS on SRX Series Devices from the Boot Loader Using a USB Storage Device

To install Junos OS Release 10.0 or later from the boot loader using a USB storage device:

1. Format a USB storage device in MS-DOS format.
2. Copy the Junos OS image onto the USB storage device.
3. Plug the USB storage device into the SRX Series device.
4. Stop the device at the loader prompt and issue the following command:

```
loader> install file:///<image-path-on-usb>
```

An example of a command is as follows:

```
loader> install file:///junos-srxsme-10.0R2-domestic.tgz
```

This formats the internal media and installs the new Junos OS image on the media with dual-root partitioning.

5. Once the system boots up with Junos OS Release 10.0 or later, upgrade the U-boot and boot loader immediately.
6. Remove the USB flash drive.

CHAPTER 5

Configuring Zero Touch Provisioning

- [Understanding Zero Touch Provisioning on page 73](#)
- [Configuring Zero Touch Provisioning on page 76](#)

Understanding Zero Touch Provisioning

NOTE: To see which platforms support Zero Touch Provisioning, in a browser, go to [Feature Explorer](#). In the Explore Features section of the Feature Explorer page, select All Features. In the Features Grouped by Feature Family box, select Zero Touch Provisioning. You can also type the name of the feature in the Search for Features edit box. In previous Junos OS releases on EX Series switches, Zero Touch Provisioning was called EZ Touchless Provisioning.

Zero Touch Provisioning allows you to provision new Juniper Networks switches in your network automatically, without manual intervention. When you physically connect a switch to the network and boot it with a default factory configuration, it attempts to upgrade the Junos OS software automatically and autoinstall a configuration file from the network. To make sure you have the default factory configuration loaded on the switch, issue the **request system zeroize** command on the switch you want to provision.

The switch uses information that you configure on a Dynamic Host Configuration Protocol (DHCP) server to locate the necessary software image and configuration files on the network. If you do not configure the DHCP server to provide this information, the switch boots with the preinstalled software and default factory configuration.

The Zero Touch Provisioning process will either upgrade or downgrade the Junos OS version. During an downgrade:

- On an EX Series switch, if you downgrade to a software version earlier than Junos OS Release 12.2, in which Zero Touch Provisioning is not supported, the configuration file autoinstall phase of the Zero Touch Provisioning process does not happen.
- On an EX Series switch, to downgrade to a software version that does not support resilient dual-root partitions (Junos OS Release 10.4R2 or earlier), you must perform some manual work on the switch. For more information, see [“Understanding Resilient Dual-Root Partitions on Switches” on page 95](#).

NOTE: On QFX3500 and QFX3600 switches running the original CLI, you cannot use ZTP to upgrade from Junos OS Release 12.2 or later to Junos OS Release 13.2X51-D15 or later.

When you boot a switch with the default factory configuration, the following process happens:

1. If DHCP option 43, suboption 00 (the name of the software image file on the FTP, HTTP, or TFTP server) is configured, the switch compares the version of the provided software image to the version of the software installed on the switch.

NOTE: When the DHCP server cannot use suboption 00, configure the image file using suboption 04. If both suboption 00 and suboption 4 are defined, suboption 04 is ignored.

2. If DHCP option 43, suboption 02 (a symbolic link to the software image file on the FTP, HTTP, or TFTP server), the switch compares the version of the provided software image to the version of the software installed on the switch.
 - If the Junos OS versions are different, the switch downloads the software image from the FTP, HTTP, or TFTP server, installs the Junos OS, and reboots using the default factory configuration.
 - If the software versions are the same, the switch does not upgrade the software.

3. If DHCP option 43, suboption 01 (the name of the configuration file on the FTP, TFTP, or HTTP server is configured, the switch compares the version of the provided configuration file to the version of the configuration file on the switch.

If DHCP option 43 suboption 01 is not specified, the switch uses the default factory configuration.

If the configuration file version on the FTP, HTTP, or TFTP server is newer than the configuration file on the switch, the configuration file is updated on the switch.

If both DHCP option 43 suboption 01 and suboption 2 are specified, suboption 01 is processed before suboption 02. The Junos OS is upgraded, and then the configuration file is applied.

4. If DHCP option 43, suboption 03 (the transfer mode setting) is configured, the switch accesses the FTP, HTTP, or TFTP server using the specified transfer mode setting—for example, FTP.

If DHCP option 43, suboption 03, is not configured, TFTP becomes the transfer mode automatically.

5. If DHCP option 43, suboption 04 (the name of the software image file on the FTP, HTTP, or TFTP server) is configured, the switch compares the version of the provided software image to the version of the software installed on the switch.

NOTE: When the DHCP server cannot use suboption 00, configure the image file using suboption 04. If both suboption 00 and suboption 4 are defined, suboption 04 is ignored.

6. If DHCP option 150 or option 66 is specified, the IP address of the FTP, HTTP, or TFTP server is configured.

NOTE: You must configure either option 150 or option 66. If you configure both option 150 and option 66, option 150 takes precedence, and option 66 is ignored. Also, make sure you specify an IP address, not a hostname, because name resolution is not supported.

7. (Optional) If DHCP option 7 is specified, you can configure one or more syslog servers.
8. (Optional) If DHCP option 42 is specified, you can configure one or more NTP servers.
9. (Optional) If DHCP option 12 is specified, you can configure the hostname of the switch.

**Related
Documentation**

- [Configuring Zero Touch Provisioning on page 76](#)

Configuring Zero Touch Provisioning

NOTE: To see which platforms support Zero Touch Provisioning, in a browser, go to [Feature Explorer](#). In the Explore Features section of the Feature Explorer page, select All Features. In the Features Grouped by Feature Family box, select Zero Touch Provisioning. You can also type the name of the feature in the Search for Features edit box. In previous Junos OS releases on EX Series switches, Zero Touch Provisioning was called EZ Touchless Provisioning. Search for that feature name if you want to know if this feature is supported on EX Series switches.

Zero Touch Provisioning allows you to provision new switches in your network automatically, without manual intervention. When you physically connect a switch to the network and boot it with a default configuration, it attempts to upgrade the Junos OS software automatically and autoinstall a configuration file from the network.

The switch uses information that you configure on a Dynamic Host Control Protocol (DHCP) server to determine whether to perform these actions and to locate the necessary software image and configuration files on the network. If you do not configure the DHCP server to provide this information, the switch boots with the preinstalled software and default configuration.

NOTE: If you have both DHCP and ZTP enabled, the switch broadcasts a DHCP DISCOVER packet every six minutes. If a DHCP server on the network responds with a DHCP ACK packet with DHCP vendor options set with the necessary values to initiate ZTP, then ZTP proceeds.

To disable broadcasting the DHCP DISCOVER packet every six minutes, without performing the ZTP process, manually delete the `auto-image-upgrade` statement located in the `[edit chassis]` hierarchy. If ZTP completes without errors, the `auto-image-upgrade` statement is automatically deleted.

NOTE: For detailed information regarding the DHCP and DHCP options, refer to RFC2131 (<http://www.ietf.org/rfc/rfc2131.txt>) and RFC2132 (www.ietf.org/rfc/rfc2132.txt). Also, this document refers to Internet Systems Consortium (ISC) DHCP version 4.2. For more information regarding this version, refer to <http://www.isc.org/software/dhcp/documentation>.

Before you begin:

- Ensure that the switch has access to the following network resources:

- The DHCP server provides the location of the software image and configuration files on the network

Refer to your DHCP server documentation for configuration instructions.

- The File Transfer Protocol (anonymous FTP), Hypertext Transfer Protocol (HTTP), Trivial File Transfer Protocol (TFTP) server on which the software image and configuration files are stored

NOTE: Although TFTP is supported, we recommend that you use FTP or HTTP instead, because these transport protocols are more reliable.

- A Domain Name System (DNS) server to perform reverse DNS lookup
- (Optional) An NTP server to perform time synchronization on the network
- (Optional) A system log (syslog) server to manage system log messages and alerts
- Locate and record the MAC address printed on the switch chassis.

CAUTION: You cannot commit a configuration while the switch is performing the software update process. If you commit a configuration while the switch is performing the configuration file autoinstallation process, the process stops, and the configuration file is not downloaded from the network.

To configure Zero Touch Provisioning for a switch:

1. Make sure the switch has the default factory configuration installed.
Issue the **request system zeroize** command on the switch that you want to provision.
2. Download the software image file and the configuration file to the FTP, HTTP, TFTP, server that the switch will download these files from.
You can download either one or both of these files.
3. Configure the DHCP server to provide the necessary information to the switch.
Configure IP address assignment.
You can configure dynamic or static IP address assignment for the switch's management address. To determine the switch's management MAC address for static IP address mapping, add 1 to the last byte of the switch's MAC address, which you noted before you began this procedure.
4. Define the format of the vendor-specific information for DHCP option 43 in the dhcpd.conf file.

Here is an example of an ISC DHCP 4.2 server dhcpd.conf file:

```
option space NEW_OP;
option NEW_OP.image-file-name code 0 = text;
option NEW_OP.config-file-name code 1 = text;
option NEW_OP.image-file-type code 2 = text;
```

```
option NEW_OP.transfer-mode code 3 = text;
option NEW_OP.alt-image-file-name code 4 = text;
option NEW_OP-encapsulation code 43 = encapsulate NEW_OP;
```

5. Configure the following DHCP option 43 suboptions:

- Suboption 00: The name of the software image file to install

NOTE: When the DHCP server cannot use suboption 00, configure the image file using suboption 04. If both suboption 00 and suboption 4 are defined, suboption 04 is ignored.

```
option NEW_OP.image-file-name
"/dist/images/jinstall-ex-4200-13.2R1.1-domestic-signed.tgz";
```

- Suboption 01: The name of the configuration file to install

```
option NEW_OP.config-file-name "/dist/config/jn-switch35.config";
```

- Suboption 02: The symbolic link to the software image file to install

```
option NEW_OP.image-file-type "symlink";
```

NOTE: If you do not specify suboption 2, the Zero Touch Provisioning process handles the software image as a filename, not a symbolic link.

- Suboption 03: The transfer mode that the switch uses to access the TFTP/FTP/HTTP server

```
option NEW_OP.transfer-mode "ftp";
```

NOTE: If suboption 03 is not configured, TFTP becomes the transfer mode by default.

- Suboption 04: The name of the software image file to install

NOTE: When the DHCP server cannot use suboption 00, configure the image file using suboption 04. If both suboption 00 and suboption 4 are defined, suboption 04 is ignored.

```
option NEW_OP.alt-image-file-name
"/dist/images/jinstall-ex-4200-13.2R1.1-domestic-signed.tgz";
```

6.

NOTE: You must configure either option 150 or option 66. If you configure both option 150 and option 66, option 150 takes precedence, and option 66 is ignored. Also, make sure you specify an IP address, not a hostname, because name resolution is not supported.

Configure DHCP option 150 to specify the IP address of the FTP, HTTP, or TFTP server.

```
option option-150 code 150 "10.100.31.71";
```

7. Configure DHCP option 66 to specify the IP address of the FTP, HTTP, or TFTP server.

```
option tftp-server-name "10.100.31.71";
```

8. (Optional) Configure DHCP option 7 to specify one or more system log (syslog) servers.

```
option log-servers 10.100.31.72;
```

9. (Optional) Configure DHCP option 42 to specify one or more NTP servers.

```
option ntp-servers 10.100.31.73;
```

10. (Optional) Configure DHCP option 12 to specify the hostname of the switch.

```
option hostname "jn-switch35";
```

The following sample configuration shows the DHCP options you just configured:

```
host jn-switch35 {
  hardware ethernet ac:4b:c8:29:5d:02;
  fixed-address 10.100.31.36;
  option tftp-server-name "10.100.31.71";
  option host-name "jn-switch35";
  option log-servers 10.100.31.72;
  option ntp-servers 10.100.31.73;
  option NEW_OP.image-file-name
    "/dist/images/jinstall-ex-4200-13.2R1.1-domestic-signed.tgz";
  option NEW_OP.transfer-mode "ftp";
  option NEW_OP.config-file-name "/dist/config/jn-switch35.config";
}
```

Based on the DHCP options you just configured, the following statements are appended to the Junos OS configuration file (for example, `jn-switch35.config`):

```
system {
  host-name jn-switch35;
  syslog {
    host 10.100.31.72 {
      any any;
    }
  }
  ntp {
    server 10.100.31.73;
  }
}
```

11. Connect the switch to the network that includes the DHCP server and the FTP, HTTP, or TFTP server.
12. Boot the switch with the default configuration.
13. Monitor the ZTP process by looking at the following log files.

NOTE: When SLAX (live operating system based on Linux) scripts are issued, the `op-script.log` and `event-script.log` files are produced.

- /var/log/dhcp_logfile
- /var/log/image_load_log
- /var/log/op-script.log
- /var/log/event-script.log

Autoinstallation Overview

If you are setting up many devices, autoinstallation can help automate the configuration process by loading configuration files onto new or existing devices automatically over the network. You can use either the J-Web configuration editor or the CLI configuration editor to configure a device for autoinstallation.

Autoinstallation provides automatic configuration for a new device that you connect to the network and turn on, or for a device configured for autoinstallation. The autoinstallation process begins anytime a device is powered on and cannot locate a valid configuration file in the CompactFlash (CF) card. Typically, a configuration file is unavailable when a device is powered on for the first time, or if the configuration file is deleted from the CF card. The autoinstallation feature enables you to deploy multiple devices from a central location in the network.

For the autoinstallation process to work, you must store one or more host-specific or default configuration files on a configuration server in the network and have a service available—typically Dynamic Host Configuration Protocol (DHCP)—to assign an IP address to the device.

Autoinstallation takes place automatically when you connect an Ethernet or serial port on a new Juniper Networks device to the network and power on the device. To simplify the process, you can explicitly enable autoinstallation on a device and specify a configuration server, an autoinstallation interface, and a protocol for IP address acquisition.

If you are setting up many devices, autoinstallation can help automate the configuration process by loading configuration files onto new or existing devices automatically over

the network. You can use either the J-Web configuration editor or the CLI configuration editor to configure a device for autoinstallation.

This section contains the following topics:

- [Automatic Installation of Configuration Files on page 82](#)
- [Supported Autoinstallation Interfaces and Protocols on page 82](#)
- [Typical Autoinstallation Process on a New Device on page 83](#)

Automatic Installation of Configuration Files

On SRX Series devices, you can specify a remote server where configuration files are located. If a configuration file cannot be found on the device's CompactFlash card, the device automatically retrieves the configuration file from this remote server. For security purposes, you can encrypt these remote files using the DES cipher, and once they have been retrieved, the device decrypts them for use on the server.

To encrypt the files, we recommend the openssl tool. You can get the open SSL tool at: <http://www.openssl.org/>. To encrypt the file, use the following syntax:

```
% openssl enc -des -k passphrase -in original-file -out encrypted-file
```

- ***passphrase***—Passphrase used to encrypt the configuration file. The passphrase should be the name of the file without the path information or file extension.
- ***original-file***—Unencrypted configuration file.
- ***encrypted-file***—Name of the encrypted configuration file.

For example, if you are encrypting the active configuration file **juniper.conf.gz**, the passphrase is **juniper.conf**. The openssl syntax used to encrypt the file is:

```
% openssl enc -des -k juniper.conf -in juniper.conf.gz -out juniper.conf.gz.enc
```

Supported Autoinstallation Interfaces and Protocols

Before autoinstallation on a device can take place, the device must acquire an IP address. The protocol or protocols you choose for IP address acquisition determine the device interface to connect to the network for autoinstallation. The device detects the connected interface and requests an IP address with a protocol appropriate for the interface. Autoinstallation is supported over an Ethernet LAN interface or a serial LAN or WAN interface. [Table 13](#) lists the protocols that the device can use on these interfaces for IP address acquisition.

Table 13: Interfaces and Protocols for IP Address Acquisition During Autoinstallation

Interface and Encapsulation Type	Protocol for Autoinstallation
Ethernet LAN interface with High-Level Data Link Control (HDLC)	DHCP, BOOTP, or Reverse Address Resolution Protocol (RARP)
Serial WAN interface with HDLC	Serial Line Address Resolution Protocol (SLARP)

Table 13: Interfaces and Protocols for IP Address Acquisition During Autoinstallation (*continued*)

Interface and Encapsulation Type	Protocol for Autoinstallation
Serial WAN interface with Frame Relay	BOOTP

If the server with the autoinstallation configuration file is not on the same LAN segment as the new device, or if a specific device is required by the network, you must configure an intermediate device directly attached to the new device through which the new device can send Trivial File Transfer Protocol (TFTP), BOOTP, and Domain Name System (DNS) requests. In this case, you specify the IP address of the intermediate device as the location to receive TFTP requests for autoinstallation.

Typical Autoinstallation Process on a New Device

When a device is powered on for the first time, it performs the following autoinstallation tasks:

1. The new device sends out DHCP, BOOTP, RARP, or SLARP requests on each connected interface simultaneously to obtain an IP address.

If a DHCP server responds, it provides the device with some or all of the following information:

- An IP address and subnet mask for the autoinstallation interface.
- The location of the TFTP (typically), Hypertext Transfer Protocol (HTTP), or FTP server on which the configuration file is stored.
- The name of the configuration file to be requested from the TFTP server.
- The IP address or hostname of the TFTP server.

If the DHCP server provides only the hostname, a DNS server must be available on the network to resolve the name to an IP address.

- The IP address of an intermediate device if the configuration server is on a different LAN segment from the new device.
2. After the new device acquires an IP address, the autoinstallation process on the device attempts to download a configuration file in the following ways:
 - a. If the DHCP server specifies the host-specific configuration file (boot file) **hostname.conf**, the device uses that filename in the TFTP server request. (In the filename, **hostname** is the hostname of the new device.) The autoinstallation process on the new device makes three unicast TFTP requests for **hostname.conf**. If these attempts fail, the device broadcasts three requests to any available TFTP server for the file.
 - b. If the new device cannot locate **hostname.conf**, the autoinstallation process unicasts or broadcasts TFTP requests for a default device configuration file called **network.conf**, which contains hostname-to-IP address mapping information, to attempt to find its hostname.

- c. If **network.conf** contains no hostname entry for the new device, the autoinstallation process sends out a DNS request and attempts to resolve the new device's IP address to a hostname.
 - d. If the new device can determine its hostname, it sends a TFTP request for the **hostname.conf** file.
 - e. If the new device is unable to map its IP address to a hostname, it sends TFTP requests for the default configuration file **router.conf**.
3. After the new device locates a configuration file on a TFTP server, autoinstallation downloads the file, installs the file on the device, and commits the configuration.

**NOTE:**

- If you configure the DHCP server to provide only the TFTP server hostname, add an IP address-to-hostname mapping entry for the TFTP server to the DNS database file on the DNS server in the network.
 - If the new device is not on the same network segment as the DHCP server (or other device providing IP address resolution), configure an existing device as an intermediate to receive TFTP and DNS requests and forward them to the TFTP server and the DNS server. You must configure the LAN or serial interface on the intermediate device with the IP addresses of the hosts providing TFTP and DNS service. Connect this interface to the new device.

Configuring Autoinstallation on SRX Series Devices

This example shows how to configure a device for autoinstallation.

- [Requirements on page 84](#)
- [Overview on page 85](#)
- [Configuration on page 85](#)
- [Verification on page 86](#)

Requirements

Before you begin:

- Configure a DHCP server on your network to meet your network requirements. You can configure a device to operate as a DHCP server.
- Create one of the following configuration files, and store it on a TFTP server in the network (see ["Configuration Files" on page 15](#)):

- A host-specific file with the name **hostname.conf** for each device undergoing autoinstallation. Replace **hostname** with the name of a device. The **hostname.conf** file typically contains all the configuration information necessary for the device with this hostname.
- A default configuration file named **router.conf** with the minimum configuration necessary to enable you to telnet into the new device for further configuration.
- Physically attach the device to the network using one or more of the following interface types:
 - Fast Ethernet
 - Gigabit Ethernet
 - Serial with HDLC encapsulation

Overview

No configuration is required on a device on which you are performing autoinstallation, because it is an automated process. However, to simplify the process, you can specify one or more interfaces, protocols, and configuration servers to be used for autoinstallation.

The device uses these protocols to send a request for an IP address for the interface.

- BOOTP—Sends requests over all interfaces.
- RARP—Sends requests over Ethernet interfaces.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system autoinstallation configuration-servers tftp://tftpconfig.sp.com
set system autoinstallation interfaces ge-0/0/0 bootp rarp
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To configure a device for autoinstallation:

1. Enable autoinstallation and specify the URL address of one or more servers from which to obtain configuration files.

```
[edit system]
user@host# set autoinstallation configuration-servers tftp://tftpconfig.sp.com
```

NOTE: You can also use an FTP address, for example, `ftp://user:password@sftpconfig.sp.com`.

2. Configure one or more Ethernet or serial interfaces to perform autoinstallation, and configure one or two procurement protocols for each interface.

[edit system]

user@host# **set autoinstallation interfaces ge-0/0/0 bootp rarp**

Results From configuration mode, confirm your configuration by entering the **show system autoinstallation status** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

[edit]

user@host# **show system autoinstallation status**

```
Autoinstallation status:
Master state: Active
Last committed file: None
Configuration server of last committed file: 10.25.100.1
Interface:
  Name: ge-0/0/0
  State: Configuration Acquisition
  Acquired:
    Address: 192.168.124.75
    Hostname: host-ge-000
    Hostname source: DNS
    Configuration filename: router-ge-000.conf
    Configuration filename server: 10.25.100.3
  Address acquisition:
    Protocol: BOOTP Client
    Acquired address: None
    Protocol: RARP Client
    Acquired address: None
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: When there is a user-specified configuration for a particular interface, the factory default for that interface should be deleted. Having two configurations for the same device might lead to errors. For example, if PPP encapsulation is set on a T1 interface through user configuration while the factory default configuration configures CISCO HLDC on the same interface, then the interface might not come up and the following error will be logged in the message file: “DCD_CONFIG_WRITE_FAILED failed.”

Verification

Confirm that the configuration is working properly.

- [Verifying Autoinstallation on page 86](#)

Verifying Autoinstallation

Purpose Verify that the device has been configured for autoinstallation.

Action From operational mode, enter the **show system autoinstallation status** command. The output shows the settings configured for autoinstallation. Verify that the values displayed are correct for the device when it is deployed on the network.

Related Documentation

- [Autoinstallation Overview on page 81](#)

Configuring Autoinstallation on JNU Satellite Devices

No configuration is required on a device on which you are performing autoinstallation because it is an automated process. However, to simplify the process, you can specify one or more interfaces, protocols, and configuration servers to be used for autoinstallation. In this scenario, satellite devices, such as EX Series Ethernet Switches, QFX Series devices, and ACX Series Universal Access Routers, that are managed by the controller are considered.

To configure autoinstallation:

1. Load the JNU factory-default configuration file on the satellite device to enable the device to function in JNU mode.

```
user@satellite# load override /etc/config/jnu-factory.conf
```

An override operation discards the current candidate configuration and loads the configuration in the specified filename or the one that you type at the terminal. When you use the override option and commit the configuration, all system processes reparse the configuration.

2. Specify the URL address of one or more servers from which to obtain configuration files.

```
[edit system]
```

```
user@host# set autoinstallation configuration-servers tftp://tftpconfig.sp.com
```

NOTE: You can also use an HTTP or FTP address—for example, `http://user:password@httpconfig.sp.com` or `ftp://user:password@sftpconfig.sp.com`.

3. Configure one or more Ethernet interfaces to perform autoinstallation and IP address acquisition protocols for each interface. The router uses the protocols to send a request for an IP address for the interface:

```
[edit system]
```

```
user@host# set autoinstallation interfaces ge-0/0/0 bootp
```

4. Set the root password, entering a clear-text password that the system will encrypt, a password that is already encrypted, or an SSH public key string.

Choose one of the following:

- To enter a clear-text password, use the following command:

```
[edit system]
```

```
user@host# set root-authentication plain-text-password
```

```
New password: type password here
```

```
Retype new password: retype password here
```

- To enter a password that is already encrypted, use the following command:

```
[edit]
```

```
root# set system root-authentication encrypted-password encrypted-password
```

- To enter an SSH public key, use the following command:

```
[edit]
```

```
root# set system root-authentication ssh-rsa key
```

5. Save the Junos OS configuration changes, activate the configuration on the device and exit configuration mode, using the **commit-and-quit** command.

```
[edit]
```

```
user@host# commit-and-quit
```

When the satellite device reboots, it triggers the autoinstallation mechanism to retrieve its initial configuration and downloads the settings from the configuration file stored on a configuration server in the network. On the controller, you must enable the FTP service by using the **set system services ftp** command and save the configuration on the satellite device at the **/var/jnu/** directory.

The following configuration is generated on the satellite device as a result of the preceding procedure to configure autoinstallation:

```
system {
  autoinstallation {
    traceoptions {
      flags {
        all;
      }
      file autod;
      level all;
    }
    delete-after-commit; /* After initial config, no need to keep */
    interfaces {
      ge-* {
        bootp;
      }
      xe-* {
        bootp;
      }
      configuration-servers {
        "ftp://192.168.0.1/var/jnu/sat1.conf";
      }
    }
  }
  root-authentication {
    encrypted-password "$ABC123";
  }
}
```

Autoinstallation Process on Satellite Devices in a Junos Node Unifier Group

Autoinstallation provides automatic configuration for a new router that you connect to the network and power on, or for a router configured for autoinstallation. The autoinstallation process begins anytime a router is powered on and cannot locate a valid configuration file in the CompactFlash card. Typically, a configuration file is unavailable when a router is powered on for the first time, or if the configuration file is deleted from the CompactFlash card. The autoinstallation feature enables you to deploy multiple routers from a central location in the network.

For the autoinstallation process to work, you must store one or more host-specific or default configuration files on a configuration server in the network and have a service available—typically Dynamic Host Configuration Protocol (DHCP)—to assign an IP address to the router.

Autoinstallation takes place automatically when you connect an Ethernet interface on a new Juniper Networks router to the network and power on the router. To simplify the process, you can explicitly enable autoinstallation on a router and specify a configuration server, an autoinstallation interface, and a protocol for IP address acquisition.

This topic describes:

- [Supported Autoinstallation Interfaces and Protocols on page 89](#)
- [Typical Autoinstallation Process on a New Router on page 90](#)

Supported Autoinstallation Interfaces and Protocols

Before autoinstallation on a router can take place, the router must acquire an IP address or a USB key. The protocol or protocols you choose for IP address acquisition determine the router interface to connect to the network for autoinstallation. The router detects the connected interface and requests an IP address with a protocol appropriate for the interface. Autoinstallation is supported over an Ethernet LAN interface. For IP address acquisition, the JNU satellite router uses DHCP, BOOTP, or Reverse Address Resolution Protocol (RARP) on an Ethernet LAN interface.

If the server with the autoinstallation configuration file is not on the same LAN segment as the new router, or if a specific router is required by the network, you must configure an intermediate router directly attached to the new router, through which the new router can send HTTP, FTP, Trivial File Transfer Protocol (TFTP), BOOTP, and Domain Name

System (DNS) requests. In this case, you specify the IP address of the intermediate router as the location to receive HTTP, FTP, or TFTP requests for autoinstallation.

Typical Autoinstallation Process on a New Router

When a router is powered on for the first time, it performs the following autoinstallation tasks:

1. The new router sends out DHCP, BOOTP, or RARP requests on each connected interface simultaneously to obtain an IP address.

If a DHCP server responds, it provides the router with some or all of the following information:

- An IP address and subnet mask for the autoinstallation interface.
- The location of the TFTP (typically), Hypertext Transfer Protocol (HTTP), or FTP server on which the configuration file is stored.
- The name of the configuration file to be requested from the HTTP, FTP, or TFTP server.
- The IP address or hostname of the HTTP, FTP, or TFTP server.

If the DHCP server provides only the hostname, a DNS server must be available on the network to resolve the name to an IP address.

- The IP address of an intermediate router if the configuration server is on a different LAN segment from the new router.
2. After the new router acquires an IP address, the autoinstallation process on the router attempts to download a configuration file in the following ways:
 - a. If the configuration file is specified as a URL, the router fetches the configuration file from the URL by using HTTP, FTP, or TFTP depending on the protocol specified in the URL.
 - b. If the DHCP server specifies the host-specific configuration file (boot file) **hostname.conf**, the router uses that filename in the TFTP server request. (In the filename, **hostname** is the hostname of the new router.) The autoinstallation process on the new router makes three unicast TFTP requests for **hostname.conf**. If these attempts fail, the router broadcasts three requests to any available TFTP server for the file.
 - c. If the new router cannot locate **hostname.conf**, the autoinstallation process unicasts or broadcasts TFTP requests for a default router configuration file called **network.conf**, which contains hostname-to-IP address mapping information, to attempt to find its hostname.
 - d. If **network.conf** contains no hostname entry for the new router, the autoinstallation process sends out a DNS request and attempts to resolve the new router's IP address to a hostname.

- e. If the new router can determine its hostname, it sends a TFTP request for the **hostname.conf** file.
 - f. If the new router is unable to map its IP address to a hostname, it sends TFTP requests for the default configuration file **router.conf**.
3. After the new router locates a configuration file on a TFTP server, the autoinstallation process downloads the file, installs the file on the router, and commits the configuration.

- [delete-after-commit \(JNU Satellites\) on page 284](#)
- [configuration-servers](#)

Autoinstallation of Satellite Devices in a Junos Node Unifier Group

In a Junos Node Unifier (JNU) group that contains an MX Series router as a controller that manages satellite devices, such as EX Series Ethernet Switches, QFX Series devices, and ACX Series Universal Access Routers, the autoinstallation functionality is supported for the satellite devices. JNU has an autoinstallation mechanism that enables a satellite device to configure itself out-of-the-box with no manual intervention, using the configuration available either on the network or locally through a removable media, or using a combination of both. This autoinstallation method is also called the *zero-touch* facility.

The zero-touch configuration delivers the following benefits:

- The router can be sent from the warehouse to the deployment site without any preconfiguration steps.
- The procedure required to deploy the device at the cell site is simplified, resulting in reduced operational and administrative costs.
- You can roll out large numbers of these devices in a very short time.

The factory default setting is autoinstallation-enabled. After you make the first configuration to the router, you can do either of the following:

- A JNU factory default file, **jnu-factory.conf**, is present in the **/etc/config/** directory and contains the configuration to perform autoinstallation on satellite devices. The zero-touch configuration can be disabled by including the **delete-after-commit** statement at the **[edit system autoinstallation]** hierarchy level and committing the configuration. This way, the saved configuration is used the next time the system reboots.

- Alternatively, if the router must get the configuration from the server each time a system reboot occurs, the zero-touch configuration must not be changed (that is, you must not include the **delete-after-commit** statement at the **[edit system autoinstallation]** hierarchy level and commit the settings).

- [configuration-servers](#)

Verifying Autoinstallation on JNU Satellite Devices

- Purpose** After you have configured autoinstallation, display the status of autoinstallation on a satellite device, such as an ACX Series router, an EX Series switch, or a QFX Series device, in a Junos Node Unifier (JNU) group that is managed by a controller, which is an MX Series router.
- Action** From the CLI, enter the **show system autoinstallation status** command. The following example displays the autoinstallation settings of an ACX Series router that operates as a satellite in a JNU group.

Sample Output

```
user@host> show system autoinstallation status
Autoinstallation status:
  Master state: Active
  Last committed file: None
  Configuration server of last committed file: 10.25.100.1
  Interface:
    Name: ge-0/1/0
    State: Configuration Acquisition
    Acquired:
      Address: 192.168.124.75
      Hostname: host-ge-000
      Hostname source: DNS
      Configuration filename: router-ge-000.conf
      Configuration filename server: 10.25.100.3
    Address acquisition:
      Protocol: DHCP Client
      Acquired address: None
      Protocol: RARP Client
      Acquired address: None
  Interface:
    Name: ge-0/1/1
    State: None
    Address acquisition:
      Protocol: DHCP Client
      Acquired address: None
      Protocol: RARP Client
```

Acquired address: None

Meaning The output shows the settings configured for autoinstallation. Verify that the values displayed are correct for the router when it is deployed on the network.

CHAPTER 7

Configuring Dual-Root Partitions for High Availability

- [Understanding Resilient Dual-Root Partitions on Switches on page 95](#)
- [Resilient Dual-Root Partitions Frequently Asked Questions on page 99](#)
- [Dual-Root Partitioning Scheme on SRX Series Devices on page 105](#)
- [Example: Installing Junos OS on SRX Series Devices Using the Partition Option on page 110](#)

Understanding Resilient Dual-Root Partitions on Switches

Resilient dual-root partitioning, introduced on Juniper Networks EX Series Ethernet Switches in Juniper Networks Junos operating system (Junos OS) Release 10.4R3, provides additional resiliency to switches in the following ways:

- Allows the switch to boot transparently from the second (alternate) root partition if the system fails to boot from the primary root partition.
- Provides separation of the root Junos OS file system from the `/var` file system. If corruption occurs in the `/var` file system (a higher probability than in the root file system because of the greater frequency of reads and writes in `/var`), the root file system is insulated from the corruption.

NOTE: For instructions on upgrading to a release that supports resilient dual-root partitions from a release that does not, see the release notes. The procedure for upgrading to a resilient dual-root partition release is different from the normal upgrade procedure.

This topic covers:

- [Resilient Dual-Root Partition Scheme \(Junos OS Release 10.4R3 and Later\) on page 96](#)
- [Automatic Fixing of Corrupted Primary Root Partition with the Automatic Snapshot Feature on page 96](#)

- [Earlier Partition Scheme \(Junos OS Release 10.4R2 and Earlier\)](#) on page 97
- [Understanding Upgrading or Downgrading Between Resilient Dual-Root Partition Releases and Earlier Releases](#) on page 98

Resilient Dual-Root Partition Scheme (Junos OS Release 10.4R3 and Later)

EX Series switches that ship with Junos OS Release 10.4R3 or later are configured with a root partition scheme that is optimized for resiliency, as shown in [Table 14](#).

Table 14: Resilient Dual-Root Partition Scheme

Slice 1	Slice 2	Slice 3		Slice 4
s1a	s2a	s3e	s3d	s4d
/	/	/var	/var/tmp	/config
(root Junos OS)	(root Junos OS)			

In the resilient dual-root partition scheme, the **/var** file system is contained in a separate slice (Slice 3) from the root file systems; the **/config** directory is contained in its own slice (Slice 4); and switches ship from the factory with identical Junos OS images in Slice 1 and Slice 2. The **/var** file system, which has a greater frequency of reads and writes than the root file systems and is therefore more likely to have corruption issues, is isolated from the root directories and the **/config** directory. If the switch fails to boot from the active partition, the switch automatically boots from the alternate root partition and triggers an alarm.

Automatic Fixing of Corrupted Primary Root Partition with the Automatic Snapshot Feature

Resilient dual-root partitioning also provides the *automatic snapshot* feature, which allows the switch to automatically fix a corrupt Junos OS file in the primary root partition. If the automatic snapshot feature is enabled, the switch automatically takes a snapshot of the Junos OS root file system in the alternate root partition and copies it onto the primary root partition, thereby repairing the corrupt file in the primary root partition. The automatic snapshot procedure takes place whenever the system reboots from the alternate root partition, regardless of whether the reboot is due to a command or due to corruption of the primary root partition.

**NOTE:**

- EX9200 switches do not support the automatic snapshot feature.
- The automatic snapshot feature is enabled by default on the following EX Series switches:
 - EX4550 switches
 - EX Series switches that ship with Junos OS Release 12.3R1 or later
- The automatic snapshot feature is disabled by default on EX Series switches (except the EX4550 switches) running Junos OS Release 12.2 or earlier.
- If the automatic snapshot feature was disabled by default before the switch was upgraded to Junos OS Release 12.3R1 or later, the feature remains disabled (for backward compatibility) by default after the upgrade.
- If the automatic snapshot feature is enabled in a Virtual Chassis configuration, the automatic snapshot procedure takes place whenever any member of the Virtual Chassis reboots from its alternate root partition.
- You can enable the automatic snapshot feature by configuring the `auto-snapshot` statement at the `[edit system]` hierarchy level.

The automatic snapshot feature provides an additional layer of fault protection if you maintain the same version of Junos OS in both partitions of resilient dual-root partitions. When **auto-snapshot** is enabled, repair happens automatically. Therefore, the switch does not issue an alarm to indicate that the system has rebooted from the alternate partition. However, it does log the event. You cannot execute a manual snapshot when an automatic snapshot procedure is in process. The login banner indicates that an automatic snapshot operation is in progress and that banner is removed only after the snapshot operation is complete. The next reboot happens from the primary partition.

NOTE: EX Series switches that ship with Junos OS Release 10.4R3 or later are configured with identical Junos OS images in the primary root partition (Slice 1) and the alternate root partition (Slice 2).

However, if you do *not* maintain the same version of Junos OS in both partitions, you might want to disable the automatic snapshot feature. If you have an earlier version of Junos OS in the alternate partition and the system reboots from the alternate root partition, the automatic snapshot feature causes the later Junos OS version to be replaced with the earlier version.

When automatic snapshot is disabled and the system reboots from the alternate root partition, it triggers an alarm indicating that the system has rebooted from its alternate partition.

Earlier Partition Scheme (Junos OS Release 10.4R2 and Earlier)

The partition scheme used in Junos OS 10.4R2 and earlier is shown in [Table 15](#).

Table 15: Earlier Partition Scheme

Slice 1		Slice 2		Slice 3	
s1a	s1f	s2a	s2f	s3d	s3e
/ (root Junos OS)		(empty until initial software upgrade)		/var/tmp	/config

This is the partitioning scheme for a switch shipped with Release 10.4R2 or earlier (or after you reformat the disk during a downgrade from Release 10.4R3 or later to Release 10.4R2 or earlier). In this partitioning scheme, the switch comes from the factory with only one Junos OS image installed in the root Junos OS partition of Slice 1. The first time that you perform a software upgrade, the new Junos OS image is installed in Slice 2. If the switch fails to boot, you must manually trigger it to boot from the alternate partition (rebooting from the alternate partition does not occur automatically).

Understanding Upgrading or Downgrading Between Resilient Dual-Root Partition Releases and Earlier Releases

Upgrading from Release 10.4R2 or earlier to Release 10.4R3 or later differs from other upgrades in two important ways:

- You must install a new loader software package in addition to installing the new Junos OS image.
- Rebooting after the upgrade reformats the disk from three partitions to four partitions. See [Table 14](#).

You can perform all operations for this special software upgrade from the CLI.

CAUTION: Back up any important log files because the `/var/log` files are not saved or restored during an upgrade from Release 10.4R2 or earlier to a release that supports resilient dual-root partitions (Release 10.4R3 or later).

We recommend that you also save your `/config` files and any important log files to an external medium because if there is a power interruption during the upgrade process, they might be lost.

Resilient Dual-Root Partitions Frequently Asked Questions

NOTE: This task uses Junos OS for EX Series switches that does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see *Resilient Dual-Root Partitions Frequently Asked Questions*. For ELS details, see *Getting Started with Enhanced Layer 2 Software*.

This FAQ addresses questions regarding resilient dual-root partitions on EX Series switches and upgrading to Junos OS releases that support resilient dual-root partitions. The resilient dual-root partition feature was introduced on EX Series switches at Junos OS Release 10.4R3. It provides additional resiliency for EX Series switches.

This FAQ covers the following questions:

- [How Does Upgrading to Junos OS Release 10.4R3 and Later Differ from Normal Upgrades? on page 99](#)
- [What Happens If I Do Not Upgrade Both the Loader Software and Junos OS at the Same Time? on page 100](#)

- [Where Can I Find Instructions for Upgrading? on page 104](#)

How Does Upgrading to Junos OS Release 10.4R3 and Later Differ from Normal Upgrades?

Upgrading from Junos OS Release 10.4R2 or earlier to Release 10.4R3 or later differs from other upgrades in these ways:

- You must upgrade the loader software in addition to installing the new Junos OS image.
- Rebooting after the upgrade reformats the disk from three partitions to four partitions.

- The upgrade process and the reboot take longer time because of the additional time required for upgrading the loader software and for the first reboot after the Junos OS installation (longer than normal because it reformats the disk from three partitions to four). Also, EX8200 switches require an additional reboot per Routing Engine as part of the loader software upgrade.

What Happens If I Do Not Upgrade Both the Loader Software and Junos OS at the Same Time?

You must install a new loader software package if you are upgrading to a release that supports resilient dual-root partitions (Release 10.4R3 and later) from an earlier release (Release 10.4R2 and earlier).

If you upgrade to Release 10.4R3 or later from Release 10.4R2 or earlier and do not upgrade the loader software, the switch will come up and function normally. However, if the switch encounters a problem and cannot boot from the active root partition, it cannot transparently boot from the alternate root partition and you will need to perform a manual reboot.

NOTE: Starting with Junos OS Release 11.4R4, when an EX Series switch boots from the flash memory, and a valid jloader firmware image does not exist or is corrupted in the upgrade bank, the following alarm is displayed: “Upgrade bank is empty or corrupted for FPC 0, please do standard upgrade sequence.” To resolve this issue, contact JTAC for assistance in determining the version of jloader firmware that you need to install.

Table 16: Combinations of Junos OS Versions and Loader Software Versions

Junos OS Release	Loader Software	Notes
Release 10.4R3 and later	<p>New loader software</p> <p>For all EX Series switches except EX8200 switches: U-Boot 1.1.6 (Mar 11 2011 - 04:39:06) 1.0.0 (Contains version 1.0.0 after the timestamp.)</p> <p>For EX8200 switches: U-Boot 1.1.6 (Jan 11 2008 - 05:24:35) 3.5.0 (Contains version 3.5.0.)</p>	Recommended
Release 10.4R2 and earlier	Old loader software	If you downgrade to Release 10.4R2 or earlier after having upgraded to the new loader software version, you do not need to downgrade the loader software. The switch will function normally.

Table 16: Combinations of Junos OS Versions and Loader Software Versions (*continued*)

Junos OS Release	Loader Software	Notes
Release 10.4R3 and later	<p>Old loader software</p> <p>For all EX Series switches except EX8200 switches: U-Boot 1.1.6 (Jan 11 2008 - 05:24:35) (Does not contain a version number after the timestamp)</p> <p>For EX8200 switches: U-Boot 1.1.6 (Jan 11 2008 - 05:24:35) 2.3.0 (Contains a version earlier than 3.5.0.)</p>	The switch will come up and function normally. However, in the event that the switch cannot boot from the active root partition, it will not transparently boot up from the alternate root partition.
Release 10.4R2 and earlier	<p>New loader software</p> <p>NOTE: For EX Series switches except EX8200 switches, in Release 10.4R2 and earlier the version number after the timestamp (shown in the previous row) is not displayed, and you cannot verify whether the old or the new loader software version is installed.</p>	The switch will come up and function normally.

Can I Downgrade Junos OS Without Downgrading the Loader Software?

Yes, when you downgrade from most releases, the new loader software runs seamlessly with the earlier Junos OS version.

NOTE: If you downgrade specifically from Release 10.4R3 or Release 11.1R1 to 10.4R2 or earlier (that is, to a release that does not support resilient dual-root partitions), you must disable the boot-sequencing function. If you do not take this action, the switch will boot on each subsequent reboot from the alternate root partition rather than from the active partition.

Disable the boot-sequencing function in one of two ways:

- From the shell as the root user:

```
% nvram setenv boot.btsq.disable 1
```
- From a console connection, reboot and stop at the u-boot prompt (Ctrl+c):

```
=> setenv boot.btsq.disable 1
=> saveenv
```

If you are downgrading from Release 10.4R4 or from Release 11.1R2 or later to Release 10.4R2 or earlier, you do not need to disable the boot-sequencing function—the software does it automatically.

Can I Upgrade to a Resilient Dual-Root Partition Release by Using the CLI?

Yes, you can perform the entire upgrade to resilient dual-root partitions from the CLI. You download both the new loader software and Junos OS packages and install them

from the CLI. During the final reboot, the disk is automatically reformatted from three to four partitions.

Will I Lose My Configuration During an Upgrade?

Configuration files are preserved and restored during the reformatting of the disk. We recommend that you save your configuration before upgrading because if there is a power interruption during the installation process, the files might be lost.

How Long Will the Upgrade Process Take?

The process of upgrading to a resilient dual-root partition release takes longer than other upgrades because of the additional step of upgrading the loader software and the longer reboot time required while the disk is reformatted to four partitions during the reboot of the switch that completes the Junos OS upgrade. The reformat results in an additional reboot time of 5 to 10 minutes for EX2200, EX3200, EX4200, and EX4500 switches. For EX8200 switches, the reboot time increases by 10 to 25 minutes per Routing Engine, and additional reboots are required.

What Happens to My Files If the System Detects a File System Corruption and Automatic Snapshot Is Enabled?

If the automatic snapshot feature is enabled during a reboot, the system automatically takes a snapshot of Junos OS from the alternate root partition (Slice 2) and copies it onto the primary root partition (Slice 1). The system checks each file system partition for corruption. [Table 17](#) shows the action the system takes if corruption is detected and the corrective action that you can take.

Table 17: Actions If Corrupt Files Are Found and Automatic Snapshot is Enabled

Slice 1	Slice 2	Slice 3		Slice 4
s1a	s2a	s3e	s3d	s4d
/	/	/var	/var/tmp	/config
(root Junos OS)	(root Junos OS)			
If a root directory (/) is corrupted, the corrupted file system is not mounted. The switch automatically takes a snapshot of the Junos OS root file system and copies it onto the primary root partition. It boots from the alternate slice, but the next reboot happens from the primary slice.		During early boot, the integrity of /var, /var/tmp, and /config files is verified. If they are corrupted, the corrupted slice is reformatted and the file directory in that slice is lost.		
Corrective action: No corrective action is required.		Corrective action: Restore the /var or /config files from the external backup.		

What Happens to My Files If the System Detects a File System Corruption and Automatic Snapshot Is Not Enabled?

During a reboot, the system checks each file system partition for corruption. [Table 18](#) shows the action the system takes if corruption is detected and the corrective action that you can take.

Table 18: Actions If Corrupt Files Are Found

Slice 1	Slice 2	Slice 3		Slice 4
s1a	s2a	s3e	s3d	s4d
/	/	/var	/var/tmp	/config
(root Junos OS)	(root Junos OS)			
If a root directory (/) is corrupted, the corrupted file system is not mounted and the switch boots from the alternate slice.		During early boot, the integrity of /var, /var/tmp, and /config files is verified. If they are corrupted, the corrupted slice is reformatted and the file directory in that slice is lost.		
Corrective action: Issue a request system snapshot command from the good root directory to the corrupted slice.		Corrective action: Restore the /var or /config files from the external backup.		

How Will I Be Informed If My Switch Boots from the Alternate Slice Because of Corruption in the Root File System?

If the switch detects corruption in the primary root file system, it boots from the alternate root partition. When this occurs, the type of notification depends on whether you have enabled the automatic snapshot feature or not:

- If the automatic snapshot feature is not enabled:
 - If you are logged in through the console port or the management port:

```
WARNING: THIS DEVICE HAS BOOTED FROM THE BACKUP JUNOS IMAGE
```

It is possible that the primary copy of JUNOS failed to boot up properly, and so this device has booted from the backup copy.

Please re-install JUNOS to recover the primary copy in case it has been corrupted.
 - The following message is displayed when you issue **show chassis alarms**:

```
user@switch> show chassis alarms
1 alarms currently active
Alarm time           Class  Description
2011-02-17 05:48:49 PST  Minor  Host 0 Boot from backup root
```

- If the automatic snapshot feature is enabled:
 - A banner message appears, indicating that an automatic snapshot operation is in progress. The banner message disappears when the snapshot operation is complete.
 - No alarm is issued to indicate that the switch has been rebooted from the alternate partition. However, the switch does log the event.

Can I Use Automatic Software Update and Download to Upgrade to a Resilient Dual-Root Partition Release?

Automatic software update and automatic software download are both supported with upgrading to releases that support resilient dual-root partitions. However, after an automatic installation, you must take the extra step of upgrading the loader software.

Automatic software update is for new members added to a Virtual Chassis that do not have the same software as the master. Once this feature is configured on the Virtual Chassis, any new member added with a different software version will be upgraded automatically.

Automatic software download uses the DHCP message exchange process to download and install software packages.

Why Is the Message "At least one package installed on this device has limited support" Displayed When Users Log In to a Switch?

The following message might be displayed when a user logs in:

```
Logging to master
..Password:
--- JUNOS 10.4R3.4 built 2011-03-19 22:06:32 UTC
At least one package installed on this device has limited support.
Run 'file show /etc/notices/unsupported.txt' for details.
```

This message can be safely ignored or you can permanently remove it. It appears because the jloader package file has been detected, and it only appears when Junos OS is installed before the loader software is upgraded (required only for EX8200 switches).

You can permanently remove this message by removing the jloader package and rebooting the system:

```
user@switch> request system software delete jloader-ex-zzzz
user@switch> request system reboot
```

Where *jloader-ex-zzzz* represents the name of the jloader software package for your platform—jloader-ex2200 for an EX2200 switch, jloader-ex3242 for an EX3200 or EX4200 switch, or jloader-ex8200 for an EX8200 switch.

Where Can I Find Instructions for Upgrading?

The procedure for upgrading to a release that supports resilient dual-root partitions (from a release that does not) is different from the normal upgrade procedure. For instructions on upgrading to a resilient dual-root partition release, see the Release Notes.

Dual-Root Partitioning Scheme on SRX Series Devices

Junos OS Release 10.0 and later support dual-root partitioning on SRX Series devices. Dual-root partitioning allows the SRX Series device to remain functional even if there is file system corruption and to facilitate easy recovery of the file system.

NOTE: Junos OS Release 12.1X45 and later do not support single root partitioning.

SRX Series devices running Junos OS Release 9.6 or earlier support a single-root partitioning scheme where there is only one root partition. Because both the primary and backup Junos OS images are located on the same root partition, the system fails to boot if there is corruption in the root file system. The dual-root partitioning scheme guards against this scenario by keeping the primary and backup Junos OS images in two independently bootable root partitions. If the primary root partition becomes corrupted, the system can still boot from the backup Junos OS image located in the other root partition and remain fully functional.

SRX Series devices that ship with Junos OS Release 10.0 or later are formatted with dual-root partitions from the factory. SRX Series devices that are running Junos OS Release 9.6 or earlier can be formatted with dual-root partitions when they are upgraded to Junos OS Release 10.0 or later.

NOTE: Although you can install Junos OS Release 10.0 or later on SRX Series devices with the single-root partitioning scheme, we strongly recommend the use of the dual-root partitioning scheme.

This section contains the following topics:

- [Boot Media and Boot Partition on SRX Series Devices on page 106](#)
- [Important Features of the Dual-Root Partitioning Scheme on page 106](#)
- [Understanding Automatic Recovery of the Primary Junos OS Image with Dual-Root Partitioning on page 106](#)
- [Understanding How the Primary Junos OS Image with Dual-Root Partitioning Recovers Devices on page 108](#)
- [Understanding How Junos OS Release 10.0 or Later Upgrades with Dual-Root Partitioning on page 109](#)

Boot Media and Boot Partition on SRX Series Devices

When the SRX Series device powers on, it tries to boot the Junos OS from the default storage media. If the device fails to boot from the default storage media, it tries to boot from the alternate storage media.

Table 19 provides information on the storage media available on SRX Series devices.

Table 19: Storage Media on SRX Series Devices

SRX Series Devices	Storage Media
SRX300, SRX320, and SRX340, and SRX345	<ul style="list-style-type: none"> eUSB disk (default; always present) USB storage device (alternate)
SRX550M	<ul style="list-style-type: none"> Internal CF (default; always present) USB storage device (alternate)

With the dual-root partitioning scheme, the SRX Series device first tries to boot Junos OS from the primary root partition and then from the backup root partition on the default storage media. If both primary and backup root partitions of a media fail to boot, then the SRX Series device tries to boot from the next available type of storage media. The SRX Series device remains fully functional even if it boots Junos OS from the backup root partition of the storage media.

Important Features of the Dual-Root Partitioning Scheme

The dual-root partitioning scheme has the following important features:

- The primary and backup copies of Junos OS images reside in separate partitions. The partition containing the backup copy is mounted only when required. With the single-root partitioning scheme, there is one root partition that contains both the primary and the backup Junos OS images.
- The **request system software add** command for a Junos OS package erases the contents of the other root partition. The contents of the other root partition will not be valid unless software installation is completed successfully.
- Add-on packages, such as **jais** or **jfirmware**, can be reinstalled as required after a new Junos OS image is installed.
- The **request system software rollback** command does not delete the current Junos OS image. It is possible to switch back to the image by issuing the **rollback** command again.
- The **request system software delete-backup** and **request system software validate** commands do not take any action.

Understanding Automatic Recovery of the Primary Junos OS Image with Dual-Root Partitioning

The auto-snapshot feature repairs the corrupted primary root when the device reboots from the alternate root. This is accomplished by taking a snapshot of the alternate root onto the primary root automatically rather than manually from the CLI.

When this feature is enabled, and the device reboots from the alternate root (because of a corrupted primary root or power cycle during restart), the following actions take place:

1. A prominent message is displayed indicating a failure to boot from the primary root.

```
*****
**                                     **
**  WARNING: THIS DEVICE HAS BOOTED FROM THE BACKUP JUNOS IMAGE             **
**                                     **
**  It is possible that the primary copy of JUNOS failed to boot up          **
**  properly, and so this device has booted from the backup copy.            **
**                                     **
**  Please re-install JUNOS to recover the primary copy in case             **
**  it has been corrupted and if auto-snapshot feature is not               **
**  enabled.                                                                  **
**                                     **
*****
```

2. A system **boot from backup root** alarm is set. This is useful for devices that do not have console access.
3. A snapshot of the alternate root onto the primary root is made.
4. Once the snapshot is complete, the system **boot from backup root** alarm is cleared.

During the next reboot, the system determines the good image on the primary root and boots normally.

NOTE: We recommend performing the snapshot once all the processes start. This is done to avoid any increase in the reboot time.

NOTE:

- Auto-snapshot feature is supported on branch SRX Series devices.
- By default the auto-snapshot feature is disabled.
- If you do not maintain the same version of Junos OS in both partitions, ensure that the automatic snapshot feature remains disabled. Otherwise, if you have an earlier version of Junos OS in the alternate partition and the system reboots from the alternate root partition, the automatic snapshot feature causes the later Junos OS version to be replaced with the earlier version.
- When automatic snapshot is disabled and the system reboots from the alternate root partition, it triggers an alarm indicating that the system has rebooted from its alternate partition.

Enable this feature with the **set system auto-snapshot** command. Once the primary root partition is recovered using this method, the device will successfully boot from the primary root partition on the next reboot.

Execute the **delete system auto-snapshot** command to delete all backed up data and disable auto-snapshot, if required.

Use the **show system auto-snapshot** command to check the auto-snapshot status.

When auto-snapshot is in progress, you cannot run a manual snapshot command concurrently and the following error message appears:

Snapshot already in progress. Please try after sometime.

NOTE: If you log into the device when the snapshot is in progress, the following banner appears: The device has booted from the alternate partition, auto-snapshot is in progress.

Understanding How the Primary Junos OS Image with Dual-Root Partitioning Recovers Devices

If the SRX Series Services Gateway is unable to boot from the primary Junos OS image, and boots up from the backup Junos OS image in the backup root partition, a message appears on the console at the time of login indicating that the device has booted from the backup Junos OS image.

```
login: user
```

```
Password:
```

```
*****
**
**  WARNING: THIS DEVICE HAS BOOTED FROM THE BACKUP JUNOS IMAGE  **
**
**  It is possible that the active copy of JUNOS failed to boot up **
**  properly, and so this device has booted from the backup copy.  **
**
**  Please re-install JUNOS to recover the active copy in case    **
**  it has been corrupted.                                         **
**
*****
```

Because the system is left with only one functional root partition, you should immediately restore the primary Junos OS image using one of the following methods:

- Install a new image using the CLI or J-Web user interface. The newly installed image will become the primary image, and the device will boot from it on the next reboot.

- Use a snapshot of the backup root partition by entering the **request system snapshot slice alternate** command. Once the primary root partition is recovered using this method, the device will successfully boot from the primary root partition on the next reboot. After the procedure, the primary root partition will contain the same version of Junos OS as the backup root partition.

NOTE: You can use the CLI command **request system snapshot slice alternate** to back up the currently running root file system (primary or secondary) to the other root partition on the system.

You can use this command to:

- Save an image of the primary root partition in the backup root partition when system boots from the primary root partition.
- Save an image of the backup root partition in the primary root partition when system boots from the backup root partition.

WARNING: The process of restoring the alternate root by using the CLI command **request system snapshot slice alternate** takes several minutes to complete. If you terminate the operation before completion, the alternate root might not have all required contents to function properly.

Understanding How Junos OS Release 10.0 or Later Upgrades with Dual-Root Partitioning

NOTE: If you are upgrading to Junos OS Release 10.0 without transitioning to dual-root partitioning, use the conventional CLI and J-Web user interface installation methods.

To format the media with dual-root partitioning while upgrading to Junos OS Release 10.0 or later, use one of the following installation methods:

- Installation from the boot loader using a TFTP server. We recommend this if console access to the system is available and a TFTP server is available in the network. See [“Installing Junos OS on SRX Series Devices from the Boot Loader Using a TFTP Server” on page 70](#)
- Installation from the boot loader using a USB storage device. We recommend this method if console access to the system is available and the system can be physically accessed to plug in a USB storage device. See [“Installing Junos OS on SRX Series Devices from the Boot Loader Using a USB Storage Device” on page 72](#)
- Installation from the CLI using the **partition** option. We recommend this method only if console access is not available. This installation can be performed remotely.

NOTE: After upgrading to Junos OS Release 10.0 or later, the U-boot and boot loader must be upgraded for the dual-root partitioning scheme to work properly.

- [Understanding Junos OS Upgrades for SRX Series Devices on page 145](#)
- [Example: Installing Junos OS on SRX Series Devices Using the Partition Option on page 110](#)

Example: Installing Junos OS on SRX Series Devices Using the Partition Option

This example shows how to install Junos OS Release 10.0 or later with the **partition** option.

- [Requirements on page 110](#)
- [Overview on page 110](#)
- [Configuration on page 111](#)
- [Verification on page 113](#)

Requirements

Before you begin, back up any important data.

Overview

This example formats the internal media and installs the new Junos OS image on the media with dual-root partitioning. Reinstall the Release 10.0 or later image from the CLI using the **request system software add** command with the **partition** option. This copies the image to the device, and then reboots the device for installation. The device boots up with the Release 10.0 or later image installed with the dual-root partitioning scheme. When the **partition** option is used, the format and install process is scheduled to run on the next reboot. Therefore, we recommend that this option be used together with the **reboot** option.

NOTE: The process might take 15 to 20 minutes. The system is not accessible over the network during this time.

WARNING: Using the partition option with the **request system software add** command erases the existing contents of the media. Only the current configuration is preserved. You should back up any important data before starting the process.

NOTE: Partition install is supported on the default media on SRX300, SRX320, 340, and SRX345 devices (internal NAND flash) and *not* supported on the alternate media (USB storage key).

In this example, add the software package `junos-srxsme-10.0R2-domestic.tgz` with the following options:

- **no-copy** option to install the software package but do not save the copies of package files. You should include this option if you do not have enough space on the internal media to perform an upgrade that keeps a copy of the package on the device.
- **no-validate** option to bypass the compatibility check with the current configuration before installation starts.
- **partition** option to format and re-partition the media before installation.
- **reboot** option to reboots the device after installation is completed.

Configuration

CLI Quick Configuration

To quickly install Junos OS Release 10.0 or later with the **partition** option, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI.

From operational mode, enter:

```
user@host>request system software add junos-srxsme-10.0R2-domestic.tgz no-copy
no-validate partition reboot
```

GUI Step-by-Step Procedure

To install Junos OS Release 10.0 or later with the **partition** option:

1. In the J-Web user interface, select **Maintain>Software>Install Package**.
2. On the Install Package page, specify the FTP or HTTP server, file path, and software package name. Type the full address of the software package location on the FTP (<ftp://hostname/pathname/junos-srxsme-10.0R2-domestic.tgz>) or HTTP server (<http://hostname/pathname/junos-srxsme-10.0R2-domestic.tgz>).

NOTE: Specify the username and password, if the server requires one.

3. Select the **Reboot If Required** check box to set the device to reboot automatically when the upgrade is complete.
4. Select the **Do not save backup** check box to bypass saving the backup copy of the current Junos OS package.
5. Select the **Format and re-partition the media before installation** check box to format the internal media with dual-root partitioning.
6. Click **Fetch and Install Package**. The software is activated after the device reboots.

This formats the internal media and installs the new Junos OS image on the media with dual-root partitioning.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To install Junos OS Release 10.0 or later with the **partition** option:

1. Upgrade the device to Junos OS Release 10.0 or later using the CLI.
2. After the device reboots, upgrade the boot loader to the latest version. See [“Preparing the USB Flash Drive to Upgrade Junos OS on SRX Series Devices” on page 66](#).
3. Reinstall the Release 10.0 or later image.

```
user@host>request system software add junos-srxsme-10.0R2-domestic.tgz no-copy
no-validate partition reboot
Copying package junos-srxsme-10.0R2-domestic.tgz to var/tmp/install
Rebooting ...
```

Results From configuration mode, confirm your configuration by entering the **show system storage partitions** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Sample output on a system with single root partitioning:

```
user@host> show system storage partitions

Boot Media: internal (da0)

Partitions Information:
  Partition  Size  Mountpoint
    s1a      898M  /
    s1e       24M  /config
    s1f        61M  /var
```

Sample output on a system with dual-root partitioning:

```
user@host> show system storage partitions

Boot Media: internal (da0)
Active Partition: da0s2a
Backup Partition: da0s1a
Currently booted from: active (da0s2a)

Partitions Information:
  Partition  Size  Mountpoint
    s1a      293M  altroot
    s2a      293M  /
    s3e       24M  /config
    s3f      342M  /var
    s4a       30M  recovery
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Partitioning Scheme Details on page 113](#)

Verifying the Partitioning Scheme Details

Purpose Verify that the partitioning scheme details on the SRX Series device were configured.

Action From operational mode, enter the **show system storage partitions** command.

Upgrading Software Packages

NOTE: When you install individual software packages, the following notes apply:

- When upgrading from Junos OS Release 8.2 or earlier to Junos OS Release 8.5, use the `system software add <image> no-validate` command option.
- Only use the `jinstall` Junos OS image when upgrading or downgrading to or from Junos OS Release 8.5. Do not use the `jbundle` image.
- Before upgrading to Junos OS Release 8.5, ensure that the routing platform's CompactFlash card is 256 MB or larger to avoid disk size restrictions. (M7i routers without a CompactFlash card are excluded.)

NOTE: If you are upgrading a Routing Engine on a PTX Series router to run Junos OS Release 13.2R2 and later, and then make that Routing Engine the master Routing Engine, then the master Routing Engine reports a major alarm `CB 0/1 ESW PFE Port Fail` even though the Control Board's Ethernet switch links are up and running on both the master and the backup Routing Engines. This is because the backup Routing Engine is still on Junos OS Release 13.2R1 or earlier. The alarm is cleared after you have completed the upgrade of Junos OS on the backup Routing Engine.

```
User@router# show chassis alarms
2 alarms currently active
Alarm time Class Description
2014-10-15 00:44:31 BST Major CB 0 ESW PFE Port Fail
2014-10-15 00:42:42 BST Minor Backup RE Active
```

To upgrade an individual Junos OS package, follow these steps:

1. Download the software packages you need from the Juniper Networks Support Web site at <http://www.juniper.net/support/>. For information about downloading software packages, see ["Downloading Software" on page 48](#).

NOTE: We recommend that you upgrade all individual software packages using an out-of-band connection from the console or management Ethernet interface, because in-band connections can be lost during the upgrade process.

2. Back up the currently running and active file system so that you can recover to a known, stable environment in case something goes wrong with the upgrade:

```
user@host> request system snapshot
```

The root file system is backed up to `/altroot`, and `/config` is backed up to `/altconfig`. The root and `/config` file systems are on the router's CompactFlash card, and the `/altroot` and `/altconfig` file systems are on the router's hard disk or solid-state drive (SSD).

NOTE: After you issue the `request system snapshot` command, you cannot return to the previous version of the software, because the running copy and the backup copy of the software are identical.

NOTE: High-end SRX Series devices, the root file system is backed up to `/altroot`, and `/config` is backed up to `/altconfig`. The root and `/config` file systems are on the router's CompactFlash card, and the `/altroot` and `/altconfig` file systems are on the router's hard disk or solid-state drive (SSD).

NOTE: This step is optional for branch SRX Series devices. For branch SRX Series devices, ensure that a USB flash drive is plugged into the USB port of the device.

3. If you are copying multiple software packages to the router, copy them to the `/var/tmp` directory on the hard disk or solid-state drive (SSD):

```
user@host> file copy ftp://username :prompt@ftp.hostname
.net/filename/var/tmp/filename
```

4. Add the new software package:

- To add an individual software package:

```
user@host> request system software add /var/tmp/ installation-package validate
```

installation-package is the full URL to the file.

NOTE: Warning: For high-end SRX Series devices, do not include the `re0 | re1` option when you install a package using the `request system software add` command, if the Routing Engine on which the package is located and the Routing Engine on which you want to install the package is the same. In such cases, the package gets deleted after a successful upgrade.

If you are upgrading more than one package at the same time, add `jbase` first. If you are using this procedure to upgrade all packages at once, add them in the following order:

```
user@host> request system software add /var/tmp/jbase-release-signed.tgz
```

```
user@host> request system software add /var/tmp/jkernel-release-signed.tgz
```

```

user@host> request system software add /var/tmp/jpfe-release-signed.tgz
user@host> request system software add /var/tmp/jdocs-release-signed.tgz
user@host> request system software add /var/tmp/jweb-release-signed.tgz
user@host> request system software add /var/tmp/jroute-release-signed.tgz
user@host> request system software add /var/tmp/jcrypto-release-signed.tgz

```

- For M Series, MX Series, and T Series routers and Branch SRX Series firewall filters running Junos OS Release 12.2 and above, you can add more than one software package at the same time. To add multiple software packages:

```

user@host> request system software add set /var/tmp/
installation-package/var/tmp/ installation-package validate

```

installation-package can be any of the following:

- A list of installation packages, each separated by a blank space. For example,

```

user@host> request system software add set /var/tmp/
jinstall-10.2R1.8-domestic-signed.tgz /var/tmp/jtools*.tgz validate

```

- The full URL to the directory or tar file containing the list of installation packages.

Use the **request system software add set** command to retain any SDK configuration by installing the SDK add-on packages along with the core Junos OS installation package.

WARNING: Do not include the *re0* | *re1* option when you install a package using the **request system software add** command, if the Routing Engine on which the package is located and the Routing Engine on which you want to install the package are the same. In such cases, the package gets deleted after a successful upgrade.

The system might display the following message:

```
pkg_delete: couldn't entirely delete package
```

This message indicates that someone manually deleted or changed an item that was in a package. You do not need to take any action; the package is still properly deleted.

For more information about the **request system software add** command, see the [CLI Explorer](#).

5. Reboot the router to start the new software:

```
user@host> request system reboot
```

6. After you have upgraded or downgraded the software and are satisfied that the new software is successfully running, issue the **request system snapshot** command to back up the new software:

```
user@host> request system snapshot
```

NOTE: On an ACX router, you must issue the `request system snapshot slice alternate` command.

The root file system is backed up to `/altroot`, and `/config` is backed up to `/altconfig`. The root and `/config` file systems are on the router's CompactFlash card, and the `/altroot` and `/altconfig` file systems are on the router's hard disk or solid-state drive (SSD).

NOTE: After you issue the `request system snapshot` command, you cannot return to the previous version of the software, because the running copy and backup copy of the software are identical.

Upgrading to 64-bit Junos OS

Just like any other operating system, the 64-bit version of Junos OS can address more memory than the 32-bit version of the operating system. In order to support larger Routing Engine memory sizes, an upgrade from the 32-bit to the 64-bit Junos OS running on the Routing Engine hardware is necessary. The upgrade path is relatively straightforward and another form of Routing Engine hardware and software upgrade. However, there are three different and distinct Routing Engine configurations that must be taken into account when upgrading to the 64-bit Junos OS. This topic covers all three.

The In Service Software Upgrade (ISSU) procedure is not supported while upgrading from the 32-bit version of Junos OS to the 64-bit version of Junos OS. The upgrade process involves some downtime, so traffic will be affected.

NOTE: The 64-bit version of Junos OS is not supported on every Routing Engine. To determine whether your router and Routing Engine support a 64-bit version of Junos OS, see *Supported Routing Engines by Router*.

Before you begin, you must have:

- A properly configured and functional router
- One or two Routing Engines installed that support the 64-bit Junos OS
- Decided to allow single Routing Engines systems to use either slot 0 or slot 1 as master or not (this decision will determine which upgrade path to follow for single Routing Engine systems)

When you upgrade a Routing Engine to the 64-bit Junos OS, you can support larger Routing Engine memory sizes. However, the exact procedure depends on whether there are one or two Routing Engines installed. For systems with a single Routing Engine, the procedure varies based on whether the master Routing Engine must always be in slot 0 or not.

To upgrade a system with two Routing Engines, refer to [Figure 7](#) and perform the following steps:

Figure 7: Upgrading to the 64-bit Junos OS with Dual Routing Engines

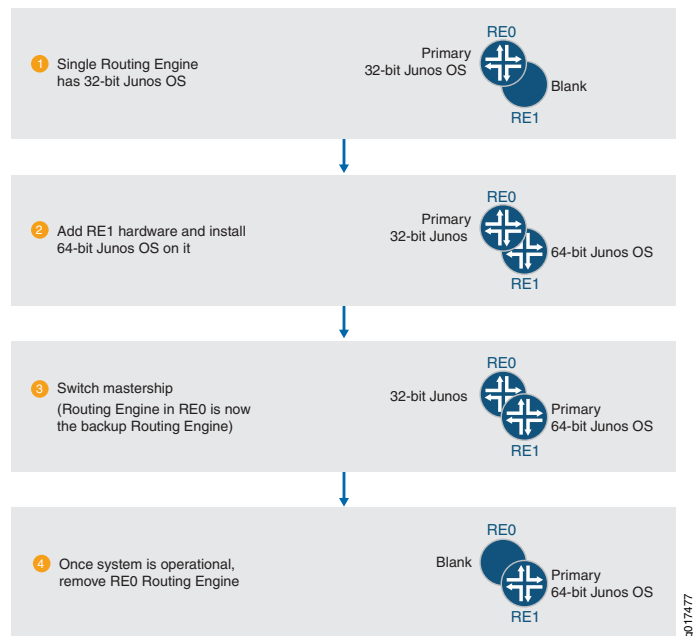

1. In the initial state, both Routing Engines are running the 32-bit Junos OS, and slot 0 has the master Routing Engine.
2. Upgrade the slot 1 Routing Engine hardware and install the 64-bit Junos OS.
For instructions on replacing a Routing Engine, see the hardware guide for your router.
3. Switch the master Routing Engine from slot 0 to slot 1 (allow the 32-bit Junos OS to co-exist with the 64-bit Junos OS).
4. Upgrade the slot 0 routing engine hardware and install the 64-bit Junos OS.
5. Both Routing Engines now run the 64-bit Junos OS. Optionally, you can switch the master Routing Engine back to slot 0.

NOTE: Mixing the 32-bit Junos OS with the 64-bit Junos OS is only supported temporarily during the upgrade process. Mixing the two operating systems is not supported for normal operations.

Figure 8: Upgrading to the 64-bit Junos OS with a Single Routing Engine (Master in Either Slot)

To upgrade a system with a single Routing Engine, where the master Routing Engine can be in either slot 0 or slot 1, refer to [Figure 7](#) and perform the following steps:

1. In the initial state, the slot 0 Routing Engine is running the 32-bit Junos OS and slot 1 is blank.
2. Install the upgraded Routing Engine hardware in slot 1 and install the 64-bit Junos OS.
For instructions on installing a Routing Engine, see the hardware guide for your router.
3. When the 64-bit Junos OS is configured properly, remove the slot 0 Routing Engine running the 32-bit Junos OS.

To upgrade a system with a single Routing Engine, where the master Routing Engine must be in slot 0, refer to [Figure 9](#) and perform the following steps:

Figure 9: Upgrading to the 64-bit Junos OS with a Single Routing Engine (Master Must Be in Slot 0)

1. In the initial state, the slot 0 Routing Engine is running the 32-bit Junos OS and slot 1 is blank.
2. Install the slot 0 Routing Engine hardware in slot 1. Install the upgraded Routing Engine hardware in slot 0 and install the 64-bit Junos OS.
For instructions on installing a Routing Engine, see the hardware guide for your router.
3. When the 64-bit Junos OS is configured properly, remove the slot 1 routing engine running the 32-bit Junos OS.

- [Checklist for Reinstalling Junos OS on page 187](#)

Upgrading Routers Using Unified ISSU

Unified in-service software upgrade (ISSU) enables you to upgrade between two different Junos OS releases with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is only supported by dual Routing Engine platforms. In addition, graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) must be enabled.

For additional information about using unified ISSU, see the *Junos OS High Availability Library for Routing Devices*.

For additional information about using unified ISSU on SRX Series devices, see the [Junos OS Chassis Cluster Library for Security Devices](#).

- [Upgrading Individual Software Packages on page 116](#)

Understanding Nonstop Software Upgrade on EX Series Switches

Nonstop software upgrade (NSSU) enables you to upgrade the software running on Juniper Networks EX Series Ethernet Switches with redundant Routing Engines and all member switches in EX Series Virtual Chassis by using a single command and with minimal network traffic disruption during the upgrade.

NSSU is supported on the following platforms:

- EX3300 Virtual Chassis
- EX4200 Virtual Chassis
- EX4300 Virtual Chassis
- EX4500 Virtual Chassis
- EX4550 Virtual Chassis
- All mixed Virtual Chassis composed of EX4200, EX4500, and EX4550 switches
- EX6200 switches
- EX8200 switches
- EX8200 Virtual Chassis

Performing an NSSU provides these benefits:

- No disruption to the control plane—An NSSU takes advantage of graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) to ensure no disruption to the control plane. During the upgrade process, interface, kernel, and routing protocol information is preserved.
- Minimal disruption to network traffic—An NSSU minimizes network traffic disruption by:
 - Upgrading line cards one at a time in an EX6200 switch, EX8200 switch, or EX8200 Virtual Chassis, permitting traffic to continue to flow through the line cards that are not being upgraded.
 - Upgrading member switches one at a time in an EX3300, EX4200, EX4300, EX4500, or mixed Virtual Chassis, permitting traffic to continue to flow through the members that are not being upgraded.

To achieve minimal disruption to traffic, you must configure link aggregation groups (LAGs) such that the member links of each LAG reside on different line cards or Virtual Chassis members. When one member link of a LAG is down, the remaining links are up, and traffic continues to flow through the LAG.

NOTE: Because NSSU upgrades the software on each line card or on each Virtual Chassis member one at a time, an upgrade using NSSU can take longer than an upgrade using the `request system software add` command.

For EX6200 switches, EX8200 switches, and EX8200 Virtual Chassis, you can reduce the amount of time an upgrade takes by configuring line-card upgrade groups. The line cards in an upgrade group are upgraded simultaneously, reducing the amount of time it takes to complete an upgrade. See *Configuring Line-Card Upgrade Groups for Nonstop Software Upgrade (CLI Procedure)*.

This topic covers:

- [Requirements for Performing an NSSU on page 124](#)
- [How an NSSU Works on page 125](#)
- [NSSU Limitations on page 128](#)
- [NSSU and Junos OS Release Support on page 128](#)
- [Overview of NSSU Configuration and Operation on page 129](#)

Requirements for Performing an NSSU

The following requirements apply to all switches and Virtual Chassis:

- All Virtual Chassis members and all Routing Engines must be running the same Junos OS release.
- Graceful Routing Engine switchover (GRES) must be enabled.
- Nonstop active routing (NSR) must be enabled.

NOTE: Although nonstop bridging (NSB) does not have to be enabled to perform an NSSU, we recommend enabling NSB before performing an NSSU. Enabling NSB ensures that all NSB-supported Layer 2 protocols operate seamlessly during the Routing Engine switchover that is part of the NSSU. See *Configuring Nonstop Bridging on EX Series Switches (CLI Procedure)*.

- For minimal traffic disruption, you must define link aggregation groups (LAGs) such that the member links reside on different Virtual Chassis members or on different line cards.

The following are requirements for EX3300, EX4200, EX4300, EX4500, and mixed Virtual Chassis:

- The Virtual Chassis members must be connected in a ring topology so that no member is isolated as a result of another member being rebooted. This topology prevents the Virtual Chassis from splitting during an NSSU.
- The Virtual Chassis master and backup must be adjacent to each other in the ring topology. Adjacency permits the master and backup to always be in sync, even when the switches in linecard roles are rebooting.
- The Virtual Chassis must be preprovisioned so that the linecard role has been explicitly assigned to member switches acting in a linecard role. During an NSSU, the Virtual Chassis members must maintain their roles—the master and backup must maintain their master and backup roles (although mastership will change), and the remaining switches must maintain their linecard roles.
- A two-member Virtual Chassis must have **no-split-detection** configured so that the Virtual Chassis does not split when an NSSU upgrades a member.

NOTE: For the EX4300 Virtual Chassis, you should enable the `vcp-no-hold-time` statement at the `[edit virtual-chassis]` hierarchy level before performing a software upgrade using NSSU. If you do not enable the `vcp-no-hold-time` statement, the Virtual Chassis may split during the upgrade. A split Virtual Chassis can cause disruptions to your network, and you may have to manually reconfigure your Virtual Chassis after the NSSU if the split and merge feature was disabled. For more information about a split Virtual Chassis, see *Understanding Split and Merge in a Virtual Chassis*

How an NSSU Works

This section describes what happens when you request an NSSU on these switches and Virtual Chassis:

- [EX3300, EX4200, EX4300, EX4500, and Mixed Virtual Chassis on page 125](#)
- [EX6200 and EX8200 Switches on page 126](#)
- [EX8200 Virtual Chassis on page 127](#)

EX3300, EX4200, EX4300, EX4500, and Mixed Virtual Chassis

When you request an NSSU on an EX3300, EX4200, EX4300, EX4500, or mixed Virtual Chassis:

1. The Virtual Chassis master verifies that:
 - The backup is online and running the same software version.
 - Graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) are enabled.
 - The Virtual Chassis has a preprovisioned configuration.
2. The master installs the new software image on the backup and reboots it.
3. The master resynchronizes the backup.

4. The master installs the new software image on member switches that are in the linecard role and reboots them, one at a time. The master waits for each member to become online and active before starting the software upgrade on the next member.
5. When all members that are in the linecard role have been upgraded, the master performs a graceful Routing Engine switchover, and the upgraded backup becomes the master.
6. The software on the original master is upgraded and the original master is automatically rebooted. After the original master has rejoined the Virtual Chassis, you can optionally return control to it by requesting a graceful Routing Engine switchover.

EX6200 and EX8200 Switches

When you request an NSSU on a standalone switch with redundant Routing Engines:

1. The switch verifies that:
 - Both Routing Engines are online and running the same software version.
 - Both Routing Engines have sufficient storage space for the new software image.
 - Graceful Routing Engine switchover and nonstop active routing are enabled.
2. The switch installs the new software image on the backup Routing Engine and reboots it.
3. The switch resynchronizes the backup Routing Engine to the master Routing Engine.
4. The line cards in the first upgrade group (or the line card in slot 0, if no upgrade groups are defined) download the new image and then restart. Traffic continues to flow through the line cards in the other upgrade groups during this process.
5. When line cards restarted in Step 4 are online again, the line cards in the next upgrade group download the new image and restart. This process continues until all online line cards have restarted with the new software.

NOTE: If you have taken a line card offline with the CLI before you start the NSSU, the line card is not restarted and remains offline.

6. The switch performs a graceful Routing Engine switchover, so that the upgraded backup Routing Engine becomes the master.
7. The switch installs the new software on the original master Routing Engine.

To complete the upgrade process, the original master Routing Engine must be rebooted. You can do so manually or have the switch perform an automatic reboot by including the **reboot** option when you request the NSSU. After the original master has been rebooted, you can optionally return control to it by requesting a graceful Routing Engine switchover.
8. (EX6200 switch only) The original master Routing Engine reboots to complete the software upgrade.

NOTE: To complete the upgrade process on an EX8200 switch, you must intervene to reboot the original master Routing Engine. You can reboot the original master Routing Engine manually or have the switch perform an automatic reboot by including the `reboot` option when you request the NSSU.

9. (Optional) After the original master has been rebooted, you can return control to it by requesting a graceful Routing Engine switchover.

The switch can maintain normal operations with either Routing Engine acting as the master Routing Engine after the software upgrade, so you only have to perform this switchover if you want to return Routing Engine control to the original master Routing Engine.

EX8200 Virtual Chassis

When you request an NSSU on an EX8200 Virtual Chassis:

1. The master external Routing Engine verifies that:
 - It has a backup external Routing Engine that is online.
 - All Virtual Chassis members have redundant Routing Engines and the Routing Engines are online.
 - All Routing Engines are running the same software version.
 - All Routing Engines have sufficient storage space for the new software image.
 - Graceful Routing Engine switchover and nonstop active routing (NSR) are enabled.
2. The master external Routing Engine installs the new software image on the backup external Routing Engine and reboots it.
3. The backup external Routing Engine resynchronizes with the master external Routing Engine.
4. The master external Routing Engine installs the new software on the backup Routing Engines in the member switches and reboots the backup Routing Engines.
5. When the reboot of the backup Routing Engines complete, the line cards in the first upgrade group download the new image and then restart. (If no upgrade groups are defined, the line card in slot 0 of member 0 downloads the new image and restarts.) Traffic continues to flow through the line cards in the other upgrade groups during this process.
6. When line cards restarted in Step 5 are online again, the line cards in the next upgrade group (or the next sequential line card) download the new image and restart. This process continues until all online line cards have restarted with the new software.

NOTE: If you have taken a line card offline with the CLI before you start the NSSU, the line card is not restarted and remains offline.

7. The new software image is installed on the master Routing Engines, both external and internal.
8. The member switches perform a graceful Routing Engine switchover, so that the upgraded backup Routing Engines become masters.
9. The master external Routing Engine performs a graceful Routing Engine switchover so that the backup external Routing Engine is now the master.

To complete the upgrade process, the original master Routing Engines, both external and internal, must be rebooted. You can do so manually by establishing a console connection to each Routing Engine or have the reboot performed automatically by including the **reboot** option when you request the NSSU. After the original master external Routing Engine has been rebooted, you can optionally return control to it by requesting a graceful Routing Engine switchover.

NSSU Limitations

You cannot use an NSSU to downgrade the software—that is, to install an earlier version of the software than is currently running on the switch. To install an earlier software version, use the **request system software add** command.

You cannot roll back to the previous software version after you perform an upgrade using NSSU. If you need to rollback to the previous software version, you can do so by rebooting from the alternate root partition if you have not already copied the new software version into the alternate root partition.

NSSU and Junos OS Release Support

A Virtual Chassis must be running a Junos OS release that supports NSSU before you can perform an NSSU. If a Virtual Chassis is running a software version that does not support NSSU, use the **request system software add** command.

Table 20 lists the EX Series switches and Virtual Chassis that support NSSU and the Junos OS release at which they began supporting it.

Table 20: Platform and Release Support for NSSU

Platform	Junos OS Release
EX3300 Virtual Chassis	12.2 or later
EX4200 Virtual Chassis	12.1 or later
EX4300 Virtual Chassis	13.2X51-D20 or later
EX4500 Virtual Chassis	12.1 or later
EX4550 Virtual Chassis	12.2 or later
Mixed EX4200 and EX4500 Virtual Chassis	12.1 or later
Mixed EX4200 and EX4550 Virtual Chassis	12.2 or later

Table 20: Platform and Release Support for NSSU (*continued*)

Platform	Junos OS Release
Mixed EX4200, EX4500, and EX4550 Virtual Chassis	12.2 or later
Mixed EX4500 and EX4550 Virtual Chassis	12.2 or later
EX6200 switch	12.2 or later
EX8200 switch	10.4 or later
EX8200 Virtual Chassis	11.1 or later

Overview of NSSU Configuration and Operation

You must ensure that the configuration of the switch or Virtual Chassis meets the requirements described in [“Requirements for Performing an NSSU” on page 124](#). NSSU requires no additional configuration.

For EX6200 switches, EX8200 switches, and EX8200 Virtual Chassis, you can optionally configure line-card upgrade groups using the CLI. See *Example: Configuring Line-Card Upgrade Groups for Nonstop Software Upgrade on EX Series Switches*.

You perform an NSSU by executing the **request system software nonstop-upgrade** command. For detailed instructions on how to perform an NSSU, see the topics in Related Documentation.

Upgrading Software by Using Automatic Software Download

The automatic software download feature uses the Dynamic Host Configuration Protocol (DHCP) message exchange process to download and install software packages. You configure the automatic software download feature on switches that act as DHCP clients. You must enable automatic software download on a switch before the software upgrade can occur.

You configure a path to a software package file on the DHCP server. The server communicates the path to the software package file through DHCP server messages.

If you enable automatic software download, the DHCP client switch compares the software package name in the DHCP server message with the name of the software package that booted the switch. If the software packages are different, the DHCP client switch downloads and installs the software package specified in the DHCP server message.

Before you upgrade software by using automatic software download, ensure that you have configured DHCP services for the switch, including configuring a path to a boot server and a boot file.

To configure a path to a boot server and a boot file:

1. Configure the name of the boot server advertised to DHCP clients. The client uses a boot file located on the boot server to complete DHCP setup. This configuration is equivalent to DHCP Option 66:

```
[edit system services dhcp]
user@switch# set boot-server (address | hostname)
```

2. Set the boot file advertised to DHCP clients. After the client receives an IP address and the boot file location from the DHCP server, the client uses the boot image stored in the boot file to complete the DHCP setup. This configuration is equivalent to DHCP Option 67:

```
[edit system services dhcp]
user@switch# set boot-file filename
```

To enable automatic software download on a switch that acts as a DHCP client:

```
[edit chassis]
user@switch# set auto-image-upgrade
```

After automatic software download is enabled on your DHCP client switch and after DHCP services are enabled on your network, an automatic software download can occur at any time as part of the DHCP message exchange process.

If an automatic software download occurs, you see the following message on the switch:

```
Auto-image upgrade started
On successful installation system will reboot automatically
```

The switch reboots automatically to complete the upgrade.

Related Documentation

- [Verifying That Automatic Software Download Is Working Correctly on page 131](#)
- [Understanding Software Installation on EX Series Switches on page 44](#)

- [Configuring DHCP Services \(J-Web Procedure\)](#)

Verifying That Automatic Software Download Is Working Correctly

Purpose Verify that the automatic software download feature is working correctly.

Action Use the `show system services dhcp client interface-name` command to verify that the automatic software download feature has been used to install a software package.

```
user@switch> show system services dhcp client ge-0/0/1.0
Logical Interface Name      ge-0/0/1.0
Hardware address           00:0a:12:00:12:12
Client Status               bound
Vendor Identifier           ether
Server Address              10.1.1.1
Address obtained            10.1.1.89
Lease Obtained at           2009-08-20 18:13:04 PST
Lease Expires at            2009-08-22 18:13:04 PST

DHCP Options :
Name: name-server, Value: [ 10.209.194.131, 2.2.2.2, 3.3.3.3 ]
Name: server-identifier, Value: 10.1.1.1
Name: router, Value: [ 10.1.1.80 ]
Name: boot-image,
Value: jinstall-ex-4200-9.6R1.5-domestic-signed.tgz
Name: boot-image-location,
Value: 10.1.1.25:/bootfiles/
```

Meaning The output from this command shows the name and location of the software package under DHCP options when automatic software download was last used to install a software package. The sample output in DHCP options shows that the last DHCP server message to arrive on the DHCP client had a boot server address of 192.168.1.165 and a boot file named jinstall-ex-4200-9.6R1.5-domestic-signed.tgz. If automatic software download was enabled on this client switch during the last DHCP message exchange, these values were used by the switch to upgrade the software.

Verifying Junos OS and Boot Loader Software Versions on an EX Series Switch

Before or after upgrading or downgrading Junos OS, you might need to verify the Junos OS version. You might also need to verify the boot loader software version if you are upgrading to or downgrading from a release that supports resilient dual-root partitions (Junos OS Release 10.4R3 and later).

This topic includes:

- [Verifying the Number of Partitions and File System Mountings on page 132](#)
- [Verifying the Loader Software Version on page 132](#)
- [Verifying Which Root Partition Is Active on page 133](#)
- [Verifying the Junos OS Version in Each Root Partition on page 134](#)

Verifying the Number of Partitions and File System Mountings

Purpose Between Junos OS Release 10.4R2 and Release 10.4R3, upgrades were made to further increase resiliency of root partitions, which required reformatting the disk from three partitions to four partitions. If your switch is running Release 10.4R2 or earlier, it has three partitions, and if it is running Release 10.4R3 or later, it has four partitions.

Action Verify how many partitions the disk has, as well as where each file system is mounted, by using the following command:

```
user@switch> show system storage
fpc0:
```

```
-----
Filesystem Size Used Avail Capacity Mounted on
/dev/da0s1a 184M 124M 45M 73% /
devfs 1.0K 1.0K 0B 100% /dev
/dev/md0 37M 37M 0B 100% /packages/mnt/jbase
/dev/md1 18M 18M 0B 100%
/packages/mnt/jcrypto-ex-10.4I20110121_0509_hbRPSRLI15184421081

procfs 4.0K 4.0K 0B 100% /proc
/var/jail/etc 123M 632K 112M 1%
/packages/mnt/jweb-ex-10.4I20110121_0509_hbRPSRLI15184421081/jail/var/etc
/var/jail/run 123M 632K 112M 1%
/packages/mnt/jweb-ex-10.4I20110121_0509_hbRPSRLI15184421081/jail/var/run
/var/jail/tmp 123M 632K 112M 1%
/packages/mnt/jweb-ex-10.4I20110121_0509_hbRPSRLI15184421081/jail/var/tmp
/var/tmp 369M 20K 339M 0%
/packages/mnt/jweb-ex-10.4I20110121_0509_hbRPSRLI15184421081/jail/var/tmp/uploads
devfs 1.0K 1.0K 0B 100%
/packages/mnt/jweb-ex-10.4I20110121_0509_hbRPSRLI15184421081/jail/dev
```

Meaning The presence of the partition name containing **s4d** indicates that there is a fourth slice. If this were a three-slice partition scheme, in place of **s1a**, **s3e**, **s3d**, and **s4d**, you would see **s1a**, **s1f**, **s2a**, **s2f**, **s3d**, and **s3e** and you would not see **s4d**.

Verifying the Loader Software Version

Purpose For the special case of upgrading from Junos OS Release 10.4R2 or earlier to Release 10.4R3 or later, you must upgrade the loader software.

Action For EX Series switches except EX8200 switches:

```
user@switch> show chassis firmware
Part          Type      Version
FPC 0         uboot     U-Boot 1.1.6 (Jan  3 2011 - 16:14:58) 1.0.0

              loader   FreeBSD/PowerPC U-Boot bootstrap loader 2.4
```

For EX8200 switches:

```
user@switch> show chassis firmware
Part          Type      Version
FPC 0         uboot     U-Boot 1.1.6 (Jan  3 2011 - 16:14:58) 3.5.0

              loader   FreeBSD/PowerPC U-Boot bootstrap loader 2.4
```

Meaning For EX Series switches other than EX8200 switches, with Junos OS Release 10.4R3 or later installed:

- If there is version information following the timestamp for **U-Boot** (1.0.0 in the preceding example), then the loader software does not require upgrading.
- If there is no version number following the timestamp for **U-boot**, then the loader software requires upgrading.

NOTE: If the software version is Release 10.4R2 or earlier, no version number is displayed following the timestamp for **U-boot**, regardless of the loader software version installed. If you do not know whether you have installed the new loader software, we recommend that you upgrade the loader software when you upgrade the software version.

For EX8200 switches, if the version number following the timestamp for **U-Boot** is earlier than **3.5.0**, you must upgrade the loader software when you upgrade the software version.

Verifying Which Root Partition Is Active

Purpose Switches running Release 10.4R3 or later have resilient dual-root partition functionality, which includes the ability to boot transparently from the inactive partition if the system fails to boot from the primary root partition.

You can verify which root partition is active using the following command:

Action user@switch> `show system storage partitions`
fpc0:

```
-----
Boot Media: internal (da0)
Active Partition: da0s1a
Backup Partition: da0s2a
Currently booted from: active (da0s1a)

Partitions information:
  Partition  Size  Mountpoint
  s1a        184M  /
  s2a        184M  altroot
  s3d        369M  /var/tmp
  s3e        123M  /var
  s4d         62M  /config
  s4e                unused (backup config)
```

Meaning The **Currently booted from:** field shows which root partition is active.

Verifying the Junos OS Version in Each Root Partition

Purpose Each switch contains two root partitions. We recommend that you copy the same Junos OS version in each partition when you upgrade. In Junos OS Release 10.4R2 and earlier, you might choose to have different Junos OS release versions in each partition. You might have different versions during a software upgrade and before you have finished verifying the new software installation. To enable a smooth reboot if corruption is found in the primary root file system, ensure that the identical Junos OS images are in each root partition. For Release 10.4R2 and earlier, you must manually reboot the switch from the backup root partition. However, for Release 10.4R3 and later, the switch reboots automatically from the backup root partition if it fails to reboot from the active root partition.

Action Verify whether both root partitions contain the same image by using the following command:

```
user@switch> show system snapshot media internal
Information for snapshot on      internal (/dev/da0s1a) (backup)
Creation date: Jan 11 03:02:59 2012
JUNOS version on snapshot:
  jbase   : ex-12.2I20120305_2240_user
  jcrypto-ex: 12.2I20120305_2240_user
  jdocs-ex: 12.2I20120305_2240_user
  jroute-ex: 12.2I20120305_2240_user
  jswitch-ex: 12.2I20120305_2240_user
  jweb-ex: 12.2I20120305_2240_user
Information for snapshot on      internal (/dev/da0s2a) (primary)
Creation date: Mar 6 02:24:08 2012
JUNOS version on snapshot:
  jbase   : ex-12.2I20120305_2240_user
  jcrypto-ex: 12.2I20120305_2240_user
  jdocs-ex: 12.2I20120305_2240_user
  jroute-ex: 12.2I20120305_2240_user
  jswitch-ex: 12.2I20120305_2240_user
  jweb-ex: 12.2I20120305_2240_user
```

Meaning The command shows which Junos OS version is installed on each media partition. Verify that the same version is installed on both partitions.

Upgrading the Loader Software on the Line Cards in a Standalone EX8200 Switch or an EX8200 Virtual Chassis

You are almost never required to upgrade the loader software on the line cards in an EX8200 switch.

Upgrading the loader software version for a line card is not a requirement to complete any software upgrade. In rare cases, a line card might go offline immediately after a software upgrade because the loader software version on the line card requires an upgrade to become compatible with the upgraded Junos OS. You can upgrade the loader software on the line cards as a best practice to avoid this problem and other less severe issues.

The loader software on any line card in an EX8200 switch is updated using the same loader software package that upgrades the EX8200 Routing Engine loader software. The line card software loader contains two banks, each with a single loader software version. This procedure is used to upgrade the loader software for both banks of a line card in a standalone EX8200 switch or an EX8200 Virtual Chassis.

NOTE: If you are upgrading Junos OS, the Routing Engine loader software, and the line card loader software, we recommend that you upgrade in this order: Junos OS, line card loader software, Routing Engine loader software.

1. Determine the version of the loader software for the line cards:

```

user@switch> show chassis firmware
Part      Type      Version
FPC 6     U-Boot    U-Boot 1.1.6 (Jan 13 2009 - 06:55:22) 2.3.0
          loader  FreeBSD/PowerPC U-Boot bootstrap loader 2.2
FPC 7     U-Boot    U-Boot 1.1.6 (Jan 13 2009 - 06:55:22) 2.3.0
          loader  FreeBSD/PowerPC U-Boot bootstrap loader 2.2
Routing Engine 0 U-Boot    U-Boot 1.1.6 (Mar 11 2011 - 04:29:01) 3.5.0
          loader  FreeBSD/PowerPC U-Boot bootstrap loader 2.4
Routing Engine 1 U-Boot    U-Boot 1.1.6 (Mar 11 2011 - 04:29:01) 2.3.0
          loader  FreeBSD/PowerPC U-Boot bootstrap loader 2.4

```

NOTE: On an EX8200 Virtual Chassis, you cannot execute the `show chassis firmware` command on the master external Routing Engine. You must execute this command on each member switch:

1. From the master external Routing Engine, start a shell session on the member switch. For example:

```
user@external-routing-engine> request session member 0
```

2. Enter the CLI and execute the `show chassis firmware` command.
3. Repeat these steps for the other member switch.

The loader software version appears after the timestamp for **U-Boot 1.1.6**. In the preceding example, the version is **2.3.0**. Ignore the U-Boot version number (1.1.6); it has nothing to do with the loader software version that you need to determine.

If the loader software version is earlier than **3.5.0** for any **FPC**, you should consider upgrading the loader software for that line card.

2. Download the loader software package from the Juniper Networks website and place the software package on an internal software distribution site or in a local directory on the switch. We recommend using `/var/tmp` as the local directory on the switch.

NOTE: To obtain the loader software package, see the Download Software page at <http://www.juniper.net/support/downloads/junos.html>. Click on the version, then the Software tab, and then the name of the software install package. In the pop-up Alert box, click the link to the PSN document.

3. Disable graceful Routing Engine switchover (GRES) and nonstop active routing (NSR), if enabled. Commit the configuration:

```

user@switch# deactivate chassis redundancy graceful-switchover
user@switch# deactivate routing-options nonstop-routing
user@switch# commit synchronize

```

4. Install the loader package:

```
user@switch> request system software add package
```

Replace **package** with one of the following paths:

- For a software package in the `/var/tmp` directory on the switch or external Routing Engine—`/var/tmp/package.tgz`
- For a software package on a remote server:
 - `ftp://hostname/pathname/package.tgz`
 - `http://hostname/pathname/package.tgz`

where *package.tgz* is, for example, `jloader-ex-8200-11.3build-signed.tgz`.

5. Upgrade the loader software.

- To upgrade the loader software for a line card on a standalone EX8200 switch:

```
user@switch> request system firmware upgrade fpc slot slot-number
Firmware upgrade initiated....
Please wait for ~2mins for upgrade to complete....
```

- To upgrade the loader software for a line card on an EX8200 member switch in an EX8200 Virtual Chassis:

```
user@switch> request system firmware upgrade fpc slot slot-number member member-id

Firmware upgrade initiated....
Please wait for ~2mins for upgrade to complete....
```

6. Confirm the loader software upgrade:

```
user@switch> show system firmware
```

Part	Type	Tag	Current version	Available version	Status
FPC 6	U-Boot	0	2.3.0		UPGRADED SUCCESSFULLY
FPC 7	U-Boot	0	2.3.0		OK
Routing Engine 0 RE BIOS		0	3.1.1		OK
Routing Engine 1		0	3.1.1		OK

The status is **UPGRADED SUCCESSFULLY** if the boot loader version update process is complete.

The status is **PROGRAMMING** if the boot loader version update process is still in progress.

Do not proceed to the next step until the **show system firmware** output confirms that the loader software upgrade is complete.

7. Restart the line card.

- To restart a line card on a standalone EX8200 switch:

```
user@switch> request chassis fpc restart slot slot-number
```

- To restart a line card on an EX8200 member switch in an EX8200 Virtual Chassis:

```
user@switch> request chassis fpc restart slot slot-number member member-id
```

NOTE: You can monitor the status of the line card restart by using the **show chassis fpc** command.

8. After the line card restart has completed, confirm the loader software version update:

```
user@switch> show chassis firmware
```

Part	Type	Tag	Current version	Available version	Status
FPC 6	U-Boot	0	3.5.0		OK
FPC 7	U-Boot	0	2.3.0		OK
Routing Engine 0	RE BIOS	0	3.1.1		OK
Routing Engine 1		0	3.1.1		OK

The current version has updated to **3.5.0**. You have upgraded the loader software for one bank of the line card.

- Repeat Steps 4 through 7 to upgrade the loader software on the other bank of the line card.

NOTE: A bank switchover occurs automatically as part of the line card restart. Repeating Steps 3 through 6 updates the loader software on the other bank.

- Repeat Steps 4 through 8 for all other line cards that require a line card loader version upgrade.

Upgrading Junos OS with Upgraded FreeBSD

Starting with Junos OS Release 15.1, certain hardware platforms run an upgraded FreeBSD kernel instead of older versions of FreeBSD.

Before you begin:

- Verify that the upgrade applies to your router or switch model, as listed in [“Understanding Junos OS with Upgraded FreeBSD” on page 19](#).
- Download the Junos OS package.
- Determine the upgrade path to follow.

The current Junos OS release determines the upgrade path to Junos OS with upgraded FreeBSD, as shown in [Table 21](#). Other upgrade paths might work, but they are not supported.

Table 21: Upgrade Path to Junos OS with the Upgraded FreeBSD

Current Router's Junos OS Release	Upgrade Path
12.3 or earlier	Upgrade to 13.3, or 14.2 first, then upgrade to 15.1 or later (multiple steps).

Table 21: Upgrade Path to Junos OS with the Upgraded FreeBSD (*continued*)

Current Router's Junos OS Release	Upgrade Path
13.3 or later	Use upgrade package to upgrade from the current Junos OS release to Junos OS with upgraded FreeBSD (single step).
15.1 or later	Use upgrade package to upgrade from the current Junos OS release to Junos OS with upgraded FreeBSD (single step).

NOTE: You can also downgrade from Junos OS Release 15.1 to an earlier release of Junos OS, as long as the path complies with the Junos OS policy of skipping at most two releases earlier.

- Understand that direct validation of running configuration does not work for upgrading to Junos OS with upgraded FreeBSD from Junos OS based on older versions of the FreeBSD kernel.

When upgrading or downgrading between Junos OS and Junos OS with upgraded FreeBSD, you might have to validate on a different host. It does not matter where that other host is, as long as you can reach it with NETCONF over SSH. See *Establishing an SSH Connection for a NETCONF Session*. The target system uses the network to contact the other host, run the validation and authentication, and return the result.

The upgrade process only preserves the following directories:

- `/config`
- `/etc/localtime`
- `/var/db`
- `/var/etc/master.passwd`
- `/var/etc/inetd.conf`
- `/var/etc/pam.conf`
- `/var/etc/resolv.conf`
- `/var/etc/syslog.conf`
- `/var/etc/localtime`
- `/var/etc/exports`
- `/var/etc/extensions.allow`
- `/var/preserve`
- `/var/tmp/baseline-config.conf`
- `/var/tmp/preinstall_boot_loader.conf`

NOTE: On EX2300 and EX3400 switches, the following directories are not applicable:

- /etc/localtime
- /var/etc/localtime
- /var/etc/exports
- /var/preserve
- /var/tmp/preinstall_boot_loader.conf

For specific installation procedures, see the following:

- [To Install Junos OS with Upgraded FreeBSD Over a Plain Junos OS on page 141](#)
- [To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of an Earlier Release on page 144](#)
- [To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of a Later Release on page 145](#)

To Install Junos OS with Upgraded FreeBSD Over a Plain Junos OS

NOTE: If you have important files in other directories, copy them from the router or switch to a secure location before upgrading the router or switch.

NOTE: The following procedure refers to routers, but it also applies to switches.

To install Junos OS with upgraded FreeBSD over a plain Junos OS:

1. Enter the **request system software add *package-name* no-validate** command from the operational mode in the CLI:

NOTE: The **no-copy** option is enabled by default.

Use the **no-validate** option with the **request system software add** command. If you leave out the **no-validate** option, the command uses the **validate** option by default, and direct validation of running configuration does not work for upgrading to Junos OS with upgraded FreeBSD from Junos OS based on older versions of the FreeBSD kernel.

NOTE: You can also use `reboot` option along with `request system software add` command, but it is not recommended to do this in a single step while upgrading from a FreeBSD 6.1 based Junos OS to FreeBSD 10 based Junos OS.

NOTE: To validate current configuration on an upgrade to Junos OS with upgraded FreeBSD from Junos OS, use the `request system software validate on (Junos OS with Upgraded FreeBSD)` command.

```
user@host>request system software add
/var/tmp/junos-install-mx-x86-32-15.1R1.9.tgz no-validate
Installing package '/var/tmp/junos-install-mx-x86-32-15.1R1.9.tgz' ...

Verified manifest signed by PackageProductionRSA_2015
Verified contents.iso
Verified issu-indb.tgz
Verified junos-x86-32.tgz
Verified kernel
Verified metatags
Verified package.xml
Verified pkgtools.tgz
camcontrol: not found
camcontrol: not found
Verified manifest signed by PackageProductionEc_2015
Saving the config files ...
NOTICE: uncommitted changes have been saved in
/var/db/config/juniper.conf.pre-install
Saving package file in
/var/sw/pkg/junos-install-x86-32-domestic-20150618.043753_builder_junos_151_r1.tgz
...
Saving state for rollback ...
```

The new Junos OS image is installed on the router.

2. Reboot the device to start the new software using the `request system reboot` command:

```
user@host> request system reboot
Reboot the system? [yes, no] (no) yes
```

NOTE: You must reboot the device to load the newly installed version of Junos OS on the device.

To abort the installation, do not reboot the device. Instead, finish the installation and then issue the `request system software delete package-name` command where package is, for example, `junos-install-mx-x86-32-15.1R1.9.tgz`. This is your last chance to stop the installation (not applicable on EX2300 and EX3400 platforms).

The software is loaded when you reboot the system. Installation can take between 5 and 10 minutes. The device then reboots from the boot device on which the software was just installed. When the reboot is complete, the device displays the login prompt.

While the software is being upgraded, the Routing Engine on which you are performing the installation does not route traffic.

3. Log in and issue the **show version** command to verify the version of the software installed.

```
user@host> show version
Hostname: host
Model: mx240
Junos: 15.1R1.9
JUNOS OS Kernel 32-bit [20150617.306001_builder_stable_10]
JUNOS OS runtime [20150617.306001_builder_stable_10]

```

NOTE: The output shows the OS kernel, OS runtime, and other packages installed on the router.

To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of an Earlier Release

NOTE: If you have important files in other directories, copy them from the router or switch to a secure location before upgrading the router or switch.

NOTE: The following procedure refers to routers, but it also applies to switches.

To install Junos OS with upgraded FreeBSD over Junos OS with upgraded FreeBSD of an earlier release:

1. Enter the **request system software add *package-name* validate reboot** command from the operational mode in the CLI:

NOTE: The **no-copy** option is enabled by default.

Use the **validate** and **reboot** options with the **request system software add** command. The command uses the **validate** option by default. We encourage users to validate using the **validate** option when upgrading from Junos OS to Junos OS or from Junos OS with upgraded FreeBSD to Junos OS with upgraded FreeBSD.

If you leave out the **reboot** option, you can take care of that in a separate reboot step.

The new Junos OS image is installed on the router.

2. Verify the installation of Junos OS with upgraded FreeBSD.

```
user@host> show version
```

NOTE: The output shows the OS kernel, OS runtime, and other packages installed on the router.

To Install Junos OS with Upgraded FreeBSD Over Junos OS with Upgraded FreeBSD of a Later Release

NOTE: If you have important files in other directories, copy them from the router or switch to a secure location before upgrading the router or switch.

NOTE: The following procedure refers to routers, but it also applies to switches.

To install Junos OS with upgraded FreeBSD over Junos OS with upgraded FreeBSD of a later release:

1. Enter the **request system software add *package-name* validate reboot** command from the operational mode in the CLI:

NOTE: The **no-copy** option is enabled by default.

Use the **validate** and **reboot** options with the **request system software add** command. The command uses the **validate** option by default. We encourage users to validate using the **validate** option when upgrading from Junos OS to Junos OS or from Junos OS with upgraded FreeBSD to Junos OS with upgraded FreeBSD.

If you leave out the **reboot** option, you can take care of that in a separate reboot step.

The new Junos OS image is installed on the router.

2. Verify the installation of Junos OS with upgraded FreeBSD.

```
user@host> show version
```

NOTE: The output shows the OS kernel, OS runtime, and other packages installed on the router.

Understanding Junos OS Upgrades for SRX Series Devices

SRX Series devices are delivered with Junos OS preinstalled on them. When you power on a device, it starts (boots) up using its primary boot device. These devices also support

secondary boot devices, allowing you to back up your primary boot device and configuration.

As new features and software fixes become available, you must upgrade Junos OS to use them. Before an upgrade, we recommend that you back up your primary boot device.

Understanding Junos OS Upgrades

On a services gateway, you can configure the primary or secondary boot device with a snapshot of the current configuration, default factory configuration, or rescue configuration. You can also replicate the configuration for use on another device.

If the SRX Series device does not have a secondary boot device configured and the primary boot device becomes corrupted, you can reload the Junos OS package onto the corrupted internal media from a USB flash drive or TFTP server.

Junos OS Upgrade Methods on the SRX Series Devices

SRX Series devices that ship from the factory with Junos OS Release 10.0 or later are formatted with the dual-root partitioning scheme.

NOTE: Junos OS Release 12.1X45 and later do not support single root partitioning.

Existing SRX Series devices that are running Junos OS Release 9.6 or earlier use the single-root partitioning scheme. While upgrading these devices to Junos OS Release 10.0 or later, you can choose to format the storage media with dual-root partitioning (strongly recommended) or retain the existing single-root partitioning.

Certain Junos OS upgrade methods format the internal media before installation, whereas other methods do not. To install Junos OS Release 10.0 or later with the dual-root partitioning scheme, you must use an upgrade method that formats the internal media before installation.

NOTE: If you are upgrading to Junos OS Release 10.0 without transitioning to dual-root partitioning, use the conventional CLI and J-Web user interface installation methods.

These upgrade methods format the internal media before installation:

- Installation from the boot loader using a TFTP server
- Installation from the boot loader using a USB storage device
- Installation from the CLI using the **partition** option (available in Junos OS Release 10.0)
- Installation using the J-Web user interface

These upgrade methods retain the existing partitioning scheme:

- Installation using the CLI

- Installation using the J-Web user interface

WARNING: Upgrade methods that format the internal media before installation wipe out the existing contents of the media. Only the current configuration will be preserved. Any important data should be backed up before starting the process.

NOTE: Once the media has been formatted with the dual-root partitioning scheme, you can use conventional CLI or J-Web user interface installation methods, which retain the existing partitioning and contents of the media, for subsequent upgrades.

Related Documentation

- [Software Naming Convention for SRX Series Devices on page 10](#)

Preparing Your SRX Series Device for Junos OS Upgrades

Before you begin upgrading Junos OS on an SRX Series device, ensure the following:

- Obtain a Juniper Networks Web account and a valid support contract. You must have an account to download software upgrades. To obtain an account, complete the registration form at the Juniper Networks website:
<https://www.juniper.net/registration/Register.jsp>.
- Back up your primary boot device onto a secondary storage device.

Creating a backup has the following advantages:

- The device can boot from backup and come back online in case of failure or corruption of the primary boot device in the event of power failure during an upgrade.
- Your active configuration files and log files are retained.
- The device can recover from a known, stable environment in case of an unsuccessful upgrade.

You can use either the J-Web user interface or the CLI to back up the primary boot device on the secondary storage device.

Secondary Storage Devices Available on SRX Series Devices

You can use either the J-Web user interface or the CLI to back up the primary boot device on the secondary storage device.

[Table 22](#) lists the secondary storage devices available on an SRX Series devices.

Table 22: Secondary Storage Devices for SRX Series Devices

Storage Device	Available on Services Gateways	Minimum Storage Required
USB storage device	SRX300, SRX320, SRX340, and SRX345 Services Gateways	1 GB
	SRX550M	2 GB
SSD Card	SRX1500	100 GB
Routing Engine (RE2) SSD card	SRX5000 line devices	120 GB

**NOTE:**

- During a successful upgrade, the upgrade package completely reinstalls the existing Junos OS. It retains configuration files, log files, and similar information from the previous version.
- After a successful upgrade, remember to back up the new current configuration to the secondary device.

Verifying Available Disk Space on SRX Series Devices

The amount of free disk space necessary to upgrade a device with a new version of Junos OS can vary from one release to another. Check the Junos OS software version you are installing to determine the free disk space requirements.

If the amount of free disk space on a device is insufficient for installing Junos OS, you might receive a warning similar to the following messages, that the /var filesystem is low on free disk space:

WARNING: The /var filesystem is low on free disk space.

WARNING: This package requires 1075136k free, but there is only 666502k available.

To determine the amount of free disk space on the device, issue the **show system storage detail** command. The command output displays statistics about the amount of free disk space in the device file systems.

A sample of the **show system storage detail** command output is shown below:

```
user> show system storage detail
```

Filesystem	1024-blocks	Used	Avail	Capacity	Mounted on
/dev/da0s2a	300196	154410	121772	56%	/
devfs	1	1	0	100%	/dev
/dev/md0	409000	409000	0	100%	/junos
/cf	300196	154410	121772	56%	/junos/cf
devfs	1	1	0	100%	/junos/dev/

procfs	4	4	0	100%	/proc

Cleaning Up the System File Storage Space

When the system file storage space on the device is full, rebooting the device does not solve the problem. The following error message is displayed during a typical operation on the device after the file storage space is full.

```
user@host% cli
user@host> configure/var: write failed, filesystem is full
```

You can clean up the file storage on the device by deleting system files using the **request system storage cleanup** command as shown in following procedure:

1. Request to delete system files on the device.

```
user@host> request system storage cleanup
```

The list of files to be deleted is displayed.

List of files to delete:

Size	Date	Name
11B	Oct 28 23:40	/var/jail/tmp/alarmd.ts
92.4K	Jan 11 17:12	/var/log/chassisd.0.gz

Delete these files ? [yes,no] (no)

2. Enter the option **yes** to proceed with deleting of the files.

Downloading Software Packages from Juniper Networks

To download Junos OS upgrades from Juniper Networks:

1. Using a Web browser, follow the links to the download URL on the Juniper Networks webpage. Depending on your location, select the Canada and U.S. version (domestic) or the Worldwide version (ww):
 - <https://www.juniper.net/support/downloads/junos.html>
 - <https://www.juniper.net/support/downloads/junos.html>
2. Log in to the Juniper Networks website using the username (generally your e-mail address) and password supplied by your Juniper Networks representative.
3. Select the appropriate software image for your platform.
4. Download Junos OS to a local host or to an internal software distribution site.

Related Documentation

Example: Installing Junos OS Upgrade Packages on SRX Series Devices

This example shows how to install Junos OS upgrades on SRX Series devices.

- [Requirements on page 150](#)
- [Overview on page 151](#)
- [Configuration on page 151](#)
- [Verification on page 152](#)

Requirements

Before you begin:

- Verify the available space on the internal media. See “[Preparing Your SRX Series Device for Junos OS Upgrades](#)” on [page 147](#) and the *Junos OS Release Notes*
- Download the software package. See “[Downloading Software Packages from Juniper Networks](#)” on [page 150](#).
- Copy the software package to the device if you are installing the software package from a local directory on the device. We recommend that you copy it to the `/var/tmp` directory.

Overview

By default, the **request system software add *package-name*** command uses the **validate** option to validate the software package against the current configuration as a prerequisite to adding the software package. This validation ensures that the device can reboot successfully after the software package is installed. This is the default behavior when you are adding a software package.

In this example, add the software package `junos-srxsme-10.0R2-domestic.tgz` (for SRX Series devices) with the following options:

- **no-copy** option to install the software package but do not save the copies of package files. You should include this option if you do not have enough space on the internal media to perform an upgrade that keeps a copy of the package on the device.
- **no-validate** option to bypass the compatibility check with the current configuration before installation starts.
- **reboot** option to reboots the device after installation is completed.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, enter:

```
user@host> request system software add /var/tmp/junos-srxsme-10.0R2-domestic.tgz
no-copy no-validate reboot
```

GUI Step-by-Step Procedure

To install Junos OS upgrades on SRX Series devices:

1. In the J-Web user interface, select **Maintain>Software>Upload Package**.
2. On the Upload Package page, specify the software package to upload. Click **Browse** to navigate to the software package location and select `junos-srxsme-10.0R2-domestic.tgz`.
3. Select the **Reboot If Required** check box to set the device to reboot automatically when the upgrade is complete.
4. Select the **Do not save backup** check box to bypass saving the backup copy of the current Junos OS package (SRX Series).
5. Click **Upload Package**. The software is activated after the device has rebooted.
6. Click **OK** to check your configuration and save it as a candidate configuration.
7. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

From operational mode, install the new package on the device with the no-copy and no-validate options, and format and re-partition the media before installation, and reboot the device after installation is completed.

To install Junos OS upgrades on SRX Series devices:

1. From operational mode, install the new package on the device

```
user@host> request system software add /var/tmp/junos-srxsme-10.0R2-domestic.tgz  
no-copy no-validate
```

2. Reboot the device.

```
user@host> request system reboot
```

When the reboot is complete, the device displays the login prompt.

Results From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Junos OS Upgrade Installation on page 152](#)

Verifying the Junos OS Upgrade Installation

Purpose Verify that the Junos OS upgrade was installed.

Action From operational mode, enter the **show system** command.

- [Configure Administration User Accounts on page 174](#)

Installing Junos OS Upgrade Packages on SRX Series Devices from a Remote Server

You can use the J-Web user interface to install Junos OS packages that are retrieved with FTP or HTTP from the specified location.

NOTE: This procedure applies only to upgrading from one Junos OS release to another.

Before installing the Junos OS upgrade:

- Verify the available space on the internal media. See “[Preparing Your SRX Series Device for Junos OS Upgrades](#)” on page 147 and the *Junos OS Release Notes*
- Download the software package. See “[Downloading Software Packages from Juniper Networks](#)” on page 150.

To install Junos OS upgrades from a remote server:

1. In the J-Web user interface, select **Maintain>Software>Install Package**.
2. On the Install Remote page, enter the required information in the fields described in [Table 10](#).

Table 23: Install Package Summary

Field	Function	Your Action
Package Location (required)	Specifies the FTP or HTTP server, file path, and Junos OS package name.	Type the full address of the Junos OS package location on the FTP or HTTP server—one of the following: <i>ftp://hostname/pathname/package-name</i> <i>http://hostname/pathname/package-name</i>
User	Specifies the username, if the server requires one.	Type the username.
Password	Specifies the password, if the server requires one.	Type the password.
Reboot If Required	Specifies that the device is automatically rebooted when the upgrade is complete.	Check the box if you want the device to reboot automatically when the upgrade is complete.
Do not save backup (SRX Series devices)	Specifies that the backup copy of the current Junos OS package is not saved.	Check the box if you want to save the backup copy of the Junos OS package.
Format and re-partition the media before installation (SRX Series devices)	Specifies that the storage media is formatted and new partitions are created.	Check the box if you want to format the internal media with dual-root partitioning.

3. Click **Fetch and Install Package**. Junos OS is activated after the device reboots.

Understanding BIOS Upgrades on SRX Series Devices

Understanding Manual BIOS Upgrade Using the Junos CLI

For these SRX Series devices, the BIOS consists of a U-boot and the Junos loader. The SRX300, and SRX320 Service Gateways also include a U-shell binary as part of the BIOS. Additionally, on SRX300, SRX320, SRX340, and SRX345 Service Gateways, a backup BIOS is supported which includes a backup copy of the U-boot in addition to the active copy from which the system generally boots up.

Table 24 Lists the CLI commands used for manual BIOS upgrade.

Table 24: CLI Commands for Manual BIOS Upgrade

Active BIOS	Backup BIOS
<code>request system firmware upgrade re bios</code>	<code>request system firmware upgrade re bios backup</code>

BIOS upgrade procedure:

1. **Install the jloader-srxsme package.**

1. Copy the jloader-srxsme signed package to the device.

NOTE: The version of the jloader-srxsme package you install must match the version of Junos OS.

2. Install the package using the `request system software add <path to jloader-srxsme package> no-copy no-validate` command.

NOTE: Installing the jloader-srxsme package places the necessary images under directory/boot.

2. Verify that the required images for upgrade are installed. Use the `show system firmware` to verify that the correct BIOS image version is available for upgrade.
3. Upgrade the BIOS (Active and backup) image.

Active BIOS:

1. Initiate the upgrade using the `request system firmware upgrade re bios` command.
2. Monitor the upgrade status using the `show system firmware` command.

NOTE: The device must be rebooted for the upgraded active BIOS to take effect.

Backup BIOS:

1. Initiate the upgrade using the **request system firmware upgrade re bios backup** command.
2. Monitor the upgrade status using the **show system firmware** command.

Understanding Auto BIOS Upgrade Methods on SRX Series Devices

The BIOS version listed in the **bios-autoupgrade.conf** file is the minimum supported version. If the current device has a BIOS version earlier than the minimum compatible version, then the auto BIOS upgrade feature upgrades the BIOS automatically to the latest version.

The BIOS upgrades automatically in the following scenarios:

- During Junos OS upgrade through either the J-Web user interface or the CLI (using the **request system software add no-copy no-validate software-image**). In this case, only the active BIOS is upgraded.
- During loader installation using TFTP or USB (using the **install tftp:///software-image** command). In this case, only the active BIOS is upgraded.
- During system boot-up. In this case, both the active BIOS and the backup BIOS are upgraded.

- [Installing Junos OS on SRX Series Devices from the Boot Loader Using a USB Storage Device on page 72](#)
- [Disabling Auto BIOS Upgrade on SRX Series Devices on page 155](#)

Disabling Auto BIOS Upgrade on SRX Series Devices

The auto BIOS upgrade feature is enabled by default. You can disable the feature using the CLI in operational mode.

To disable the automatic upgrade of the BIOS on an SRX Series device, set the **chassis routing-engine bios** command.

```
user@host> set chassis routing-engine bios no-auto-upgrade
```

NOTE: The command disables automatic upgrade of the BIOS only during Junos OS upgrade or system boot-up. It does not disable automatic BIOS upgrade during loader installation.

Example: Downgrading Junos OS on SRX Series Devices

This example shows how to downgrade Junos OS on the SRX Series devices.

- [Requirements on page 156](#)
- [Overview on page 156](#)
- [Configuration on page 156](#)
- [Verification on page 158](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

When you upgrade your software, the device creates a backup image of the software that was previously installed in addition to installing the requested software upgrade.

To downgrade the software, you can revert to the previous image using the backup image. You can use this method to downgrade to only the software release that was installed on the device before the current release. To downgrade to an earlier version, follow the procedure for upgrading, using the software image labeled with the appropriate release. This example returns software to the previous Junos OS version.

NOTE: This procedure applies only to downgrading from one Junos OS software release to another or from one Junos OS services release to another.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, enter:

```
user@host>
request system software rollback
```

request system reboot**GUI Step-by-Step Procedure**

To downgrade Junos OS on SRX Series devices:

1. In the J-Web user interface, select **Maintain>Software>Downgrade**. The image of the previous version (if any) appears on this page.

NOTE: After you perform this operation, you cannot undo it.

2. Select **Downgrade** to downgrade to the previous version of the software or **Cancel** to cancel the downgrade process.
3. Click **Maintain>Reboot** from the J-Web user interface to reboot the device.

NOTE: To downgrade to an earlier version, follow the procedure for upgrading, using the software image labeled with the appropriate release.

4. Click **OK** to check your configuration and save it as a candidate configuration.
5. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To downgrade Junos OS on SRX Series devices:

1. From operational mode, return to the previous Junos OS version.

```
user@host> request system software rollback
```

2. Reboot the device.

```
user@host> request system reboot
```

The device is now running the previous version of Junos OS. To downgrade to an earlier version, follow the procedure for upgrading, using the software image labeled with the appropriate release.

Results

From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Junos OS Downgrade Installation on page 158](#)

Verifying the Junos OS Downgrade Installation

Purpose Verify that the Junos OS downgrade was installed.

Action From operational mode, enter the **show system** command.

Booting a Device Using a System Snapshot

- [Understanding System Snapshot on EX Series Switches on page 159](#)
- [Creating a Snapshot and Using It to Boot an EX Series Switch on page 160](#)
- [Verifying That a System Snapshot Was Created on an EX Series Switch on page 161](#)
- [Booting an EX Series Switch Using a Software Package Stored on a USB Flash Drive on page 162](#)

Understanding System Snapshot on EX Series Switches

You can create copies of the software running a Juniper Networks EX Series Ethernet Switch using the system snapshot feature. The system snapshot feature takes a “snapshot” of the files currently used to run the switch and copies them to an alternate storage location. You can then use this snapshot to boot the switch at the next bootup or as a backup boot option.

The switch can boot from either internal flash media or external (USB) flash media. The contents of the snapshot vary depending on whether you create the snapshot on the media that the switch booted from or on the media that it did not boot from:

Snapshots are particularly useful for moving files onto USB flash drives. You cannot use the **copy** command or any other file-moving technique to move files from an internal memory source to USB memory on the switch.

- If you create the snapshot on the media that the switch did not boot from, the following partitions on the boot media are included in the snapshot: **root**, **altroot**, **var**, **var/tmp**, **config**.

The **root** partition is the primary boot partition, and the **altroot** partition is the backup boot partition.

- If you create the snapshot on the media that the switch booted from, the root partition that the switch booted from is copied to the alternate root partition. The **var**, **var/tmp**, and **config** partitions are not copied as part of the snapshot because they already exist on the boot media.

The system snapshot feature has the following limitations:

- You cannot use snapshots to move files to any destination outside the switch other than an installed external USB flash drive or switches that are members of the same Virtual Chassis as the switch on which you created the snapshot..
- Snapshot commands, like all commands executed on a Virtual Chassis, are executed on the local member switch. If different member switches request the snapshot, the snapshot command is pushed to the Virtual Chassis member creating the snapshot and is executed on that member, and the output is then returned to the switch that initiated the process. For instance, if the command to create an external snapshot on member 3 is entered on member 1, the snapshot of internal memory on member 3 is taken on external memory on member 3. The output of the process is seen on member 1. No files move between the switches.

Creating a Snapshot and Using It to Boot an EX Series Switch

The system snapshot feature takes a “snapshot” of the files currently used to run the switch and copies them to an alternate storage location. You can then use this snapshot to boot the switch at the next bootup or as a backup boot option.

This topic includes the following tasks:

- [Creating a Snapshot on a USB Flash Drive and Using It to Boot the Switch on page 160](#)

Creating a Snapshot on a USB Flash Drive and Using It to Boot the Switch

You can create a snapshot on USB flash memory after a switch is booted by using files stored in internal memory.

Ensure that you have the following tools and parts available before creating a snapshot on a USB flash drive:

- A USB flash drive that meets the switch USB port specifications. See *USB Port Specifications for an EX Series Switch*.

To create a snapshot on USB flash memory and use it to boot the switch:

1. Place the snapshot into USB flash memory:

```
user@switch> request system snapshot partition media usb
```
2. (Optional) Perform this step if you want to boot the switch now using the snapshot stored on the USB flash drive.

```
user@switch> request system reboot media usb
```

**Related
Documentation**

- [Verifying That a System Snapshot Was Created on an EX Series Switch on page 161](#)
- [Understanding System Snapshot on EX Series Switches on page 159](#)

Verifying That a System Snapshot Was Created on an EX Series Switch

Purpose Verify that a system snapshot was created with the proper files on an EX Series switch.

Action View the snapshot:

```
user@switch> show system snapshot media external
Information for snapshot on      external (/dev/da1s1a) (backup)
Creation date: Mar 19 03:37:18 2012
JUNOS version on snapshot:
  jbase : ex-12.1I20120111_0048_user
  jcrypto-ex: 12.1I20120111_0048_user
  jdocs-ex: 12.1I20120111_0048_user
  jroute-ex: 12.1I20120111_0048_user
  jswitch-ex: 12.1I20120111_0048_user
  jweb-ex: 12.1I20120111_0048_user
Information for snapshot on      external (/dev/da1s2a) (primary)
Creation date: Mar 19 03:38:25 2012
JUNOS version on snapshot:
  jbase : ex-12.2I20120305_2240_user
  jcrypto-ex: 12.2I20120305_2240_user
  jdocs-ex: 12.2I20120305_2240_user
  jroute-ex: 12.2I20120305_2240_user
  jswitch-ex: 12.2I20120305_2240_user
  jweb-ex: 12.2I20120305_2240_user
```

Meaning The output shows the date and time when the snapshot was created and the packages that are part of the snapshot. Check to see that the date and time match the time when you created the snapshot.

You can compare the output of this command to the output of the **show system software** command to ensure that the snapshot contains the same packages as the software currently running the switch.

Related Documentation

- [Creating a Snapshot and Using It to Boot an EX Series Switch on page 160](#)

Booting an EX Series Switch Using a Software Package Stored on a USB Flash Drive

There are two methods of getting Junos OS stored on a USB flash drive before using the software to boot the switch. You can pre-install the software onto the USB flash drive before inserting the USB flash drive into the USB port, or you can use the system snapshot feature to copy files from internal switch memory to the USB flash drive.

To move files into USB flash memory by using a system snapshot and use those files to boot the switch, see [“Creating a Snapshot and Using It to Boot an EX Series Switch” on page 160](#). We recommend that you use this method to boot the switch from a USB flash drive if your switch is running properly.

If you need to pre-install the software onto the USB flash drive, you can use the method described in this topic. Pre-installing Junos OS onto a USB flash drive to boot the switch can be done at any time and is particularly useful when the switch boots to the loader prompt because the switch cannot locate the Junos OS in internal flash memory.

Ensure that you have the following tools and parts available to boot the switch from a USB flash drive:

- A USB flash drive that meets the EX Series switch USB port specifications. See *USB Port Specifications for an EX Series Switch*.
- A computer or other device that you can use to download the software package from the Internet and copy it to the USB flash drive.

To download a Junos OS package onto a USB flash drive before inserting the USB flash drive:

1. Download the Junos OS package that you want to place onto the EX Series switch from the Internet onto the USB flash drive by using your computer or other device. See [“Downloading Software Packages from Juniper Networks” on page 51](#).
2. Remove the USB flash drive from the computer or other device.
3. Insert the USB flash drive into the USB port on the switch.
4. This step can be performed only when the prompt for the loader script (**loader>**) is displayed. The loader script starts when the Junos OS loads but the CLI is not working for any reason or if the switch has no software installed.

Install the software package onto the switch:

```
loader> install source
```

where **source** represents the name and location of the Junos OS package on the USB flash drive. The Junos OS package on a flash drive is commonly stored in the root drive as the only file—for example, **file:///jinstall-ex-4200-9.4R1.5-domestic-signed.tgz**.

- [Reverting to the Rescue Configuration on page 186](#)

Creating an Emergency Boot Device

If the device's Junos OS software is damaged in some way that prevents Junos OS software from loading completely, you can use the emergency boot device to revive the device. The emergency boot device repartitions the primary disk and reloads a fresh installation of Junos OS software.

The procedures outlined in this section discuss how to create an emergency boot device for any ACX Series, M Series, MX Series, T Series, TX Matrix, and TX Matrix Plus router.

To create an emergency boot device:

1. Use FTP to copy the installation media into the router's **/var/tmp** directory.
2. Insert the PC Card into the external PC Card slot or USB storage device into the USB port.
3. In the UNIX shell, navigate to the **/var/tmp** directory:

```
start shell
cd /var/tmp
```
4. Log in as **su**:

```
su [enter]
```

```
password: [enter SU password]
```

5. Issue the following commands:

```
dd if=/dev/zero of=/dev/externalDrive count=20
dd if=installMedia of=/dev/externalDrive bs=64k
```

where:

- **externalDrive**—Refers to the removable media name of the emergency boot device. For example, the removable media name for an emergency boot device on the M120 router is *da0* for both Routing Engines. For the names of the storage media, see [“Routing Engines and Storage Media Names \(ACX Series, M Series, MX Series, PTX Series, T Series, TX Matrix, TX Matrix Plus, and JCS 1200 Routers\)” on page 32](#).
- **installMedia**—Refers to the installation media downloaded into the */var/tmp* directory. For example, **install-media-9.0R2.10-domestic.tgz**.

The following code example can be used to create an emergency boot device using a PC Card on an M20 router:

```
dd if=/dev/zero of=/dev/ad3 count=20
dd if=install-media-9.0R2.10-domestic.tgz of=/dev/ad3 bs=64k
```

The following code example can be used to create an emergency boot device using a USB storage device on an M120 router or a TX Matrix Plus router:

```
dd if=/dev/zero of=/dev/da0 count=20
dd if=install-media-9.0R2.10-domestic.tgz of=/dev/da0 bs=64k
```

6. Log out as **su**:

```
exit
```

Configuring Boot Devices for SRX Series Devices

This topic includes the following sections:

- [Example: Creating a Snapshot and Using It to Boot an SRX Series Device on page 166](#)

Example: Creating a Snapshot and Using It to Boot an SRX Series Device

This example shows how to configure a boot device.

- [Requirements on page 166](#)
- [Overview on page 167](#)
- [Configuration on page 167](#)
- [Verification on page 168](#)

Requirements

Before you begin, ensure that the backup device has a storage capacity of at least 1 GB. See [“Preparing Your SRX Series Device for Junos OS Upgrades” on page 147](#).

Overview

You can configure a boot device to replace the primary boot device on your SRX Series device or to act as a backup boot device. Use either the J-Web user interface or the CLI to take a snapshot of the configuration currently running on the device, or of the original factory configuration and a rescue configuration, and save it to an alternate medium.

NOTE: For media redundancy, we recommend that you keep a secondary storage medium attached to the SRX Series device and updated at all times.

If the primary storage medium becomes corrupted and no backup medium is in place, you can recover the primary internal media from the TFTP installation.

You can also configure a boot device to store snapshots of software failures for use in troubleshooting.

NOTE: You cannot copy software to the active boot device.

NOTE: After a boot device is created with the default factory configuration, it can operate only in an internal media slot.

This example configures a boot device to back up the currently running and active file system partitions by rebooting from internal media and including only files shipped from the factory.

Configuration

CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, enter:

```
user@host> request system snapshot partition media internal factory
```

GUI Step-by-Step Procedure

To configure a boot device:

1. In the J-Web user interface, select **Maintain>Snapshot**.
2. On the Snapshot page, specify the boot device to copy the snapshot to. From the Target Media list, select the **internal** boot device.
3. Select the Factory check box to copy only default files that were loaded on the internal media when it was shipped from the factory, plus the rescue configuration if one has been set.

4. Select the Partition check box to partition the medium that you are copying the snapshot to. This process is usually necessary for boot devices that do not already have software installed on them.
5. Click **Snapshot**.
6. Click **OK** to check your configuration and save it as a candidate configuration.
7. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To configure a boot device:

From operational mode, create a boot device from the internal media including only files shipped from the factory that will be used to back up the currently running and active file system partitions.

```
user@host> request system snapshot partition media internal factory
```

Results From configuration mode, confirm your configuration by entering the **show system snapshot media internal** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host> show system snapshot media internal
```

```
Information for snapshot on      internal (/dev/ad0s1a) (backup)
Creation date: Oct 9 13:30:06 2009
JUNOS version on snapshot:
  junos : 10.0B3.10-domestic
Information for snapshot on      internal (/dev/ad0s2a) (primary)
Creation date: Jan 6 15:45:35 2010
JUNOS version on snapshot:
  junos : 10.2-20091229.2-domestic
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Snapshot Information on page 168](#)

Verifying the Snapshot Information

Purpose Verify that the snapshot information for both root partitions on SRX Series devices were configured.

Action From operational mode, enter the **show system snapshot media** command.

The command output displays the snapshot creation time and Junos OS Release version on a media for both the primary and backup roots.

NOTE: With the dual-root partitioning scheme, performing a snapshot to a USB storage device that is less than 1 GB is not supported.

NOTE: You can use the `show system snapshot media internal` command to determine the partitioning scheme present on the internal media. Information for only one root is displayed for single-root partitioning, whereas information for both roots is displayed for dual-root partitioning.

NOTE: Any removable media that has been formatted with dual-root partitioning will not be recognized correctly by the `show system snapshot CLI` command on systems that have single-root partitioning. Intermixing dual-root and single-root formatted media on the same system is strongly discouraged.

Related Documentation

- [Preparing Your SRX Series Device for Junos OS Upgrades on page 147](#)
- [Understanding Junos OS Upgrades for SRX Series Devices on page 145](#)
- [Example: Installing Junos OS Upgrade Packages on SRX Series Devices on page 150](#)

Understanding Integrity Check and Autorecovery of Configuration, Licenses, and Disk Information on SRX Series Devices

This topic includes the following sections:

- [Overview on page 169](#)
- [How Autorecovery Works on page 170](#)
- [How to Use Autorecovery on page 170](#)
- [Data That Is Backed Up in an Autorecovery on page 170](#)
- [Troubleshooting Alarms on page 171](#)
- [Considerations on page 171](#)

Overview

The autorecovery feature is supported on dual-partitioned SRX Series devices. With this feature, information on disk partitioning, configuration, and licenses is recovered automatically in the event it becomes corrupted.

Autorecovery provides the following functions:

- Detect corruption in disk partitioning during system bootup and attempt to recover partitions automatically

- Detect corruption in the Junos OS rescue configuration during system bootup and attempt to recover the rescue configuration automatically
- Detect corruption in Junos OS licenses during system bootup and attempt to recover licenses automatically

How Autorecovery Works

The feature works in the following ways:

- The feature provides the **request system autorecovery state save** command, which backs up important data such as disk partitioning information, licenses, and Junos OS rescue configuration.
- Once the backup copies are saved, they are used to check the integrity of the working copies of the data on every bootup.
- The working copies are automatically recovered if any corruption is detected.

How to Use Autorecovery

You use autorecovery in the following ways:

- Prepare the router for deployment with the necessary licenses and configuration.
- After you finalize the state, execute the **request system autorecovery state save** command to back up the state.
- After you save the state, integrity check and recovery actions (if any) occur automatically on every bootup.
- If subsequent maintenance activities change the state of the router by adding licenses or updating the configuration, you need to execute the **request system autorecovery state save** command again to update the saved state.
- Execute the **show system autorecovery state** command any time to view the status of the saved information and the integrity check status of each saved item.
- Execute the **request system autorecovery state clear** command to delete all backed up data and disable autorecovery, if required.

Data That Is Backed Up in an Autorecovery

The following data is backed up during the autorecovery process:

- Rescue configuration (regenerated from the current configuration)
- License keys
- BSD labels (disk-partitioning information)

Data is backed up only when you execute the **request system autorecovery state save** command. Disk-partitioning information is backed up automatically from factory defaults (for new systems), on installation from the boot loader, and on snapshot creation.

Troubleshooting Alarms

Table 25 lists types of autorecovery alarms, descriptions, and required actions.

Table 25: Autorecovery Alarms

Alarm	Alarm Type	Description	Action Required
Autorecovery information needs to be saved	Minor	This alarm indicates: <ul style="list-style-type: none"> Unsaved data needs to be saved, or saved data contains problems and another save is required. 	<ul style="list-style-type: none"> Ensure that the system has all required licenses and configuration. Execute the request system autorecovery state save command.
Autorecovery has recovered corrupted information	Minor	This alarm indicates: <ul style="list-style-type: none"> Boot time integrity check failed for certain items; however, the items have been recovered successfully. 	<ul style="list-style-type: none"> No action is required. Alarm will be cleared on next bootstrap.
Autorecovery was unable to recover data completely	Major	This alarm indicates: <ul style="list-style-type: none"> Boot time integrity check failed for certain items, which could not be recovered successfully. 	<ul style="list-style-type: none"> The system might be experiencing a fatal malfunction.

Considerations

- Devices must have dual-root partitioning for autorecovery to work.
- The **request system configuration rescue save** command regenerates the rescue configuration from the current Junos OS configuration and then saves it. Therefore, executing the **save** command overwrites any existing rescue configuration.
- In general, the saved contents of the rescue configuration are not updated automatically. If you add licenses, you should execute the **request system autorecovery state save** command again.

NOTE: The rescue configuration is backed up. If /config is corrupted, the system boots from the rescue configuration.

Related Documentation

- [Example: Creating a Snapshot and Using It to Boot an SRX Series Device on page 166](#)
- [Example: Installing Junos OS Upgrade Packages on SRX Series Devices on page 150](#)
- [Example: Downgrading Junos OS on SRX Series Devices on page 156](#)

Performing a Recovery Installation

If the device's software is corrupted or otherwise damaged, you may need to perform a recovery installation, using the emergency boot device to restore the default factory installation. Once you have recovered the software you will need to restore the router or switch's configuration. You can either create a new configuration as you did when the device was shipped from the factory, or if you saved the device's previous configuration, you can simply restore that file to the system.

Depending on the situation, you should try to perform the following steps before you perform the recovery installation:

1. Ensure you have an emergency recovery disk to use during the installation. When the router or switch is first shipped, an emergency recovery disk is provided with it. For instructions on creating an emergency boot device, see ["Creating an Emergency Boot Device" on page 165](#)
2. Copy the existing configuration in the file `/config/juniper.conf.gz` from the device to a remote system. For extra safety, you can also copy the backup configurations (the files named `/config/juniper.conf.n`, where *n* is a number from 0 through 9).

WARNING: The recovery installation process completely overwrites the entire contents of the fixed storage media.

3. Copy any other stored files to a remote system as desired.

To reinstall Junos OS:

1. Insert the removable media emergency boot device into the device.

NOTE: You can store a configuration on installation media such as a PC Card or USB stick.

2. Reboot the device.

If the CLI is still active, issue the **request system reboot** command from command mode to reboot the device.

If the CLI is not working, manually power off the device using the main power switch, wait 10 seconds, and then power the device back on.

3. When the software prompts you with the following question, type **y**:

WARNING: The installation will erase the contents of your disk. Do you wish to continue (y/n)? **y**

The device copies the software from the removable media emergency boot device onto your system, occasionally displaying status messages. Copying the software can take up to 45 minutes depending on the device. When the process is complete, the router boots into Amnesiac state and the login prompt is displayed.

4. Remove the removable media emergency boot device.
5. Login as root on the device's console port and issue the **request system reboot** command from command mode to reboot the device.

The device reboots from the boot device on which the software was just installed. When the reboot is complete, the device displays the login prompt.

6. Create a new configuration as you did when the device was shipped from the factory, or restore a previously saved configuration file to the system. For more information, see [“Creating a New Configuration on a Single Routing Engine” on page 173](#), [“Creating a New Configuration with Redundant Routing Engines” on page 177](#), and [“Restoring a Saved Configuration” on page 184](#).

Creating a New Configuration on a Single Routing Engine

To create a new base configuration on a single Routing Engine:

- [Log In to the Router Console on page 173](#)
- [Configure Administration User Accounts on page 174](#)
- [Add the Management Console to the Network on page 174](#)
- [Commit Changes on page 175](#)

Log In to the Router Console

To log in to the device's console interface and open the CLI in configuration mode:

1. Verify the device is powered on.
2. Log in through the console port as root.

```
Amnesiac <tttyd0>
```

```
login: root
```

NOTE: From the factory, the root administration user account is not associated with a password. However, you must add a password to the root administration account before you can successfully commit a configuration.

3. Start the CLI, which initially opens in operational mode. Note the command prompt ends with > in the CLI operational mode.

```
root@% cli
root>
```

4. Enter the CLI configuration mode. Note the command prompt ends with # in the CLI configuration mode.

```
root> configure
[edit]
root#
```

Configure Administration User Accounts

Set the root administration user account password. You also need to set up one or more administration user accounts. These administration user accounts are used to log in to the device through the management console. To configure administration user accounts:

1. Add a password to the root (superuser) administration user account.

```
[edit]
root# set system root-authentication plain-text-password
New password: password
Retype new password: password
```

2. Create a management console user account.

```
[edit]
root# set system login user user-name authentication plain-text-password
New Password: password
Retype new password: password
```

3. Set the user account class to **super-user**.

```
[edit]
root# set system login user user-name class super-user
```

Add the Management Console to the Network

To add the management console to the network:

1. Specify the device hostname.

NOTE: The hostname specified in the device configuration is not used by the DNS server to resolve to the correct IP address. This hostname is used to display the name of the Routing Engine in the CLI. For example, this hostname appears on the command line prompt when the user is logged in to the CLI:

```
user-name@host-name>
```

```
[edit]
root# set system host-name host-name
```

2. Configure the IP address of the DNS server.

```
[edit]
root# set system name-server address
```

3. Configure the router or switch domain name.

```
[edit]
root# set system domain-name domain-name
```

4. Configure the IP address and prefix length for the router or switch Ethernet interface.

- For all devices *except* the TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers:

```
[edit]
```

```
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- For TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix only, and PTX Series Packet Transport Routers:

```
[edit]
```

```
root@# set interfaces em0 unit 0 family inet address address/prefix-length
```

To use **em0** as an out-of-band management Ethernet interface, you must configure its logical port, **em0.0**, with a valid IP address.

- For a T1600 standalone router (not connected to a TX Matrix Plus router and not in a routing matrix):

```
[edit]
```

```
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- Configure the IP address of a backup router. The backup router is used while the local router is booting and if the routing process fails to start. Once the routing process starts, the backup router address is removed from the local routing and forwarding tables. For more information about the backup router, see the *Getting Started Guide for Routing Devices*.

```
[edit]
```

```
root# set system backup-router address
```

- (Optional) Configure the static routes to remote subnets with access to the management port. Access to the management port is limited to the local subnet. To access the management port from a remote subnet, you need to add a static route to that subnet within the routing table.

```
[edit]
```

```
root# set routing-options static route remote-subnet next-hop destination-IP retain no-readvertise
```

- Configure telnet service at the **[edit system services]** hierarchy level.

```
[edit]
```

```
root# set system services telnet
```

Commit Changes

Now that you have completed your changes to the configuration file, commit the configuration changes.

- Before committing the configuration, you can review your changes to the configuration with the **show** command.

```
root# show
## Last changed: 2008-08-27 22:30:42 UTC
version 9.3B1.5;
system {
  host-name tp8;
  domain-name subnet.device1.example.com;
  backup-router 192.168.71.254;

```

```
        172.17.28.101;
    }
    login {
        user PE1 {
            class super-user;
            authentication {
                encrypted-password "$ABC123"; ## SECRET-DATA
            }
        }
    }
    services {
        telnet;
    }
    syslog {
        user * {
            any emergency;
        }
        file messages {
            any notice;
            authorization info;
        }
        file interactive-commands {
            interactive-commands any;
        }
    }
}
interfaces {
    fxp0 {
        unit 0 {
            family inet {
                address 192.168.69.205/21;
            }
        }
    }
}
routing-options {
    static {
        route 172.16.0.0/12 {
            next-hop 192.168.71.254;
            retain;
            no-readvertise;
        }
        route 192.168.0.0/16 {
            next-hop 192.168.71.254;
            retain;
            no-readvertise;
        }
    }
}
```

On a TX Matrix Plus router and PTX Series Packet Transport Routers, the management Ethernet interface is **em0** and not **fxp0**. Therefore, when you issue the **show** command in the configuration mode, the configuration statements would be:

```
[edit]
root@ show
system {
    host-name hostname;
    domain-name domain.name;
    backup-router address;
    root-authentication {
```

```

        (encrypted-password "password" | public-key);
        ssh-rsa "public-key";
        ssh-dsa "public-key";
    }
    name-server {
        address;
    }
    interfaces {
        em0 {
            unit 0 {
                family inet {
                    address address ;
                }
            }
        }
    }
}

```

2. Commit the configuration.

```

[edit]
root# commit
commit complete

```

NOTE: If you receive an error message after you issue the `commit` statement, you can review the configuration using the `show` command to find the errors in your configuration. You can delete incorrect entries using the `delete` command. For example, to delete a hostname from the configuration, issue the following statement:

```

[edit]
root# delete system host-name host-name

```

3. Exit configuration mode.

```

[edit]
root# exit
Exiting configuration mode

root>

```

Creating a New Configuration with Redundant Routing Engines

To create a new base configuration on a router with redundant Routing Engines:

- [Configure Administration User Accounts on page 178](#)
- [Set Up Routing Engine Configuration Groups on page 178](#)
- [Complete the Management Console Configuration on page 180](#)
- [Commit and Synchronize Changes on page 181](#)

Configure Administration User Accounts

Set the root administration user account password. You also need to set up one or more administration user accounts. These administration user accounts are used to log in to the device through the management console. To configure administration user accounts:

1. Add a password to the root (superuser) administration user account.

```
[edit]
root# set system root-authentication plain-text-password
New password: password
Retype new password: password
```

2. Create a management console user account.

```
[edit]
root# set system login user user-name authentication plain-text-password
New Password: password
Retype new password: password
```

3. Set the user account class to **super-user**.

```
[edit]
root# set system login user user-name class super-user
```

Set Up Routing Engine Configuration Groups

In a router with two Routing Engines, one configuration should be shared between both Routing Engines. This ensures that both Routing Engine configurations are identical. Within this configuration, create two Routing Engine groups, one for each Routing Engine. Within these groups, you specify the Routing Engine–specific parameters.

For more information about creating configuration groups, see *CLI User Guide*.

For more information about the initial configuration for redundant Routing Engine systems and the re0 group, see *Junos OS High Availability Library for Routing Devices*.

1. Create the configuration group **re0**. The **re0** group is a special group designator that is only used by **RE0** in a redundant routing platform.

```
[edit]
root# set groups re0
```

2. Navigate to the **groups re0** level of the configuration hierarchy.

```
[edit]
root# edit groups re0
```

3. Specify the router hostname.

```
[edit groups re0]
root# set system host-name host-name
```

NOTE: The hostname specified in the router configuration is not used by the DNS server to resolve to the correct IP address. This hostname is used to display the name of the Routing Engine in the CLI. For example, the hostname appears at the command-line prompt when the user is logged in to the CLI:

```
user-name@host-name>
```

4. Configure the IP address and prefix length for the router Ethernet interface.

- For all devices *except* the TX Matrix Plus router, T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- For TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix only, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces em0 unit 0 family inet address address/prefix-length
```

To use **em0** as an out-of-band management Ethernet interface, you must configure its logical port, **em0.0**, with a valid IP address.

- For a T1600 standalone router (not connected to a TX Matrix Plus router and not in a routing matrix):

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

5. Return to the top level of the hierarchy.

```
[edit groups re0]
root# top
```

6. Create the configuration group **re1**.

```
[edit]
root# set groups re1
```

7. Navigate to the **groups re1** level of the configuration hierarchy.

```
[edit]
root# edit groups re1
```

8. Specify the router hostname.

```
[edit groups re1]
root# set system host-name host-name
```

9. Configure the IP address and prefix length for the router Ethernet interface.

- For all devices *except* the TX Matrix Plus router, T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- For TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix only:

```
[edit]
root@# set interfaces em0 unit 0 family inet address address/prefix-length
```

To use **em0** as an out-of-band management Ethernet interface, you must configure its logical port, **em0.0**, with a valid IP address.

- For a T1600 standalone router (not connected to a TX Matrix Plus router, and not in a routing matrix):

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

10. Return to the top level of the hierarchy.

```
[edit groups re0]
root# top
```

11. Specify the group application order.

```
[edit]
root# set apply-groups [ re0 re1 ]
```

Complete the Management Console Configuration

To configure the global management console parameters.

1. Configure the IP address of the DNS server.

```
[edit]
root# set system name-server address
```

2. Configure the router domain name.

```
[edit]
root# set system domain-name domain-name
```

3. Configure the IP address of a backup router. The backup router is used while the local router is booting and if the routing process fails to start. Once the routing process starts, the backup router address is removed from the local routing and forwarding tables. For more information about the backup router, see the *Getting Started Guide for Routing Devices*.

```
[edit]
root# set system backup-router address
```

4. (Optional) Configure the static routes to remote subnets with access to the management port. Access to the management port is limited to the local subnet. To access the management port from a remote subnet, you need to add a static route to that subnet within the routing table.

```
[edit]
root# set routing-options static route remote-subnet next-hop destination-IP retain
no-readvertise
```

5. Configure telnet service at the **[edit system services]** hierarchy level.

```
[edit]
root# set system services telnet
```

Commit and Synchronize Changes

Commit the configuration changes. When you issue the **synchronize** command, the configuration is shared between both Routing Engines and committed on both Routing Engines simultaneously.

1. Before committing the configuration, you can review the configuration entries using the **show** command.

```

root# show
## Last changed: 2008-10-17 18:32:25 UTC
version 9.1R1.8;
groups {
  re0 {
    system {
      host-name spice-re0;
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 192.168.69.155/21;
          }
        }
      }
    }
  }
  re1 {
    system {
      host-name spice-re1;
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address 192.168.70.72/21;
          }
        }
      }
    }
  }
}
global;
}
apply-groups [ re0 re1 ];
system {
  domain-name devicex.example.com;
  backup-router 192.168.71.254;
  root-authentication {
    encrypted-password "$ABC123"; ## SECRET-DATA
  }
  name-server {
    192.168.1.1;
  }
  login {
    user user1 {
      uid 2001;
      class super-user;
      authentication {
        encrypted-password "$ABC123"; ## SECRET-DATA
      }
    }
  }
}

```

```
    }  
  }  
  services {  
    telnet;  
  }  
  syslog {  
    user * {  
      any emergency;  
    }  
    file messages {  
      any notice;  
      authorization info;  
    }  
    file interactive-commands {  
      interactive-commands any;  
    }  
  }  
}  
routing-options {  
  static {  
    /* corporate office */  
    route 172.16.0.0/12 {  
      next-hop 192.168.71.254;  
      retain;  
      no-readvertise;  
    }  
  }  
}
```

2. Commit and synchronize the configuration. The **commit synchronize** command commits this new configuration on both Routing Engines simultaneously.

```
[edit]  
root# commit synchronize  
re0:  
configuration check succeeds  
re1:  
commit complete  
re0:  
commit complete
```

If you receive an error message after you issue the **commit** statement, you can review the configuration using the **show** command to find the errors in your configuration. You can delete incorrect entries using the **delete** command. For example, to delete a hostname from the configuration, issue the following command:

```
[edit]  
root# delete system host-name host-name
```

3. Exit configuration mode.

```
[edit]  
root# exit  
Exiting configuration mode  
  
root>
```

Saving a Rescue Configuration File

A rescue configuration file is helpful in the event that your device's configuration file has been misconfigured. You can restore the device to this rescue configuration to bring the device back online. If you save this file off the device, the rescue configuration can also be used to restore your device in the event of a software failure.

To save a current device configuration as a rescue configuration file:

1. Edit the configuration file on the device to reflect the base configuration you wish to use.

For more information about editing the configuration, see *Overview for Routing Devices*.

2. In the CLI operational mode, save this edited base configuration as the rescue configuration file:

```
user@host> request system configuration rescue save
```

The rescue configuration file is automatically saved under **/config** directory.

3. Copy the rescue configuration to a remote server:

```
user@host1> cd /config/
user@host1> ls -ltr rescue.conf.gz

user@host1 ftp host2
Name: username
Password: password
User user logged in.
ftp> cd /var/tmp
ftp> lcd /config
ftp> bi
ftp> put rescue.conf.gz
local: rescue.conf.gz remote: rescue.conf.gz

Transfer complete.
ftp> bye
Goodbye.
```

To roll back to the rescue configuration, use the **rollback rescue** command.

```
user@host# rollback rescue
```

```
load complete
```

NOTE: After rolling back to the rescue configuration, you must commit the configuration to activate it:

```
user@host#commit
```

Restoring a Saved Configuration

To restore a saved configuration, perform the following tasks:

1. [Copy Saved Files to the Router on page 184](#)
2. [Loading and Committing the Configuration File on page 184](#)

Copy Saved Files to the Router

To copy the saved configuration to the router:

1. Log in to the console as **root**. There is no password.

```
Escape character is '^['.  
[Enter]  
router (ttyd0)
```

```
login: root  
Password: [Enter]
```

Initially, access to the router is limited to the console port after a recovery installation. Access through the management ports and interfaces is set in the configuration. For information about accessing the router through the console port, see the administration guide for your particular router.

2. Start the CLI:

```
# cli
```

3. Copy the configuration file on the remote server to the router's **/var/tmp** directory:

```
root@host> ftp remote-server  
user: username  
password: password  
ftp> bin  
Type set to I.  
ftp> get /path/file  
ftp> bye  
Goodbye.
```

Loading and Committing the Configuration File

Once the saved configuration file is copied to the router, you load and commit the file:

1. Start the CLI configuration mode.

```
user@routername> configure  
Entering configuration mode
```

```
[edit]  
user@host#
```

2. Load the file into the current configuration. You should override the existing file.

```
user@host#  
load override /var/tmp/filename  
load complete
```

3. Commit the file.

```
user@host# commit
commit complete
```

4. Exit the CLI configuration mode.

```
user@host# exit
user@host>
```

5. Back up Junos OS.

After you have installed the software on the router, committed the configuration, and are satisfied that the new configuration is successfully running, issue the **request system snapshot** command to back up the new software to the **/altconfig** file system. If you do not issue the **request system snapshot** command, the configuration on the alternate boot drive will be out of sync with the configuration on the primary boot drive.

The **request system snapshot** command causes the root file system to be backed up to **/altroot**, and **/config** to be backed up to **/altconfig**. The root and **/config** file systems are on the router's CompactFlash card, and the **/altroot** and **/altconfig** file systems are on the router's hard disk or solid-state drive (SSD).

Reverting to the Default Factory Configuration by Using the **request system zeroize** Command

The **request system zeroize** command is a standard Junos OS operational mode command that removes all configuration information and resets all key values. The operation unlinks all user-created data files, including customized configuration and log files, from their directories. The switch then reboots and reverts to the factory-default configuration.

To completely erase user-created data so that it is unrecoverable, use the **request system zeroize media** command.

CAUTION: Before issuing **request system zeroize**, use the **request system snapshot** command to back up the files currently used to run the switch to a secondary device.

To revert to the factory-default configuration by using the **request system zeroize** command:

1. `user@switch> request system zeroize`
warning: System will be rebooted and may not boot without configuration
Erase all data, including configuration and log files? [yes,no] (yes)
2. Type **yes** to remove configuration and log files and revert to the factory default configuration.
3. Complete the initial configuration of the switch.

Related Documentation • [request system zeroize on page 377](#)

Reverting to the Rescue Configuration

If someone inadvertently commits a configuration that denies management access to a device and the console port is not accessible, you can overwrite the invalid configuration and replace it with the rescue configuration. The rescue configuration is a previously committed, valid configuration.

To revert the switch to the rescue configuration:

1. Enter the **load override** command.

```
[edit]  
user@switch# load override filename
```

2. Commit your changes.

```
[edit]  
user@switch# commit filename
```

jroute-dd release 5.0R5 built by builder on 2002-03-02 04:41:21 UTC
jdocs-dd release 5.0R5 built by builder on 2002-03-02 04:39:11 UTC
```

Meaning The sample output shows the hostname, router model, and the different Junos OS packages, processes, and documents.

Log the Hardware Version Information

Purpose You should log hardware version information in the rare event that a router cannot successfully reboot and you cannot obtain the Routing Engine serial number. The Routing Engine serial number is necessary for Juniper Networks Technical Assistance Center (JTAC) to issue a return to manufacturing authorization (RMA). Without the Routing Engine serial number, an onsite technician must be dispatched to issue the RMA.

Action To log the router chassis hardware version information, use the following Junos OS CLI operational mode command:

```
user@host> show chassis hardware | save filename
```

Sample Output The output for the M-series routers varies depending on the chassis components of each router. All routers have a chassis, midplanes or backplanes, power supplies, and Flexible

PIC Concentrators (FPCs). Refer to the hardware guides for information about the different chassis components.

```
user@host> show chassis hardware | save test
Wrote 43 lines of output to 'test'
```

```
user@host> show chassis hardware
Item          Version  Part number  Serial number  Description
Chassis                               101          M160
Midplane      REV 02   710-001245   S/N AB4107
FPM CMB       REV 01   710-001642   S/N AA2911
FPM Display   REV 01   710-001647   S/N AA2999
CIP           REV 02   710-001593   S/N AA9563
PEM 0         Rev 01   740-001243   S/N KJ35769    DC

PIC 0         REV 01                                1x OC-192 SM SR-2
```

Meaning The sample output shows the hardware inventory for an M160 router with a chassis serial number of 101. For each component, the output shows the version number, part number, serial number, and description.

Log the Chassis Environment Information

Action To log the router chassis environment information, use the following Junos OS CLI operational mode command:

```
user@host> show chassis environment | save filename
```

Sample Output The following example shows output from the `show chassis environment` command for an M5 router:

```
user@m5-host> show chassis environment | save test
Wrote 14 lines of output to 'test'
```

```
user@m5-host> show chassis environment
Class Item          Status  Measurement
Power Power Supply A  OK
        Power Supply B  OK
Temp  FPC Slot 0      OK      32 degrees C / 89 degrees F
```

	FEB	OK	31 degrees C / 87 degrees F
	PS Intake	OK	26 degrees C / 78 degrees F
	PS Exhaust	OK	31 degrees C / 87 degrees F
Fans	Left Fan 1	OK	Spinning at normal speed
	Left Fan 2	OK	Spinning at normal speed
	Left Fan 3	OK	Spinning at normal speed
	Left Fan 4	OK	Spinning at normal speed

Meaning The sample output shows the environmental information about the router chassis, including the temperature and information about the fans, power supplies, and Routing Engine.

Log the System Boot-Message Information

Action To log the system boot-message information, use the following Junos OS CLI operational mode command:

```
user@host> show system boot-messages | save filename
```

```

Sample Output user@host> show system boot-messages | save test
Wrote 80 lines of output to 'test'

user@host> show system boot-messages

/dev/rwd1s1f: clean, 4301055 free (335 frags, 537590 blocks, 0.0% fragmentation)
```

Meaning The sample output shows the initial messages generated by the system kernel upon boot. This is the content of the `/var/run/dmesg.boot` file.

Log the Active Configuration

Action To log the active configuration on the router, use the following Junos OS CLI operational mode command:

```
user@host> show configuration | save filename
```

Sample Output user@host> show configuration | save test
Wrote 4076 lines of output to 'test'

```
user@host> show configuration
system {
  host-name lab8;
  domain-name device1.example.com;
  backup-router 10.1.1.254;
    time-zone America/Los_Angeles;
  default-address-selection;
    dump-on-panic;
  name-server {
  [...Output truncated...]
```

Meaning The sample output shows the configuration currently running on the router, which is the last committed configuration.

Log the Interfaces on the Router

Action To log the interfaces on the router, use the following Junos OS CLI operational mode command:

```
user@host> show interface terse | save filename
```

Sample Output user@host> show interfaces terse | save test
Wrote 81 lines of output to 'test'

```

user@host> show interfaces terse
Interface      Admin Link Proto Local Remote
at-1/3/0       up    up
at-1/3/0.0     up    up    inet  1.0.0.1    --> 1.0.0.2
               iso
fxp0           up    up
fxp0.0         up    up    inet  10.168.5.59/24

so-2/0/0.0     up    up    inet  1.2.3.4      --> 1.2.3.5
               iso
[...Output truncated...]

```

Meaning The sample output displays summary information about the physical and logical interfaces on the router.

Log the BGP, IS-IS, and OSPF Adjacency Information

Purpose The following commands log useful information about Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), and Open Shortest Path First (OSPF) protocols. If you have other protocols installed, such as Multiprotocol Label Switching (MPLS), Resource Reservation Protocol (RSVP), or Protocol Independent Multicast (PIM), you also might log summary information for them.

Action To log the protocol peer information, use the following Junos OS CLI operational mode commands:

```

user@host> show bgp summary | save filename
user@host> show isis adjacency brief | save filename
user@host> show ospf neighbor brief | save filename

```

Sample Output 1 user@host> show bgp summary | save test
Wrote 45 lines of output to 'test'

```

user@host> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table          Tot Paths  Act Paths Suppressed    History Damp State   Pending
inet.0          4          4          0          0          0          0

so-2/0/0.0 1921.6800.5066 2 Up          19
so-2/1/0.0 1921.6800.5066 2 Up          17
so-2/2/0.0 1921.6800.5066 2 Up          20
so-2/3/0.0 1921.6800.5066 2 Up          20
so-5/0/0.0 ranier      2 Up          17

```

Sample Output 3 user@host> show ospf neighbor brief | save test
Wrote 10 lines of output to 'test'

```

user@host> show ospf neighbor brief
Address      Intf      State      ID          Pri  Dead
10.168.254.225 fxp3.0    2Way       10.250.240.32 128  36
10.168.254.230 fxp3.0    Full       10.250.240.8  128  38
10.168.254.229 fxp3.0    Full       10.250.240.35 128  33
10.1.1.129      fxp2.0    Full       10.250.240.12 128  37
10.1.1.131      fxp2.0    Full       10.250.240.11 128  38
10.1.2.1        fxp1.0    Full       10.250.240.9  128  32
10.1.2.81       fxp0.0    Full       10.250.240.10 128  33

```

Meaning Sample output 1 displays summary information about BGP and its neighbors. Sample output 2 displays information about IS-IS neighbors. Sample output 3 displays information about all OSPF neighbors.

Log the System Storage Information

Action To log the system storage statistics for the amount of free disk space in the router's file system, use the following Junos OS CLI operational mode command:

```
user@host> show system storage | save filename
```

Sample Output user@host> show system storage | save test
Wrote 14 lines of output to 'test'

```
user@host> show system storage
Filesystem 1K-blocks    Used    Avail Capacity  Mounted on
/dev/ad0s1a  65687    26700   33733    44%      /
devfs        16        16        0   100%    /dev/
/dev/vn1     9310     9310        0   100%    /packages/mnt/jbase
/dev/vn2     8442     8442        0   100%    /packages/mnt/jkernel-5.0R5.1
/dev/vn3    11486    11486        0   100%    /packages/mnt/jpfe-5.0R5.1
/dev/vn4     5742     5742        0   100%    /packages/mnt/jroute-5.0R5.1
/dev/vn5     1488     1488        0   100%    /packages/mnt/jcrypto-5.0R5.1
/dev/vn6       792      792        0   100%    /packages/mnt/jdocs-5.0R5.1
mfs:2373    1015815        3  934547     0%    /tmp
/dev/ad0s1e  25263        11  23231     0%    /config
procfs        4         4        0   100%    /proc
/dev/ad1s1f  9825963  1811085  7228801    20%    /var
```

Meaning The sample output displays statistics about the amount of free disk space in the router's file system. Values are displayed in 1024-byte (1-KB) blocks.

Back Up the Currently Running and Active File System

Action To back up the currently running and active file system so that you can recover to a known, stable environment in case there is a problem during the reinstall, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

Sample Output user@host> request system snapshot
umount: /altroot: not currently mounted
Copying / to /altroot.. (this may take a few minutes)
umount: /altconfig: not currently mounted
Copying /config to /altconfig.. (this may take a few minutes)
The following filesystems were archived: / /config

Meaning The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Reinstall Junos OS

Action To reinstall Junos OS, follow these steps:

1. Insert the removable medium (boot floppy) into the router.
2. Reboot the router, either by power-cycling it or by issuing the **request system reboot** command from the CLI.
3. At the following prompt, type **y**:

`WARNING: The installation will erase the contents of your disk. Do you wish to continue (y/n)?`

The router copies the software from the removable medium onto your system, occasionally displaying status messages. This can take up to 10 minutes.
4. Remove the removable medium when prompted.

The router reboots from the primary boot device on which the software is installed. When the reboot is complete, the router displays the login prompt.

Reconfigure Junos OS

Purpose After you have reinstalled the software, you must copy the router's configuration files back to the router. (You also can configure the router from scratch, as described in *Junos System Basics Configuration Guide*) However, before you can copy the configuration files, you must establish network connectivity.

To reconfigure the software, follow these steps:

1. [Configure Host Names, Domain Names, and IP Addresses on page 198](#)
2. [Protecting Network Security by Configuring the Root Password on page 200](#)
3. [Check Network Connectivity on page 201](#)
4. [Copy Backup Configurations to the Router on page 202](#)

Configure Host Names, Domain Names, and IP Addresses

Action To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

`root# cli`
`root@>`
3. Enter configuration mode:

`cli> configure`
`[edit]`
`root@#`
4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

`[edit]`
`root@# set system host-name host-name`
5. Configure the machine's domain name:

```
[edit]  
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]  
root@# set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

```
[edit]  
root@# set system backup-router address
```

8. Configure the IP address of a Domain Name Server (DNS) server:

```
[edit]  
root@# set system name-server address
```

Protecting Network Security by Configuring the Root Password

Configuring the root password on your Junos OS-enabled router helps prevent unauthorized users from making changes to your network. The root user (also referred to as superuser) has unrestricted access and full permissions within the system, so it is crucial to protect these functions by setting a strong password when setting up a new router.

After a new router is initially powered on, you log in as the user **root** with no password. Junos OS requires configuration of the root password before it accepts a commit operation. On a new device, the root password must always be a part of the configuration submitted with your initial commit.

To set the root password, you have a few options as shown in Step 1 of the following procedure.

- Enter a plain-text password that Junos OS encrypts.
- Enter a password that is already encrypted.
- Enter a secure shell (ssh) public key string.

The most secure options of these three are using an already encrypted password or an ssh public key string. Pre-encrypting your password or using a ssh public key string means the plain-text version of your password will never be transferred over the internet, protecting it from being intercepted by a man-in-the-middle attack.

.....

BEST PRACTICE: Optionally, instead of configuring the root password at the **[edit system]** hierarchy level, you can use a configuration group to strengthen security, as shown in Step 2 of this procedure. This step uses a group called **global** as an example.

.....

To set the root password:

1. Use one of these methods to configure the root password:

- To enter a plain-text password that the system encrypts for you:

```
[edit groups global system]
root@# set root-authentication plain-text-password
New Password: type password here
Retype new password: retry password here
```

If you use a plain-text password, Junos OS displays the password as an encrypted string so that users viewing the configuration cannot see it. As you enter the password in plain text, Junos OS encrypts it immediately. You do not have to configure Junos OS to encrypt the password as in some other systems. Plain-text passwords are hidden and marked as **## SECRET-DATA** in the configuration.

- To enter a password that is already encrypted:

CAUTION: Do not use the `encrypted-password` option unless the password is *already* encrypted, and you are entering the encrypted version of the password.

If you accidentally configure the `encrypted-password` option with a plain-text password or with blank quotation marks (""), you will not be able to log in to the device as root, and you will need to complete the root password recovery process.

```
[edit groups global system]
root@# set root-authentication encrypted-password password
```

- To enter an ssh public key string:

```
[edit groups global system]
root@# set root-authentication (ssh-dsa | ssh-eccdsa | ssh-rsa key)
```

2. (Optional) Strengthen security by only allowing root access from the console port.

```
[edit groups global system]
root@# set services ssh root-login deny
```

3. If you used a configuration group in Step 2, apply the configuration group, substituting **global** with the appropriate group name.

```
[edit]
user@host# set apply-groups global
```

4. Commit the changes.

```
root@# commit
```

Check Network Connectivity

Purpose Establish that the router has network connectivity.

Action To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the ***address*** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Copy Backup Configurations to the Router

Action To copy backup configurations to the router, follow these steps:

1. To copy the existing configuration and any backup configurations back onto the router, use the **file copy** command. Place the files in the **/var/tmp** directory.

```
user@host> file copy var/tmp/filename
```

2. Load and activate the desired configuration:

```
root@> configure
[edit]
root@# load merge/config/filename or load replace/config/filename
[edit]
root@# commit
```

Configure Host Names, Domain Names, and IP Addresses

Action To configure the machine name, domain name, and various addresses, follow these steps:

1. Log in as **root**. There is no password.
2. Start the CLI:

```
root# cli
root@>
```

3. Enter configuration mode:

```
cli> configure
[edit]
root@#
```

4. Configure the name of the machine. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit]
root@# set system host-name host-name
```

5. Configure the machine's domain name:

```
[edit]
root@# set system domain-name domain-name
```

6. Configure the IP address and prefix length for the router's management Ethernet interface:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address / prefix-length
```

7. Configure the IP address of a default router. This system is called the backup router because it is used only while the routing protocol process is not running.

[edit]

root@# **set system backup-router *address***

8. Configure the IP address of a Domain Name Server (DNS) server:

[edit]

root@# **set system name-server *address***

Protecting Network Security by Configuring the Root Password

Configuring the root password on your Junos OS-enabled router helps prevent unauthorized users from making changes to your network. The root user (also referred to as superuser) has unrestricted access and full permissions within the system, so it is crucial to protect these functions by setting a strong password when setting up a new router.

After a new router is initially powered on, you log in as the user **root** with no password. Junos OS requires configuration of the root password before it accepts a commit operation. On a new device, the root password must always be a part of the configuration submitted with your initial commit.

To set the root password, you have a few options as shown in Step 1 of the following procedure.

- Enter a plain-text password that Junos OS encrypts.
- Enter a password that is already encrypted.
- Enter a secure shell (ssh) public key string.

The most secure options of these three are using an already encrypted password or an ssh public key string. Pre-encrypting your password or using a ssh public key string means the plain-text version of your password will never be transferred over the internet, protecting it from being intercepted by a man-in-the-middle attack.

BEST PRACTICE: Optionally, instead of configuring the root password at the **[edit system]** hierarchy level, you can use a configuration group to strengthen security, as shown in Step 2 of this procedure. This step uses a group called **global** as an example.

To set the root password:

1. Use one of these methods to configure the root password:

- To enter a plain-text password that the system encrypts for you:

```
[edit groups global system]
root@# set root-authentication plain-text-password
New Password: type password here
Retype new password: retype password here
```

If you use a plain-text password, Junos OS displays the password as an encrypted string so that users viewing the configuration cannot see it. As you enter the password in plain text, Junos OS encrypts it immediately. You do not have to configure Junos OS to encrypt the password as in some other systems. Plain-text passwords are hidden and marked as **## SECRET-DATA** in the configuration.

- To enter a password that is already encrypted:

CAUTION: Do not use the `encrypted-password` option unless the password is *already* encrypted, and you are entering the encrypted version of the password.

If you accidentally configure the `encrypted-password` option with a plain-text password or with blank quotation marks (" "), you will not be able to log in to the device as root, and you will need to complete the root password recovery process.

```
[edit groups global system]
root@# set root-authentication encrypted-password password
```

- To enter an ssh public key string:

```
[edit groups global system]
root@# set root-authentication (ssh-dsa | ssh-eccdsa | ssh-rsa key)
```

2. (Optional) Strengthen security by only allowing root access from the console port.

```
[edit groups global system]
root@# set services ssh root-login deny
```

3. If you used a configuration group in Step 2, apply the configuration group, substituting **global** with the appropriate group name.

```
[edit]
user@host# set apply-groups global
```

4. Commit the changes.

```
root@# commit
```

Check Network Connectivity

Purpose Establish that the router has network connectivity.

Action To check that the router has network connectivity, issue a **ping** command to a system on the network:

```
root@> ping address
```

If there is no response, verify that there is a route to the **address** using the **show route** command. If the address is outside your **fxp0** subnet, add a static route. Once the backup configuration is loaded and committed, the static route is no longer needed and should be deleted.

Copy Backup Configurations to the Router

Action To copy backup configurations to the router, follow these steps:

1. To copy the existing configuration and any backup configurations back onto the router, use the **file copy** command. Place the files in the **/var/tmp** directory.

```
user@host> file copy var/tmp/filename
```

2. Load and activate the desired configuration:

```
root@> configure
[edit]
root@# load merge/config/filename or load replace/config/filename
[edit]
root@# commit
```

After You Reinstall Junos OS

To verify that the new version of the Junos OS is running as expected after the reinstall, follow these steps:

1. [Compare Information Logged Before and After the Reinstall on page 206](#)
2. [Back Up the New Software on page 207](#)

Compare Information Logged Before and After the Reinstall

Purpose Compare the operation of the system before and after the reinstall to ensure that everything is working as expected.

Action To obtain system information, use the following commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show chassis environment
user@host> show system boot-messages
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
```

```
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you obtained before the reinstall.

Back Up the New Software

Purpose After a week or so, when you are satisfied that the new software is running successfully, we recommend that you back up the reinstalled software.

Action To back up the reinstalled software, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Compare Information Logged Before and After the Reinstall

Purpose Compare the operation of the system before and after the reinstall to ensure that everything is working as expected.

Action To obtain system information, use the following commands:

```
user@host> show version
user@host> show chassis hardware
user@host> show chassis environment
user@host> show system boot-messages
user@host> show configuration
user@host> show interface terse
user@host> show bgp summary
user@host> show isis adjacency brief
user@host> show ospf neighbor brief
user@host> show system storage
```

Compare the information from these commands with the information you obtained before the reinstall.

Back Up the New Software

Purpose After a week or so, when you are satisfied that the new software is running successfully, we recommend that you back up the reinstalled software.

Action To back up the reinstalled software, use the following Junos OS CLI operational mode command:

```
user@host> request system snapshot
```

The root file system is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's internal flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.

NOTE: After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

Downgrading Software

- [Downgrading Junos OS from Upgraded FreeBSD on page 209](#)

Downgrading Junos OS from Upgraded FreeBSD

Starting with Junos OS Release 15.1, certain hardware platforms run a Junos OS based on an upgraded FreeBSD kernel instead of older versions of FreeBSD. If you have previously upgraded to Junos OS with upgraded FreeBSD, you can downgrade to earlier versions of Junos OS, as long as the downgrade conforms to the Junos OS policy of skipping at most two earlier releases.

Before you begin:

1. Verify that you have previously upgraded to Junos OS with the upgraded FreeBSD kernel, as described in [“Upgrading Junos OS with Upgraded FreeBSD” on page 139](#).
2. Download the Junos OS package.

Select and perform the procedure that matches your conditions:

- [Downgrading from Junos OS with Upgraded FreeBSD to Junos OS on page 209](#)
- [Downgrading from Junos OS with Upgraded FreeBSD to an Earlier Release of Junos OS with Upgraded FreeBSD on page 211](#)

Downgrading from Junos OS with Upgraded FreeBSD to Junos OS

This example uses the package `/var/tmp/jinstall-13.3R2.7-domestic-signed.tgz` to install Junos OS with a pre-upgraded FreeBSD kernel on the master Routing Engine (re0).

NOTE: The following procedure refers to routers, but it also applies to switches.

To downgrade from Junos OS with upgraded FreeBSD to Junos OS:

1. Enter the **request system software add *package-name* no-validate reboot** command from the operational mode in the CLI.

Use the **no-validate** and **reboot** options with the **request system software add** command. If you leave out the **no-validate** option, the command uses the **validate** option by

default, and direct validation of running configuration does not work for downgrading to Junos OS from Junos OS with upgraded FreeBSD.

NOTE: To validate current configuration on an downgrade to Junos OS from Junos OS with upgraded FreeBSD, use the `request system software validate on (Junos OS with Upgraded FreeBSD)` command.

If you leave out the **reboot** option, you can take care of that in a separate reboot step.

The following example uses the **re0** option:

```
user@host>request system software add
/var/tmp/jinstall-13.3R2.7-domestic-signed.tgz re0 no-validate reboot
THIS IS A SIGNED PACKAGE Saving the config files ...
NOTICE: uncommitted changes have been saved in
/var/db/config/juniper.conf.pre-install Rebooting. Please wait ...
shutdown: [pid 11001] Shutdown NOW! *** FINAL System shutdown message
from root@host *** System going down IMMEDIATELY Shutdown NOW! System
shutdown time has arrived\x07\x07 users@host> Connection to
device1.example.com closed by remote host. Connection to
device1.example.com closed. ... user@router> show version
Hostname: host
Model: mx240
Junos: 13.3R2.7
JUNOS Base OS boot [13.3R2.7]
JUNOS Base OS Software Suite [13.3R2.7]
JUNOS Kernel Software Suite [13.3R2.7]
JUNOS Crypto Software Suite [13.3R2.7]
JUNOS Packet Forwarding Engine Support (M/T/EX Common) [13.3R2.7]
JUNOS Packet Forwarding Engine Support (MX Common) [13.3R2.7]
JUNOS Online Documentation [13.3R2.7]
JUNOS Services AACL Container package [13.3R2.7]
...
```

2. Verify the downgrade of the software package.

```
user@host> show version
```

NOTE: The output shows the OS kernel, OS runtime, and other packages installed on the router.

Downgrading from Junos OS with Upgraded FreeBSD to an Earlier Release of Junos OS with Upgraded FreeBSD

This example uses the package `/var/tmp/jinstall-13.3R2.7-domestic-signed.tgz` to install Junos OS with a pre-upgraded FreeBSD kernel on the master Routing Engine (**re0**).

NOTE: The following procedure refers to routers, but it also applies to switches.

To downgrade from Junos OS with upgraded FreeBSD to an earlier release of Junos OS with upgraded FreeBSD:

1. Enter the **request system software add *package-name* validate reboot** command from the operational mode in the CLI:

Use the **validate** and **reboot** options with the **request system software add** command. The command uses the **validate** option by default.

If you leave out the **reboot** option, you can take care of that in a separate reboot step.
2. Verify the downgrade of the software package.

```
user@host> show version
```

NOTE: The output shows the OS kernel, OS runtime, and other packages installed on the router.

CHAPTER 13

Rebooting or Halting Software Processes on a Device

- [Restarting and Halting SRX Series Devices on page 213](#)
- [Bringing Chassis Components Online and Offline on SRX Series Devices on page 218](#)
- [Restarting the Chassis on SRX Series Devices on page 218](#)
- [Rebooting or Halting the EX Series Switch \(J-Web Procedure\) on page 219](#)

Restarting and Halting SRX Series Devices

This topic includes the following sections:

- [Rebooting SRX Series Devices on page 213](#)
- [Halting SRX Series Devices on page 215](#)
- [Bringing Chassis Components Online and Offline on SRX Series Devices on page 217](#)
- [Restarting the Chassis on SRX Series Devices on page 217](#)

Rebooting SRX Series Devices

This example shows how to reboot a SRX Series device.

- [Requirements on page 213](#)
- [Overview on page 213](#)
- [Configuration on page 214](#)
- [Verification on page 215](#)

Requirements

Before rebooting the device, save and commit any Junos OS updates.

Overview

This example shows how to reboot a device fifty minutes from when you set the time from the internal media while sending a text message of 'stop' to all system users before the device reboots.

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, enter:

```
user@host> request system reboot at 5 in 50 media internal message stop
```

GUI Step-by-Step Procedure To reboot a device:

1. In the J-Web user interface, select **Maintain>Reboot**.
2. Select **Reboot in 50 minutes** to reboot the device fifty minutes from the current time.
3. Select the **internal** (for SRX Series devices) boot device from the Reboot From Media list.
4. In the Message box, type **stop** as the message to display to any user on the device before the reboot occurs.
5. Click **Schedule**. The J-Web user interface requests confirmation to perform the reboot.
6. Click **OK** to confirm the operation.
 - If the reboot is scheduled to occur immediately, the device reboots. You cannot access J-Web until the device has restarted and the boot sequence is complete. After the reboot is complete, refresh the browser window to display the J-Web login page.
 - If the reboot is scheduled to occur in the future, the Reboot page displays the time until reboot. You have the option to cancel the request by clicking **Cancel Reboot** on the J-Web user interface Reboot page.
7. Click **OK** to check your configuration and save it as a candidate configuration.
8. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To reboot a device:

From operational mode, schedule a reboot of the device to occur fifty minutes from when you set the time from the internal media while sending a text message of 'stop' to all system users before the device reboots.

Enter:

```
user@host> request system reboot at 5 in 50 media internal message stop
```

Results From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Device Reboot on page 215](#)

Verifying the Device Reboot

Purpose Verify that the device rebooted.

Action From operational mode, enter the **show system** command.

Halting SRX Series Devices

This example shows how to halt a device.

- [Requirements on page 215](#)
- [Overview on page 215](#)
- [Configuration on page 215](#)
- [Verification on page 216](#)

Requirements

Before halting the device, save and commit any Junos OS updates.

Overview

When the device is halted, all software processes stop and you can access the device through the console port only. Reboot the device by pressing any key on the keyboard.

NOTE: If you cannot connect to the device through the console port, shut down the device by pressing and holding the power button on the front panel until the **POWER LED** turns off. After the device has shut down, you can power on the device by pressing the power button again. The **POWER LED** turns on during startup and remains steadily green when the device is operating normally.

This example shows how to halt the system and stop software processes on the device immediately.

Configuration

CLI Quick Configuration To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your

network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

From operational mode, enter:

```
user@host>request system halt at now
```

NOTE: The **request system halt** command used for halting the system and stopping software processes on the device is not supported on SRX1500 devices.

GUI Step-by-Step Procedure

To halt a device immediately:

1. In the J-Web user interface, select **Maintain>Reboot**.
2. Select **Halt Immediately**. After the software stops, you can access the device through the console port only.
3. Click **Schedule**. The J-Web user interface requests confirmation to halt.
4. Click **OK** to confirm the operation. If the device halts, all software processes stop and you can access the device through the console port only. Reboot the device by pressing any key on the keyboard.
5. Click **OK** to check your configuration and save it as a candidate configuration.
6. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To halt a device:

From operational mode, halt the SRX Series device immediately.

```
user@host> request system halt at now
```

Results

From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying the Device Halt on page 217](#)

Verifying the Device Halt

Purpose Verify that the device halted.

Action From operational mode, enter the **show system** command.

Bringing Chassis Components Online and Offline on SRX Series Devices

You can use the **request** commands to bring chassis components online and offline.

To bring chassis components online and offline, enter these **request chassis** commands:

```
user@host> request chassis <fru> slot <slot#> pic <pic#> online
```

```
user@host> request chassis <fru> slot <slot#> pic <pic#> offline
```

Where **<fru>** in the request chassis command can be any of the following (for Branch SRX Series devices):

- **fpc**—Changes the Flexible PIC Concentrator (FPC) status.

Where **<fru>** in the request chassis command can be any of the following (for High-End SRX Series devices):

- **cb**—Changes the control board status.
- **fabric**—Changes the fabric status.
- **fpc**—Changes the Flexible PIC Concentrator (FPC) status.
- **fpm**—Changes the craft interface status.
- **pic**—Changes the physical interface card status.
- **routing-engine**—Changes the routing engine status.

NOTE: The **request chassis** command is not supported for bringing SPCs online and offline.

Example:

To bring specific pic and the corresponding fpc slot online, from operational mode enter the following **request chassis** command:

```
user@host> request chassis pic pic-slot 1 fpc-slot 1 online
```

Restarting the Chassis on SRX Series Devices

You can restart the chassis using the **restart chassis-control** command with the following options:

- To restart the process gracefully:

```
user@host> restart chassis-control gracefully
```

- To restart the process immediately:
`user@host> restart chassis-control immediately`
- To restart the process softly:
`user@host> restart chassis-control soft`

Bringing Chassis Components Online and Offline on SRX Series Devices

You can use the **request** commands to bring all chassis components (except Power Entry Modules and fans) online and offline.

To bring chassis components online and offline, enter these **request chassis** commands:

```
user@host> request chassis <fru> slot <slot#> pic <pic#> offline
user@host> request chassis <fru> slot <slot#> pic <pic#> online
```

Where **<fru>** in the request chassis command can be any of the following:

- **cluster**—Changes the chassis cluster status.
- **fpc**—Changes the Flexible PIC Concentrator (FPC) status.

Related Documentation

- [Example: Creating a Snapshot and Using It to Boot an SRX Series Device on page 166](#)
- [Junos OS Upgrade Methods on the SRX Series Devices](#)

- [Restarting the Chassis on SRX Series Devices on page 218](#)

Restarting the Chassis on SRX Series Devices

You can use the **request** commands to bring all chassis components (except Power Entry Modules and fans) online and offline.

To bring chassis components online and offline, enter these **request chassis** commands:

```
user@host> request chassis <fru> slot <slot#> pic <pic#> offline
user@host> request chassis <fru> slot <slot#> pic <pic#> online
```

Where **<fru>** in the request chassis command can be any of the following:

- **cluster**—Changes the chassis cluster status.
- **fpc**—Changes the Flexible PIC Concentrator (FPC) status.

- [Restarting the Chassis on SRX Series Devices on page 218](#)

Rebooting or Halting the EX Series Switch (J-Web Procedure)

You can use the J-Web interface to schedule a reboot or to halt the switching platform.

To reboot or halt the switching platform by using the J-Web interface:

1. In the J-Web interface, select **Maintain > Reboot**.
2. Select one:
 - **Reboot Immediately**—Reboots the switching platform immediately.
 - **Reboot in *number of minutes***—Reboots the switch in the number of minutes from now that you specify.
 - **Reboot when the system time is *hour:minute***—Reboots the switch at the absolute time that you specify, on the current day. You must select a 2-digit hour in 24-hour format and a 2-digit minute.
 - **Halt Immediately**—Stops the switching platform software immediately. After the switching platform software has stopped, you can access the switching platform through the console port only.
3. (Optional) In the Message box, type a message to be displayed to any users on the switching platform before the reboot occurs.
4. Click **Schedule**. The J-Web interface requests confirmation to perform the reboot or halt.
5. Click **OK** to confirm the operation.
 - If the reboot is scheduled to occur immediately, the switch reboots. You cannot access the J-Web interface until the switch has restarted and the boot sequence is complete. After the reboot is complete, refresh the browser window to display the J-Web interface login page.
 - If the reboot is scheduled to occur in the future, the Reboot page displays the time until reboot. You have the option to cancel the request by clicking **Cancel Reboot** on the J-Web interface Reboot page.
 - If the switch is halted, all software processes stop and you can access the switching platform through the console port only. Reboot the switch by pressing any key on the keyboard.

PART 3

Installing and Managing Software Licenses

- [Software License Overview on page 223](#)
- [Installing and Managing Licenses on page 257](#)

Software License Overview

- [Junos OS Feature Licenses on page 223](#)
- [License Enforcement on page 224](#)
- [Junos OS Feature License Keys on page 225](#)
- [Software Feature Licenses on page 228](#)
- [Understanding Software Licenses for EX Series Switches on page 246](#)

Junos OS Feature Licenses

Some Junos OS software features require a license to activate the feature. To enable a licensed feature, you need to purchase, install, manage, and verify a license key that corresponds to each licensed feature. To conform to Junos OS feature licensing requirements, you must purchase one license per feature per device. The presence of the appropriate software license key on your device determines whether you are eligible to configure and use the licensed feature.

To speed deployment of licensed features, Junos OS software implements an honor-based licensing structure and provides you with a 30-day grace period to use a licensed feature without a license key installed. The grace period begins when you configure the feature and your device uses the licensed feature for the first time, but not necessarily when you install the license. After the grace period expires, the system generates system log messages saying that the feature requires a license. To clear the error message and use the licensed feature properly, you must install and verify the required license.

For information about how to purchase software licenses, contact your Juniper Networks sales representative.

Related Documentation

- [License Enforcement on page 224](#)
- [Junos OS Feature License Model Number for SRX Series Services Gateways on page 236](#)
- [Adding New Licenses \(CLI Procedure\) on page 257](#)
- [Deleting a License \(CLI Procedure\) on page 258](#)
- [Saving License Keys on page 259](#)
- [Verifying Junos OS License Installation on page 260](#)

License Enforcement

For features or scaling levels that require a license, you must install and properly configure the license to meet the requirements for using the licensable feature or scale level. The device enables you to commit a configuration that specifies a licensable feature or scale without a license for a 30-day grace period. The grace period is a short-term grant that enables you to start using features in the pack or scale up to the system limits (regardless of the license key limit) without a license key installed. The grace period begins when the licensable feature or scaling level is actually used by the device (not when it is first committed). In other words, you can commit licensable features or scaling limits to the device configuration, but the grace period does not begin until the device uses the licensable feature or exceeds a licensable scaling level.

NOTE: Configurations might include both licensed and nonlicensed features. For these situations, the license is enforced up to the point where the license can be clearly distinguished. For example, an authentication-order configuration is shared by both Authentication, Authorization, and Accounting (AAA), which is licensed, and by Layer 2 Tunneling Protocol (L2TP), which is not licensed. When the configuration is committed, the device does not issue any license warnings, because it is not yet known whether AAA or L2TP is using the configuration. However, at runtime, the device checks for a license when AAA authenticates clients, but does not check when L2TP authenticates clients.

The device reports any license breach as a warning log message whenever a configuration is committed that contains a feature or scale limit usage that requires a license. Following the 30-day grace period, the device periodically reports the breach to syslog messages until a license is installed and properly configured on the device to resolve the breach.

NOTE: Successful commitment of a licensable feature or scaling configuration does not imply that the required licenses are installed or not required. If a required license is not present, the system issues a warning message after it commits the configuration.

Junos OS Feature License Keys

Some Junos OS software features require a license to be activated. To enable each licensed feature, you must purchase, install, manage, and verify a license key that corresponds to the licensed feature.

Release-Tied License Keys and Upgrade Licenses on MX Series Routers

The Junos OS licensing infrastructure currently associates a license feature with attributes such as date, platform, and validity. In addition to these attributes, for MX Series routers running Junos OS Release 12.2 and later, a licensed feature can be associated with a release number at the time of generating the license key. This type of release-tied license key is used to validate a particular licensed feature while attempting a software upgrade. The upgrade process aborts if the release number in the license key is earlier than the Junos OS release number to which the system is being upgraded.

Additionally, an upgrade license key can be generated for a release-tied licensed feature. An upgrade license key is used for carrying forward a capacity license to the upgrade release. Although an upgrade license might be an acceptable license on the current release, it does not add to the existing capacity limit. The capacity added in the upgrade license key is valid for the upgrade software release only.

The release number embedded in the license key indicates the maximum release number up to which Junos OS can be upgraded.

As an example, assume that your system is running Junos OS Release 12.2 and is using the **scale-subscriber** licensed feature with a later release-tied upgrade license key installed. If you request a software upgrade to the later release of Junos OS, the software upgrade operation fails and the following error message is displayed:

```
mgd: error: No valid upgrade license found for feature 'scale-subscriber'.  
Aborting Software upgrade.  
Validation failed
```

In this example, to successfully upgrade to the later release of Junos OS, the release number included in the upgrade license key should be greater than or equal to the later release number. Also, you can perform software upgrades up to the previous release without any additional license keys to retain the existing scale limit.

**NOTE:**

When you install a release-tied license, the following apply:

- You can purchase an upgrade capacity license only if a base capacity license for the same scale-tier has already been generated or purchased.
- You cannot install an upgrade license if the capacity does not match any of the existing base capacity licenses on the system.
- The license installation fails when you install a lower release number license key on a higher software release number.
- A release-tied license can be installed on a Junos OS release number that is lower than or equal to the release number included in the license key. For example, a 12.2 license key is valid on Junos OS Release 12.1.
- An upgrade license is valid only on the target release number specified in the license key, but can be installed on an earlier Junos OS release. For example, a 4 K scale-tier upgrade license for Junos OS Release 12.2 can be installed on an earlier release, and the installed count of licenses remains unaltered.
- Release-tied licenses of the previous release are not deleted on upgrading Junos OS to a newer release version.

Licensable Ports on MX5, MX10, and MX40 Routers

Starting with Junos OS Release 12.2, license keys are available to enhance the port capacity on MX5, MX10, and MX40 routers up to the port capacity of an MX80 router. The MX5, MX10, and MX40 routers are derived from the modular MX80 chassis with similar slot and port assignments, and provide all functionality available on an MX80 router, but at a lower capacity. Restricting port capacity is achieved by making a set of MIC slots and ports licensable. MICs without a license are locked, and are unlocked or made usable by installing appropriate upgrade licenses.

The base capacity of a router is identified by the Ideeprom assembly ID (I2C ID), which defines the board type. However, the Junos OS licensing infrastructure allows the use of restricted ports without a license for a grace period of 30 days. After the grace period expires, the router reverts back to the base capacity if no upgrade license is purchased and installed for the locked ports. The I2C ID along with an upgrade license determine the final capacity of an MX5, MX10, or MX40 router.

The MX5, MX10, MX40, and MX80 routers support the following types of MICs:

- A built-in 10-Gigabit Ethernet MIC with four 10-Gigabit Ethernet ports
- Two front-pluggable MICs

A feature ID is assigned to every license upgrade for enhancing port capacity. [Table 27](#) displays the chassis types and their associated port capacity, I2C ID, base capacity, feature ID, feature name, and the final capacity after a license upgrade.

Table 27: Upgrade Licenses for Enhancing Port Capacity

Chassis Type	Port Capacity	I2C ID	Base Capacity	Feature ID and Feature Name	Upgrade Capacity
MX5	20G	0x556	Slot 1 • 1/MIC0	f1—MX5 to MX10 upgrade	Slot 1 and 2 • 1/MIC0 • 1/MIC1
MX10	40G	0x555	Slot 1 and 2 • 1/MIC0 • 1/MIC1	f2—MX10 to MX40 upgrade	Slot 2 and first 2 ports on Slot 0 • 1/MIC1 • First 2 ports on 0/MIC0
MX40	60G	0x554	Slot 1, Slot 2 and first 2 ports on Slot 0 • 1/MIC0 • 1/MIC1 • First 2 ports on 0/MIC0	f3—MX40 to MX80 upgrade	Slot 2 and all ports on Slot 0 • 1/MIC1 • All 4 ports on 0/MIC0

When installing an upgrade license for enhancing port capacity on MX5, MX10 and MX40 routers, consider the following:

- To upgrade an MX5 router to MX80 router capacity, licenses for all three features (f1, f2, f3) must be installed. All three features can be provided in a single license key.
- To upgrade an MX10 router to MX40 router capacity, installing a license key with f2 feature is sufficient.
- Non-applicable feature IDs in a license key reject the upgrade license. For example:
 - An f1 feature ID on an MX10 upgrade license key rejects the license.
 - Feature IDs f1 and f2 on an MX40 upgrade license key reject the entire license.

Port Activation on MX104 Routers

Starting with Junos OS Release 13.3, license keys are available to activate the ports on the MX104 router. MX104 routers have four built-in ports. By default, in the absence of valid licenses, all four built-in ports are deactivated. By installing licenses, you can activate any two of the four or all of the four built-in ports. For instance, you can install a license to activate the first two built-in ports (xe-2/0/0 and xe-2/0/1) or you can install a license to activate the next two built-in ports (xe-2/0/2 and xe-2/0/3). You can also install a license to activate all four built-in ports (xe-2/0/0, xe-2/0/1, xe-2/0/2, and xe-2/0/3). If you have already activated two of the built-in ports, you can install an additional license to activate the other two built-in ports on the MX104 router.

A feature ID is assigned to every license for activating the built-in ports on the MX104 router. The port license model with the feature ID is described in [Table 28](#).

Table 28: Port Activation License Model for MX104 Routers

Feature ID	Feature Name	Functionality
F1	MX104 2X10G Port Activate (0 and 1)	Ability to activate first two built-in ports (xe-2/0/0 and xe-2/0/1)
F2	MX104 2X10G Port Activate (2 and 3)	Ability to activate next two built-in ports (xe-2/0/2 and xe-2/0/3)

Both the features are also provided in a single license key for ease of use. To activate all four ports, you must either install the licenses for both the features listed in [Table 28](#) or the single license key for both features. If you install the single license key when feature IDs F1 and F2 are already installed, the license does not get rejected. Also, MX104 routers do not support the graceful license expiry policy. A graceful license expiry policy allows the use of a feature for a certain period of time (usually a grace period of 30 days), and reverts if the license for that feature is not installed after the grace period.

Software Features That Require Licenses on M Series, MX Series, and T Series Routers

[Table 29](#) lists the licenses you can purchase for each M Series, MX Series, and T Series software feature. Each license allows you to run the specified software feature on a single device.

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Table 29: Junos OS Feature License Model Number for M Series, MX Series, and T Series Routers

Licensed Software Feature	Supported Devices	Model Number
Generalized Multi-Protocol Label Switching (GMPLS) Support on Junos OS	M10i, M7i, M120, M160, M20, M320, M40e, T320, T640, and MX Series Routers	JS-GMPLS
IPv6 Support on Junos OS	M120, M160, M20, M320, M40e, T320, T640, and MX Series Routers	JS-IPv6
Logical Router Support for Junos OS	M10i, M120, M160, M20, M320, M40e, M7i, T320, T640, and MX Series Routers	JS-LR
J- Flow accounting license for Adaptive Services (AS) PIC and Multiservices PIC	M10i, M120, M160, M20, M320, M40e, M7i, T320, M10, M5, T640, and T1600	S-ACCT
Chassis license for Application Traffic Optimization service, policy enforcement and application statistics. This license includes S-AI and S-LDPF functionality, and 1 Year Signature Subscription License	MX104, MX240, MX480, MX960, M Series, and T Series Routers	S-ATO
Software License for Passive Monitoring Flow Collector Application, supporting 100Kpps throughput; Chassis based license for Multiservices PIC.	M320, T640, T320, T1600	S-COLLECTOR-100K
License to use Compressed Real-Time Transport Protocol (CRTP) feature in AS PIC and Multiservices PIC	M10i, M120, M160, M20, M320, M40e, M7i, T320, M10, M5, T640, and T1600	S-CRTP
Software License for Passive Monitoring DFC Application, supporting 100Kpps throughput; Chassis based license for Multiservices PIC	M320, T640, T320, T1600	S-DFC-100K
Security Services license for AS PIC and Multiservices PIC	M10i, M7i, M5, M120, M160, M20, M320, M40e, T320, T640, M10, T1600	S-ES
Chassis license for IDP service, policy enforcement. This license includes S-AI and S-LDPF functionality, and 1 Year Signature Subscription License	MX104, MX240, MX480, MX960, M Series, and T Series Routers	S-IDP
Junos-FIPS Software License	M10i, M7i, M320, M40e, T320, T640	S-JUNOS-FIPS
Link Services Software License—up to 1023 ML bundles per Chassis for Multiservices PIC and Multiservices Dense Port Concentrator (DPC)	M5, M7i, M10, M10i, M20, M40e, M120, M320, T320, T640, T1600, MX240, MX480, MX960	S-LSSL-1023

Table 29: Junos OS Feature License Model Number for M Series, MX Series, and T Series Routers (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Link Services Software Upgrade License—from 255 to 1023 ML bundles per Chassis for Multiservices PIC and Multiservices DPC	M5, M7i, M10, M10i, M20, M40e, M120, M320, T320, T640, T1600, MX240, MX480, MX960	S-LSSL-1023-UPG
Link Services Software Upgrade License—from 64 to 255 ML bundles per Chassis for AS PIC, Multiservices PIC, and Multiservices DPC	M5, M7i, M10, M10i, M20, M40e, M120, M320, T320, T640, T1600, MX240, MX480, MX960	S-LSSL-255-UPG
Link Services Software License—up to 255 ML bundles per Chassis for AS PIC, Multiservices PIC, and Multiservices DPC	M10, M7i, M5, M120, M20, M320, M40e, T320, T640, M10i, T1600, MX240, MX480, MX960	S-LSSL-256
Link Services Software License—up to 4 ML bundles per Chassis for AS PIC, Multiservices PIC, and Multiservices DPC	M10i, M120, M20, M320, M40e, M7i, T320, M10, M5, T640, T1600, MX240, MX480, MX960	S-LSSL-4
Link Services Software License—up to 64 ML bundles per Chassis for AS PIC, MS PIC and MS DPC	M10, M7i, M5, M120, M20, M320, M40e, T320, T640, M10i, T1600, MX240, MX480, MX960	S-LSSL-64
Link Services Software Upgrade License—from 4 to 64 ML bundles per Chassis for AS PIC, Multiservices PIC, and Multiservices DPC	M5, M7i, M10, M10i, M20, M40e, M120, M320, T320, T640, T1600, MX240, MX480, MX960	S-LSSL-64-UPG
Software License for Passive Monitoring Flow Monitor Application, supporting 1M flows. Chassis based license for Multiservices PIC	M320, T640, T320, T1600	S-MONITOR-1M
Network Address Translation (NAT), FW license on AS PIC and Multiservices PIC: Multi-instance	M10, M7i, M5, M120, M160, M20, M320, M40e, T320, T640, M10i, T1600	S-NAT-FW-MULTI
NAT, FW license on AS PIC and Multiservices PIC: Single-instance	M10, M7i, M5, M120, M160, M20, M320, M40e, T320, T640, M10i, T1600	S-NAT-FW-SINGLE
Software license for Packet trigger subscriber policy	MX240, MX480, MX960, M120, M320	S-PTSP
Subscriber Access Feature Pack License Scaling (128000)	MX104, MX240, MX480, MX960, M120, M320	S-SA-128K
Subscriber Access Feature Pack License Scaling (32000)	MX104, MX240, MX480, MX960, M120, M320	S-SA-32K
Subscriber Access Feature Pack License Scaling (4000)	MX104, MX240, MX480, MX960, M120, M320, MX80	S-SA-4K
Subscriber Access Feature Pack License Scaling (64000)	MX104, MX240, MX480, MX960, M120, M320	S-SA-64K

Table 29: Junos OS Feature License Model Number for M Series, MX Series, and T Series Routers (continued)

Licensed Software Feature	Supported Devices	Model Number
Subscriber Access Feature Pack License Scaling (8000)	MX104, MX240, MX480, MX960, M120, M320, MX80	S-SA-8K
Subscriber Access Feature Pack License Scaling (96000)	MX104, MX240, MX480, MX960, M120, M320	S-SA-96K
Subscriber Access Feature Pack license	MX104, MX240, MX480, MX960, M120, M320	S-SA-FP
Stateful Failover for Services on AS PIC and Multiservices PIC: Multilink PPP (MLPPP) only	M10, M7i, M5, M120, M160, M20, M320, M40e, T320, T640, M10i, T1600	S-SERVICES-SFO
Subscriber Service Management Feature Packet License (RADIUS/SRC based Service Activation and Deactivation) Per-Service Accounting Features for Subscribers	MX104, MX240, MX480, MX960, M120, M320	S-SSM-FP
Subscriber Traffic Lawful Intercept Feature Pack License	MX240, MX480, MX960, M120, M320, MX80	S-SSP-FP
Software license for application aware traffic direct feature	MX240, MX480, MX960, M120, M320	S-TFDIRECT-APP
Software license for subscriber aware traffic direct feature	MX240, MX480, MX960, M120, M320	S-TFDIRECT-SUB
Video Services Feature Pack license	M120, M320, MX80, MX104, MX240, MX480, MX960	S-VIDEO-FP
Port capacity enhancement Feature Pack License for MX5 routers	MX5	mx5-to-mx10-upgrade
Port capacity enhancement Feature Pack License for MX10 routers	MX10	mx10-to-mx40-upgrade
Port capacity enhancement Feature Pack License for MX40 routers	MX40	mx40-to-mx80-upgrade

Software Features That Require Licenses on M Series Routers Only

Table 30 lists the licenses you can purchase for each M Series software feature. Each license allows you to run the specified software feature on a single device.

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Table 30: Junos OS Feature License Model Number for M Series Routers

Licensed Software Feature	Supported Devices	Model Number
J-Flow accounting license on Integrated Adaptive Services Module (ASM) and Integrated Multi-Services Module	M7i	S-ACCT-BB
Security Services license on ASM and Integrated Multi-Services Module	M7i	S-ES-BB
Layer 2 Tunneling Protocol (L2TP) L2TP Network Server (LNS) license for 16000 sessions on Multiservices PIC	M120	S-LNS-16K
L2TP LNS license Upgrade—from 8000 to 16000 sessions on Multiservices PIC	M120	S-LNS-16K-UPG
L2TP LNS license for 2000 sessions on AS PIC or Integrated Adaptive Services Module and Multiservices PIC	M7i, M10i, M120	S-LNS-2K
L2TP LNS license for 4000 sessions on AS PIC or Integrated Adaptive Services Module and Multiservices PIC	M7i, M10i, M120	S-LNS-4K
L2TP LNS license Upgrade—from 2000 to 4000 sessions on AS PIC or Integrated Adaptive Services Module and Multiservices PIC	M7i, M10i, M120	S-LNS-4K-UPG
L2TP LNS license for 8000 sessions on Multiservices PIC	M7i, M10i, M120	S-LNS-8K
L2TP LNS license Upgrade—from 4000 to 8000 sessions on AS PIC and Multiservices PIC	M7i, M10i, M120	S-LNS-8K-UPG
Link services software license on integrated ASM and Integrated Multi Services Module—up to 4 ML bundles	M7i	S-LSSL-BB
NAT, FW license on Integrated ASM and Integrated Multi Services Module: Multi instance	M7i	S-NAT-FW-MULTI-BB
NAT, FW license on Integrated ASM and Integrated Multi Services Module: Single instance	M7i	S-NAT-FW-SINGLE-BB
Tunnel services software license for AS PIC and Multiservices PIC (chassis license)	M7i, M10i	S-TUNNEL

Software Features That Require Licenses on MX Series Routers Only

Table 31 lists the licenses you can purchase for each MX Series software feature. Each license allows you to run the specified software feature on a single device.

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Table 31: Junos OS Feature License Model Number for MX Series Routers

Licensed Software Feature	Supported Devices	Model Number
Upgrade license—from MX80-10G-ADV to MX80-40G-ADV	MX80	MX80-10G40G-UPG-ADV-B
Upgrade license—from MX80-10G to MX80-40G	MX80	MX80-10G40G-UPG-B
Upgrade license—from MX80-40G-ADV to full MX80	MX80	MX80-40G-UPG-ADV-B
Upgrade license—from MX80-40G to full MX80	MX80	MX80-40G-UPG-B
Upgrade license—from MX80-5G-ADV to MX80-10G-ADV	MX80	MX80-5G10G-UPG-ADV-B
Upgrade license—from MX80-5G to MX80-10G	MX80	MX80-5G10G-UPG-B
Upgrade license to activate 2x10GE P2&3	MX104	S-MX104-ADD-2X10GE
Upgrade license to activate 2X10GE P0&1	MX104	S-MX104-UPG-2X10GE
Upgrade license to activate 4X10GE fixed ports on MX104	MX104	S-MX104-UPG-4X10GE
License to support per VLAN queuing on MX104	MX104	S-MX104-Q
Chassis-based software license for inline J-Flow monitoring on MX5, MX10, M40, MX80, and MX104 Series routers	MX5, MX10, M40, MX80, and MX104	S-JFLOW-CH-MX5-104
Flow monitoring and accounting features using J-Flow service on any Modular Port Concentrator (MPC) or MS-DPC	MX240, MX480, MX960	S-ACCT-JFLOW-CHASSIS
Software License for in-line J-Flow service on Trio MPCs	MX240, MX480, MX960	S-ACCT-JFLOW-IN
Flow monitoring and accounting features using J-Flow service on any MPC limited to 10G of total JFLOW traffic	MX80	S-ACCT-JFLOW-IN-10G
Flow monitoring and accounting features using J-Flow service on any MPC limited to 10G of total JFLOW traffic	MX80	S-ACCT-JFLOW-IN-10G-UPG
Flow monitoring and accounting features using J-Flow service on any MPC limited to 5G of total JFLOW traffic	MX80	S-ACCT-JFLOW-IN-5G
2000 IKE sessions on MS-DPC; Chassis based, limited to 6000 per Chassis	MX240, MX480, MX960	S-ES-2K
4000 IKE sessions on MS-DPC; Chassis based, limited to 6000 per Chassis	MX240, MX480, MX960	S-ES-4K
Upgrade from 2000 IKE sessions to 4000 IKE sessions on MS-DPC; Chassis based, limited to 6000 per Chassis	MX240, MX480, MX960	S-ES-4K-UPG
6000 IKE sessions on MS-DPC; Chassis based, limited to 6000 per Chassis	MX240, MX480, MX960	S-ES-6K

Table 31: Junos OS Feature License Model Number for MX Series Routers (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Upgrade from 4000 IKE sessions to 6000 IKE Sessions on MS-DPC; Chassis based, limited to 6000 per Chassis	MX240, MX480, MX960	S-ES-6K-UPG
License to support DS3 Channelization (down to DS0) on each Modular Interface Card (MIC) for MIC-3D-8DS3-E3; also requires license S-MX80-Q when used on the MX80 platform	MX80, MX104, MX240, MX480, MX960	S-MIC-3D-8CHDS3
License to support full-scale L3 routes and L3 VPN	MX80	S-MX80-ADV-R
License to support 256K routes	MX104	S-MX104-ADV-R1
License to support scaling L3 and VPN routes to 1 million or more entries on MX104 platforms	MX104	S-MX104-ADV-R2
License to support full-scale L3 routes and L3 VPN on each slot for MPC-3D-16XGE-SFPP	MX240, MX480, MX960	S-MPC-3D-16XGE-ADV-R
License to support full-scale L3 routes and L3 VPN on each slot for port queuing MPCs	MX240, MX480, MX960	S-MPC-3D-PQ-ADV-R
License to support full-scale L3 routes and L3 VPN on each slot for hierarchical quality of service (HQoS) MPCs	MX240, MX480, MX960	S-MPC-3D-VQ-ADV-R
Subscriber Management Feature Pack License for MX80	MX80	S-MX80-SA-FP
Subscriber Management Feature Pack for MX104 series	MX104	S-MX104-SA-FP
Subscriber Service Management Feature Packet License—RADIUS and SRC-based service activation and deactivation per-service accounting features	MX80	S-MX80-SSM-FP
Subscriber Service Management Feature Packet License	MX104	S-MX104-SSM-FP
Upgrade to Traffic Direct Advanced (per MS-DPC)	MX960	S-MX-TD-UPG
License to run one instance of the NAT software on one NPU per MS-DPC	MX240, MX480, MX960	S-NAT
License to support inline NAT software on MX5, MX10, MX40, MX80, MX104	MX5, MX10, MX40, MX80, MX104	S-NAT-IN-MX5-104 (Replaces S-NAT-IN-MX40-MX80 and S-NAT-IN-MX5-MX10)
License to run one instance of the NAT software on one NPU per MS-MIC, MS-DPC, or MS-MPC	MX80, MX104, MX240, MA480, MX960, MX2010, MX2020	S-NAT-NPU (Replaces S-NAT-IN-MX40-MX80-UPG)
License to run NAT using any MPC in an MX Chassis	MX240, MX480, MX960	S-NAT-IN-MX-CHASSIS
Subscriber Access Feature Pack License Scaling (4000)	MX240, MX480, MX960, M120, M320, MX80	S-SA-4K

Table 31: Junos OS Feature License Model Number for MX Series Routers (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Subscriber Access Feature Pack License Scaling (8000)	MX240, MX480, MX960, M120, M320, MX80	S-SA-8K
Subscriber Access Feature Pack License Scaling (16,000)	MX240, MX480, MX960, MX80	S-SA-16K
Subscriber Access Feature Pack License Scaling (32,000)	MX240, MX480, MX960, M120, M320	S-SA-32K
Subscriber Access Feature Pack License Scaling (64,000)	MX240, MX480, MX960, M120, M320	S-SA-64K
Subscriber Access Feature Pack License Scaling (96,000)	MX240, MX480, MX960, M120, M320	S-SA-96K
Subscriber Access Feature Pack License Scaling (128,000)	MX240, MX480, MX960, M120, M320	S-SA-128K
Subscriber Access Feature Pack License Scaling (256,000)	MX240, MX480, MX960	S-SA-256K
Subscriber Access Feature Pack License	MX240, MX480, MX960, M120, M320	S-SA-FP
Software License for Secure Flow Mirroring Service (FlowTap) (does not require MS-DPC)	MX80, MX104, MX240, MX480, MX960	S-SFM-FLOWTAP-IN
License to run one instance of the SFW and software on a MS-DPC	MX960, MX480, MX240	S-SFW
Subscriber Service Management Feature Packet License—RADIUS and SRC-based service activation and deactivation per-service accounting features	MX240, MX480, MX960, M120, M320	S-SSM-FP
Software license for one member of an MX Virtual Chassis	MX960, MX480, MX240	S-VCR
Upgrade license—from MX10 to equivalent of MX40; allows additional 2x10G fixed ports to be used on the MX10 router	MX10-T	MX10-40-UPG
Upgrade license—from MX10 to equivalent of MX80; allows additional 4x10G fixed ports to be used on the MX10 router	MX10-T	MX10-80-UPG
Upgrade license—from MX40 to equivalent of MX80; allows additional 2x10G fixed ports to be used on the MX40 router	MX40-T	MX40-80-UPG
Upgrade license—from MX5 to equivalent of MX10; allows second MIC slot to be used on the MX5 router	MX5-T	MX5-10-UPG
Upgrade license—from MX5 to equivalent of MX40; allows second MIC slot and 2x10G fixed ports to be used on the MX5 router	MX5-T	MX5-40-UPG

Table 31: Junos OS Feature License Model Number for MX Series Routers (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Upgrade license—from MX5 to equivalent of MX80. Allows second MIC slot and 4x10G fixed ports to be used on the MX5 router	MX5-T	MX5-80-UPG
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 4000 through 8000 subscribers	MX80, MX960, MX480, MX240	S-SA-UP-8K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 8000 through 16,000 subscribers	MX80, MX960, MX480, MX240	S-SA-UP-16K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 16,000 through 32,000 subscribers	MX240, MX480, MX960	S-SA-UP-32K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 32,000 through 64,000 subscribers	MX240, MX480, MX960	S-SA-UP-64K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 64,000 through 96,000 subscribers	MX240, MX480, MX960	S-SA-UP-96K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 96,000 through 128,000 subscribers	MX240, MX480, MX960	S-SA-UP-128K
Upgrade license—Subscriber Access Feature Pack scaling license upgrade from 128,000 through 256,000 subscribers	MX240, MX480, MX960	S-SA-UP-256K

Software Feature Licenses for SRX Series Devices

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Each feature license is tied to exactly one software feature, and that license is valid for exactly one device. [Table 32](#) describes the Junos OS features that require licenses.

Table 32: Junos OS Feature Licenses

Junos OS License Requirements			
Feature	SRX550M	SRX1500	SRX5000 line
Access Manager	X		
BGP Route Reflectors			
Dynamic VPN	X		
IDP Signature Update*	X	X	X
Application Signature Update (Application Identification)*	X		X

Table 32: Junos OS Feature Licenses (*continued*)

Junos OS License Requirements			
Feature	SRX550M	SRX1500	SRX5000 line
Juniper-Kaspersky Antivirus*	X		
Juniper-Sophos Antivirus*	X	X	X
Juniper-Sophos Antispam*	X	X	X
Juniper-Enhanced Web filtering*	X	X	X
Juniper-Websense Web filtering*	X		
Logical Systems			X
UTM	X	X	X

* Indicates support on high-memory devices only.

Table 33 lists the licenses you can purchase for each SRX Series software feature. Each license allows you to run the specified advanced software features on a single device.

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Table 33: Junos OS Feature License Model Number for SRX Series Devices

Licensed Software Feature	Supported Devices	Model Number
Application Security and IDP updates (1 year, 3 years, and 5 years)	SRX550	SRX550-APPSEC-A-1
		SRX550-APPSEC-A-3
		SRX550-APPSEC-A-5
	SRX5400	SRX5400-APPSEC-1
		SRX5400-APPSEC-3
		SRX5400-APPSEC-5
	SRX5600	SRX5600-APPSEC-A-1
		SRX5600-APPSEC-A-3
		SRX5600-APPSEC-A-5
	SRX5800	SRX5800-APPSEC-A-1
		SRX5800-APPSEC-A-3
		SRX5800-APPSEC-A-5
IDP updates (1 year, 3 years, and 5 years)	SRX550	SRX550-IDP
		SRX550-IDP-3
		SRX550-IDP-5
IDP subscription (1 year and 3 years)	SRX1500	SRX1500-IPS-1
		SRX1500-IPS-3
	SRX5400, SRX5600, SRX5800	SRX5K-IDP
		SRX5K-IDP-3
		SRX5K-IDP-3-R
		SRX5K-IDP-R
Juniper-Kaspersky Antivirus updates (1 year, 3 years, and 5 years)	SRX550	SRX550-K-AV
		SRX550-K-AV-3
		SRX550-K-AV-5
Juniper-Sophos Antivirus updates (1 year, 3 years, and 5 years)	SRX550	SRX550-S-AV
		SRX550-S-AV-3
		SRX550-S-AV-5

Table 33: Junos OS Feature License Model Number for SRX Series Devices (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Juniper-Sophos Antivirus updates (1 year, 3 years, and 5 years)	SRX5400	SRX5400-S-AV-1
		SRX5400-S-AV-3
		SRX5400-S-AV-5
Juniper-Sophos Antivirus updates (1 year)	SRX5600	SRX5600-S-AV-1
	SRX5800	SRX5800-S-AV-1
Juniper-Sophos Antispam updates (1 year, 3 years, and 5 years)	SRX550	SRX550-S2-AS
		SRX550-S2-AS-3
		SRX550-S2-AS-5
Juniper-Sophos Antispam updates (1 year, 3 years, and 5 years)	SRX5400	SRX5400-S-AV-1
		SRX5400-S-AV-3
		SRX5400-S-AV-5
Juniper-Sophos Antispam updates (1 year, 3 years, and 5 years)	SRX5600	SRX5600-S-AV-1
	SRX5800	SRX5800-S-AV-1
Juniper-Enhanced Web filtering (1 year, 3 years, and 5 years)	SRX550	SRX550-W-EWF
		SRX550-W-EWF-3
		SRX550-W-EWF-5
Juniper-Enhanced Web filtering (1 year, 3 years, and 5 years)	SRX5400	SRX5400-W-EWF-1
		SRX5400-W-EWF-3
		SRX5400-W-EWF-5
Juniper-Enhanced Web filtering (1 year)	SRX5600	SRX5600-W-EWF-1
	SRX5800	SRX5800-W-EWF-1
Enterprise Bundle—Kaspersky Antivirus, Enhanced Web Filtering, Sophos Antispam, AppSecure, and IDP (1 year, 3 years, and 5 years)	SRX550	SRX550-SMB4-CS
		SRX550-SMB4-CS-3
		SRX550-SMB4-CS-5

Table 33: Junos OS Feature License Model Number for SRX Series Devices (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Enterprise Bundle—includes Sophos Antivirus, Enhanced Web Filtering, Sophos Antispam, AppSecure, and IDP (1 year, 3 years, and 5 years)	SRX550	SRX550-S-SMB4- CS
		SRX550-S-SMB4- CS-3
		SRX550-S-SMB4- CS-5
Enterprise Bundle—includes Sophos Antivirus, Enhanced Web Filtering, Sophos Antispam, AppSecure, and IDP (1 year, 3 years)	SRX1500	SRX1500-CS-BUN-1
		SRX1500-CS-BUN-3
Enterprise Bundle—includes Sophos Antivirus, Enhanced Web Filtering, Sophos Antispam, AppSecure, and IDP (1 year, 3 years, and 5 years)	SRX5400	SRX5400-CS-BUN-1
		SRX5400-CS-BUN-3
		SRX5400-CS-BUN-5
Enterprise Bundle—includes Sophos Antivirus, Enhanced Web Filtering, Sophos Antispam, AppSecure, and IDP (1 year)	SRX5600	SRX5600-CS-BUN-1
	SRX5800	SRX5800-CS-BUN-1
Dynamic VPN Client (5, 10, and 25 simultaneous users)	SRX550	SRX-RAC-5-LTU
		SRX-RAC-10-LTU
		SRX-RAC-25-LTU
Dynamic VPN Service (5, 10, 25, and 50 simultaneous users)	SRX550	SRX-RAC-5-LTU
	SRX550	SRX-RAC-10-LTU
	SRX550	SRX-RAC-25-LTU
	SRX550	SRX-RAC-50-LTU
Dynamic VPN Service (100 and 150 simultaneous users)	SRX550	SRX-RAC-100-LTU
		SRX-RAC-150-LTU
Dynamic VPN Service (250 simultaneous users)	SRX550 <i>NOTE:</i> Requires Junos OS 11.2R3 or later	SRX-RAC-250-LTU
Dynamic VPN Service (500 simultaneous users)	SRX550 <i>NOTE:</i> Requires Junos OS 11.2R3 or later	SRX-RAC-500-LTU

Table 33: Junos OS Feature License Model Number for SRX Series Devices (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Express Path License (formerly known as <i>services offloading</i>)	SRX5400, SRX5600, SRX5800	SRX5K-SVCS-OFFLOAD-RTU
<p>NOTE: Prior to Junos OS Release 12.3X48-D10, Express Path was a licensed software feature. Starting with Junos OS Release 12.3X48-D10, the Express Path license is no longer required to enable this functionality. Your previously acquired Express Path license will not be effective anymore.</p>		
Logical Systems License (incremental 1, 5, and 25 numbers)	SRX5400	SRX-5400-LSYS-1
		SRX-5400-LSYS-5
		SRX-5400-LSYS-25
	SRX5600	SRX-5600-LSYS-1
		SRX-5600-LSYS-5
		SRX-5600-LSYS-25
	SRX5800	SRX-5800-LSYS-1
		SRX-5800-LSYS-5
		SRX-5800-LSYS-25
Sky Advanced Threat protection (1 year, 3 years)	SRX1500	SRX1500-ATP-1
		SRX1500-ATP-3
Command and Control feeds (1 year, 3 years)	SRX1500	SPOT-CC-1500-1Y
		SPOT-CC-1500-3Y

Software Features That Require Licenses on EX Series Switches

The following Junos OS features require an Enhanced Feature License (EFL) or Advanced Feature License (AFL) on EX Series devices:

- (EX2200 only) Bidirectional forwarding detection (BFD)
- (EX2200 only) Connectivity fault management (IEEE 802.lag)
- (EX2200 only) Internet Group Management Protocol version 1 (IGMPv1), IGMPv2, and IGMPv3

- (EX2200 and EX3300) OSPFv1/v2 (with 4 active interfaces)
- (EX2200 only) Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- (EX2200 and EX3300) Q-in-Q tunneling (IEEE 802.1ad)
- (EX2200 only) Real-time performance monitoring (RPM)
- (EX3200, EX4200, EX4500, EX6200, and EX8200) Border Gateway Protocol (BGP) and multiprotocol BGP (MBGP)
- (EX3200, EX4200, EX4500, EX6200, and EX8200) Intermediate System-to-Intermediate System (IS-IS)
- (EX3200, EX4200, EX4500, EX6200, and EX8200) IPv6 protocols: OSPFv3, PIPng, IS-IS for IPv6, IPv6 BGP
- (EX3200, EX4200, EX4500, EX6200, and EX8200) MPLS with RSVP-based label-switched paths (LSPs) and MPLS-based circuit cross-connects (CCCs)

Table 34 lists the licenses you can purchase for each EX Series software feature. Each license allows you to run the specified enhanced software features on a single device.

NOTE:

For a Virtual Chassis deployment, two license keys are recommended for redundancy—one for the device in the master role and the other for the device in the backup role:

- In an EX8200 Virtual Chassis, the devices in the master and backup roles are always XRE200 External Routing Engines.
- In all other Virtual Chassis, the devices in the master and backup roles are switches.

You do not need additional license keys for Virtual Chassis member switches that are in the licensed role or for the redundant Routing Engine (RE) modules or the redundant Switch Fabric and Routing Engine (SRE) modules in an EX8200 member switch.

For more details regarding EX Series feature licenses, see “[Understanding Software Licenses for EX Series Switches](#)” on page 246.

For information about how to purchase a software license, contact your Juniper Networks sales representative at <http://www.juniper.net/in/en/contact-us/>.

Table 34: Junos OS Enhanced Feature License (EFL) and Advanced Feature License (AFL) Model Number for EX Series Devices

Licensed Software Feature	Supported Devices	Model Number
Enhanced Feature License for EX 2200-24T/P	EX2200	EX-24-EFL
Enhanced Feature License for EX 2200-48T/P	EX2200	EX-48-EFL

Table 34: Junos OS Enhanced Feature License (EFL) and Advanced Feature License (AFL) Model Number for EX Series Devices (*continued*)

Licensed Software Feature	Supported Devices	Model Number
Enhanced Feature License for EX2200-C	EX2200-C	EX-12-EFL
Advanced Feature License for EX 3200-24T/P and EX 4200-24T/P/F/PX	EX3200, EX4200	EX-24-AFL
Advanced Feature License for EX 3200-48T/P, EX 4200-48T/P/F/PX, and EX4500-40F	EX3200, EX4200, EX4500	EX-48-AFL
Advanced Feature License for EX6200	EX6200	EX6200-AFL
XRE200 Advanced Feature License for EX8200	EX8200	EX-XRE200-AFL
Advanced Feature License for EX8208	EX8208	EX8208-AFL
Advanced Feature License for EX8216	EX8216	EX8216-AFL

Software Features That Require Licenses on the QFX Series

NOTE: If you try to configure a feature that is not licensed, you will receive syslog messages saying that you are using a feature that is licensable and that you do not possess a license for the feature. If you try to commit configuration changes for a feature that is not licensed, you will receive a commit warning saying that you have exceeded the allowed license limit for the feature.

NOTE: Virtual Extensible Local Area Network (VXLAN) is not supported on QFX3500 and QFX3600 devices. When you issue the `show licenses` command, you will see VXLAN in the CLI output, but the feature is not enabled.

NOTE: There is no separate license for Virtual Chassis like there is for Virtual Chassis Fabric.

Table 35 lists the standard Junos OS features licenses and supported QFX Series devices. For information on disaggregated Junos OS feature licenses, see *Disaggregated Software Features That Require Licenses on the QFX Series*.

For information about how to purchase a software license, contact your Juniper Networks sales representative.

Table 35: Standard Junos OS Feature Licenses and Model Numbers for QFX Series Devices

Licensed Software Feature	Supported Devices	Number of Licenses Required	Model Number
QFX Series premium feature license for Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), and Virtual Extensible Local Area Network (VXLAN), and Open vSwitch Database (OVSDB)	QFX10002-36Q switch	One per switch	QFX10002-36Q-PFL
	QFX10002-72Q switch		QFX10002-72Q-PFL
	QFX10008 switch		QFX10008-PFL
	QFX10016 switch		QFX10016-PFL
QFX Series advanced feature license for Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), Multi-protocol Label Switching (MPLS), and Virtual Extensible Local Area Network (VXLAN), and Open vSwitch Database (OVSDB)	QFX10002-36Q switch	One per switch	QFX10002-36Q-AFL
	QFX10002-72Q switch		QFX10002-72Q-AFL
	QFX10008 switch		QFX10008-AFL
	QFX10016 switch		QFX10016-AFL
QFX Series advanced feature license for Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), Multi-protocol Label Switching (MPLS), and Virtual Extensible Local Area Network (VXLAN), and Open vSwitch Database (OVSDB)	QFX3500, QFX3600, QFX5100-48S, and QFX5100-48T switches	One per switch, two per Virtual Chassis, and two per Virtual Chassis Fabric	QFX-JSL-EDGE-ADV1
QFX Series advanced feature license for Border Gateway Protocol (BGP), Intermediate System-to-Intermediate System (IS-IS), Multi-protocol Label Switching (MPLS), and Virtual Extensible Local Area Network (VXLAN) and Open vSwitch Database (OVSDB)	QFX5100-24Q and QFX5100-96S switches	One per switch, two per Virtual Chassis, and two per Virtual Chassis Fabric	QFX5100-HDNSE-LIC

Table 35: Standard Junos OS Feature Licenses and Model Numbers for QFX Series Devices (*continued*)

Licensed Software Feature	Supported Devices	Number of Licenses Required	Model Number
QFX Series advanced feature license for Border Gateway Protocol (BGP)	QFX3100 Director device	One per Node device in a network Node group	QFX-JSL-DRCTR-ADV1
QFX Series advanced feature license for Fibre Channel	QFX3500 switch	One per switch on which fibre channel ports are configured	QFX-JSL-EDGE-FC
QFX Series advanced feature license for Fibre Channel	QFX3100 Director device	One per QFX3500 Node device on which fibre channel ports are configured	QFX-JSL-DRCTR-FC
QFX Series advanced feature license for Fibre Channel - Capacity 16	QFX3100 Director device	One for up to 16 QFX3500 Node devices on which fibre channel ports are configured	QFX-JSL-DRCTR-FC-C16
QFX Series feature license for enabling fabric mode	QFX3500 and QFX3600 device	One per device	QFX3000-JSL-EDGE-FAB
QFX Series feature license for base software for QFX3000-G QFabric system	QFX3100 Director device	One per QFX3000-G QFabric system	QFX3008-JSL-DRCTR-FAB
QFX Series feature license for base software for QFX3000-M QFabric system	QFX3100 Director device	One per QFX3000-M QFabric system	QFX3000M-JSL-DRCTR-FAB
QFX and EX Series feature license for enabling Media Access Control security (MACsec)	QFX switches that support MACsec. See <i>Understanding Media Access Control Security (MACsec)</i> .	One per switch, two per Virtual Chassis,	EX-QFX-MACSEC-AGG
Virtual Chassis Fabric (VCF)	All member devices in a Virtual Chassis Fabric (VCF)	Two per Virtual Chassis Fabric (VCF)	QFX-VCF-LIC

Understanding Software Licenses for EX Series Switches

To enable and use some of the Juniper Networks operating system (Junos OS) features, you must purchase, install, and manage separate software licenses. If the switch has the appropriate software license, you can configure and use these features.

The Junos OS feature license (that is, the purchased authorization code) is universal. However, to conform to Junos OS feature licensing requirements, you must install a unique license key (a combination of the authorization code and the switch's serial number) on each switch.

For a Virtual Chassis deployment, two license keys are recommended for redundancy—one for the device in the master role and the other for the device in the backup role:

- In an EX8200 Virtual Chassis, the devices in the master and backup roles are always XRE200 External Routing Engines.
- In all other Virtual Chassis, the devices in the master and backup roles are switches.

You do not need additional license keys for Virtual Chassis member switches that are in the linecard role or for the redundant Routing Engine (RE) modules or the redundant Switch Fabric and Routing Engine (SRE) modules in an EX8200 member switch.

This topic describes:

- [Features Requiring a License on EX3400 Switches on page 249](#)
- [Features Requiring a License on EX4300 Switches on page 250](#)
- [Features Requiring a License on EX4600 Switches on page 252](#)
- [Features Requiring a License on EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 Switches on page 253](#)
- [License Warning Messages on page 254](#)

Purchasing a Software Feature License

The following sections list features that require separate licenses. To purchase a software license, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). You will be asked to supply the chassis serial number of your switch; you can obtain the serial number by running the **show chassis hardware** command.

NOTE: You are required to provide the 12-digit serial number when purchasing a license for an XRE200 External Routing Engine in an EX8200 Virtual Chassis.

The serial number listed on the XRE200 External Routing Engine serial ID label is 16 digits long. Use the last 12 digits of the 16-digit serial number to purchase the license.

You can use the `show chassis hardware` command output to display the 12-digit serial number of the XRE200 External Routing Engine.

Features Requiring a License on EX2200 Switches

For EX2200 switches, the following features can be added to basic Junos OS by installing an enhanced feature license (EFL):

- Bidirectional Forwarding Detection (BFD)
- Connectivity fault management (IEEE 802.1ag)
- IGMP (Internet Group Management Protocol) version 1 (IGMPv1), IGMPv2, and IGMPv3
- OSPFv1/v2 (with four active interfaces)
- Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- Q-in-Q tunneling (IEEE 802.1ad)
- Real-time performance monitoring (RPM)
- Virtual Router
- Virtual Router Redundancy Protocol (VRRP)

Table 36 lists the EFLs that you can purchase for EX2200 switch models. If you have the license, you can run all of the enhanced software features mentioned above on your EX2200 switch.

Table 36: Junos OS EFL Part Number on EX2200 Switches

Switch Model	EFL Part Number
EX2200-C-12P-2G EX2200-C-12T-2G	EX-12-EFL
EX2200-24T-4G EX2200-24P-4G EX2200-24T-DC-4G	EX-24-EFL
EX2200-48T-4G EX2200-48P-4G	EX-48-EFL

Features Requiring a License on EX2300 Switches

EX2300 switches has an enhanced feature licenses (EFLs).

To use the following features on the EX2300 switches, you must install an EFL:

- Bidirectional Forwarding Detection (BFD)
- IGMP (Internet Group Management Protocol) version 1 (IGMPv1), IGMPv2, and IGMPv3
- IPv6 routing protocols: Multicast Listener Discovery version 1 and 2 (MLD v1/v2), OSPFv3, PIM multicast, VRRPv6
- Multicast Source Discovery protocol (MSDP)
- OSPF v2/v3
- Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- Real-time performance monitoring (RPM)
- RIPng
- Virtual Router Redundancy Protocol (VRRP)

[Table 37](#) lists the EFLs that you can purchase for EX2300 switch models. If you have the license, you can run all of the enhanced software features mentioned above on your EX2300 switch.

Table 37: Junos OS EFL Part Number on EX2300 Switches

Switch Model	EFL Part Number
EX2300-24T EX2300-24P EX2300-C-12P EX2300-C-12T	EX-24-EFL

Features Requiring a License on EX3300 Switches

Two types of licenses are available on EX3300 switches: enhanced feature licenses (EFLs) and advanced feature licenses (AFLs).

To use the following features on the EX3300 switches, you must install an EFL:

- Bidirectional Forwarding Detection (BFD)
- IGMP (Internet Group Management Protocol) version 1 (IGMPv1), IGMPv2, and IGMPv3
- IPv6 routing protocols: Multicast Listener Discovery version 1 and 2 (MLD v1/v2), OSPFv3, PIM multicast, VRRPv6, virtual router support for unicast and filter-based forwarding (FBF)
- OSPFv1/v2

- Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- Q-in-Q tunneling (IEEE 802.1ad)
- Real-time performance monitoring (RPM)
- Virtual Router
- Virtual Router Redundancy Protocol (VRRP)

Table 38 lists the EFLs that you can purchase for EX3300 switch models. If you have the license, you can run all of the enhanced software features mentioned above on your EX3300 switch.

Table 38: Junos OS EFL Part Number on EX3300 Switches

Switch Model	EFL Part Number
EX3300-24T EX3300-24P EX3300-24T-DC	EX-24-EFL
EX3300-48T EX3300-48T-BF EX3300-48P	EX-48-EFL

To use the following feature on EX3300 switches, you must install an AFL:

- Border Gateway Protocol (BGP) and multiprotocol BGP (MBGP)
- IPv6 routing protocols: IPv6 BGP and IPv6 for MBGP
- Virtual routing and forwarding (VRF) BGP

Table 39 lists the AFLs that you can purchase for EX3300 switch models. For EX3300 switches, you must purchase and install a corresponding EFL along with the AFL to enable the advanced license features. If you have both these licenses, you can run all of the advanced software features mentioned above on your EX3300 switch.

Table 39: Junos OS AFL Part Number on EX3300 Switches

Switch Model	AFL Part Number
EX3300-24T EX3300-24P EX3300-24T-DC	EX-24-AFL
EX3300-48T EX3300-48T-BF EX3300-48P	EX-48-AFL

Features Requiring a License on EX3400 Switches

EX3400 switches has an enhanced feature licenses (EFLs) and MACSec license.

To use the following features on the EX3400 switches, you must install an EFL:

- Bidirectional Forwarding Detection (BFD)
- IGMP (Internet Group Management Protocol) version 1 (IGMPv1), IGMPv2, and IGMPv3
- IPv6 routing protocols : Multicast Listener Discovery version 1 and 2 (MLD v1/v2), OSPFv3, PIM multicast, VRRPv6, virtual router support for unicast and filter-based forwarding (FBF)
- Multicast Source Discovery Protocol (MSDP)
- OSPF v2/v3
- Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- Real-time performance monitoring (RPM)
- RIPng
- Unicast reverse-path forwarding (RPF)
- Virtual Router
- Virtual Router Redundancy Protocol (VRRP)

Table 40 lists the EFLs that you can purchase for EX3400 switch models. If you have the license, you can run all of the enhanced software features mentioned above on your EX3400 switch.

Table 40: Junos OS EFL Part Number on EX3400 Switches

Switch Model	EFL Part Number
EX3400-24T EX3400-24P	EX-24-EFL
EX3400-48T EX3400-48P EX3400-48T-AFI	EX-48-EFL

Features Requiring a License on EX4300 Switches

Two types of licenses are available on EX4300 switches: enhanced feature licenses (EFLs) and advanced feature licenses (AFLs).

To use the following features on the EX4300 switches, you must install an EFL:

- Bidirectional Forwarding Detection (BFD)
- Connectivity fault management (IEEE 802.1ag)
- IGMP (Internet Group Management Protocol) version 1 (IGMPv1), IGMPv2, and IGMPv3
- Multicast Source Discovery Protocol (MSDP)
- OSPFv2/v3

- Protocol Independent Multicast (PIM) dense mode, PIM source-specific mode, PIM sparse mode
- Real-time performance monitoring (RPM)
- RIPng (RIP next generation)
- Unicast reverse-path forwarding (RPF)
- Virtual Router
- Virtual Router Redundancy Protocol (VRRP)

Table 41 lists the EFLs that you can purchase for EX4300 switch models. If you have the license, you can run all of the enhanced software features mentioned above on your EX4300 switch.

Table 41: Junos OS EFL Part Number on EX4300 Switches

Switch Model	EFL Part Number
EX4300-24T EX4300-24P	EX4300-24-EFL
EX4300-48P EX4300-48T EX4300-48T-AFI EX4300-48T-DC EX4300-48T-DC-AFI	EX4300-48-EFL
EX4300-32F EX4300-32F-DC	EX4300-32F-EFL

To use the following features on EX4300 switches, you must install an AFL:

- Border Gateway Protocol (BGP) and multiprotocol BGP (MBGP)
- Intermediate System-to-Intermediate System (IS-IS)

Table 42 lists the AFLs that you can purchase for EX4300 switch models. For EX4300 switches, you must purchase and install a corresponding EFL along with the AFL to enable the advanced license features. If you have both these licenses, you can run all of the advanced software features mentioned above on your EX4300 switch.

Table 42: Junos OS AFL Part Number on EX4300 Switches

Switch Model	AFL Part Number
EX4300-24T EX4300-24P	EX4300-24-AFL
EX4300-48P EX4300-48T EX4300-48T-AFI EX4300-48T-DC EX4300-48T-DC-AFI	EX4300-48-AFL

Table 42: Junos OS AFL Part Number on EX4300 Switches (*continued*)

Switch Model	AFL Part Number
EX4300-32F EX4300-32F-DC	EX4300-32F-AFL

You must download a MACsec feature license to enable MACsec. The MACsec feature license is an independent feature license; the enhanced feature licenses (EFLs) or advanced feature licenses (AFLs) that must be purchased to enable some features on EX Series switches cannot be purchased to enable MACsec.

To purchase a feature license for MACsec, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). The Juniper sales representative will provide you with a feature license file and a license key.

MACsec is supported on EX4300 switches.

Features Requiring a License on EX4600 Switches

To use the following features on EX4600 switches, you must install an advanced feature license:

- Border Gateway Protocol (BGP) and multiprotocol BGP (MBGP)
- Intermediate System-to-Intermediate System (IS-IS)
- Multiprotocol Label Switching (MPLS)

Table 43 lists the AFLs that you can purchase for EX4600 switch models.

Table 43: Junos OS AFL Part Number on EX4600 Switches

Switch Model	AFL Part Number
EX4600-40F	EX4600-AFL

You must download a MACsec feature license to enable MACsec. The MACsec feature license is an independent feature license; the enhanced feature licenses (EFLs) or advanced feature licenses (AFLs) that must be purchased to enable some features on EX Series switches cannot be purchased to enable MACsec.

To purchase a feature license for MACsec, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). The Juniper sales representative will provide you with a feature license file and a license key.

MACsec is supported on EX4600 switches.

Features Requiring a License on EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 Switches

To use the following features on EX3200, EX4200, EX4500, EX4550, EX8200, and EX9200 switches, you must install an advanced feature license (AFL):

- Border Gateway Protocol (BGP) and multiprotocol BGP (MBGP)
- Ethernet VPN (available only on EX9200 switches)
- Intermediate System-to-Intermediate System (IS-IS)
- IPv6 routing protocols: IS-IS for IPv6, IPv6 BGP, IPv6 for MBGP
- Logical systems (available only on EX9200 switches)
- MPLS with RSVP-based label-switched paths (LSPs) and MPLS-based circuit cross-connects (CCCs) (Not supported on EX9200 switches)
- Open vSwitch Database (OVSDb) (available only on EX9200 switches)
- Virtual Extensible LAN (VXLAN) (available only on EX9200 switches)

To use the following features on Juniper Networks EX6200 Ethernet Switches, you must install an advanced feature license (AFL):

- Border Gateway Protocol (BGP)
- Intermediate System-to-Intermediate System (IS-IS)
- IPv6 routing protocols: IS-IS for IPv6, IPv6 BGP

Table 34 lists the AFLs that you can purchase for EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 switches. If you have the license, you can run all of the advanced software features mentioned above on your EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, or EX9200 switch.

Table 44: Junos OS AFL Part Number on EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 Switches

Switch Model	AFL Part Number
EX3200-24P EX3200-24T EX4200-24F EX4200-24P EX4200-24PX EX4200-24T	EX-24-AFL
EX3200-48P EX3200-48T EX4200-48F EX4200-48P EX4200-48PX EX4200-48T	EX-48-AFL

Table 44: Junos OS AFL Part Number on EX3200, EX4200, EX4500, EX4550, EX6200, EX8200, and EX9200 Switches (*continued*)

Switch Model	AFL Part Number
EX4500-40F-BF EX4500-40F-BF-C EX4500-40F-FB EX4500-40F-FB-C	EX-48-AFL
EX4550	EX4550-AFL
EX6210	EX6210-AFL
EX8208	EX8208-AFL
EX8216	EX8216-AFL
EX-XRE200	EX-XRE200-AFL
EX9204	EX9204-AFL
EX9208	EX9208-AFL
EX9214	EX9214-AFL

You must download a MACsec feature license to enable MACsec. The MACsec feature license is an independent feature license; the enhanced feature licenses (EFLs) or advanced feature licenses (AFLs) that must be purchased to enable some features on EX Series switches cannot be purchased to enable MACsec.

To purchase a feature license for MACsec, contact your Juniper Networks sales representative (<http://www.juniper.net/us/en/contact-us/sales-offices>). The Juniper sales representative will provide you with a feature license file and a license key.

MACsec is supported on EX4200 and EX4550 switches.

License Warning Messages

For using features that require a license, you must install and configure a license key. To obtain a license key, use the contact information provided in your certificate.

If you have not purchased the AFL or EFL and installed the license key, you receive warnings when you try to commit the configuration:

```
[edit protocols]
  'bgp'
    warning: requires 'bgp' license
error: commit failed: (statements constraint check failed)
```

The system generates system log (**syslog**) alarm messages notifying you that the feature requires a license—for example:

```
Sep 3 05:59:11 craftd[806]: Minor alarm set, BGP Routing Protocol usage
requires a license
Sep 3 05:59:11 alarmd[805]: Alarm set: License color=YELLOW, class=CHASSIS,
reason=BGP Routing Protocol usage requires a license
Sep 3 05:59:11 alarmd[805]: LICENSE_EXPIRED: License for feature bgp(47) expired
```

Output of the **show system alarms** command displays the active alarms:

```
user@switch> show system alarms
1 alarm currently active
Alarm time          Class  Description
2009-09-03 06:00:11 UTC  Minor  BGP Routing Protocol usage requires a license
```

Documentation**

- *Managing Licenses for the EX Series Switch (CLI Procedure)*
- *Managing Licenses for the EX Series Switch (J-Web Procedure)*
- *Monitoring Licenses for the EX Series Switch*
- *License Key Components for the EX Series Switch*

Installing and Managing Licenses

- [Adding New Licenses \(CLI Procedure\) on page 257](#)
- [Deleting a License \(CLI Procedure\) on page 258](#)
- [Saving License Keys on page 259](#)
- [Verifying Junos OS License Installation on page 260](#)

Adding New Licenses (CLI Procedure)

Before adding new licenses, complete the following tasks:

- Purchase the required licenses.
- Establish basic network connectivity with the router or switch. For instructions on establishing basic connectivity, see the *Getting Started Guide* or *Quick Start Guide* for your device.

NOTE: On QFabric systems, install your licenses in the default partition of the QFabric system and not on the individual components (Node devices and Interconnect devices).

To add a new license key to the device using the CLI:

1. From the CLI operational mode, enter one of the following CLI commands:

- To add a license key from a file or URL, enter the following command, specifying the filename or the URL where the key is located:

```
user@host> request system license add filename | url
```

- To add a license key from the terminal, enter the following command:

```
user@host> request system license add terminal
```

2. When prompted, enter the license key, separating multiple license keys with a blank line.

If the license key you enter is invalid, an error appears in the CLI output when you press Ctrl+d to exit license entry mode.

3. Go on to [“Verifying Junos OS License Installation” on page 260](#).

On routers that have graceful Routing Engine switchover (GRES) enabled, after successfully adding the new license on the master Routing Engine, the license keys are automatically synchronized on the backup Routing Engine as well. However, in case GRES is not enabled, the new license is added on each Routing Engine separately. This ensures that the license key is enabled on the backup Routing Engine during changeover of mastership between the Routing Engines.

To add a new license key to a router with dual Routing Engines without GRES:

1. After adding the new license key on the master Routing Engine, use the **request chassis routing-engine master switch** command to have the backup Routing Engine become the master Routing Engine.
2. Log in to the active Routing Engine and add the new license key, repeat the same step.

NOTE: Adding a license key to the router or switch might be delayed if a kernel resynchronization operation is in progress at that time. The following message is displayed on the CLI when the license-adding operation is about to be delayed:

A kernel re-sync operation is in progress. License update may take several minutes to complete.

Related Documentation

- [Deleting a License \(CLI Procedure\) on page 258](#)
- [Junos OS Feature Licenses on page 223](#)

Deleting a License (CLI Procedure)

Before deleting a license, establish basic network connectivity with the router or switch. For instructions on establishing basic connectivity, see the *Getting Started Guide* or *Quick Start Guide* for your router or switch.

You have the options to delete a single license, delete all licenses, or delete a list of licenses enclosed in brackets.

1. Display the licenses available to be deleted.

```
user@host> request system license delete license-identifier-list ?
```

Possible completions:

E00468XXX4	License key identifier
JUNOS10XXX1	License key identifier
JUNOS10XXX2	License key identifier
JUNOS10XXX3	License key identifier
JUNOS10XXX4	License key identifier
[Open a set of values

2. To delete a license key or keys from a device using the CLI operational mode, select one of the following methods:

- Delete a single license by specifying the license ID. Using this option, you can delete only one license at a time.

```
user@host> request system license delete license-identifier
```

- Delete all license keys from the current device.

```
user@host> request system license delete all
```

- Delete multiple license keys from the current device. Specify the license identifier for each key and enclose the list of identifiers in brackets.

```
user@host> request system license delete license-identifier-list [JUNOS10XXX1  
JUNOS10XXX3 JUNOS10XXX4 ...]
```

```
Delete license(s) ?  
[yes,no] (no) yes
```

3. Go on to “[Verifying Junos OS License Installation](#)” on page 260.

NOTE: Deleting a license key from the router or switch might be delayed if a kernel resynchronization operation is in progress at that time. The following message is displayed on the CLI when the license-deleting operation is about to be delayed:

A kernel re-sync operation is in progress. License update may take several minutes to complete.

Saving License Keys

Before saving a license, establish basic network connectivity with the router or switch. For instructions on establishing basic connectivity, see the *Getting Started Guide* or *Quick Start Guide* for your router or switch.

To save the licenses installed on a device to a file using the CLI:

1. From the CLI operational mode, enter one of the following CLI commands:

- To save the installed license keys to a file or URL, enter the following command:

```
user@host> request system license save filename | url
```

For example, the following command saves the installed license keys to a file named **license.config**:

- To save a license key from the terminal, enter the following command:

```
user@host> request system license save ftp://user@host/license.config
```

2. Go on to “Verifying Junos OS License Installation” on page 260.

Related Documentation

- [Adding New Licenses \(CLI Procedure\) on page 257](#)
- [Deleting a License \(CLI Procedure\) on page 258](#)
- [Junos OS Feature Licenses on page 223](#)
- [Verifying Junos OS License Installation on page 260](#)

Verifying Junos OS License Installation

To verify Junos OS license management, perform the following tasks:

- [Displaying Installed Licenses on page 260](#)
- [Displaying License Usage on page 261](#)

Displaying Installed Licenses

Purpose Verify that the expected licenses are installed and active on the router or switch.

Action From the CLI, enter the **show system license** command.

Sample Output

```
user@host> show system license
```

License usage:

Feature name	Licenses used	Licenses installed	Licenses needed	Expiry
subscriber-acct	0	1	0	permanent
subscriber-auth	0	1	0	permanent
subscriber-addr	0	1	0	permanent
subscriber-vlan	0	1	0	permanent
subscriber-ip	0	1	0	permanent
scale-subscriber	0	1000	0	permanent
scale-l2tp	0	1000	0	permanent
scale-mobile-ip	0	1000	0	permanent

Licenses installed:

License identifier: E000185416

License version: 2

Features:

```
subscriber-acct - Per Subscriber Radius Accounting
permanent
subscriber-auth - Per Subscriber Radius Authentication
permanent
subscriber-addr - Address Pool Assignment
permanent
subscriber-vlan - Dynamic Auto-sensed Vlan
permanent
subscriber-ip   - Dynamic and Static IP
permanent
```

Meaning The output shows a list of the license usage and a list of the licenses installed on the router or switch. Verify the following information:

- Each license is present. Licenses are listed in ascending alphanumeric order by license ID.
- The state of each license is **permanent**.

NOTE: A state of invalid indicates that the license key is not a valid license key. Either it was entered incorrectly or it is not valid for the specific device.

- The feature for each license is the expected feature. The features enabled are listed by license. An all-inclusive license has all features listed.
- All configured features have the required licenses installed. The Licenses needed column must show that no licenses are required.

Displaying License Usage

Purpose Verify that the licenses fully cover the feature configuration on the router or switch.

Action From the CLI, enter the **show system license usage** command.

Sample Output

```
user@host> show system license usage
```

	Licenses used	Licenses installed	Licenses needed	Expiry
Feature name				
subscriber-addr	1	0	1	29 days
scale-subscriber	0	1000	0	permanent
scale-l2tp	0	1000	0	permanent
scale-mobile-ip	0	1000	0	permanent

Meaning The output shows any licenses installed on the router or switch and how they are used. Verify the following information:

- Any configured licenses appear in the output. The output lists features in ascending alphabetical order by license name. The number of licenses appears in the third column. Verify that you have installed the appropriate number of licenses.
- The number of licenses used matches the number of configured features. If a licensed feature is configured, the feature is considered used. The sample output shows that the subscriber address pooling feature is configured.
- A license is installed on the router or switch for each configured feature. For every feature configured that does not have a license, one license is needed.

For example, the sample output shows that the subscriber address feature is configured but that the license for the feature has not yet been installed. The license must be installed within the remaining grace period to be in compliance.

Troubleshooting Software Installation

This topic describes troubleshooting issues with software installations on EX Series switches.

- [Recovering from a Failed Software Upgrade on an EX Series Switch on page 265](#)
- [Rebooting from the Inactive Partition on page 266](#)
- [Freeing Disk Space for Software Installation on page 267](#)
- [Installation from the Boot Loader Generates 'cannot open package' Error on page 267](#)

Recovering from a Failed Software Upgrade on an EX Series Switch

Problem **Description:** If Junos OS loads but the CLI is not working, or if the switch has no software installed, use this recovery installation procedure to install Junos OS.

Solution If there is already a Junos OS image on the system, you can either install the new Junos OS package in a separate partition and have both Junos OS images remain on the system, or you can wipe the disk clean before the new installation proceeds.

If there is no Junos OS image on the system, follow the instructions in "[Booting an EX Series Switch Using a Software Package Stored on a USB Flash Drive](#)" on page 162 to get an image on the system and boot the switch.

To perform a recovery installation:

1. Power on the switch. The loader script starts.

After the message **Loading /boot/defaults/loader.conf** displays, you are prompted with:

Hit [Enter] to boot immediately, or space bar for command prompt.
2. Press the space bar to enter the manual loader. The **loader>** prompt displays.

3. Enter the following command:

```
loader> install [--format] [--external] source
```

where:

- **format**—Use this option to wipe the installation media before installing the software package. If you do not include this option, the system installs the new Junos OS package in a different partition from the partition used by the most recently installed Junos OS package.
- **external**—Use this option to install the software package on an external medium.
- **source**—Represents the name and location of the Junos OS package either on a server on the network or as a file on the USB flash drive:
 - Network address of the server and the path on the server; for example, **tftp://192.171.28/junos/jinstall-ex-4200-9.4R1.5-domestic-signed.tgz**
 - The Junos OS package on a USB device is commonly stored in the root drive as the only file; for example, **file:///jinstall-ex-4200-9.4R1.5-domestic-signed.tgz**

The boot process proceeds as normal and ends with a login prompt.

Rebooting from the Inactive Partition

Problem **Description:** EX Series switches shipped with Junos OS Release 10.4R2 or earlier have Junos OS loaded on the system disk in partition 1. The first time you upgrade, the new software package is installed in partition 2. When you finish the installation and reboot, partition 2 becomes the active partition. Similarly, subsequent software packages are installed in the inactive partition, which becomes the active partition when you reboot at the end of the installation process.

On switches shipped with Release 10.4R3 and later, the same Junos OS image is loaded in each of the two root partitions, and you should copy the new software image to the alternate partition each time you upgrade.

If you performed an upgrade and rebooted, the system resets the active partition. You can use this procedure to manually boot from the inactive partition.

NOTE: If you have completed the installation of the software image but have not yet rebooted, issue the **request system software rollback** command to return to the original software installation package.

Solution Reboot from the inactive partition:

```
user@switch> request system reboot slice alternate
```

NOTE: If you cannot access the CLI, you can reboot from the inactive partition using the following procedure from the loader script prompt:

1. Unload and clear the interrupted boot from the active partition:

```
loader> unload
loader> unset vfs.root.mountfrom
```

2. Select the new (inactive) partition to boot from:

```
loader> set currdev=diskxsy:
```

where *x* is either 0 (internal) or 1 (external) and the *y* indicates the number of the inactive partition, either 1 or 2.

You must include the colon (:) at the end of this command.

3. Boot Junos OS from the inactive partition:

```
loader> boot
```

Freeing Disk Space for Software Installation

Problem **Description:** The software installation process requires a certain amount of unused disk space. If there is not enough space, you might receive an error message such as:

```
fetch: /var/tmp/incoming-package.tgz: No space left on device
```

Solution Identify and delete unnecessary files by using the [request system storage cleanup](#) command.

Installation from the Boot Loader Generates 'cannot open package' Error

Problem **Description:** When installing a Junos OS software image from the loader prompt, a "cannot open package error" is generated:

```
loader> install - -format
tftp://10.204.33.248/images/Flash_corr/official/jinstall-ex-4200-10.4I2011012-domestic-signed.tgz
Speed: 1000, full duplex
bootp: no reply
No response for RARP request
net_open: RARP failed
cannot open package (error 5)
```

Solution This might be due to the IP address, gateway IP address, netmask address, or server IP address not being properly set. You can set these values either from the shell or from the u-boot prompt.

To set these values from the shell:

```
% nvram setenv ipaddr 10.204.35.235
% nvram setenv netmask 255.255.240.0
```

```
% nvram setenv gatewayip 10.204.47.254
% nvram setenv serverip 10.204.33.248
```

To set these values from the u-boot prompt, log in to a console connection, reboot, and stop at the u-boot prompt (Cntrl+c):

```
=> setenv ipaddr 10.204.35.235
=> setenv gatewayip 10.204.47.254
=> setenv serverip 10.204.33.248
=> setenv netmask 255.255.240.0
=> saveenv
=> printenv Verify whether variables are set properly or not
=> boot
```

Troubleshooting a Switch That Has Booted from the Backup Junos OS Image

Problem **Description:** The switch boots from the backup root file partition. It is possible that the primary copy of JUNOS OS failed to boot properly, which could indicate that it is corrupted. This event is flagged in two ways:

- Upon login through the console or management port, the following warning message is displayed:

```
WARNING: THIS DEVICE HAS BOOTED FROM THE BACKUP JUNOS IMAGE
```

It is possible that the primary copy of JUNOS failed to boot up properly, and so this device has booted from the backup copy.

Please re-install JUNOS to recover the primary copy in case it has been corrupted.

- The following alarm message is generated:

```
user@switch> show chassis alarms
1 alarms currently active
Alarm time          Class  Description
2011-02-17 05:48:49 PST  Minor  Host 0 Boot from backup root
```

If the switch is in a Virtual Chassis, the switch member number appears in the **Description** field, where the switch is called a host.

Solution Install a new Junos OS image on the partition that had the corruption, or take a snapshot (use [request system snapshot](#)) of the currently active partition and use it to replace the image in the alternate partition:

If the switch is a standalone switch or a Virtual Chassis master switch, enter this command:

```
user@switch> request system snapshot slice alternate
```

If the switch is a Virtual Chassis member switch (not the master), enter this command on the Virtual Chassis:

```
user@switch> request system snapshot slice alternate member member-id
```

where *member-id* is the Virtual Chassis member ID number.

Disk Space Management for Junos OS Installation

A Junos OS installation or upgrade may fail if your router has a shortage of disk space. If a disk space error occurs, use one or more of the following options to complete the installation:

- Use the **request system storage cleanup** command to delete unnecessary files and increase storage space on the router.
- Specify the **unlink** option when you use the **request system software add** command to install the Junos OS:
 - On the M Series, MX Series, and T Series routers, the **unlink** option removes the software package after a successful upgrade.
- Download the software packages you need from the Juniper Networks Support Web site, <http://www.juniper.net/support/>. The download program provides intelligent disk space management to enable installation.

Verifying PIC Combinations

SRX5600 and SRX5800 devices support IOC or SPC on any given card slot, and there is no complexity in equipping the services gateways with the perfect balance of processing and I/O capacity. You can install up to 11 (on SRX5800) and five (SRX5600) SPCs and IOCs on the device. However you must install at least one SPC on device. For more details, see [SRX5600 and SRX5800 Services Gateway Card Guide](#).

For more information about PIC combinations or about unsupported PIC combinations, see the corresponding PIC guide or *Hardware Guide* for your device, and the *Junos OS Release Notes* on the Juniper Networks Support website at <http://www.juniper.net/support/>.

auto-configuration

Syntax	auto-configuration { command <i>binary-file-path</i> ; disable; }
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Configure the autoconfiguration process.
Options	<ul style="list-style-type: none">• command <i>binary-file-path</i>—Path to the binary process.• disable—Disable the autoconfiguration process.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Autoinstallation Overview on page 81• Configuring Autoinstallation on SRX Series Devices on page 84

auto-configuration (System)

Syntax	<pre> auto-configuration { traceoptions { file { filename; files number; match regular-expression; size maximum-file-size; (world-readable no-world-readable); } flag flag; level (all error info notice verbose warning); no-remote-trace; } } </pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure the autoconfiguration process.
Options	<p>traceoptions—Set the trace options.</p> <ul style="list-style-type: none"> file—Configure the trace file information. <ul style="list-style-type: none"> filename—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. By default, the name of the file is the name of the process being traced. files number—Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed to trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten. <p>If you specify a maximum number of files, you also must specify a maximum file size with the size option and a filename.</p> <p>Range: 2 through 1000 files</p> <p>Default: 10 files</p> match regular-expression—Refine the output to include lines that contain the regular expression. size maximum-file-size—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named trace-file reaches this size, it is renamed trace-file.0. When trace-file again reaches its maximum size, trace-file.0 is renamed trace-file.1 and trace-file is renamed trace-file.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option and a filename.

Syntax: x K to specify KB, x m to specify MB, or x g to specify GB

Range: 10 KB through 1 GB

Default: 128 KB

- **world-readable | no-world-readable**—By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag**—Specify the tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags.
 - **all**—Trace all events.
 - **auth**—Trace VLAN authentication.
 - **configuration**—Trace configurations.
 - **interfaces**—Trace interface operations.
 - **io**—Trace I/O operations.
 - **rtsock**—Trace routing socket operations.
 - **ui**—Trace user interface operations.

Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

auto-image-upgrade

Syntax	auto-image-upgrade;
Hierarchy Level	[edit chassis]
Release Information	Statement introduced in Junos OS Release 9.6 for EX Series switches.
Description	<p>Enable automatic software download on an EX Series switch acting as a DHCP client.</p> <p>The DHCP client EX Series switch compares the software package name in the DHCP server message to the name of the software package that booted the switch. If the software packages are different, the DHCP client EX Series switch downloads and installs the software package specified in the DHCP server message.</p> <p>Before you upgrade software using automatic software download, ensure that you have configured DHCP services for the switch, including configuring a path to a boot server and a boot file. See the Junos OS System Basics Configuration Guide for information about using the CLI to configure DHCP services and settings. See <i>Configuring DHCP Services (J-Web Procedure)</i> for information about using the J-Web interface to configure DHCP services and settings.</p>
Default	Automatic software download is disabled.
Required Privilege Level	interface—To view this statement in the configuration. interface-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Upgrading Software by Using Automatic Software Download on page 129 • Understanding Software Installation on EX Series Switches on page 44 • <i>Understanding DHCP Services for Switches</i>

auto-snapshot

Syntax	auto-snapshot;
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 12.3 for EX Series switches.
Description	Enable the automatic snapshot feature, which allows the switch to automatically fix a corrupt Junos OS file in the primary root partition. If the automatic snapshot feature is enabled, the switch automatically takes a snapshot of the Junos OS root file system in the alternate root partition and copies it onto the primary root partition, thereby repairing the corrupt file in the primary root partition. The automatic snapshot procedure takes place whenever the system reboots from the alternate root partition, regardless of whether the reboot is due to a command or due to corruption of the primary root partition.
<div>  NOTE: EX9200 switches do not support the automatic snapshot feature. </div>	
Default	<ul style="list-style-type: none"> The automatic snapshot feature is enabled by default on the following EX Series switches: <ul style="list-style-type: none"> EX4550 switches EX Series switches that ship with Junos OS Release 12.3R1 or later The automatic snapshot feature is disabled by default on EX Series switches (except the EX4550 switches) running Junos OS Release 12.2 or earlier. If the automatic snapshot feature was disabled by default before the switch was upgraded to Junos OS Release 12.3R1 or later, the feature remains disabled (for backward compatibility) by default after the upgrade.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

autoinstallation

Syntax	<pre> autoinstallation { configuration-servers { url { password <i>password</i>; } } interfaces { <i>interface-name</i> { bootp; rarp; } } usb { disable; } } </pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Specify the configuration for autoinstallation.
Options	The remaining statements are explained separately. See CLI Explorer .
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none"> • Configuring Autoinstallation on SRX Series Devices on page 84

autoinstallation (JNU Satellite Devices)

Syntax	<pre>autoinstallation { delete-after-commit; configuration-servers { url; } interfaces { interface-name { bootp; rarp; } } }</pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 13.3 for satellite devices in a Junos Node Unifier (JNU) group.
Description	(Satellite devices in a JNU group). Download a configuration file automatically from an FTP or HTTP server. When you power on a router or switch configured for autoinstallation, it requests an IP address from a Dynamic Host Configuration Protocol (DHCP) server. When the router or switch has an address, it sends a request to a configuration server and downloads and installs a configuration.
Options	The remaining statements are explained separately.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Autoinstallation of Satellite Devices in a Junos Node Unifier Group on page 91• Autoinstallation Process on Satellite Devices in a Junos Node Unifier Group on page 89• Configuring Autoinstallation on JNU Satellite Devices on page 87• Verifying Autoinstallation on JNU Satellite Devices on page 92• delete-after-commit (JNU Satellites) on page 284• configuration-servers

bootp

Syntax	<pre>bootp { command <i>binary-file-path</i>; disable; failover (alternate-media other-routing-engine); }</pre>
Hierarchy Level	[edit system processes]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify the booting process.
Options	<ul style="list-style-type: none"> • command <i>binary-file-path</i>—Path to the binary process. • disable —Disable the booting process. • failover—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot. <ul style="list-style-type: none"> • alternate-media—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly. • other-routing-engine—Instruct the secondary Routing Engine to take mastership if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.

configuration-servers

Syntax	<pre>configuration-servers { url { password <i>password</i>; } }</pre>
Hierarchy Level	[edit system autoinstallation]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>Configure the URL address of a server from which the configuration files must be obtained.</p> <p>You can download a configuration file automatically from an FTP, Hypertext Transfer Protocol (HTTP), or Trivial FTP (TFTP) servers. Examples of URLs:</p> <ul style="list-style-type: none"> • tftp://hostname/path/filename • ftp://username:password@ftp.hostname.net • http://hostname/path/filename • http://username:password@httpconfig.sp.com
Options	<ul style="list-style-type: none"> • url—Specify the URL address of the server containing the configuration files. • password—Specify the password for authentication with the configuration server. Specifying a password in URLs and in the <i>password</i> option might result in commit failure. We recommend you to use the <i>password</i> option for specifying the password.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Configuring Autoinstallation on SRX Series Devices on page 84

delete-after-commit (JNU Satellites)

Syntax	delete-after-commit;
Hierarchy Level	[edit system autoinstallation]
Release Information	Statement introduced in Junos OS Release 13.3 for satellite devices in a Junos Node Unifier (JNU) group.
Description	<p>Specify that during the subsequent commit operation of configuration settings (after the autoinstallation process successfully retrieves, installs, and commits the configuration), the autoinstallation configuration parameters be removed from the router. Removal of the autoinstallation parameters and statements from the committed configuration on the router ensures that the router does not attempt to perform an autoinstallation process when it is powered on the next time. Although you can optionally specify the interfaces to perform autoinstallation or configuration servers from which the files are to be downloaded, you must include the delete-after-commit statement to prevent the router from entering a recursive loop and repeatedly performing an autoinstallation every time it is powered on.</p>
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Autoinstallation of Satellite Devices in a Junos Node Unifier Group on page 91• Autoinstallation Process on Satellite Devices in a Junos Node Unifier Group on page 89• Configuring Autoinstallation on JNU Satellite Devices on page 87• Verifying Autoinstallation on JNU Satellite Devices on page 92• autoinstallation on page 280• configuration-servers

interfaces (Autoinstallation)

Syntax	<pre> interfaces { interface-name { bootp; rarp; } } </pre>
Hierarchy Level	[edit system autoinstallation]
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Configure the interface on which to perform autoinstallation. A request for an IP address is sent from the interface. Specify the IP address procurement protocol.
<div>  <p>NOTE: When you run the <code>system autoinstallation</code> command, the command will configure unit 0 logical interface for all the active state physical interfaces. However, few commands like <code>fabric-options</code> do not allow its physical interface to be configured with a logical interface. If the <code>system autoinstallation</code> and the <code>fabric-options</code> commands are configured together the following message is displayed incompatible with 'system autoinstallation'.</p> </div>	
Options	<ul style="list-style-type: none"> • bootp—Enables BOOTP or DHCP during autoinstallation. • rarp—Enables RARP during autoinstallation.
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Autoinstallation Overview on page 81 • Configuring Autoinstallation on SRX Series Devices on page 84

license

Syntax	<pre> license { autoupdate { url <i>url</i>; password <i>password</i>; } renew { before-expiration <i>number</i>; interval <i>interval-hours</i>; } traceoptions { file { <i>filename</i> ; files <i>number</i>; match <i>regular-expression</i>; size <i>maximum-file-size</i>; (world-readable no-world-readable); } flag <i>flag</i>; no-remote-trace; } } </pre>
Hierarchy Level	[edit system]
Release Information	Statement introduced in Junos OS Release 8.5.
Description	Specify license information for the device.
Options	<ul style="list-style-type: none"> • autoupdate—Autoupdate license keys from license servers. <ul style="list-style-type: none"> • url—URL of a license server. • renew—License renewal lead time and checking interval. <ul style="list-style-type: none"> • before-expiration <i>number</i>—License renewal lead time before expiration in days. Range : 0 through 60 days • interval <i>interval-hours</i>—License checking interval in hours. Range : 1 through 336 hours • traceoptions—Set the trace options. <ul style="list-style-type: none"> • file—Configure the trace file information. <ul style="list-style-type: none"> • <i>filename</i>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory /var/log. By default, the name of the file is the name of the process being traced. • files <i>number</i>— Maximum number of trace files. When a trace file named trace-file reaches its maximum size, it is renamed trace-file.0, then trace-file.1, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the **size *maximum file-size*** option.

Range : 2 through 1000 files

Default : 10 files

- **match *regular-expression***—Refine the output to include lines that contain the regular expression.
- **size *maximum-file-size***—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

Range : 10 KB through 1 GB

Default : 128 KB

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files *number*** option.

- **(world-readable | no-world-readable)**— By default, log files can be accessed only by the user who configures the tracing operation. The **world-readable** option enables any user to read the file. To explicitly set the default behavior, use the **no-world-readable** option.
- **flag *flag***—Specify which tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. You can include the following flags.
 - **all**—Trace all operations
 - **config**—Trace license configuration processing.
 - **events**—Trace licensing events and their processing.
 - **no-remote-trace**—Disable the remote tracing.

clear system login logout

Syntax	clear system login logout <all> <user <i>username</i> >
Release Information	Command introduced in Junos OS Release 11.2.
Description	Unlock the user account locked as a result of invalid login attempts.
Options	all —Clear all locked user accounts. user <i>username</i> —Clear the specified locked user account.
Required Privilege Level	clear
Related Documentation	<ul style="list-style-type: none">• lockout-period on page 1244• show system login logout on page 409
Output Fields	This command produces no output.

request system autorecovery state

Syntax	request system autorecovery state (save recover clear)
Release Information	Command introduced in Junos OS Release 11.2.
Description	Prepare the system for autorecovery of configuration, licenses, and disk information.
Options	<p>save—Save the current state of the disk partitioning, configuration, and licenses for autorecovery.</p> <p>The active Junos OS configuration is saved as the Junos rescue configuration, after which the rescue configuration, licenses, and disk partitioning information is saved for autorecovery. Autorecovery information must be initially saved using this command for the autorecovery feature to verify integrity of data on every bootup.</p>
	<div>  <p>NOTE:</p> <ul style="list-style-type: none"> Any recovery performed at a later stage will restore the data to the same state as it was when the save command was executed. A fresh rescue configuration is generated when the command is executed. Any existing rescue configuration will be overwritten. </div>
	<p>recover—Recover the disk partitioning, configuration, and licenses.</p> <p>After autorecovery data has been saved, the integrity of saved items is always checked automatically on every bootup. The recovery command allows you to forcibly re-run the tests at any time if required.</p>
	<p>clear—Clear all saved autorecovery information.</p> <p>Only the autorecovery information is deleted; the original copies of the data used by the router are not affected. Clearing the autorecovery information also disables all autorecovery integrity checks performed during bootup.</p>
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> show system autorecovery state on page 385

request system download abort

Syntax	<code>request system download abort <download-id></code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Abort a download. The download instance is stopped and cannot be resumed. Any partially downloaded file is automatically deleted to free disk space. Information regarding the download is retained and can be displayed with the show system download command until a request system download clear operation is performed.
<div> NOTE: Only downloads in the active, paused, and error states can be aborted.</div>	
Options	download-id —(Required) The ID number of the download to be aborted.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• request system download start on page 298• request system download pause on page 296• request system download resume on page 297• request system download clear on page 295

Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system download pause

```
user@host> request system download pause 1
Paused download #1
```

request system download resume

Syntax	<code>request system download resume <i>download-id</i> <max-rate></code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Resume a download that has been paused. Download instances that are not in progress because of an error or that have been explicitly paused by the user can be resumed by the user. The file will continue downloading from the point where it paused. By default, the download resumes with the same bandwidth specified with the request system download start command. The user can optionally specify a new (maximum) bandwidth with the request system download resume command.
<div>  NOTE: Only downloads in the paused and error states can be resumed. </div>	
Options	download-id —(Required) The ID number of the download to be resumed. max-rate —(Optional) The maximum bandwidth for the download.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> • request system download start on page 298 • request system download pause on page 296 • request system download abort on page 294 • request system download clear on page 295

Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system download resume

```
user@host> request system download resume 1
Resumed download #1
```

request system download start

Syntax	<code>request system download start (<i>url</i> <i>max-rate</i> <i>save as</i> <i>login</i> <i>delay</i>)</code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Creates a new download instance and identifies it with a unique integer called the download ID.
Options	<p>url—(Required) The FTP or HTTP URL location of the file to be downloaded.</p> <p>max-rate—(Optional) The maximum average bandwidth for the download. Numbers with the suffix k or K, m or M, and g or G are interpreted as kbps, mbps, or gbps, respectively.</p> <p>save-as—(Optional) The filename to be used for saving the file in the <code>/var/tmp</code> location.</p> <p>login—(Optional) The username and password for the server in the format <code>username:password</code>.</p> <p>delay—(Optional) The number of hours after which the download should start.</p>
Required Privilege Level	maintenance

request system partition compact-flash

Syntax	request system partition compact-flash
Release Information	Command introduced in Junos OS Release 9.2. Command deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.
<div>  NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in “Understanding Junos OS with Upgraded FreeBSD” on page 19. </div>	
Description	Reboots the device and repartitions the compact flash. The CompactFlash card is repartitioned only if it is possible to restore all the data on the CompactFlash card. Otherwise, the operation is aborted, and a message is displayed indicating that the current disk usage needs to be reduced.
Required Privilege Level	maintenance
List of Sample Output	request system partition compact-flash (If Yes) on page 306 request system partition compact-flash (If No) on page 306
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system partition compact-flash (If Yes)

```

user@host> request system partition compact-flash
Are you sure you want to reboot
and partition the compact-flash ? [yes,no] yes
Initiating repartition operation.
The operation may take several minutes to complete.
System will reboot now...
<System reboots>
<Repartition operation is performed>
<System reboots and starts up normally>

```

Sample Output

request system partition compact-flash (If No)

```

user@host> request system partition compact-flash
Are you sure you want to reboot
and partition the compact-flash ? [yes,no] no

```

request system power-off

Syntax	<pre>request system power-off at <time> both-routing-engines in <minutes> media (compact-flash disk usb) messages <message> other-routing-engine</pre>
Release Information	Command introduced in Junos OS Release 11.4.
Description	Power off the system.
Options	<p>at <i>time</i>— Time at which to power off the system.</p> <p>both-routing-engines— Both routing engines are powered off and both the primary and the secondary devices are rebooted at the same time.</p> <p>in <i>minutes</i>— Number of minutes to delay before powering off the system.</p> <p>media —Boot media for the next boot.</p> <ul style="list-style-type: none"> • compact-flash— Standard boot from a flash device. • disk— Boot from a hard disk. • usb— Boot from a USB device. <p>message <i>message</i>— Message that is displayed to all system users before powering off the system.</p> <p>other-routing-engine— The other routing engine is powered off.</p>

```
<media (external | internal)>
<member member-id>
<message "text">
<other-routing-engine>
```

Release Information Command introduced before Junos OS Release 7.4.
Option **other-routing-engine** introduced in Junos OS Release 8.0.
Command introduced in Junos OS Release 9.0 for EX Series switches.
Option **sfc** introduced for the TX Matrix Plus router in Junos OS Release 9.6.
Option **both-routing-engines** introduced in Junos OS Release 12.1.

Description Reboot the software.

Options **none**—Reboot the software immediately.

all-chassis—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router or TX Matrix Plus router, reboot all routers connected to the TX Matrix or TX Matrix Plus router, respectively.

all-lcc—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router or TX Matrix Plus router, reboot all line card chassis connected to the TX Matrix or TX Matrix Plus router, respectively.

all-members—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on all members of the Virtual Chassis configuration.

at *time*—(Optional) Time at which to reboot the software, specified in one of the following ways:

- **now**—Stop or reboot the software immediately. This is the default.
- **+*minutes***—Number of minutes from now to reboot the software.
- ***yymmddhhmm***—Absolute time at which to reboot the software, specified as year, month, day, hour, and minute.
- ***hh:mm***—Absolute time on the current day at which to stop the software, specified in 24-hour time.

both-routing-engines—(Optional) Reboot both Routing Engines at the same time.

in *minutes*—(Optional) Number of minutes from now to reboot the software. This option is an alias for the **at +*minutes*** option.

lcc *number*—(TX Matrix routers and TX Matrix Plus routers only) (Optional) Line-card chassis number.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.

- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

local—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on the local Virtual Chassis member.

media (compact-flash | disk)—(Optional) Boot medium for next boot.

media (external | internal)—(EX Series switches and MX Series routers only) (Optional) Reboot the boot media:

- **external**—Reboot the external mass storage device.
- **internal**—Reboot the internal flash device.

member *member-id*—(EX4200 switches and MX Series routers only) (Optional) Reboot the software on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

message "*text*"—(Optional) Message to display to all system users before stopping or rebooting the software.

other-routing-engine—(Optional) Reboot the other Routing Engine from which the command is issued. For example, if you issue the command from the master Routing Engine, the backup Routing Engine is rebooted. Similarly, if you issue the command from the backup Routing Engine, the master Routing Engine is rebooted.

partition—(TX Matrix Plus routers only) (Optional) Reboot using the specified partition on the boot media. This option has the following suboptions:

- **1**—Reboot from partition 1.
- **2**—Reboot from partition 2.
- **alternate**—Reboot from the alternate partition.

scc—(TX Matrix routers only) (Optional) Reboot the Routing Engine on the TX Matrix switch-card chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted.

sfc *number*—(TX Matrix Plus routers only) (Optional) Reboot the Routing Engine on the TX Matrix Plus switch-fabric chassis. If you issue the command from re0, re0 is rebooted. If you issue the command from re1, re1 is rebooted. Replace *number* with 0.

slice *slice*—(EX Series switches only) (Optional) Reboot a partition on the boot media. This option has the following suboptions:

- **1**—Power off partition 1.
- **2**—Power off partition 2.

- **alternate**—Reboot from the alternate partition.

Additional Information Reboot requests are recorded in the system log files, which you can view with the **show log** command (see *show log*). Also, the names of any running processes that are scheduled to be shut down are changed. You can view the process names with the **show system processes** command (see *show system processes*).

On a TX Matrix or TX Matrix Plus router, if you issue the **request system reboot** command on the master Routing Engine, all the master Routing Engines connected to the routing matrix are rebooted. If you issue this command on the backup Routing Engine, all the backup Routing Engines connected to the routing matrix are rebooted.

NOTE: Before issuing the **request system reboot** command on a TX Matrix Plus router with no options or the **all-chassis**, **all-lcc**, **lcc number**, or **sfc** options, verify that master Routing Engine for all routers in the routing matrix are in the same slot number. If the master Routing Engine for a line-card chassis is in a different slot number than the master Routing Engine for a TX Matrix Plus router, the line-card chassis might become logically disconnected from the routing matrix after the **request system reboot** command.

NOTE: To reboot a router that has two Routing Engines, reboot the backup Routing Engine (if you have upgraded it) first, and then reboot the master Routing Engine.

Required Privilege Level maintenance

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system reboot

```
user@host> request system reboot
Reboot the system ? [yes,no] (no)
```

request system reboot (at 2300)

```
user@host> request system reboot at 2300 message ?Maintenance time!?
Reboot the system ? [yes,no] (no) yes
```

```
shutdown: [pid 186]
*** System shutdown message from root@berry.network.net ***
System going down at 23:00
```

request system reboot (in 2 Hours)

The following example, which assumes that the time is 5 PM (17:00), illustrates three different ways to request the system to reboot in two hours:

```
user@host> request system reboot at +120
user@host> request system reboot in 120
user@host> request system reboot at 19:00
```

request system reboot (Immediately)

```
user@host> request system reboot at now
```

request system reboot (at 1:20 AM)

To reboot the system at 1:20 AM, enter the following command. Because 1:20 AM is the next day, you must specify the absolute time.

```
user@host> request system reboot at 06060120
request system reboot at 120
Reboot the system at 120? [yes,no] (no) yes
```

request system reboot

Syntax	<pre>request system reboot <all-members local member member-id> <at time> <in minutes> <media (external internal)> <message "text"> <slice (1 2 alternate)></pre>
Release Information	<p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Option partition changed to slice in Junos OS Release 10.0 for EX Series switches.</p>
Description	<p>Reboot the Junos OS.</p> <p>Reboot requests are recorded in the system log files, which you can view with the show log command. You can view the process names with the show system processes command.</p>
Options	<p>none—Reboots the software immediately.</p> <p>all-members local member member-id—(Optional) Specify which member of the Virtual Chassis to reboot:</p> <ul style="list-style-type: none"> • all-members—Reboots each switch that is a member of the Virtual Chassis. • local—Reboots the local switch, meaning the switch you are logged into, only. • member member-id—Reboots the specified member switch of the Virtual Chassis. <p>at time—(Optional) Time at which to reboot the software, specified in one of the following ways:</p> <ul style="list-style-type: none"> • +minutes—Number of minutes from now to reboot the software. • hh:mm—Absolute time on the current day at which to reboot the software, specified in 24-hour time. • now—Stop or reboot the software immediately. This is the default. • yymmddhhmm—Absolute time at which to reboot the software, specified as year, month, day, hour, and minute. <p>in minutes—(Optional) Number of minutes from now to reboot the software. This option is an alias for the at +minutes option.</p> <p>media (external internal)—(Optional) Boot medium for the next boot. The external option reboots the switch using a software package stored on an external boot source, such as a USB flash drive. The internal option reboots the switch using a software package stored in an internal memory source.</p> <p>message "text"—(Optional) Message to display to all system users before rebooting the software.</p>

slice (1 | 2 | alternate)—(Optional) Reboot using the specified partition on the boot media.

This option has the following suboptions:

- **1**—Reboot from partition 1.
- **2**—Reboot from partition 2.
- **alternate**—Reboot from the alternate partition, which is the partition that did not boot the switch at the last bootup.

List of Sample Output

[request system reboot on page 317](#)
[request system reboot \(at 2300\) on page 317](#)
[request system reboot \(in 2 Hours\) on page 318](#)
[request system reboot \(Immediately\) on page 318](#)
[request system reboot \(at 1:20 AM\) on page 318](#)

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system reboot

```
user@host> request system reboot
Reboot the system ? [yes,no] (no)
```

request system reboot (at 2300)

```
user@host> request system reboot at 2300 message "Maintenance time!"
```

```
Reboot the system ? [yes,no] (no) yes
```

```
shutdown: [pid 186]
```

```
*** System shutdown message from root@berry.network.net ***
```

```
System going down at 23:00
```

request system reboot (in 2 Hours)

The following example, which assumes that the time is 5 PM (17:00), illustrates three different ways to request the system to reboot in two hours:

```
user@host> request system reboot at +120
```

```
user@host> request system reboot in 120
```

```
user@host> request system reboot at 19:00
```

request system reboot (Immediately)

```
user@host> request system reboot at now
```

request system reboot (at 1:20 AM)

To reboot the system at 1:20 AM, enter the following command. Because 1:20 AM is the next day, you must specify the absolute time.

```
user@host> request system reboot at 06060120
```

```
request system reboot at 120
```

```
Reboot the system at 120? [yes,no] (no) yes
```

request system scripts add

Syntax	<code>request system scripts add <package-name></code> <code><no-copy></code> <code><unlink></code>
Release Information	Command introduced before Junos OS Release 9.0.
Description	CLI command to install AI-Script (jais) packages on Juniper Networks devices.
Options	no-copy —Don't save a copy of the jais package file. user@host> <code>request system scripts add no-copy <package-name></code>

NOTE: If you use the no-copy option during the jais installation, the jais package cannot be rolled back.

unlink—Remove the package after successful installation.

user@host> `request system scripts add unlink <package-name>`

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in [“Understanding Junos OS with Upgraded FreeBSD” on page 19](#).

- Description**
- On the router, back up the currently running and active file system partitions to standby partitions that are not running. Specifically, the root file system (/) is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.
 - On the switch, take a snapshot of the files currently used to run the switch—the complete contents of the root (/), **/altroot**, **/config**, **/var**, and **/var-tmp** directories, which include the running Junos OS, the active configuration, and log files.

CAUTION: After you run the **request system snapshot** command, you cannot return to the previous version of the software, because the running and backup copies of the software are identical.

Options The specific options available depend upon the router or switch:

none—Back up the currently running software as follows:

- On the router, back up the currently running and active file system partitions to standby partitions that are not running. Specifically, the root file system (/) is backed up to **/altroot**, and **/config** is backed up to **/altconfig**. The root and **/config** file systems are on the router's flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard drive.
- On the switch, take a snapshot of the files currently used to run the switch and copy them to the media that the switch did not boot from. If the switch is booted from internal media, the snapshot is copied to external (USB) media. If the switch is booted from external (USB) media, the snapshot is copied to internal media.
 - If the snapshot destination is external media but a USB flash drive is not connected, an error message is displayed.
 - If the automatic snapshot procedure is already in progress, the command returns the following error: **Snapshot already in progress. Cannot start manual snapshot**. For additional information about the automatic snapshot feature, see [“Understanding Resilient Dual-Root Partitions on Switches” on page 95](#).

all-chassis | all-lcc | lcc *number* —(TX Matrix and TX Matrix Plus router only) (Optional)

- all-chassis**—On a TX Matrix router, archive data and executable areas for all Routing Engines in the chassis. On a TX Matrix Plus router, archive data and executable areas for all Routing Engines in the chassis.

- **all-lcc**—On a TX Matrix router, archive data and executable areas for all T640 routers (or line-card chassis) connected to a TX Matrix router. On a TX Matrix Plus router, archive data and executable areas for all routers (or line-card chassis) connected to a TX Matrix Plus router.
- **lcc *number***—On a TX Matrix router, archive data and executable areas for a specific T640 router (or line-card chassis) that is connected to a TX Matrix router. On a TX Matrix Plus router, archive data and executable areas for a specific router (line-card chassis) that is connected to a TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

all-members | local | member *member-id*—(EX Series switch Virtual Chassis and MX Series routers only) (Optional) Specify where to place the snapshot (archive data and executable areas) in a Virtual Chassis:

- **all-members**—Create a snapshot (archive data and executable areas) for all members of the Virtual Chassis.
- **local**—Create a snapshot (archive data and executable areas) on the member of the Virtual Chassis that you are currently logged into.
- **member *member-id***—Create a snapshot (archive data and executable areas) for the specified member of the Virtual Chassis.

config-partition—(M, MX, T, TX Series routers only) Create a snapshot of the configuration partition only and store it onto the default **/altconfig** on the hard disk device or an **/altconfig** on a USB device.

Option deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in [“Understanding Junos OS with Upgraded FreeBSD” on page 19](#).

media *type*—(ACX Series, M320, T640, MX960 routers, and EX Series switches only)(Optional) Specify the boot device the software is copied to:

- **compact-flash**—Copy software to the primary compact flash drive.
- **external**—(Switches only) Copy software to an external mass storage device, such as a USB flash drive. If a USB drive is not connected, the switch displays an error message.
- **internal**—Copy software to an internal flash drive.
- **removable-compact-flash**—Copy software to the removable compact flash drive.
- **usb**—(ACX Series, M320, T640, MX960 routers only) Copy software to the device connected to the USB port.
- **usb0**—(MX104 routers only) Copy software to the device connected to the USB0 port.
- **usb1**—(MX104 routers only) Copy software to the device connected to the USB1 port.

partition—(Optional) Repartition the flash drive before a snapshot occurs. If the partition table on the flash drive is corrupted, the **request system snapshot** command fails and reports errors. The partition option is only supported for restoring the software image from the hard drive to the flash drive.

(Routers only) You cannot issue the request system snapshot command when you enable flash disk mirroring. We recommend that you disable flash disk mirroring when you upgrade or downgrade the software. For more information, see the *Junos OS Administration Library for Routing Devices*.

(EX Series switches only) If the snapshot destination is the media that the switch did not boot from, you must use the **partition** option.

re0 | re1 | routing-engine routing-engine-id—(EX6200 and EX8200 switches only) Specify where to place the snapshot in a redundant Routing Engine configuration.

- **re0**—Create a snapshot on Routing Engine 0.
- **re1**—Create a snapshot on Routing Engine 1.
- **routing-engine routing-engine-id**—Create a snapshot on the specified Routing Engine.

root-partition—(M, MX, T, TX Series routers only) Create a snapshot of the root partition only and store it onto the default **/altroot** on the hard disk device or an **/altroot** on a USB device.

Option deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19.

slice alternate—(EX Series switches only) (Optional) Take a snapshot of the active root partition and copy it to the alternate slice on the boot media.

Option deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19.

scc—(TX Matrix router only) (Optional) Archive data and executable areas for a TX Matrix router (or switch-card chassis).

sfc number—(TX Matrix Plus router only) (Optional) Archive data and executable areas for a TX Matrix Plus router (or switch-fabric chassis). Replace *number* with 0.

Additional Information

- (Routers only) Before upgrading the software on the router, when you have a known stable system, issue the **request system snapshot** command to back up the software, including the configuration, to the **/altroot** and **/altconfig** file systems. After you have upgraded the software on the router and are satisfied that the new packages are successfully installed and running, issue the **request system snapshot** command again to back up the new software to the **/altroot** and **/altconfig** file systems.
- (Routers only) You cannot issue the **request system snapshot** command when you enable flash disk mirroring. We recommend that you disable flash disk mirroring when you upgrade or downgrade the software. For more information, see the *Junos OS Administration Library for Routing Devices*.
- (TX Matrix and TX Matrix Plus router only) On a routing matrix, if you issue the **request system snapshot** command on the master Routing Engine, all the master Routing Engines connected to the routing matrix are backed up. If you issue this command on the backup Routing Engine, all the backup Routing Engines connected to the routing matrix are backed up.

request system snapshot (Junos OS with Upgraded FreeBSD)

Syntax	request system snapshot <delete <i>snapshot-name</i> > <load <i>snapshot-name</i> > <media <i>type</i> > <recovery>
Release Information	Command introduced in Junos OS Release 15.1 for MX240, MX480, MX960, MX2010, and MX2020 routers and EX9200 switches. Command introduced in Junos OS Release 15.1X53-D30 for QFX5200 switches.
Description	On the router or switch, back up the currently running and active file system partitions to standby partitions that are not running. Non-recovery snapshots are named snap.date.time and stored in the /packages/sets directory.
<div>  <p>CAUTION: After you run the request system snapshot command, you cannot return to the previous version of the software, because the running and backup copies of the software are identical.</p> </div>	
Options	<p>none—On the router or switch, back up the currently running and active file system partitions to standby partitions that are not running. Specifically, this creates a non-recovery snapshot named snap.<date>.<time> which is stored in /packages/sets.</p> <p>delete <i>snapshot-name</i>—(Optional) Delete a specific non-recovery snapshot from /packages/sets. Wildcards are supported, so request system snapshot delete snap* deletes all snapshots.</p> <p>load <i>snapshot-name</i>—(Optional) Load a specific snapshot from /packages/sets.</p> <p>media <i>type</i>—(Optional) Specify the boot device the software is copied to:</p> <ul style="list-style-type: none"> usb—(MX960 routers only) Copy software to the device connected to the USB port. <p>recovery—Create a recovery snapshot and store it in the /oam volume.</p>
Additional Information	Before upgrading the software on the router or switch, when you have a known stable system, issue the request system snapshot command to back up the software, including the configuration, to the /packages/sets file systems. After you have upgraded the software on the router or switch and are satisfied that the new packages are successfully installed and running, issue the request system snapshot command again to back up the new software to the /packages/sets file systems.

request system snapshot (SRX Series)

Syntax request system snapshot
 <factory>
 <media (compact-flash | hard-disk | internal | usb)>
 <node (all | local | node-id | primary)>
 <partition>
 <slice (alternate) >

Release Information Command introduced in Junos OS Release 10.2.

Description Back up the currently running and active file system partitions on the device.

- Options**
- **media—** (Optional) Specifies the media to be included in the snapshot:
 - **compact-flash—** Copies the snapshot to the CompactFlash card.
 - **hard-disk—** Copies the snapshot to the hard disk.
 - **usb—** Copies the snapshot to the USB storage device.
 - **node—** (Optional) Specifies the archive data and executable areas of a specific node.
 - **node-id—** Specifies for node(0, 1).
 - **all—** Specifies for all nodes.
 - **local—** Specifies for local nodes.
 - **primary—** Specifies for primary nodes.
 - **partition -** (Default) Specifies that the target media should be repartitioned before the backup is saved to it.

NOTE: The target media is partitioned whether or not it is specified in the command, because this is a mandatory option.

Example: request system snapshot media usb partition

Example: request system snapshot media usb partition factory

- **slice—** (Optional) Takes a snapshot of the root partition the system has currently booted from to another slice in the same media.
- **alternate—** (Optional) Stores the snapshot on the other root partition in the system.

NOTE: The slice option cannot be used along with the other request system snapshot options, because the options are mutually exclusive. If you use the factory, media, or partition option, you cannot use the slice option; if you use the slice option, you cannot use any of the other options.

Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• Example: Installing Junos OS on SRX Series Devices Using the Partition Option on page 110

```

request system software abort in-service-upgrade (ICU)

Syntax	request system software abort in-service-upgrade
Release Information	Command introduced in Junos OS Release 11.2.
Description	Abort an in-band cluster upgrade (ICU). This command must be issued from a router session other than the one on which you issued the request system in-service-upgrade command that launched the ICU. If an ICU is in progress, this command aborts it. If the node is being upgraded, this command will cancel the upgrade. The command is also helpful in recovering the node in case of a failed ICU.
Options	This command has no options.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • <i>request system software in-service-upgrade (Maintenance)</i>
List of Sample Output	request system software abort in-service-upgrade on page 333
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

<upgrade-with-config-format format>
<validate>
```

Release Information Command introduced before Junos OS Release 7.4.
best-effort-load and **unlink** options added in Junos OS Release 7.4.
 Command introduced in Junos OS Release 9.0 for EX Series switches.
sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6.
 Command introduced in Junos OS Release 11.1 for the QFX Series.
set [package-name package-name] option added in Junos OS Release 11.1 for EX Series switches.
set [package-name package-name] option added in Junos OS Release 12.2 for M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways.

NOTE: On EX Series switches, the **set [package-name package-name]** option allows you to install only two software packages on a mixed EX4200 and EX4500 Virtual Chassis, whereas, on M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways, the **set [package-name package-name]** option allows you to install multiple software packages and software add-on packages at the same time.

upgrade-with-config and **upgrade-with-config-format *format*** options added in Junos OS Release 12.3 for M Series routers, MX Series routers, T Series routers, EX Series Ethernet switches, and QFX Series devices.

Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

device-alias, **satellite**, **upgrade-group**, and **version** options introduced in Junos OS Release 14.2R3 for Junos Fusion.

Description

NOTE: We recommend that you always download the software image to **/var/tmp** only. On EX Series and QFX Series switches, you must use the **/var/tmp** directory. Other directories are not supported.

Install a software package or bundle on the router or switch.

WARNING: Any configuration changes performed after inputting the `request system software add` command will be lost when the system reboots with an upgraded version of Junos OS.

NOTE: When graceful Routing Engine switchover (GRES) is enabled on a device, you must perform a unified ISSU operation to update the software running on the device. With GRES enabled, if you attempt to perform a software upgrade by entering the `request system software add package-name` command, an error message is displayed stating that only in-service-software-upgrades are supported when GRES is configured. In such a case, you must either remove the GRES configuration before you attempt the upgrade or perform a unified ISSU.

Options *package-name*—Location from which the software package or bundle is to be installed.

For example:

- */var/tmp/package-name*—For a software package or bundle that is being installed from a local directory on the router or switch.
- *protocol://hostname/pathname/package-name*—For a software package or bundle that is to be downloaded and installed from a remote location. Replace *protocol* with one of the following:
 - **ftp**—File Transfer Protocol.
Use *ftp://hostname/pathname/package-name*. To specify authentication credentials, use *ftp://<username>:<password>@hostname/pathname/package-name*. To have the system prompt you for the password, specify **prompt** in place of the password. If a password is required, and you do not specify the password or **prompt**, an error message is displayed.
 - **http**—Hypertext Transfer Protocol.
Use *http://hostname/pathname/package-name*. To specify authentication credentials, use *http://<username>:<password>@hostname/pathname/package-name*. If a password is required and you omit it, you are prompted for it.
 - **scp**—Secure copy (available only for Canada and U.S. version).
Use *scp://hostname/pathname/package-name*. To specify authentication credentials, use *scp://<username>:<password>@hostname/pathname/package-name*.

**NOTE:**

- The *pathname* in the protocol is the relative path to the user's home directory on the remote system and not the root directory.
- Do not use the `scp` protocol in the `request system software add` command to download and install a software package or bundle from a remote location. The previous statement does not apply to the QFabric switch. The software upgrade is handled by the MGD process which does not support `scp`.
Use the `file copy` command to copy the software package or bundle from the remote location to the `/var/tmp` directory on the hard disk:
`file copy scp://source/package-name /var/tmp`
Then install the software package or bundle using the `request system software add` command:
`request system software add /var/tmp/package-name`

best-effort-load—(Optional) Activate a partial load and treat parsing errors as warnings instead of errors.

component all—(QFabric systems only) (Optional) Install software package on all of the QFabric components.

delay-restart—(Optional) Install a software package or bundle, but do not restart software processes.

device-alias *alias-name*—(Junos Fusion only) (Optional) Install the satellite software package onto the specified satellite device using the satellite device's alias name.

force—(Optional) Force the addition of the software package or bundle (ignore warnings).

force-host—(Optional) Force the addition of host software package or bundle (ignore warnings) on the QFX5100 device.

lcc *number*—(TX Matrix routers and TX Matrix Plus routers only) (Optional) In a routing matrix based on the TX Matrix router, install a software package or bundle on a T640 router that is connected to the TX Matrix router. In a routing matrix based on the TX Matrix Plus router, install a software package or bundle on a router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.

- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

member *member-id*—(MX Series routers only) (Optional) Install a software package on the specified Virtual Chassis member. Replace *member-id* with a value of 0 or 1.

partition—(QFX3500 switches only) (Optional) Format and repartition the media before installation.

satellite *slot-id*—(Junos Fusion only) (Optional) Install the satellite software package onto the specified satellite device using the satellite devices FPC slot identifier.

scc—(TX Matrix routers only) (Optional) Install a software package or bundle on a Routing Engine on a TX Matrix router (or switch-card chassis).

sfc *number*—(TX Matrix Plus routers only) (Optional) Install a software package or bundle on a Routing Engine on a TX Matrix Plus router. Replace *number* with 0.

no-copy—(Optional) Install a software package or bundle, but do not save copies of the package or bundle files.

no-validate—(Optional) When loading a software package or bundle with a different release, suppress the default behavior of the **validate** option.

re0 | re1—(Optional) On routers or switches that support dual or redundant Routing Engines, load a software package or bundle on the Routing Engine in slot 0 (re0) or the Routing Engine in slot 1 (re1).

reboot—(Optional) After adding the software package or bundle, reboot the system. On a QFabric switch, the software installation is not complete until you reboot the component for which you have installed the software.

set [*package-name package-name*]—(Mixed EX4200 and EX4500 Virtual Chassis only) (Optional) Install two software packages—a package for an EX4200 switch and the same release of the package for an EX4500 switch—to upgrade all member switches in a mixed EX4200 and EX4500 Virtual Chassis.

set [*package-name package-name*]—(M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways only) (Optional) Install multiple software packages and software add-on packages at the same time.

unlink—(Optional) On M Series, T Series, and MX Series routers, use the unlink option to remove the software package from this directory after a successful upgrade is completed.

upgrade-group [all |*upgrade-group-name*]—(Junos Fusion only) (Required to configure a Junos Fusion using autoconversion or manual conversion) Associate a satellite software image with a satellite software upgrade group. The satellite software package is associated with the specified satellite software upgrade group using the

upgrade-group-name, or for all satellite software upgrade groups in a Junos Fusion when the *all* keyword is specified.

A satellite software upgrade group is a group of satellite devices in a Junos Fusion that are designated to upgrade to the same satellite software version using the same satellite software package. See *Understanding Software in a Junos Fusion* and *Managing Satellite Software Upgrade Groups in a Junos Fusion*.

upgrade-with-config—(Optional) Install one or more configuration files.

upgrade-with-config-format *format*—(Optional) Specify the configuration file format, **text** or **xml**. The default format is **text**.

NOTE: The **upgrade-with-config** and **upgrade-with-config-format** options are only available locally on the router or switch. In a routing matrix, the configuration is applied only to the local router and is not propagated to other routers.

The options are validated during the validation process and applied to the router or switch during the upgrade process. If the upgrade process is successful, the options are removed from the configuration. If the upgrade process fails, the configuration file is renamed with the **.failed** suffix.

validate—(Optional) Validate the software package or bundle against the current configuration as a prerequisite to adding the software package or bundle. This is the default behavior when the software package or bundle being added is a different release.

NOTE: The **validate** option only works on systems that do not have graceful-switchover (GRES) enabled. To use the **validate** option on a system with GRES, either disable GRES for the duration of the installation, or install using the command **request system software in-service-upgrade**, which requires nonstop active routing (NSR) to be enabled when using GRES.

version *version-string*—(Junos Fusion only) (Optional) Associate a satellite software package with a satellite software upgrade group by selecting the satellite software package's version. This option can only be used if the specified version of the satellite software has previously been installed on the aggregation device.

Additional Information Before upgrading the software on the router or switch, when you have a known stable system, issue the **request system snapshot** command to back up the software, including the configuration, to the **/altroot** and **/altconfig** file systems. After you have upgraded the software on the router or switch and are satisfied that the new package or bundle is

successfully installed and running, issue the **request system snapshot** command again to back up the new software to the **/altroot** and **/altconfig** file systems.

NOTE: The **request system snapshot** command is currently not supported on the QFabric system. Also, you cannot add or install multiple packages on a QFabric system.

After you run the **request system snapshot** command, you cannot return to the previous version of the software, because the running and backup copies of the software are identical.

If you are upgrading more than one package at the same time, delete the operating system package, **jkernl**, last. Add the operating system package, **jkernl**, first and the routing software package, **jroute**, last. If you are upgrading all packages at once, delete and add them in the following order:

```
user@host> request system software add /var/tmp/jbase
user@host> request system software add /var/tmp/jkernl
user@host> request system software add /var/tmp/jpfe
user@host> request system software add /var/tmp/jdocs
user@host> request system software add /var/tmp/jroute
user@host> request system software add /var/tmp/jcrypto
```

By default, when you issue the **request system software add package-name** command on a TX Matrix master Routing Engine, all the T640 master Routing Engines that are connected to it are upgraded to the same version of software. If you issue the same command on the TX Matrix backup Routing Engine, all the T640 backup Routing Engines that are connected to it are upgraded to the same version of software.

Likewise, when you issue the **request system software add package-name** command on a TX Matrix Plus master Routing Engine, all the T1600 or T4000 master Routing Engines that are connected to it are upgraded to the same version of software. If you issue the same command on the TX Matrix Plus backup Routing Engine, all the T1600 or T4000 backup Routing Engines that are connected to it are upgraded to the same version of software.

request system software add (Maintenance)

Syntax	<code>request system software add <i>package-name</i></code>
Release Information	Partition option introduced in the command in Junos OS Release 10.1.
Description	Install the new software package on the device. For example: request system software add junos-srxsme-10.0R2-domestic.tgz no-copy no-validate partition reboot.
Options	<ul style="list-style-type: none">• <code>delay-restart</code> — Installs the software package but does not restart the software process• <code>best-effort-load</code> — Activate a partial load and treat parsing errors as warnings instead of errors• <code>no-copy</code> — Installs the software package but does not saves the copies of package files• <code>no-validate</code> — Does not check the compatibility with current configuration before installation starts• <code>partition</code> — Formats and re-partitions the media before installation• <code>reboot</code> — Reboots the device after installation is completed• <code>unlink</code> — Removes the software package after successful installation• <code>validate</code> — Checks the compatibility with current configuration before installation starts
Required Privilege Level	maintenance

request system software configuration-backup

Syntax	request system software configuration-backup (<i>path</i>)
Release Information	Command introduced in Junos OS Release 11.3 for the QFX Series.
Description	Save the currently active configuration and any installation-specific parameters such as a configuration that you have entered outside of the CLI, Director group IP addresses, and the default partition IP address.
Options	path —(QFabric System) Provide the path to the location of the backup configuration files. You can save the backup configuration files to either a URL, local directory, remote server, or removable drive.
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none"> • request system software configuration-restore on page 346 • <i>Performing a QFabric System Recovery Installation on the Director Group</i>
List of Sample Output	request system software configuration-backup on page 345
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system software configuration-backup

```

user@switch request system software configuration-backup ftp://ftp.test.net/test
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current

Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Option sfc introduced for the TX Matrix Plus router in Junos OS Release 9.6.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>Option set [<i>package-name package-name</i>] added in Junos OS Release 12.2 for M Series, MX Series, T Series routers, and Branch SRX Services Gateways.</p> <p>Option reboot introduced in Junos OS Release 12.3.</p> <p>Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.</p> <p>Options upgrade-group, and version introduced in Junos OS Release 14.2R3 for Junos Fusion.</p>
Description	Remove a software package or bundle from the router or switch.
<div style="text-align: center;">  <p>CAUTION: Before removing a software package or bundle, make sure that you have already placed the new software package or bundle that you intend to load onto the router or switch.</p> </div>	
Options	<p><i>software-package</i>—Software package or bundle name. You can delete any or all of the following software bundles or packages:</p> <ul style="list-style-type: none"> jbase—(Optional) Junos base software suite jcrypto—(Optional, in domestic version only) Junos security software

- **jdocs**—(Optional) Junos online documentation file
- **jkernel**—(Optional) Junos kernel software suite
- **jpfe**—(Optional) Junos Packet Forwarding Engine support
- **jroute**—(Optional) Junos routing software suite
- **junos**—(Optional) Junos base software

NOTE: On EX Series switches, some of the package names are different than those listed. To see the list of packages that you can delete on an EX Series switch, enter the command **show system software**.

force—(Optional) Ignore warnings and force removal of the software.

lcc number—(TX Matrix routers and TX Matrix Plus routers only) (Optional) In a routing matrix, delete a software package or bundle on a T640 router indicated by **lcc number** that is connected to the TX Matrix router. In a routing matrix, delete a software package or bundle on a router indicated by **lcc number** that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

re0 | re1—(Optional) On routers or switches that support dual or redundant Routing Engines, delete a software package or bundle on the Routing Engine in slot 0 (**re0**) or the Routing Engine in slot 1 (**re1**).

reboot—As of Junos OS 12.3 and greater, automatically reboot upon completing the **request system software delete** command.

scc—(TX Matrix routers only) (Optional) Remove an extension or upgrade package from the TX Matrix router (or switch-card chassis).

set [package-name package-name]—(M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways only) (Optional) Install multiple software packages or software add-on packages at the same time.

sfc number—(TX Matrix Plus routers only) (Optional) Remove an extension or upgrade package from the TX Matrix Plus router. Replace *number* with 0.

upgrade-group [**all** [*upgrade-group-name*]]—(Junos Fusion only) Delete the satellite software image association with the specified satellite software upgrade group.

A satellite software upgrade group is a group of satellite devices in the same Junos Fusion that are designated to upgrade to the same satellite software version using the same satellite software package.

version *version-string*—(Junos Fusion only) (Optional) Delete a satellite software package association with a satellite software upgrade group by selecting the satellite software package's version.

Additional Information Before upgrading the software on the router or switch, when you have a known stable system, issue the **request system snapshot** command to back up the software, including the configuration, to the /altroot and /altconfig file systems (on routers) or the /, /altroot, /config, /var, and /var/tmp file systems (on switches). After you have upgraded the software on the router or switch and are satisfied that the new packages are successfully installed and running, issue the **request system snapshot** command again to back up the new software to the /altroot and /altconfig file systems (on routers) or the /, /altroot, /config, /var, and /var/tmp file systems (on switches). After you run the **request system snapshot** command, you cannot return to the previous version of the software, because the running and backup copies of the software are identical.

Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. Option sfc introduced for the TX Matrix Plus router in Junos OS Release 9.6. Command introduced in Junos OS Release 11.1 for the QFX Series. Command behavior changed in Junos OS Release 12.1. Option reboot introduced in Junos OS Release 12.3. Options device-alias , satellite , and upgrade-group introduced in Junos OS Release 14.2R3 for Junos Fusion. Option force deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19.

Description For all versions of Junos OS up to and including Junos OS 11.4, revert to the software that was loaded at the last successful **request system software add** command.

As of Junos OS 12.1 and greater, revert to the last known good state before the most recent **request system software (add | delete)** command. For example, using **rollback** in Junos OS 12.1 after using **request system software add** restores the system to a known good state prior to using the **add** command. Similarly, using **rollback** in Junos OS 12.1 after using **request system software delete** restores the system to a known good state prior to using the **delete** command.

A software rollback fails if any required package (or a **bundle** package containing the required package) cannot be found in `/var/sw/pkg`.

Additional Information

- On a Junos Fusion, the **request system software rollback** command can be used to roll back the version of satellite software associated with a satellite software upgrade group. Rolling back the version of satellite software associated with a satellite software upgrade group triggers a satellite software upgrade.
- On M Series and T Series routers, if **request system software add <jinstall> reboot** was used for the previous installation, then **request system software rollback** has no effect. In this case, use **jinstall** to reinstall the required package.
- On M Series and T Series routers, if **request system software add <sdk1>** was used for the previous installation, then **request system software rollback** removes the last installed SDK package (**sdk1** in this example).
- On SRX Series devices with dual root systems, when **request system software rollback** is run, the system switches to the alternate root. Each root can have a different version of Junos OS. Roll back takes each root back to the previously installed image.
- On QFX3500 and QFX3600 devices in a mixed Virtual Chassis, when the **request system software rollback** command is issued, the system does not rollback to the image stored in the alternate partition.
- On QFX5100 switches, the **reboot** option has been removed. To reboot the switch after a software rollback, issue the **request system reboot** command as a separate, secondary command.

Options **all-members**—(EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on all members of the Virtual Chassis configuration.

device-alias *alias-name*—(Junos Fusion only) (Optional) Rollback the satellite software package onto the specified satellite device using the satellite devices FPC slot identifier.

lcc *number*—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, attempt to roll back to the previous set of packages on a T640 router connected to the TX Matrix router. On a TX Matrix Plus router, attempt to roll back to the previous set of packages on a connected router connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

local—(EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on the local Virtual Chassis member.

member *member-id*—(EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

none—For all versions of Junos OS up to and including Junos OS 11.4, revert to the set of software as of the last successful **request system software add**. As of Junos OS 12.1 and greater, revert to the last known good state before the most recent **request system software (add | delete)** command.

reboot—As of Junos OS 12.3 and greater, automatically reboot upon completing the **request system software rollback** command.

satellite *slot-id*—(Junos Fusion only) (Optional) Roll back the satellite software package onto the specified satellite device using the satellite devices FPC slot identifier.

scc—(TX Matrix routers only) (Optional) Attempt to roll back to the previous set of packages on the TX Matrix router (or switch-card chassis).

sfc *number*—(TX Matrix Plus routers only) (Optional) Attempt to roll back to the previous set of packages on the TX Matrix Plus router. Replace *number* with 0.

upgrade-group [all | *upgrade-group-name*]—(Junos Fusion only) Roll back the satellite software image associated with the specified satellite software upgrade group, or for all satellite software upgrade groups in the Junos Fusion when **all** is entered.

Required Privilege Level

maintenance

request system software rollback (SRX Series)

Syntax	<code>request system software rollback <node-id></code>
Release Information	Command introduced in Junos OS Release 10.1. Command introduced in Junos OS Release 15.1X49-D50 for SRX1500 devices.
Description	Revert to the software that was loaded at the last successful request system software add command. Example: request system software rollback .
Options	<i>node-id</i> —Identification number of the chassis cluster node. It can be 0 or 1.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none">• request system reboot on page 1334

request system software validate

List of Syntax	Syntax on page 357 Syntax (TX Matrix Router) on page 357 Syntax (TX Matrix Plus Router) on page 357 Syntax (MX Series Router) on page 357
Syntax	<p><i>Reviewer: Can you use this command on OCX? Or does ONIE method replace this entirely?</i></p> <pre>request system software validate <i>package-name</i> <set [<i>package-name package-name</i>]> <upgrade-with-config> <upgrade-with-config-format <i>format</i>></pre>
Syntax (TX Matrix Router)	<pre>request system software validate <i>package-name</i> <lcc <i>number</i> scc> <set [<i>package-name package-name</i>]> <upgrade-with-config> <upgrade-with-config-format <i>format</i>></pre>
Syntax (TX Matrix Plus Router)	<pre>request system software validate <i>package-name</i> <lcc <i>number</i> sfc <i>number</i>> <set [<i>package-name package-name</i>]> <upgrade-with-config> <upgrade-with-config-format <i>format</i>></pre>
Syntax (MX Series Router)	<pre>request system software validate <i>package-name</i> <member <i>member-id</i>> <set [<i>package-name package-name</i>]> <upgrade-with-config> <upgrade-with-config-format <i>format</i>></pre>
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>set [<i>package-name package-name</i>] option added in Junos OS Release 12.2 for M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways.</p> <p>upgrade-with-config and upgrade-with-config-format <i>format</i> options added in Junos OS Release 12.3 for M Series routers, MX Series routers, and T Series routers.</p> <p>Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.</p>
Description	Validate candidate software against the current configuration of the router.
Options	<p>lcc <i>number</i>—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, validate the software bundle or package on a specific T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, validate the software bundle or package for a specific router that is connected to the TX Matrix Plus router.</p>

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

member *member-id*—(MX Series routers only) (Optional) Validate the software bundle or package on the specified member of the Virtual Chassis configuration. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

package-name—Name of the software bundle or package to test.

scc—(TX Matrix routers only) (Optional) Validate the software bundle or package for the TX Matrix router (or switch-card chassis).

set [*package-name package-name*]—(M Series, MX Series, T Series routers, and Branch SRX Series Services Gateways only) (Optional) Install multiple software packages or software add-on packages at the same time.

sfc *number*—(TX Matrix Plus routers only) (Optional) Validate the software bundle or package for the TX Matrix Plus router.

upgrade-with-config—(Optional) Install one or more configuration files.

upgrade-with-config-format *format*—(Optional) Specify the configuration file format, **text** or **xml**. The default format is **text**.

NOTE: The **upgrade-with-config** and **upgrade-with-config-format** options are only available locally on the router or switch. In a routing matrix, the configuration is applied only to the local router and is not propagated to other routers.

The options are validated during the validation process and applied to the router or switch during the upgrade process. If the upgrade process is successful, the options are removed from the configuration. If the upgrade process fails, the configuration file is renamed with the **.failed** suffix.

Additional Information By default, when you issue the **request system software validate** command on a TX Matrix master Routing Engine, all the T640 master Routing Engines that are connected to it are validated. If you issue the same command on the TX Matrix backup Routing Engine, all

the T640 backup Routing Engines that are connected to it are upgraded to the same version of software.

Likewise, if you issue the **request system software validate** command on a TX Matrix Plus master Routing Engine, all the T1600 or T4000 master Routing Engines that are connected to it are validated. If you issue the same command on a TX Matrix Plus backup Routing Engine, all the T1600 or T4000 backup Routing Engines that are connected to it are upgraded to the same version of software.

request system software validate on (Junos OS with Upgraded FreeBSD)

Syntax (MX240, MX480, MX960, MX2010, MX2020 Routers only)	request system software validate on <host <i>host-name</i> [username <i>user-name</i>]> <routing-engine (re0 re1)>
Release Information	Command introduced in Junos OS Release 15.1 for MX240, MX480, MX960, MX2010, MX2020 routers only.
Description	<p>Direct validation of a running configuration is not possible on a device running Junos OS with upgraded FreeBSD. Nevertheless, validation is an important step in the installation of an upgraded operating system. This command allows validation on a device that is not running Junos OS with upgraded FreeBSD.</p> <p>This command validates the current configuration on a Routing Engine that is not running Junos OS with upgraded FreeBSD or a remote host.</p>
Options	<p>The specific options available are:</p> <p>host <i>host-name</i> [username <i>user-name</i>]—Validate the current configuration on a remote host. The host-name is resolved through DNS. Optionally, you can supply a user-name to employ on the remote host. If you omit the user-name option, the currently logged-in user-name is sent to the remote host.</p> <p>routing-engine (re0 re1)—Validate the current configuration on another Routing Engine on the same device. The other Routing Engine cannot be running Junos OS with upgraded FreeBSD or the validation does not succeed.</p>
Additional Information	If the authenticity of the remote host cannot be established, you are prompted to continue the validation or not. If you choose not to continue, the validation process does not take place.
Required Privilege Level	maintenance

request system storage cleanup

List of Syntax	Syntax on page 364 Syntax (EX Series Switches) on page 364 Syntax (MX Series Router) on page 364 Syntax (QFX Series) on page 364 Syntax (SRX Series) on page 364
Syntax	request system storage cleanup <dry-run>
Syntax (EX Series Switches)	request system storage cleanup <all-members> <dry-run> <local> <member <i>member-id</i> > <satellite [slot-id <i>slot-id</i> device-alias <i>alias-name</i>]>
Syntax (MX Series Router)	request system storage cleanup <all-members> <dry-run> <local> <member <i>member-id</i> > <satellite [slot-id <i>slot-id</i> device-alias <i>alias-name</i>]>
Syntax (QFX Series)	request system storage cleanup <component (<i>serial number</i> <i>UUID</i> all)> <director-group <i>name</i> > <dry-run> <infrastructure <i>name</i> > <interconnect-device <i>name</i> > <name-tag <i>name-tag</i> > <node-group <i>name</i> > <prune> <qfabric (component <i>name</i>) dry-run name-tag repository> <repository (core log)>
Syntax (SRX Series)	request system storage cleanup <dry-run>
Release Information	Command introduced in Junos OS Release 7.4. dry-run option introduced in Junos OS Release 7.6. Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 9.2 for SRX Series. Command introduced in Junos OS Release 11.1 for the QFX Series. Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series. satellite option introduced in Junos OS Release 14.2R3.
Description	Free storage space on the router or switch by rotating log files and proposing a list of files for deletion. User input is required for file deletion. On a QFabric system, you can delete debug files located on individual devices or on the entire QFabric system.

Options **all-members**—(EX4200 switches and MX Series routers only) (Optional) Delete files on the Virtual Chassis master Routing Engine only.

NOTE: To delete files on the other members of the Virtual Chassis configuration, log in to each backup Routing Engine and delete the files using the **request system storage cleanup local** command.

component (*UUID | serial number | all*)—(QFabric systems only) (Optional) Delete files located on individual QFabric system devices or on the entire QFabric system.

director-group *name*—(QFabric systems only) (Optional) Delete files on the Director group.

dry-run—(Optional) List files proposed for deletion (without deleting them).

infrastructure *name*—(QFabric systems only) (Optional) Delete files on the fabric control Routing Engine and fabric manager Routing Engine.

interconnect-device *name*—(QFabric systems only) (Optional) Delete files on the Interconnect device.

local—(EX4200 switches and MX Series routers only) (Optional) Delete files on the local Virtual Chassis member.

member *member-id*—(EX4200 switches and MX Series routers only) (Optional) Delete files on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

name-tag *name-tag*—(QFabric systems only) (Optional) Delete debug files that match a specific regular expression.

node-group *name*—(QFabric systems only) (Optional) Delete files on the Node group.

prune—(QFabric systems only) (Optional) Delete debug files located in either the core or log debug repositories of a QFabric system device.

qfabric component *name*—(QFabric systems only) (Optional) Delete debug files located in the debug repositories of a QFabric system device.

repository (*core | log*)—(QFabric systems only) (Optional) Specify the repository on the QFabric system device for which you want to delete debug files.

satellite [*slot-id slot-id | device-alias alias-name*]—(Junos Fusion only) (Optional) Specify the satellite device in the Junos Fusion by FPC ID or device alias name for which you want to delete debug files.

Additional Information If logging is configured and being used, the **dry-run** option rotates the log files. In that case, the output displays the message “Currently rotating log files, please wait.” If no logging is currently under way, the output displays only a list of files to delete.

Required Privilege Level maintenance

Output Fields [Table 45](#) describes the output fields for the **request system storage cleanup** command. Output fields are listed in the approximate order in which they appear.

Table 45: request system storage cleanup Output Fields

Field Name	Field Description
List of files to delete:	Shows list of files available for deletion.
Size	Size of the core-dump file.
Date	Last core-dump file modification date and time.
Name	Name of the core-dump file.
Directory to delete:	Shows list of directories available for deletion.
Repository scope:	Repository where core-dump files and log files are stored. The core-dump files are located in the core repository, and the log files are located in the log repository. The default Repository scope is shared since both the core and log repositories are shared by all of the QFabric system devices.
Repository head:	Name of the top-level repository location.
Repository name:	Name of the repository: core or log .
Creating list of debug artifacts to be removed under:	Shows location of files available for deletion.
List of debug artifacts to be removed under:	Shows list of files available for deletion.

Sample Output

request system storage cleanup (SRX Series)

Syntax	<code>request system storage cleanup <dry-run></code>
Release Information	Command introduced in Junos OS Release 9.2 for SRX Series.
Description	Free storage space on the device by rotating log files and proposing a list of files for deletion. User input is required for file deletion.
Options	dry-run —(Optional) List files proposed for deletion (without deleting them).
Additional Information	If logging is configured and being used, the dry-run option rotates the log files. In that case, the output displays the message “Currently rotating log files, please wait.” If no logging is currently under way, the output displays only a list of files to delete.
Required Privilege Level	maintenance
Related Documentation	<ul style="list-style-type: none"> Cleaning Up Files with the CLI on page 1135
List of Sample Output	request system storage cleanup dry-run on page 374 request system storage cleanup on page 376
Output Fields	Table 45 describes the output fields for the request system storage cleanup command. Output fields are listed in the approximate order in which they appear.

Table 46: request system storage cleanup Output Fields

Field Name	Field Description
List of files to delete:	Shows list of files available for deletion.
Size	Size of the core-dump file.
Date	Last core-dump file modification date and time.
Name	Name of the core-dump file.

Sample Output

request system storage cleanup dry-run

```

user@host> request system storage cleanup dry-run

request system zeroize

Syntax request system zeroize
 <media>
 <local>

Release Information Command introduced before Junos OS Release 9.0.
 Command introduced in Junos OS Release 11.2 for EX Series switches.
 Option **media** added in Junos OS Release 11.4 for EX Series switches.
 Command introduced in Junos OS Release 12.2 for MX Series routers.
 Command introduced in Junos OS Release 12.3 for the QFX Series.
 Option **local** added in Junos OS Release 14.1.
 Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

NOTE: The **media** option is not available on the QFX Series.

Remove all configuration information on the Routing Engines and reset all key values. If the device has dual Routing Engines, the command is broadcast to all Routing Engines on the device. The command removes all data files, including customized configuration and log files, by unlinking the files from their directories. The command removes all user-created files from the system including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as **root** and start the Junos OS CLI by typing **cli** at the prompt.

NOTE: If you configure the **commit synchronize** statement at the **[edit system]** hierarchy level and issue a **commit** in the master Routing Engine, the master configuration is automatically synchronized with the backup. However, if the backup Routing Engine is down when you issue the **commit**, the Junos OS displays a warning and commits the candidate configuration in the master Routing Engine. When the backup Routing Engine comes up, its configuration will automatically be synchronized with the master. A newly inserted backup Routing Engine automatically synchronizes its configuration with the master Routing Engine configuration.

To completely erase user-created data so that it is unrecoverable, use the **media** option.

Options **media**—(Optional) In addition to removing all configuration and log files, causes memory and the media to be scrubbed, removing all traces of any user-created files. Every storage device attached to the system is scrubbed, including disks, flash drives, removable USBs, and so on. The duration of the scrubbing process is dependent on the size of the media being erased. As a result, the **request system zeroize media**

operation can take considerably more time than the **request system zeroize** operation. However, the critical security parameters are all removed at the beginning of the process.

local—(Optional) Remove all the configuration information and restore all the key values on the active Routing Engine.

Required Privilege Level maintenance

show system autoinstallation status

Syntax	show system autoinstallation status
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Command supported in Junos OS Release 12.2 for ACX Series Universal Access Routers.</p> <p>Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.</p>
Description	(ACX Series routers, and EX Series switches only) Display autoinstallation status information.
Options	This command has no options.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • <i>ACX Series Autoinstallation Overview</i> • <i>Before You Begin Autoinstallation on an ACX Series Universal Access Router</i> • <i>Autoinstallation Configuration of ACX Series Universal Access Routers</i> • <i>USB Autoinstallation on ACX Series Routers</i> • <i>Autoinstalling a Configuration File from a Disk-on-Key USB Memory Stick onto an EX2200 or EX3300 Switch</i> • <i>Verifying Autoinstallation on ACX Series Universal Access Routers</i> • <i>autoinstallation</i>
List of Sample Output	show system autoinstallation status on page 384
Output Fields	Table 47 describes the output fields for the show system autoinstallation status command. Output fields are listed in the approximate order in which they appear.

Table 47: show system autoinstallation status Output Fields

Field Name	Field Description
Autoinstallation status	<p>Display autoinstallation status information:</p> <ul style="list-style-type: none"> • Last committed file—File last committed for autoinstallation configuration. • Configuration server of last committed file—IP address or URL of the server configured to retrieve configuration information for the last committed configuration file. • Interface—Interface configured for autoinstallation. <ul style="list-style-type: none"> • Name—Name of the interface. • State—Interface state. • Address acquisition—Display IP address acquired and protocol used for acquisition upon startup. <ul style="list-style-type: none"> • Protocol—Protocol used for acquisition: BOOTP/DHCP or RARP. • Acquired address—IP address acquired from the DHCP server.

Sample Output

show system autoinstallation status

```
user@host> show system autoinstallation status
Autoinstallation status:
Master state: Active
Last committed file: None
Configuration server of last committed file: 0.0.0.0
Interface:
  Name: ge-0/0/1
  State: None
  Address acquisition:
    Protocol: DHCP Client
    Acquired address: None
    Protocol: RARP Client
    Acquired address: None
```

show system autorecovery state

Syntax	show system autorecovery state
Release Information	Command introduced in Junos OS Release 11.2.
Description	Perform checks and show status of all autorecovered items.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • request system autorecovery state on page 292 • Understanding Integrity Check and Autorecovery of Configuration, Licenses, and Disk Information on SRX Series Devices on page 169
List of Sample Output	show system autorecovery state on page 385
Output Fields	Table 48 lists the output fields for the show system autorecovery state command. Output fields are listed in the approximate order in which they appear.

Table 48: show system autorecovery state Output Fields

Field Name	Field Description
File	The name of the file on which autorecovery checks are performed.
Slice	The disk partition on which autorecovery checks are performed.
Recovery Information	Indicates whether autorecovery information for the file or slice has been saved.
Integrity Check	Displays the status of the file's integrity check (passed or failed).
Action / Status	Displays the status of the item, or the action required to be taken for that item.

Sample Output

show system autorecovery state

```
user@host> show system autorecovery state
```

```
Configuration:
File          Recovery Information Integrity Check Action / Status
rescue.conf.gz Saved          Passed          None
Licenses:
File          Recovery Information Integrity Check Action / Status
JUNOS282736.lic Saved          Passed          None
JUNOS282737.lic Not Saved      Not checked     Requires save
BSD Labels:
Slice         Recovery Information Integrity Check Action / Status
s1            Saved          Passed          None
s2            Saved          Passed          None
```

s3	Saved	Passed	None
s4	Saved	Passed	None

show system boot-messages

List of Syntax	Syntax on page 387 Syntax (EX Series Switches) on page 387 Syntax (TX Matrix Router) on page 387 Syntax (TX Matrix Plus Router) on page 387 Syntax (MX Series Router) on page 387 Syntax (QFX Series) on page 387
Syntax	show system boot-messages
Syntax (EX Series Switches)	show system boot-messages <all-members> <local> <member <i>member-id</i> >
Syntax (TX Matrix Router)	show system boot-messages <all-chassis all-lcc lcc <i>number</i> scc>
Syntax (TX Matrix Plus Router)	show system boot-messages <all-chassis all-lcc lcc <i>number</i> sfc <i>number</i> >
Syntax (MX Series Router)	show system boot-messages <all-members> <local> <member <i>member-id</i> >
Syntax (QFX Series)	show system boot-messages infrastructure <i>name</i> interconnect-device <i>name</i> node-group <i>name</i>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6. Command introduced in Junos OS Release 11.1 for the QFX Series. Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
Description	Display initial messages generated by the system kernel upon startup. These messages are the contents of <code>/var/run/dmesg.boot</code> .
Options	none —Display all boot time messages. all-chassis —(TX Matrix routers and TX Matrix Plus routers only) (Optional) Display boot time messages for all of the chassis. all-lcc —(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display boot time messages for all T640 routers connected to a TX Matrix router. On a TX Matrix Plus router, display boot time messages for all connected T1600 or T4000 LCCs. all-members —(EX4200 switches and MX Series routers only) (Optional) Display boot time messages on all members of the Virtual Chassis configuration.

infrastructure *name*—(QFabric systems only) (Optional) Display boot time messages on the fabric control Routing Engine or fabric manager Routing engines.

interconnect-device *name*—(QFabric systems only) (Optional) Display boot time messages on the Interconnect device.

lcc *number*—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display boot time messages for a specific T640 router connected to a TX Matrix router. On a TX Matrix Plus router, display boot time messages for a specific router connected to a TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

local—(EX4200 switches and MX Series routers only) (Optional) Display boot time messages on the local Virtual Chassis member.

member *member-id*—(EX4200 switches and MX Series routers only) (Optional) Display boot time messages on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.

node-group *name*—(QFabric systems only) (Optional) Display boot time messages on the Node group.

scc—(TX Matrix routers only) (Optional) Display boot time messages for the TX Matrix router (or switch-card chassis).

sfc *number*—(TX Matrix Plus routers only) (Optional) Display boot time messages for the TX Matrix Plus router. Replace *number* with 0.

Additional Information By default, when you issue the **show system boot-messages** command on the master Routing Engine of a TX Matrix router or a TX Matrix Plus router, the command is broadcast to all the master Routing Engines of the LCCs connected to it in the routing matrix. Likewise, if you issue the same command on the backup Routing Engine of a TX Matrix or a TX Matrix Plus router, the command is broadcast to all backup Routing Engines of the LCCs that are connected to it in the routing matrix.

show system auto-snapshot

Syntax	show system auto-snapshot
Release Information	Command introduced in Junos OS Release 12.3 for EX Series switches. Command introduced in Junos OS Release 12.1X45-D10 for SRX Series devices.
Description	Display automatic snapshot status information. When the automatic snapshot feature is enabled and the system reboots from the alternate root partition, the switch automatically takes a snapshot of the root file system in the alternate root partition and copies it onto the primary root partition. This automatic snapshot procedure takes place whenever the system reboots from the alternate partition, regardless of whether the reboot from the alternate partition is due to a command or due to a corruption of the primary partition.
Options	This command has no options.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> • Understanding Resilient Dual-Root Partitions on Switches on page 95
List of Sample Output	show system auto-snapshot on page 395
Output Fields	Table 49 describes the output fields for the show system auto-snapshot command. Output fields are listed in the approximate order in which they appear.

Table 49: show system auto-snapshot status Output Fields

Field Name	Field Description
Auto-snapshot configuration	<p>Status of the configuration:</p> <ul style="list-style-type: none"> • Enabled—If the system reboots from the alternate partition, the automatic snapshot feature automatically takes a snapshot of the alternate partition and copies it onto the primary partition. • Disabled—The system does not automatically take a snapshot of the alternate partition. You must use the manual snapshot command, request system snapshot, to take a snapshot of one partition and copy it onto the other.
Auto-snapshot state	<p>Status of the automatic snapshot procedure:</p> <ul style="list-style-type: none"> • Completed—The automatic snapshot procedure has completed copying the alternate partition to the primary partition and the alarm has been cleared. • Disabled—The automatic snapshot procedure is inactive. • In progress—The automatic snapshot procedure is in progress. It takes about 10 to 15 minutes to complete, depending upon disk size.

Sample Output

show system auto-snapshot

```
user@switch> show system auto-snapshot
Auto-snapshot Configuration: Enabled
Auto-snapshot State: Disabled
```

show system download

Syntax	<code>show system download <download-id></code>
Release Information	Command introduced in Junos OS Release 11.2. Command introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Description	Display a brief summary of all the download instances along with their current state and extent of progress. If a download-id is provided, the command displays a detailed report of the particular download instance.
Options	<ul style="list-style-type: none"> download-id—(Optional) The ID number of the download instance.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none"> request system download start on page 298 Understanding Download Manager for SRX Series Devices on page 51 Understanding Download Manager for EX Series Devices
List of Sample Output	show system download on page 396 show system download 1 on page 397
Output Fields	Table 50 lists the output fields for the show system download command. Output fields are listed in the approximate order in which they appear.

Table 50: show system download Output Fields

Field Name	Field Description
ID	Displays the download identification number.
Status	Displays the state of a particular download.
Start Time	Displays the start time of a particular download.
Progress	Displays the percentage of a download that has been completed.
URL	Displays the URL from which the file was downloaded.

Sample Output

show system download

```

user@host> show system download
Download Status Information:
ID  Status  Start Time      Progress  URL
1   Active   May 4 06:28:36  5%        ftp://ftp-server//tftpboot/1m_file

```

show system license

Syntax	show system license <installed keys usage>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 11.1 for the QFX Series. Command introduced in Junos OS Release 13.3 for the MX104 3D Universal Edge Routers.
Description	Display licenses and information about how they are used.
Options	<p>none—Display all license information.</p> <p>installed—(Optional) Display installed licenses only.</p> <p>keys—(Optional) Display a list of license keys. Use this information to verify that each expected license key is present.</p> <p>usage—(Optional) Display the state of licensed features.</p>
Required Privilege Level	maintenance
List of Sample Output	show system license on page 399 show system license installed on page 400 show system license keys on page 400 show system license usage on page 400 show system license (MX104 Routers) on page 400 show system license installed (MX104 Routers) on page 401 show system license keys (MX104 Routers) on page 401 show system license usage (MX104 Routers) on page 401 show system license (MX104 Routers) on page 401 show system license installed (MX104 Routers) on page 402 show system license keys (MX104 Routers) on page 402 show system license usage (MX104 Routers) on page 403 show system license (MX104 Routers) on page 403 show system license installed (MX104 Routers) on page 403 show system license keys (MX104 Routers) on page 404 show system license usage (MX104 Routers) on page 404 show system license (QFX Series) on page 404 show system license (QFX5110 Switch with Disaggregated Feature License) on page 404
Output Fields	Table 51 lists the output fields for the show system license command. Output fields are listed in the approximate order in which they appear. <i>Reviewer: Anything more I should add for disaggregated licenses below?</i>

Table 51: show system license Output Fields

Field Name	Field Description
Feature name	Name assigned to the configured feature. You use this information to verify that all the features for which you installed licenses are present.
Licenses used	<p>Number of licenses used by a router or switch. You use this information to verify that the number of licenses used matches the number configured. If a licensed feature is configured, the feature is considered used.</p> <p>NOTE: In Junos OS Release 10.1 and later, the Licenses used column displays the actual usage count based on the number of active sessions or connections as reported by the corresponding feature daemons. This is applicable for scalable license-based features such as Subscriber Access (scale-subscriber), L2TP (scale-l2tp), Mobile IP (scale-mobile-ip), and so on.</p>
Licenses installed	<p>Information about the installed license key:</p> <ul style="list-style-type: none"> • License identifier—Identifier associated with a license key. • State—State of the license key: valid or invalid. An invalid state indicates that the key was entered incorrectly or is not valid for the specific device. • License version—Version of a license. The version indicates how the license is validated, the type of signature, and the signer of the license key. • Software Serial Number—Serial number of the disaggregated software feature license. License Management System (LMS) uses the software serial number, not the chassis ID, to generate a disaggregated feature license. • Customer ID—what is this exactly? • Valid for device—Device that can use a license key. • Group defined—Group membership of a device. • Features—Feature associated with a license, such as data link switching (DLSw).
Licenses needed	Number of licenses required for features being used but not yet properly licensed.
Expiry	Amount of time left within the grace period before a license is required for a feature being used.

Sample Output

show system license

show system snapshot

List of Syntax [Syntax on page 410](#)
 [Syntax \(EX Series Switches\) on page 410](#)

Syntax show system snapshot

Syntax (EX Series Switches) show system snapshot
 <all-members|local|member *member-id*>
 <media (external | internal)>

Release Information Command introduced in Junos OS Release 7.6.
 Command introduced in Junos OS Release 10.0 for EX Series switches.
 Option **slice** deprecated for Junos OS with Upgraded FreeBSD in Junos OS Release 15.1.

NOTE: To determine which platforms run Junos OS with Upgraded FreeBSD, see the table listing the platforms currently running Junos OS with upgraded FreeBSD in “[Understanding Junos OS with Upgraded FreeBSD](#)” on page 19.

Description Display information about the backup software:

- On the routers, display information about the backup software, which is located in the **/altroot**, and **/altconfig** file systems or on the alternate media.
- On the switches, display information about the backup of the root file system (**/**) and directories **/altroot**, **/config**, **/var**, and **/var/tmp**, which are located either on an external USB flash drive or in internal flash memory.

NOTE: To back up software, use the **request system snapshot** command.

Options **none**—Display information about the backup software.

all-members | local | member *member-id*—(EX Series switch Virtual Chassis only)
 (Optional) Display the snapshot in a Virtual Chassis:

- **all-members**—Display the snapshot for all members of the Virtual Chassis.
- **local**—Display the snapshot on the member of the Virtual Chassis that you are currently logged into.
- **member *member-id***—Display the snapshot for the specified member of the Virtual Chassis.

media (external | internal)—(EX Series switch only) (Optional) Display the destination media location for the snapshot. The **external** option specifies the snapshot on an external mass storage device, such as a USB flash drive. The **internal** option specifies

the snapshot on an internal memory source, such as internal flash memory. If no additional options are specified, the command displays the snapshot stored in both slices.

Required Privilege Level view

CLI User Guide

CHAPTER 19

Overview

- [Introducing the Junos OS Command-Line Interface on page 421](#)
- [Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies on page 423](#)
- [Other Tools to Configure and Monitor Devices Running Junos OS on page 426](#)
- [Commands and Configuration Statements for Junos-FIPS on page 426](#)

Introducing the Junos OS Command-Line Interface

The Junos[®] operating system (Junos OS) command-line interface (CLI) is the software interface you use to access a device running Junos OS—whether from the console or through a network connection.

The Junos OS CLI is a Juniper Networks-specific command shell that runs on top of a FreeBSD UNIX-based operating system kernel. By leveraging industry-standard tools and utilities, the CLI provides a powerful set of commands that you can use to monitor and configure devices running Junos OS (see [Figure 10](#)).

The Junos OS CLI has two modes:

- **Operational mode**—This mode displays the current status of the device. In operational mode, you enter commands to monitor and troubleshoot the Junos OS, devices, and network connectivity.
- **Configuration mode**—This mode enables you to configure the device. A configuration is stored as a hierarchy of configuration statements. In this mode, you enter statements to configure all properties of the device, including interfaces, general routing information, routing protocols, user access, and several system and hardware properties.

When you enter configuration mode, you are actually viewing and changing a file called the *candidate configuration*. The candidate configuration file enables you to make configuration changes without causing operational changes to the current operating configuration, called the *active configuration*. The router or switch does not implement the changes you added to the candidate configuration file until you commit them, which activates the configuration on the device. Candidate configurations enable you to alter your configuration without causing potential damage to your current network operations.

Figure 10: Monitoring and Configuring Routers

Use the JUNOS CLI to monitor and configure Juniper Networks routers.

Key Features of the CLI

The Junos OS CLI commands and statements follow a hierarchal organization and have a regular syntax. The Junos OS CLI provides the following features to simplify CLI use:

- Consistent command names—Commands that provide the same type of function have the same name, regardless of the portion of the software on which they are operating. For example, all **show** commands display software information and statistics, and all **clear** commands erase various types of system information.
- Lists and short descriptions of available commands—Information about available commands is provided at each level of the CLI command hierarchy. If you type a question mark (?) at any level, you see a list of the available commands along with a short description of each command. This means that if you already are familiar with the Junos OS or with other routing software, you can use many of the CLI commands without referring to the documentation.
- Command completion—Command completion for command names (keywords) and for command options is available at each level of the hierarchy. To complete a command or option that you have partially typed, press the Tab key or the Spacebar. If the partially typed letters begin a string that uniquely identifies a command, the complete command name appears. Otherwise, a beep indicates that you have entered an ambiguous command, and the possible completions are displayed. Completion also applies to other strings, such as filenames, interface names, usernames, and configuration statements.

If you have typed the mandatory arguments for executing a command in the operational or configuration mode the CLI displays **<[Enter]>** as one of the choices when you type a question mark (?). This indicates that you have entered the mandatory arguments and can execute the command at that level without specifying any further options. Likewise, the CLI also displays **<[Enter]>** when you have reached a specific hierarchy level in the configuration mode and do not have to enter any more mandatory arguments or statements.

- Industry-standard technology—With FreeBSD UNIX as the kernel, a variety of UNIX utilities are available on the Junos OS CLI. For example, you can:
 - Use regular expression matching to locate and replace values and identifiers in a configuration, filter command output, or examine log file entries.

- Use Emacs-based key sequences to move around on a command line and scroll through the recently executed commands and command output.
- Store and archive Junos OS device files on a UNIX-based file system.
 - Use standard UNIX conventions to specify filenames and paths.
- Exit from the CLI environment and create a UNIX C shell or Bourne shell to navigate the file system, manage router processes, and so on.

Related Documentation

- [Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies on page 423](#)
- [Getting Started with the Junos OS Command-Line Interface on page 429](#)
- [Other Tools to Configure and Monitor Devices Running Junos OS on page 426](#)
- [Commands and Configuration Statements for Junos-FIPS on page 426](#)

Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies

The Junos OS command-line interface (CLI) commands and statements are organized under two command modes and various hierarchies. The following sections provide you an overview of the Junos OS CLI command modes and commands and statements hierarchies:

- [Junos OS CLI Command Modes on page 423](#)
- [CLI Command Hierarchy on page 424](#)
- [Configuration Statement Hierarchy on page 424](#)
- [Moving Among Hierarchy Levels on page 425](#)

Junos OS CLI Command Modes

The Junos OS CLI has two modes:

- **Operational mode**—This mode displays the current status of the device. In operational mode, you enter commands to monitor and troubleshoot the Junos OS, devices, and network connectivity.
- **Configuration mode**—A configuration for a device running on Junos OS is stored as a hierarchy of statements. In configuration mode, you enter these statements to define all properties of the Junos OS, including interfaces, general routing information, routing protocols, user access, and several system and hardware properties.

When you enter configuration mode, you are actually viewing and changing a file called the *candidate configuration*. The candidate configuration file enables you to make configuration changes without causing operational changes to the current operating configuration, called the *active configuration*. The router or switch does not implement the changes you added to the candidate configuration file until you commit them, which activates the configuration on the router or switch (see [Figure 11](#)). Candidate configurations

enable you to alter your configuration without causing potential damage to your current network operations.

Figure 11: Committing a Configuration

CLI Command Hierarchy

CLI commands are organized in a hierarchy. Commands that perform a similar function are grouped together under the same level of the hierarchy. For example, all commands that display information about the system and the system software are grouped under the **show system** command, and all commands that display information about the routing table are grouped under the **show route** command.

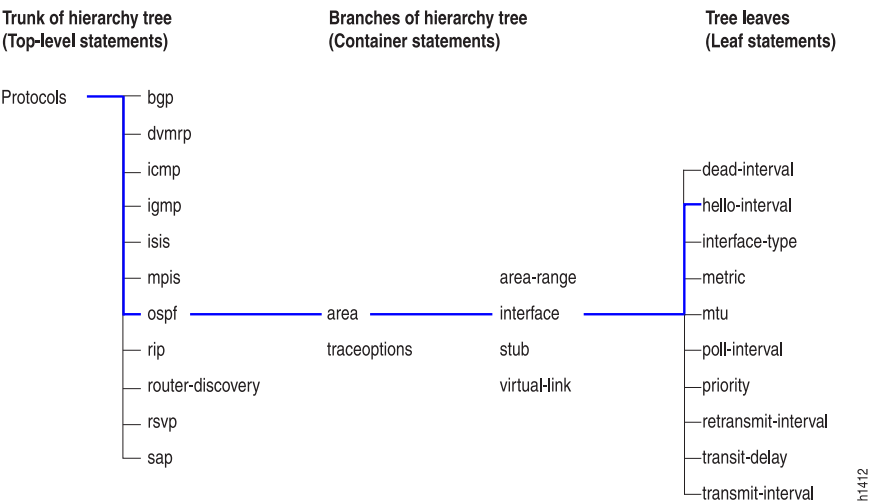

To execute a command, you enter the full command name, starting at the top level of the hierarchy. For example, to display a brief view of the routes in the routing table, use the command **show route brief**.

Configuration Statement Hierarchy

The configuration statement hierarchy has two types of statements: *container statements*, which are statements that contain other statements, and *leaf statements*, which do not contain other statements. All of the container and leaf statements together form the *configuration hierarchy*.

Figure 12 illustrates a part of the hierarchy tree. The **protocols** statement is a top-level statement at the trunk of the configuration tree. The **ospf**, **area**, and **interface** statements are all subordinate container statements of a higher statement (they are branches of the hierarchy tree), and the **hello-interval** statement is a leaf on the tree.

Figure 12: Configuration Statement Hierarchy Example

Moving Among Hierarchy Levels

You can use the CLI commands in Table 56 to navigate the levels of the configuration statement hierarchy.

Table 56: CLI Configuration Mode Navigation Commands

Command	Description
edit <i>hierarchy-level</i>	Moves to an existing configuration statement hierarchy or creates a hierarchy and moves to that level.
exit	Moves up the hierarchy to the previous level where you were working. This command is, in effect, the opposite of the edit command. Alternatively, you can use the quit command. The exit and quit commands are interchangeable.
up	Moves up the hierarchy one level at a time.
top	Moves directly to the top level of the hierarchy.

Other Tools to Configure and Monitor Devices Running Junos OS

Apart from the command-line interface, Junos OS also supports the following applications, scripts, and utilities that enable you to configure and monitor devices running Junos OS:

- J-Web graphical user interface (GUI)—Allows you to monitor, configure, troubleshoot, and manage the router on a client by means of a Web browser with Hypertext Transfer Protocol (HTTP) or HTTP over Secure Sockets Layer (HTTPS) enabled. For more information, see the *J-Web Interface User Guide*.
- Junos XML management protocol—Application programmers can use the Junos XML management protocol to monitor and configure Juniper Networks routers. Juniper Networks provides a Perl module with the API to help you more quickly and easily develop custom Perl scripts for configuring and monitoring routers. For more information, see the *Junos XML Management Protocol Developer Guide*.
- NETCONF Application Programming Interface (API)—Application programmers can also use the NETCONF XML management protocol to monitor and configure Juniper Networks routers. For more information, see the *NETCONF XML Management Protocol Developer Guide*.
- Junos OS commit scripts and self-diagnosis features—You can define scripts to enforce custom configuration rules, use commit script macros to provide simplified aliases for frequently used configuration statements, and configure diagnostic event policies and actions associated with each policy. For more information, see the *Automation Scripting Feature Guide*.
- Management Information Bases (MIBs)—You can use enterprise-specific and standard MIBs to retrieve information about the hardware and software components on a Juniper Networks router. For more information about MIBs, see the *Network Management Administration Guide for Routing Devices*.

Commands and Configuration Statements for Junos-FIPS

Junos-FIPS enables you to configure a network of Juniper Networks routers in a Federal Information Processing Standards (FIPS) 140-2 environment.

The Junos-FIPS software environment requires the installation of FIPS software by a crypto officer. In Junos-FIPS, some Junos OS commands and statements have restrictions and some additional configuration statements are available. For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*.

Getting Started with the Junos OS Command-Line Interface

As an introduction to the Junos OS command-line interface (CLI), this topic provides instructions for simple steps you take after installing Junos OS on the device. It shows you how to start the CLI, view the command hierarchy, and make small configuration changes. The related topics listed at the end of this topic provide you more detailed information about using the CLI.

NOTE:

- The instructions and examples in this topic are based on sample M Series and T Series routers. You can use them as a guideline for entering commands on your devices running Junos OS.
- Before you begin, make sure your device hardware is set up and Junos OS is installed. You must have a direct console connection to the device or network access using SSH or Telnet. If your device is not set up, follow the installation instructions provided with the device before proceeding.

To log in to a router and start the CLI:

1. Log in as **root**.

The root login account has superuser privileges, with access to all commands and statements.

2. Start the CLI:

```
root# cli
```

```
root@>
```

The > command prompt shows you are in operational mode. Later, when you enter configuration mode, the prompt will change to #.

NOTE: If you are using the root account for the first time on the device, remember that the device ships with no password required for root, but the first time you commit a configuration with Junos OS Release 7.6 or later, you must set a root password. Root access is not allowed over a telnet session. To enable root access over an SSH connection, you must configure the `system services ssh root-login allow` statement.

The CLI includes several ways to get help about commands. This section shows some examples of how to get help:

1. Type `?` to show the top-level commands available in operational mode.

```
root@> ?
Possible completions:
clear          Clear information in the system
configure      Manipulate software configuration information
diagnose       Invoke diagnose script
file           Perform file operations
help           Provide help information
monitor        Show real-time debugging information
mtrace         Trace multicast path from source to receiver
ping           Ping remote target
quit           Exit the management session
request        Make system-level requests
restart        Restart software process
set            Set CLI properties, date/time, craft interface message
show           Show system information
ssh            Start secure shell on another host
start          Start shell
telnet         Telnet to another host
test           Perform diagnostic debugging
traceroute     Trace route to remote host
```

2. Type `file ?` to show all possible completions for the `file` command.

```
root@> file ?
Possible completions:
<[Enter]>      Execute this command
archive        Archives files from the system
checksum       Calculate file checksum
compare        Compare files
copy           Copy files (local or remote)
delete         Delete files from the system
list           List file information
rename         Rename files
show           Show file contents
source-address Local address to use in originating the connection
|             Pipe through a command
```

3. Type `file archive ?` to show all possible completions for the `file archive` command.

```
root@> file archive ?
```

Possible completions:

compress	Compresses the archived file using GNU gzip (.tgz)
destination	Name of created archive (URL, local, remote, or floppy)
source	Path of directory to archive

Switching Between Junos OS CLI Operational and Configuration Modes

When you monitor and configure a device running Junos OS, you may need to switch between operational mode and configuration mode. When you change to configuration mode, the command prompt also changes. The operational mode prompt is a right angle bracket (>) and the configuration mode prompt is a pound sign (#).

To switch between operational mode and configuration mode:

1. When you log in to the router and type the **cli** command, you are automatically in operational mode:

```
--- JUNOS 9.2B1.8 built 2008-05-09 23:41:29 UTC
% cli
user@host>
```

2. To enter configuration mode, type the **configure** command or the **edit** command from the CLI operation mode. For example:

```
user@host> configure
Entering configuration mode
```

```
[edit]
user@host#
```

The CLI prompt changes from **user@host>** to **user@host#** and a banner appears to indicate the hierarchy level.

3. You can return to operational mode in one of the following ways:

- To commit the configuration and exit:

```
[edit]
user@host# commit and-quit
commit complete
Exiting configuration mode
user@host>
```

- To exit without committing:

```
[edit]
```

```
user@host# exit
Exiting configuration mode
user@host>
```

When you exit configuration mode, the CLI prompt changes from **user@host#** to **user@host>** and the banner no longer appears. You can enter or exit configuration mode as many times as you wish without committing your changes.

4. To display the output of an operational mode command, such as **show**, while in configuration mode, issue the **run** configuration mode command and then specify the operational mode command:

```
[edit]
user@host# run operational-mode-command
```

For example, to display the currently set priority value of the Virtual Router Redundancy Protocol (VRRP) primary router while you are modifying the VRRP configuration for a backup router:

```
[edit interfaces xe-4/2/0 unit 0 family inet vrrp-group 27]
user@host# show
virtual-address [ 192.168.1.15 ];
[edit interfaces xe-4/2/0 unit 0 family inet vrrp-group 27]
user@host# run show vrrp detail
Physical interface: xe-5/2/0, Unit: 0, Address: 192.168.29.10/24
Interface state: up, Group: 10, State: backup
Priority: 190, Advertisement interval: 3, Authentication type: simple
Preempt: yes, VIP count: 1, VIP: 192.168.29.55
Dead timer: 8.326, Master priority: 201, Master router: 192.168.29.254
[edit interfaces xe-4/2/0 unit 0 family inet vrrp-group 27]
user@host# set priority ...
```

Configuring a User Account on a Device Running Junos OS

This topic describes how to log on to a device running Junos OS using a root account and configure a new user account. You can configure an account for your own use or create a test account.

To configure a new user account on the device:

1. Log in as root and enter configuration mode:

```
root@host> configure
[edit]
root@host#
```

The prompt in brackets (**[edit]**), also known as a *banner*, shows that you are in configuration edit mode at the top of the hierarchy.

2. Change to the **[edit system login]** section of the configuration:

```
[edit]
root@host# edit system login
[edit system login]
root@host#
```

The prompt in brackets changes to **[edit system login]** to show that you are at a new level in the hierarchy.

3. Now add a new user account:

```
[edit system login]
root@host# edit user nchen
```

This example adds an account **nchen** (for Nathan Chen).

NOTE: In Junos OS Release 12.2 and later, user account names can contain a period (.) in the name. For example, you can have a user account named **nathan.chen**. However, the username cannot begin or end with a period.

4. Configure a full name for the account. If the name includes spaces, enclose the entire name in quotation marks (" "):

```
[edit system login user nchen]
root@host# set full-name "Nathan Chen"
```

5. Configure an account class. The account class sets the user access privileges for the account:

```
[edit system login user nchen]
root@host# set class super-user
```

6. Configure an authentication method and password for the account:

```
[edit system login user nchen]
root@host# set authentication plain-text-password
New password:
Retype new password:
```

When the new password prompt appears, enter a clear-text password that the system can encrypt, and then confirm the new password.

7. Commit the configuration:

```
[edit system login user nchen]
root@host# commit
commit complete
```

Configuration changes are not activated until you commit the configuration. If the commit is successful, a **commit complete** message appears.

8. Return to the top level of the configuration, and then exit:

```
[edit system login user nchen]
root@host# top
[edit]
root@host# exit
Exiting configuration mode
```

9. Log out of the device:

```
root@host> exit
% logout Connection closed.
```

10. To test your changes, log back in with the user account and password you just configured:

```
login: nchen
Password: password
--- Junos 8.3-R1.1 built 2005-12-15 22:42:19 UTC
nchen@host>
```

When you log in, you should see the new username at the command prompt.

You have successfully used the CLI to view the device status and perform a simple configuration change. See the related topics listed in this section for more information about the Junos OS CLI features.

NOTE: For complete information about the commands to issue to configure your device, including examples, see the Junos OS configuration guides.

Using the CLI Editor in Configuration Mode

This topic describes some of the basic commands that you must use to enter configuration mode in the command-line interface (CLI) editor, navigate through the configuration hierarchy, get help, and commit or revert the changes that you make during the configuration session.

Task	Command/Statement	Example
Edit Your Configuration		
Enter configuration mode.	configure	user@host> configure
When you first log in to the device, the device is in operational mode. You must explicitly enter configuration mode. When you do, the CLI prompt changes from user@host> to user@host# and the hierarchy level appears in square brackets.		[edit] user@host#

Task	Command/Statement	Example
<p>Create a statement hierarchy.</p> <p>You can use the edit command to simultaneously create a hierarchy and move to that new level in the hierarchy. You cannot use the edit command to change the value of identifiers.</p>	edit <i>hierarchy-level value</i>	<pre>[edit] user@host# edit security zones security-zone myzone [edit security zones security-zone myzone] user@host#</pre>
<p>Create a statement hierarchy and set identifier values.</p> <p>The set command is similar to edit except that your current level in the hierarchy does not change.</p>	set <i>hierarchy-level value</i>	<pre>[edit] user@host# set security zones security-zone myzone [edit] user@host#</pre>
Navigate the Hierarchy		
Navigate down to an existing hierarchy level.	edit <i>hierarchy-level</i>	<pre>[edit] user@host# edit security zones [edit security zones] user@host#</pre>
Navigate up one level in the hierarchy.	up	<pre>[edit security zones] user@host# up [edit security] user@host#</pre>
Navigate to the top of the hierarchy.	top	<pre>[edit security zones] user@host# top [edit] user@host#</pre>
Commit or Revert Changes		
Commit your configuration.	commit	<pre>[edit] user@host# commit commit complete</pre>
<p>Roll back changes from the current session.</p> <p>Use the rollback command to revert all changes from the current configuration session. When you run the rollback command before exiting your session or committing changes, the software loads the most recently committed configuration onto the device. You must enter the rollback statement at the edit level in the hierarchy.</p>	rollback	<pre>[edit] user@host# rollback load complete</pre>
Exit Configuration Mode		

Task	Command/Statement	Example
Commit the configuration and exit configuration mode.	commit and-quit	[edit] user@host# commit and-quit user@host>
Exit configuration mode without committing your configuration. You must navigate to the top of the hierarchy using the up or top commands before you can exit configuration mode.	exit	[edit] user@host# exit The configuration has been changed but not committed Exit with uncommitted changes? [yes,no] (yes)
Get Help		
Display a list of valid options for the current hierarchy level.	?	[edit] user@host# edit security zones ? Possible completions: <[Enter]> Execute this command > functional-zone Functional zone > security-zone Security zones Pipe through a command [edit]

Checking the Status of a Device Running Junos OS

You can use **show** commands to check the status of the device and monitor the activities on the device.

To help you become familiar with **show** commands:

- Type **show ?** to display the list of **show** commands you can use to monitor the router:

```
root@> show ?
Possible completions:
accounting      Show accounting profiles and records
aps             Show Automatic Protection Switching information
arp            Show system Address Resolution Protocol table entries
as-path        Show table of known autonomous system paths
bfd            Show Bidirectional Forwarding Detection information
bgp            Show Border Gateway Protocol information
chassis        Show chassis information
class-of-service Show class-of-service (CoS) information
cli            Show command-line interface settings
configuration   Show current configuration
connections     Show circuit cross-connect connections
dvmrp          Show Distance Vector Multicast Routing Protocol
info
dynamic-tunnels Show dynamic tunnel information information
esis           Show end system-to-intermediate system information
```

firewall	Show firewall information
helper	Show port-forwarding helper information
host	Show hostname information from domain name server
igmp	Show Internet Group Management Protocol information
ike	Show Internet Key Exchange information
ilmi	Show interim local management interface information
interfaces	Show interface information
ipsec	Show IP Security information
ipv6	Show IP version 6 information
isis	Show Intermediate System-to-Intermediate System info
l2circuit	Show Layer 2 circuit information
l2vpn	Show Layer 2 VPN information
lacp	Show Link Aggregation Control Protocol information
ldp	Show Label Distribution Protocol information
link-management	Show link management information
llc2	Show LLC2 protocol related information
log	Show contents of log file
mld	Show multicast listener discovery information
mpls	Show Multiprotocol Label Switching information
msdp	Show Multicast Source Discovery Protocol information
multicast	Show multicast information
ntp	Show Network Time Protocol information
ospf	Show Open Shortest Path First information

snmp	Show Simple Network Management Protocol information
system	Show system information
task	Show routing protocol per-task information
ted	Show Traffic Engineering Database information
version	Show software process revision levels
vpls	Show VPLS information
vrrp	Show Virtual Router Redundancy Protocol information

- Use the **show chassis routing-engine** command to view the Routing Engine status:

```

root@> show chassis routing-engine
Routing Engine status:
Slot 0:
  Current state           Master
  Election priority       Master (default)
  Temperature             31 degrees C / 87 degrees F
  CPU temperature         32 degrees C / 89 degrees F
  DRAM                    768 MB
  Memory utilization      84 percent
  CPU utilization:
    User                  0 percent
    Background            0 percent
    Kernel                1 percent
    Interrupt             0 percent

```

```

Idle 99 percent
Model RE-2.0
Serial ID b10000078c10d701
Start time 2005-12-28 13:52:00 PST
Uptime 12 days, 3 hours, 44 minutes, 19 seconds
Load averages: 1 minute 5 minute 15 minute
                 0.02      0.01      0.00

```

- Use the **show system storage** command to view available storage on the device:

```
root@> show system storage
```

- [Viewing Files and Directories on a Device Running Junos OS on page 573](#)

Example: Configuring a Routing Protocol

This topic provides a sample configuration that describes how to configure an OSPF backbone area that has two SONET interfaces.

The final configuration looks like this:

```

[edit]
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {
        hello-interval 5;
        dead-interval 20;
      }
      interface so-0/0/1 {

```

```

        hello-interval 5;
        dead-interval 20;
    }
}
}
}

```

This topic contains the following examples of configuring a routing protocol:

- [Shortcut on page 439](#)
- [Longer Configuration on page 439](#)
- [Making Changes to a Routing Protocol Configuration on page 441](#)

Shortcut

You can create a shortcut for this entire configuration with the following two commands:

```

[edit]
user@host# set protocols ospf area 0.0.0.0 interface so-0/0/0 hello-interval 5
               dead-interval 20
[edit]
user@host# set protocols ospf area 0.0.0.0 interface so-0/0/1 hello-interval 5
               dead-interval 20

```

Longer Configuration

This section provides a longer example of creating the previous OSPF configuration. In the process, it illustrates how to use the different features of the CLI.

1. Enter configuration mode by issuing the **configure** top-level command:

```

user@host> configure
entering configuration mode
[edit]
user@host#

```

Notice that the prompt has changed to a pound sign (#) to indicate configuration mode.

2. To create the above configuration, you start by editing the **protocols ospf** statements:

```

[edit]
user@host# edit protocols ospf
[edit protocols ospf]
user@host#

```

3. Now add the OSPF area:

```

[edit protocols ospf]
user@host# edit area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@host#

```

4. Add the first interface:

```

[edit protocols ospf area 0.0.0.0]
user@host# edit interface so0
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]

```

```
user@host#
```

You now have four nested statements.

5. Set the hello and dead intervals.

```
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]
user@host# set ?
user@host# set hello-interval 5
user@host# set dead-interval 20
user@host#
```

6. You can see what is configured at the current level with the **show** command:

```
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]
user@host# show
hello-interval 5;
dead-interval 20;
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]
user@host#
```

7. You are finished at this level, so back up a level and take a look at what you have so far:

```
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]
user@host# up
[edit protocols ospf area 0.0.0.0]
user@host# show
interface so-0/0/0 {
    hello-interval 5;
    dead-interval 20;
}
[edit protocols ospf area 0.0.0.0]
user@host#
```

The **interface** statement appears because you have moved to the **area** statement.

8. Add the second interface:

```
[edit protocols ospf area 0.0.0.0]
user@host# edit interface so-0/0/1
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# set hello-interval 5
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# set dead-interval 20
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# up
[edit protocols ospf area 0.0.0.0]
user@host# show
interface so-0/0/0 {
    hello-interval 5;
    dead-interval 20;
}
interface so-0/0/1 {
    hello-interval 5;
    dead-interval 20;
}
[edit protocols ospf area 0.0.0.0]
user@host#
```

9. Back up to the top level and see what you have:

```
[edit protocols ospf area 0.0.0.0]
user@host# top
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {
        hello-interval 5;
        dead-interval 20;
      }
      interface so-0/0/1 {
        hello-interval 5;
        dead-interval 20;
      }
    }
  }
}
[edit]
user@host#
```

This configuration now contains the statements you want.

10. Before committing the configuration (and thereby activating it), verify that the configuration is correct:

```
[edit]
user@host# commit check
configuration check succeeds
[edit]
user@host#
```

11. Commit the configuration to activate it on the router:

```
[edit]
user@host# commit
commit complete
[edit]
user@host#
```

Making Changes to a Routing Protocol Configuration

Suppose you decide to use different dead and hello intervals on interface **so-0/0/1**. You can make changes to the configuration.

1. Go directly to the appropriate hierarchy level by typing the full hierarchy path to the statement you want to edit:

```
[edit]
user@host# edit protocols ospf area 0.0.0.0 interface so-0/0/1
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# show
hello-interval 5;
dead-interval 20;
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
```

```

user@host# set hello-interval 7
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# set dead-interval 28
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# top
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {
        hello-interval 5;
        dead-interval 20;
      }
      interface so-0/0/1 {
        hello-interval 7;
        dead-interval 28;
      }
    }
  }
}
[edit]
user@host#

```

2. If you decide not to run OSPF on the first interface, delete the statement:

```

[edit]
user@host# edit protocols ospf area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@host# delete interface so-0/0/0
[edit protocols ospf area 0.0.0.0]
user@host# top
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/1 {
        hello-interval 7;
        dead-interval 28;
      }
    }
  }
}
[edit]
user@host#

```

Everything inside the statement you deleted was deleted with it. You can also eliminate the entire OSPF configuration by simply entering **delete protocols ospf** while at the top level.

3. If you decide to use the default values for the hello and dead intervals on your remaining interface but you want OSPF to run on that interface, delete the hello and dead interval timers:

```

[edit]
user@host# edit protocols ospf area 0.0.0.0 interface so-0/0/1

```

```

[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# delete hello-interval
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# delete dead-interval
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# top
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/1;
    }
  }
}
[edit]
user@host#

```

You can set multiple statements at the same time as long as they are all part of the same hierarchy (the path of statements from the top inward, as well as one or more statements at the bottom of the hierarchy). This feature can reduce considerably the number of commands you must enter.

4. To go back to the original hello and dead interval timers on interface **so-0/0/1**, enter:

```

[edit]
user@host# edit protocols ospf area 0.0.0.0 interface so-0/0/1
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# set hello-interval 5 dead-interval 20
[edit protocols ospf area 0.0.0.0 interface so-0/0/1]
user@host# exit
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/1 {
        hello-interval 5;
        dead-interval 20;
      }
    }
  }
}
[edit]
user@host#

```

5. You also can recreate the other interface, as you had it before, with only a single entry:

```

[edit]
user@host# set protocols ospf area 0.0.0.0 interface so-0/0/1 hello-interval 5
dead-interval 20
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {

```

```
        hello-interval 5;
        dead-interval 20;
    }
    interface so-0/0/1 {
        hello-interval 5;
        dead-interval 20;
    }
}
}
[edit]
user@host#
```

 - [Interface Naming Conventions Used in the Junos OS Operational Commands on page 572](#)

Rolling Back Junos OS Configuration Changes

This topic shows how to use the **rollback** command to return to the most recently committed Junos OS configuration. The **rollback** command is useful if you make configuration changes and then decide not to keep the changes.

The following procedure shows how to configure an SNMP health monitor on a device running Junos OS and then return to the most recently committed configuration that does not include the health monitor. When configured, the SNMP health monitor provides the network management system (NMS) with predefined monitoring for file system usage, CPU usage, and memory usage on the device.

1. Enter configuration mode:

```
user@host> configure
entering configuration mode
[edit]
user@host#
```

2. Show the current configuration (if any) for SNMP:

```
[edit]
user@host# show snmp
```

No **snmp** statements appear because SNMP has not been configured on the device.

3. Configure the health monitor:

```
[edit]
user@host# set snmp health-monitor
```

4. Show the new configuration:

```
[edit]
user@host# show snmp
health-monitor;
```

The **health-monitor** statement indicates that SNMP health monitoring is configured on the device.

5. Enter the **rollback** configuration mode command to return to the most recently committed configuration:

```
[edit]
user@host# rollback
load complete
```

6. Show the configuration again to make sure your change is no longer present:

```
[edit]
user@host# show snmp
```

No **snmp** configuration statements appear. The health monitor is no longer configured.

7. Enter the **commit** command to activate the configuration to which you rolled back:

```
[edit]
user@host# commit
```

8. Exit configuration mode:

```
[edit]
user@host# exit
Exiting configuration mode
```

You can also use the **rollback** command to return to earlier configurations.

CHAPTER 21

Getting Online Help

- [Getting Online Help from the Junos OS Command-Line Interface on page 447](#)
- [Junos OS CLI Online Help Features on page 450](#)
- [Examples: Using Command Completion in Configuration Mode on page 451](#)
- [Examples: Using the Junos OS CLI Command Completion on page 453](#)
- [Displaying the Junos OS CLI Command and Word History on page 454](#)

Getting Online Help from the Junos OS Command-Line Interface

The Junos OS command-line interface (CLI) has a context-sensitive online help feature that enables you to access information about commands and statements from the Junos OS CLI. This topic contains the following sections:

- [Getting Help About Commands on page 447](#)
- [Getting Help About a String in a Statement or Command on page 448](#)
- [Getting Help About Configuration Statements on page 449](#)
- [Getting Help About System Log Messages on page 449](#)

Getting Help About Commands

Information about commands is provided at each level of the CLI command hierarchy. You can type a question mark to get help about commands:

- If you type the question mark at the command-line prompt, the CLI lists the available commands and options. For example, to view a list of top-level operational mode commands, type a question mark (?) at the command-line prompt.

```
user@host> ?
Possible completions:
clear          Clear information in the system
configure      Manipulate software configuration information
file           Perform file operations
help           Provide help information
mtrace         Trace mtrace packets from source to receiver.
monitor        Real-time debugging
ping           Ping a remote target
quit           Exit the management session
request        Make system-level requests
restart        Restart a software process
set            Set CLI properties, date, time, craft display text
```

```
show      Show information about the system
ssh       Open a secure shell to another host
start     Start a software process
telnet    Telnet to another host
test      Diagnostic debugging commands
traceroute Trace the route to a remote host
user@host>
```

- If you type the question mark after entering the complete name of a command or command option, the CLI lists the available commands and options and then redisplay the command names and options that you typed.

```
user@host> clear ?
Possible completions:
arp        Clear address-resolution information
bgp        Clear BGP information
chassis    Clear chassis information
firewall   Clear firewall counters
igmp       Clear IGMP information
interfaces Clear interface information
ilmi       Clear ILMI statistics information
isis       Clear IS-IS information
ldp        Clear LDP information
log        Clear contents of a log file
mpls       Clear MPLS information
msdp       Clear MSDP information
multicast  Clear Multicast information
ospf       Clear OSPF information
pim        Clear PIM information
rip        Clear RIP information
route      Clear routing table information
rsvp       Clear RSVP information
snmp       Clear SNMP information
system     Clear system status
vrrp       Clear VRRP statistics information
user@host> clear
```

- If you type the question mark in the middle of a command name, the CLI lists possible command completions that match the letters you have entered so far. It then redisplay the letters that you typed. For example, to list all operational mode commands that start with the letter *c*, type the following:

```
user@host> c?
Possible completions:
clear      Clear information in the system
configure  Manipulate software configuration information
user@host> c
```

- For introductory information on using the question mark or the help command, you can also type **help** and press Enter:

```
user@host> help
```

Getting Help About a String in a Statement or Command

You can use the **help** command to display help about a text string contained in a statement or command name:

```
help apropos string
```

string is a text string about which you want to get help. This string is used to match statement or command names as well as to match the help strings that are displayed for the statements or commands.

If the string contains spaces, enclose it in quotation marks (" "). You can also specify a regular expression for the string, using standard UNIX-style regular expression syntax.

For statements or commands which need input data type as STRING, the supported characters set are as follows:

- Any printable ASCII characters
- For characters with space, it should be enclosed in double-quotes
- To have double-quote as the input, it should be escaped with '\'

NOTE: No escape characters are supported in a string other than to escape from double quotes.

Range of supported characters for attributes is 0 through 65499 characters.

Range of supported characters for string type identifiers is 1 through 255 characters.

In configuration mode, this command displays statement names and help text that match the string specified. In operational mode, this command displays command names and help text that match the string specified.

Getting Help About Configuration Statements

You can display help based on text contained in a statement name using the **help topic** and **help reference** commands:

help topic *word*
help reference *statement-name*

The **help topic** command displays usage guidelines for the statement based on information that appears in the Junos OS configuration guides. The **help reference** command displays summary information about the statement based on the summary descriptions that appear in the Junos OS configuration guides.

Getting Help About System Log Messages

You can display help based on a system log tag using the **help syslog** command:

help syslog *syslog-tag*

The **help syslog** command displays the contents of a system log message.

Related Documentation

- [Getting Started with the Junos OS Command-Line Interface on page 429](#)

Junos OS CLI Online Help Features

The Junos OS CLI online help provides the following features for ease of use and error prevention:

- [Help for Omitted Statements on page 450](#)
- [Using CLI Command Completion on page 450](#)
- [Using Command Completion in Configuration Mode on page 451](#)
- [Displaying Tips About CLI Commands on page 451](#)

Help for Omitted Statements

If you have omitted a required statement at a particular hierarchy level, when you attempt to move from that hierarchy level or when you issue the **show** command in configuration mode, a message indicates which statement is missing. For example:

```
[edit protocols pim interface so-0/0/0]
user@host# top
Warning: missing mandatory statement: 'mode'
[edit]
user@host# show
protocols {
  pim {
    interface so-0/0/0 {
      priority 4;
      version 2;
      # Warning: missing mandatory statement(s): 'mode'
    }
  }
}
```

Using CLI Command Completion

The Junos OS CLI provides you a command completion option that enables Junos OS to recognize commands and options based on the initial few letters you typed. That is, you do not always have to remember or type the full command or option name for the CLI to recognize it.

- To display all possible command or option completions, type the partial command followed immediately by a question mark.
- To complete a command or option that you have partially typed, press Tab or the Spacebar. If the partially typed letters begin a string that uniquely identifies a command, the complete command name appears. Otherwise, a prompt indicates that you have entered an ambiguous command, and the possible completions are displayed.

Command completion also applies to other strings, such as filenames, interface names, and usernames. To display all possible values, type a partial string followed immediately by a question mark. To complete a string, press Tab.

Using Command Completion in Configuration Mode

The CLI command completion functions also apply to the commands in configuration mode and to configuration statements. Specifically, to display all possible commands or statements, type the partial string followed immediately by a question mark. To complete a command or statement that you have partially typed, press Tab or the Spacebar.

Command completion also applies to identifiers, with one slight difference. To display all possible identifiers, type a partial string followed immediately by a question mark. To complete an identifier, you must press Tab. This scheme allows you to enter identifiers with similar names; then press the Spacebar when you are done typing the identifier name.

Displaying Tips About CLI Commands

To get tips about CLI commands, issue the **help tip cli** command. Each time you enter the command, a new tip appears. For example:

```
user@host> help tip cli
Junos tip:
Use 'request system software validate' to validate the incoming software
against the current configuration without impacting the running system.
user@host> help tip cli
Junos tip:
Use 'commit and-quit' to exit configuration mode after the commit has
succeeded. If the commit fails, you are left in configuration mode.
```

You can also enter **help tip cli *number*** to associate a tip with a number. This enables you to recall the tip at a later time. For example:

```
user@host> help tip cli 10
JUNOS tip:
Use '#' in the beginning of a line in command scripts to cause the
rest of the line to be ignored.

user@host> help tip cli
JUNOS tip:
Use the 'apply-groups' statement at any level of the configuration
hierarchy to inherit configuration statements from a configuration group.

user@host>
```

- [Examples: Using the Junos OS CLI Command Completion on page 453](#)

Examples: Using Command Completion in Configuration Mode

List the configuration mode commands:

```
[edit]
user@host# ?
  <[Enter]>      Execute this command
  activate      Remove the inactive tag from a statement
```

annotate	Annotate the statement with a comment
commit	Commit current set of changes
copy	Copy a statement
deactivate	Add the inactive tag to a statement
delete	Delete a data element
edit	Edit a sub-element
exit	Exit from this level
extension	Extension operations
help	Provide help information
insert	Insert a new ordered data element
load	Load configuration from ASCII file
quit	Quit from this level
rename	Rename a statement
replace	Replace character string in configuration
rollback	Roll back to previous committed configuration
run	Run an operational-mode command
save	Save configuration to ASCII file
set	Set a parameter
show	Show a parameter
status	Show users currently editing configuration
top	Exit to top level of configuration
up	Exit one level of configuration
wildcard	Wildcard operations

[edit]user@host#

List all the statements available at a particular hierarchy level:

```
[edit]
user@host# edit ?
Possible completions:
> accounting-options  Accounting data configuration
> chassis             Chassis configuration
> class-of-service    Class-of-service configuration
> firewall            Define a firewall configuration
> forwarding-options  Configure options to control packet sampling
> groups              Configuration groups
> interfaces          Interface configuration
> policy-options      Routing policy option configuration
> protocols            Routing protocol configuration
> routing-instances   Routing instance configuration
> routing-options      Protocol-independent routing option configuration
> snmp                Simple Network Management Protocol
> system              System parameters

user@host# edit protocols ?
Possible completions:
<[Enter]>             Execute this command
> bgp                 BGP options
> connections         Circuit cross-connect configuration
> dvmrp               DVMRP options
> igmp                IGMP options
> isis                IS-IS options
> ldp                 LDP options
> mpls                Multiprotocol Label Switching options
> msdp                MSDP options
> ospf                OSPF configuration
> pim                 PIM options
> rip                 RIP options
> router-discovery    ICMP router discovery options
> rsvp                RSVP options
> sapSession          Advertisement Protocol options
```

```

> vrrp                VRRP options
|                    Pipe through a command

[edit]
user@host# edit protocols
List all commands that start with a particular letter or string:

user@host# edit routing-options a?
Possible completions:
> aggregate           Coalesced routes
> autonomous-system   Autonomous system number

[edit]
user@host# edit routing-options a
List all configured Asynchronous Transfer Mode (ATM) interfaces:

[edit]
user@host# edit interfaces at?
<interface_name>      Interface name
  at-0/2/0             Interface name
  at-0/2/1             Interface name
[edit]
user@host# edit interfaces at

Display a list of all configured policy statements:

[edit]
user@host# show policy-options policy-statement ?
<policy_name>         Name to identify a policy filter
user@host# show policy-options policy-statement
  <policy_name>       Name to identify a policy filter
  lo0only-v4          Name to identify a policy filter
  lo0only-v6          Name to identify a policy filter
  lo2bgp              Name to identify a policy filter

```

- Related Documentation**
- [Examples: Using the Junos OS CLI Command Completion on page 453](#)
 - [Displaying the Junos OS CLI Command and Word History on page 454](#)

Examples: Using the Junos OS CLI Command Completion

The following examples show how you can use the command completion feature in Junos OS. Issue the **show interfaces** command:

```

user@host> sh<Space>ow i<Space>
'i' is ambiguous.
Possible completions:
igmp                Show information about IGMP
interface           Show interface information
isis                Show information about IS-IS

user@host> show in<Space>terfaces
Physical interface: at-0/1/0, Enabled, Physical link is Up
Interface index: 11, SNMP ifIndex: 65
Link-level type: ATM-PVC, MTU: 4482, Clocking: Internal, SONET mode
Speed: OC12, Loopback: None, Payload scrambler: Enabled
Device flags: Present Running
Link flags: 0x01
...

```

```
user@host>
```

Display a list of all log files whose names start with the string “messages,” and then display the contents of one of the files:

```
user@myhost> show log mes?
```

Possible completions:

```
<filename>Log file to display
messagesSize: 1417052, Last changed: Mar 3 00:33
messages.0.gzSize: 145575, Last changed: Mar 3 00:00
messages.1.gzSize: 134253, Last changed: Mar 2 23:00
messages.10.gzSize: 137022, Last changed: Mar 2 14:00
messages.2.grSize: 137112, Last changed: Mar 2 22:00
messages.3.gzSize: 121633, Last changed: Mar 2 21:00
messages.4.gzSize: 135715, Last changed: Mar 2 20:00
messages.5.gzSize: 137504, Last changed: Mar 2 19:00
messages.6.gzSize: 134591, Last changed: Mar 2 18:00
messages.7.gzSize: 132670, Last changed: Mar 2 17:00
messages.8.gzSize: 136596, Last changed: Mar 2 16:00
messages.9.gzSize: 136210, Last changed: Mar 2 15:00
```

```
user@myhost> show log mes<Tab>sages.4<Tab>.gz<Enter>
Jan 15 21:00:00 myhost newsyslog[1381]: logfile turned over
...
```

Related Documentation

- [Displaying the Junos OS CLI Command and Word History on page 454](#)

Displaying the Junos OS CLI Command and Word History

To display a list of recent commands that you issued, use the **show cli history** command:

```
user@host> show cli history 3
01:01:44 -- show bgp next-hop-database
01:01:51 -- show cli history
01:02:51 -- show cli history 3
```

You can press Esc+. (period) or Alt+. (period) to insert the last word of the previous command. Repeat Esc+. or Alt+. to scroll backwards through the list of recently entered words. For example:

```
user@host> show interfaces terse fe-0/0/0
Interface      Admin  Link  Proto  Local  Remote
fe-0/0/0        up     up    inet   192.168.220.1/30
fe-0/0/0.0      up     up    inet   192.168.220.1/30

user@host> <Esc>
user@host> fe-0/0/0
```

If you scroll completely to the beginning of the list, pressing Esc+. or Alt+. again restarts scrolling from the last word entered.

[Understanding Junos OS CLI Configuration Mode](#)

You can configure all properties of Junos OS, including interfaces, general routing information, routing protocols, and user access, as well as several system hardware properties.

As described in “[Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies](#)” on [page 423](#), a router configuration is stored as a hierarchy of statements. In configuration mode, you create the specific hierarchy of configuration statements that you want to use. When you have finished entering the configuration statements, you commit them, which activates the configuration on the router.

You can create the hierarchy interactively or you can create an ASCII text file that is loaded onto the router or switch and then committed.

This topic covers:

- [Configuration Mode Commands on page 457](#)
- [Configuration Statements and Identifiers on page 458](#)
- [Configuration Statement Hierarchy on page 460](#)

Configuration Mode Commands

Table 57 summarizes each CLI configuration mode command. The commands are organized alphabetically.

Table 57: Summary of Configuration Mode Commands

Command	Description
activate	Remove the inactive: tag from a statement, effectively reading the statement or identifier to the configuration. Statements or identifiers that have been activated take effect when you next issue the commit command.
annotate	Add comments to a configuration. You can add comments only at the current hierarchy level.
commit	Commit the set of changes to the database and cause the changes to take operational effect.
copy	Make a copy of an existing statement in the configuration.
deactivate	Add the inactive: tag to a statement, effectively commenting out the statement or identifier from the configuration. Statements or identifiers marked as inactive do not take effect when you issue the commit command.
delete	Delete a statement or identifier. All subordinate statements and identifiers contained within the specified statement path are deleted with it.
edit	Move inside the specified statement hierarchy. If the statement does not exist, it is created.
exit	Exit the current level of the statement hierarchy, returning to the level prior to the last edit command, or exit from configuration mode. The quit and exit commands are synonyms.
extension	Manage configurations that are contributed by SDK application packages. Either display or delete user-defined configuration contributed by the named SDK application package. A configuration defined in any native Junos OS package is never deleted by the extension command.
help	Display help about available configuration statements.
insert	Insert an identifier into an existing hierarchy.
load	Load a configuration from an ASCII configuration file or from terminal input. Your current location in the configuration hierarchy is ignored when the load operation occurs.

Table 57: Summary of Configuration Mode Commands (*continued*)

Command	Description
quit	Exit the current level of the statement hierarchy, returning to the level prior to the last edit command, or exit from configuration mode. The quit and exit commands are synonyms.
rename	Rename an existing configuration statement or identifier.
replace	Replace identifiers or values in a configuration.
rollback	Return to a previously committed configuration. The software saves the last 10 committed configurations, including the rollback number, date, time, and name of the user who issued the commit configuration command.
run	Run a top-level CLI command without exiting from configuration mode.
save	Save the configuration to an ASCII file. The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.
set	Create a statement hierarchy and set identifier values. This is similar to edit except that your current level in the hierarchy does not change.
show	Display the current configuration.
status	Display the users currently editing the configuration.
top	Return to the top level of configuration command mode, which is indicated by the [edit] banner.
up	Move up one level in the statement hierarchy.
update	Update a private database.
wildcard	Delete a statement or identifier. All subordinate statements and identifiers contained within the specified statement path are deleted with it. You can use regular expressions to specify a pattern. Based on this pattern, you search for items that contain these patterns and delete them.

Configuration Statements and Identifiers

You can configure router or switch properties by including the corresponding statements in the configuration. Typically, a statement consists of a keyword, which is fixed text, and, optionally, an identifier. An identifier is an identifying name that you can define, such as

the name of an interface or a username, which enables you and the CLI to differentiate among a collection of statements.

Table 58 describes top-level CLI configuration mode statements.

NOTE: The QFX3500 switch does not support the IS-IS, OSPF, BGP, LDP, MPLS, and RSVP protocols.

Table 58: Configuration Mode Top-Level Statements

Statement	Description
access	Configure the Challenge Handshake Authentication Protocol (CHAP). For information about the statements in this hierarchy, see the <i>Junos OS Administration Library for Routing Devices</i> .
accounting-options	Configure accounting statistics data collection for interfaces and firewall filters. For information about the statements in this hierarchy, see the <i>Network Management Administration Guide for Routing Devices</i> .
chassis	Configure properties of the router chassis, including conditions that activate alarms and SONET/SDH framing and concatenation properties. For information about the statements in this hierarchy, see the <i>Junos OS Administration Library for Routing Devices</i> .
class-of-service	Configure class-of-service parameters. For information about the statements in this hierarchy, see the <i>Class of Service Feature Guide for Routing Devices</i> .
firewall	Define filters that select packets based on their contents. For information about the statements in this hierarchy, see the <i>Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices</i> .
forwarding-options	Define forwarding options, including traffic sampling options. For information about the statements in this hierarchy, see the <i>Junos OS Network Interfaces Library for Routing Devices</i> .
groups	Configure configuration groups. For information about statements in this hierarchy, see the <i>Junos OS Administration Library for Routing Devices</i> .
interfaces	Configure interface information, such as encapsulation, interfaces, virtual channel identifiers (VCIs), and data-link connection identifiers (DLCIs). For information about the statements in this hierarchy, see the <i>Junos OS Network Interfaces Library for Routing Devices</i> .
policy-options	Define routing policies, which allow you to filter and set properties in incoming and outgoing routes. For information about the statements in this hierarchy, see the <i>Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices</i> .
protocols	Configure routing protocols, including BGP, IS-IS, LDP, MPLS, OSPF, RIP, and RSVP. For information about the statements in this hierarchy, see the chapters that discuss how to configure the individual routing protocols in the <i>Junos OS Routing Protocols Library for Routing Devices</i> and the <i>MPLS Applications Feature Guide for Routing Devices</i> .

Table 58: Configuration Mode Top-Level Statements (*continued*)

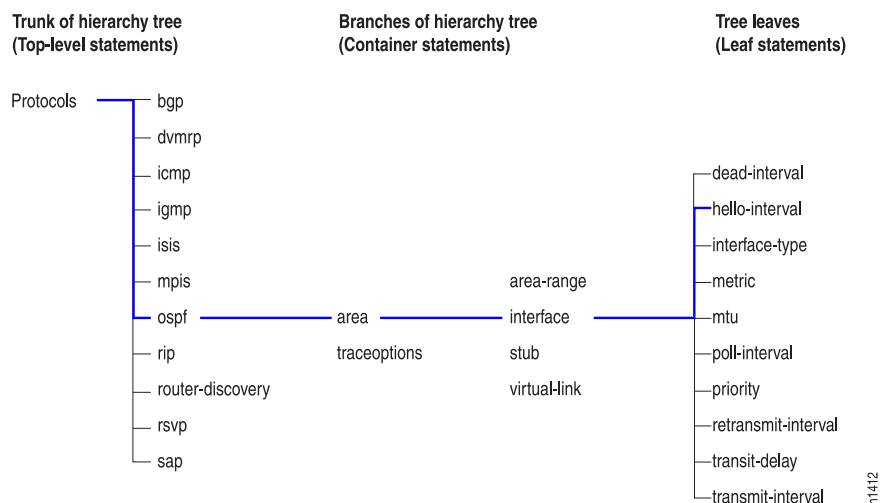

Statement	Description
routing-instances	Configure multiple routing instances. For information about the statements in this hierarchy, see the <i>Junos OS Routing Protocols Library for Routing Devices</i> .
routing-options	Configure protocol-independent routing options, such as static routes, autonomous system numbers, confederation members, and global tracing (debugging) operations to log. For information about the statements in this hierarchy, see the <i>Junos OS Routing Protocols Library for Routing Devices</i> .
security	Configure IP Security (IPsec) services. For information about the statements in this hierarchy see the <i>Junos OS Administration Library for Routing Devices</i> .
snmp	Configure SNMP community strings, interfaces, traps, and notifications. For information about the statements in this hierarchy, see the <i>Network Management Administration Guide for Routing Devices</i> .
system	Configure systemwide properties, including the hostname, domain name, Domain Name System (DNS) server, user logins and permissions, mappings between hostnames and addresses, and software processes. For information about the statements in this hierarchy, see the <i>Junos OS Administration Library for Routing Devices</i> .

For specific information on configuration statements, see the Junos OS configuration guides.

Configuration Statement Hierarchy

The Junos OS configuration consists of a hierarchy of *statements*. There are two types of statements: *container statements*, which are statements that contain other statements, and *leaf statements*, which do not contain other statements (see Figure 13). All of the container and leaf statements together form the *configuration hierarchy*.

Figure 13: Configuration Mode Hierarchy of Statements

Each statement at the top level of the configuration hierarchy resides at the trunk (or root level) of a hierarchy tree. The top-level statements are container statements, containing other statements that form the tree branches. The leaf statements are the leaves of the hierarchy tree. An individual hierarchy of statements, which starts at the trunk of the hierarchy tree, is called a *statement path*. [Figure 13](#) illustrates the hierarchy tree, showing a statement path for the portion of the protocol configuration hierarchy that configures the hello interval on an interface in an OSPF area.

The **protocols** statement is a top-level statement at the trunk of the configuration tree. The **ospf**, **area**, and **interface** statements are all subordinate container statements of a higher statement (they are branches of the hierarchy tree); and the **hello-interval** statement is a leaf on the tree which in this case contains a data value: the length of the hello interval, in seconds.

The CLI represents the statement path shown in [Figure 13](#) as **[edit protocols ospf area *area-number* interface *interface-name*]** and displays the configuration as follows:

```
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {
        hello-interval 5;
      }
      interface so-0/0/1 {
        hello-interval 5;
      }
    }
  }
}
```

The CLI indents each level in the hierarchy to indicate each statement's relative position in the hierarchy and generally sets off each level with braces, using an open brace at the beginning of each hierarchy level and a closing brace at the end. If the statement at a hierarchy level is empty, the braces are not printed.

Each leaf statement ends with a semicolon. If the hierarchy does not extend as far as a leaf statement, the last statement in the hierarchy ends with a semicolon.

The configuration hierarchy can also contain “oneliners” at the last level in the hierarchy. Oneliners remove one level of braces in the syntax and display the container statement, its identifiers, the child or leaf statement and its attributes all on one line. For example, in the following sample configuration hierarchy, the line **level 1 metric 10** is a oneliner because the **level** container statement with identifier **1**, its child statement **metric**, and its corresponding attribute **10** all appear on a single line in the hierarchy:

```
[edit protocols]
isis {
  interface ge-0/0/0.0 {
    level 1 metric 10;
  }
}
```

Likewise, in the following example, **dynamic-profile *dynamic-profile-name* aggregate-clients;** is a oneliner because the **dynamic-profile** statement, its identifier ***dynamic-profile-name***, and leaf statement **aggregate-clients** all appear on one line when you run the **show** command in the configuration mode:

```
[edit forwarding-options]
user@host# show
dhcp-relay {
  dynamic-profile dynamic-profile-name aggregate-clients;
}
```

Related Documentation • [Entering and Exiting the Junos OS CLI Configuration Mode on page 462](#)

Entering and Exiting the Junos OS CLI Configuration Mode

You configure Junos OS by entering configuration mode and creating a hierarchy of configuration mode statements.

- To enter configuration mode, use the **configure** command.

When you enter configuration mode, the following configuration mode commands are available:

```
user@host>configure
entering configuration mode

[edit]
user@host#?
possible completions:
  <[Enter]>      Execute this command
  activate      Remove the inactive tag from a statement
  annotate      Annotate the statement with a comment
  commit        Commit current set of changes
  copy          Copy a statement
  deactivate    Add the inactive tag to a statement
  delete        Delete a data element
  edit          Edit a sub-element
  exit          Exit from this level
  help          Provide help information
  insert        Insert a new ordered data element
  load          Load configuration from ASCII file
  quit          Quit from this level
  rename        Rename a statement
  replace       Replace character string in configuration
  rollback      Roll back to previous committed configuration
  run           Run an operational-mode command
  save          Save configuration to ASCII file
  set           Set a parameter
  show          Show a parameter
  status        Show users currently editing configuration
  top           Exit to top level of configuration
  up            Exit one level of configuration
  wildcard      Wildcard operations
[edit]
user@host>
```

Users must have configure permission to view and use the **configure** command. When in configuration mode, a user can view and modify only those statements for which they have access privileges set. For more information, see the *Junos OS Administration Library for Routing Devices*.

- If you enter configuration mode and another user is also in configuration mode, a message shows the user's name and what part of the configuration the user is viewing or editing:

```
user@host> configure
Entering configuration mode
Users currently editing the configuration:
  root terminal d0 (pid 4137) on since 2008-04-09 23:03:07 PDT, idle 7w6d 08:22
```

```
[edit]
The configuration has been changed but not committed
```

```
[edit]
user@host#
```

Up to 32 users can be in configuration mode simultaneously, and they all can make changes to the configuration at the same time.

- To exit configuration mode, use the **exit configuration-mode** configuration mode command from any level, or use the **exit** command from the top level. For example:

```
[edit protocols ospf area 0.0.0.0 interface so-0/0/0]
user@host# exit configuration-mode
exiting configuration mode
user@host>

[edit]
user@host# exit
exiting configuration mode
user@host>
```

If you try to exit from configuration mode using the **exit** command and the configuration contains changes that have not been committed, you see a message and prompt:

```
[edit]
user@host# exit
The configuration has been changed but not committed
Exit with uncommitted changes? [yes,no] (yes) <Enter>
Exiting configuration mode
user@host>
```

- To exit with uncommitted changes without having to respond to a prompt, use the **exit configuration-mode** command. This command is useful when you are using scripts to perform remote configuration.

```
[edit]
user@host# exit configuration-mode
The configuration has been changed but not committed
Exiting configuration mode
user@host>
```

Notational Conventions Used in Junos OS Configuration Hierarchies

When you are working in Junos OS command-line interface (CLI) configuration mode, the banner on the line preceding the prompt indicates the current hierarchy level. In the following example, the level is **[edit protocols ospf]**:

```
[edit protocols ospf]  
user@host#
```

(The Junos OS documentation uses **user@host#** as the standard configuration mode prompt. In an actual CLI session, the prompt shows your user ID and the name of the Juniper Networks device you are working on.)

Use the **set ?** command to display the statements that you can include in the configuration at the current level. The **help apropos** command is also context-sensitive, displaying matching statements only at the current level and below.

NOTE: In this document, statements are listed alphabetically within each hierarchy and subhierarchy. If a subhierarchy is sufficiently long that it might be difficult to determine where it ends and its next peer statement begins, the subhierarchy appears at the end of its parent hierarchy instead of in alphabetical order. In this case, a placeholder appears in its actual alphabetical position.

For example, at the [edit interfaces *interface-name* unit *logical-unit-number*] hierarchy level, the family *family-name* subhierarchy has more than 20 child statements, including several subhierarchies with child statements of their own. The full family *family-name* hierarchy appears at the end of its parent hierarchy ([edit interfaces *interface-name* unit *logical-unit-number*]), and the following placeholder appears at its actual alphabetical position:

```
family family-name {
    ... the family subhierarchy appears after the main [edit interfaces interface-name
        unit logical-unit-number] hierarchy ...
}
```

Another exception to alphabetical order is that the **disable** statement always appears first in any hierarchy that includes it.

Forms of the configure Command

The Junos OS supports three forms of the **configure** command: **configure**, **configure private**, and **configure exclusive**. These forms control how users edit and commit configurations and can be useful when multiple users configure the software. See [Table 59](#).

Table 59: Forms of the configure Command

Command	Edit Access	Commit Access
configure	<ul style="list-style-type: none"> No one can lock the configuration. All users can make configuration changes. <p>When you enter configuration mode, the CLI displays the following information:</p> <ul style="list-style-type: none"> A list of other users editing the configuration. Hierarchy levels the users are viewing or editing. Whether the configuration has been changed, but not committed. When multiple users enter conflicting configurations, the most recent change to be entered takes precedence. 	<ul style="list-style-type: none"> No one can lock the configuration. All users can commit all changes to the configuration. If you and another user make changes and the other user commits changes, your changes are committed as well.
configure exclusive	<ul style="list-style-type: none"> One user locks the configuration and makes changes without interference from other users. Other users can enter and exit configuration mode, but they cannot commit the configuration. If you enter configuration mode while another user has locked the configuration (with the configure exclusive command), the CLI displays the user and the hierarchy level the user is viewing or editing. If you enter configuration mode while another user has locked the configuration, you can forcibly log out that user with the request system logout operational mode command. For details, see the CLI Explorer. 	
configure private	<ul style="list-style-type: none"> Multiple users can edit the configuration at the same time. Each user has a private candidate configuration to edit independently of other users. When multiple users enter conflicting configurations, the first commit operation takes precedence over subsequent commit operations. 	<ul style="list-style-type: none"> When you commit the configuration, the router verifies that the operational (running) configuration has not been modified by another user before accepting your private candidate configuration as the new operational configuration. If the configuration has been modified by another user, you can merge the modifications into your private candidate configuration and attempt to commit again.

Related Documentation

- [Committing a Junos OS Configuration on page 508](#)
- [Using the configure Command on page 468](#)
- [Displaying Users Currently Editing the Junos OS Configuration on page 504](#)
- [Using the configure exclusive Command on page 467](#)
- [Updating the configure private Configuration on page 496](#)
- [Displaying set Commands from the Junos OS Configuration on page 501](#)

Using the configure exclusive Command

If you enter configuration mode with the **configure exclusive** command, you lock the candidate *global* configuration (also known as the *shared configuration* or *shared configuration database*) for as long as you remain in configuration mode, allowing you to make changes without interference from other users. Other users can enter and exit configuration mode, but they cannot commit the configuration.

If another user has locked the configuration, and you need to forcibly log the person out, enter the operational mode command **request system logout pid *pid_number***.

If you enter configuration mode and another user is also in configuration mode and has locked the configuration, a message identifies the user and the portion of the configuration that the user is viewing or editing:

```
user@host> configure
Entering configuration mode
Users currently editing the configuration:
root terminal p3 (pid 1088) on since 2000-10-30 19:47:58 EDT, idle 00:00:44
exclusive [edit interfaces so-3/0/0 unit 0 family inet]
```

In configure exclusive mode, any uncommitted changes are discarded when you exit:

```
user@host> configure exclusive
warning: uncommitted changes will be discarded on exit
Entering configuration mode
[edit]
user@host# set system host-name cool
[edit]
user@host# quit
The configuration has been changed but not committed
warning: Auto rollback on exiting 'configure exclusive'
Discard uncommitted changes? [yes,no] (yes)
warning: discarding uncommitted changes
load complete
Exiting configuration mode
```

When you use the **yes** option to exit configure exclusive mode, Junos OS discards your uncommitted changes and rolls back your configuration. The **no** option allows you to continue editing or to commit your changes in configure exclusive mode.

When a user exits from configure exclusive mode while another user is in configure private mode, Junos OS will roll back any uncommitted changes.

- Related Documentation**

 - [Forms of the configure Command on page 465](#)

Using the configure Command

You can use the **configure** command to not only enter the CLI configuration mode but also to gather other information, such as other users currently in configuration mode.

Up to 32 users can be in configuration mode simultaneously, and they all can make changes to the configuration at the same time. When you commit changes to the configuration, you may be committing a combination of changes you and other users have made. For this reason, you will want to keep track on who if anyone is in configuration mode with you.

To see other users currently logged onto the same device in configuration mode:

- Use the **configure** command to enter the CLI configuration mode.

If there are other users, the message displayed indicates who the users are and what portion of the configuration the each person is viewing or editing.

```
user@host> configure
Entering configuration mode
Current configuration users:
root terminal p3 (pid 1088) on since 1999-05-13 01:03:27 EDT
[edit interfaces so-3/0/0 unit 0 family inet]
The configuration has been changed but not committed
[edit]
user@host#
```

Notice also that If, when you enter configuration mode, the configuration contains changes that have not been committed, another message is displayed:

```
user@host> configure
Entering configuration mode
The configuration has been changed but not committed
[edit]
user@host#
```

This tells you that another user has already made changes to the configuration.

- Related Documentation**
- [Forms of the configure Command on page 465](#)

Modifying the Junos OS Configuration

To configure a device running Junos OS or to modify an existing Junos OS configuration, you add statements to the configuration. For each statement hierarchy, you create the hierarchy starting with a statement at the top level and continuing with statements that move progressively lower in the hierarchy.

To modify the hierarchy, you use two configuration mode commands:

- **edit**—Moves to a particular hierarchy level. If that hierarchy level does not exist, the **edit** command creates it. The **edit** command has the following syntax:

```
edit <statement-path>
```

- **set**—Creates a configuration statement and sets identifier values. After you issue a **set** command, you remain at the same level in the hierarchy. The **set** command has the following syntax:

```
set <statement-path> statement <identifier>
```

statement-path is the hierarchy to the configuration statement and the statement itself. If you have already moved to the statement's hierarchy level, you can omit the statement path. **statement** is the configuration statement itself. **identifier** is a string that identifies an instance of a statement.

You cannot use the **edit** command to change the value of identifiers. You must use the **set** command.

- [Issuing Relative Junos OS Configuration Mode Commands on page 475](#)

Adding Junos OS Configuration Statements and Identifiers

All properties of a device running Junos OS are configured by including *statements* in the configuration. A statement consists of a keyword, which is fixed text, and, optionally, an *identifier*. An identifier is an identifying name which you define, such as the name of an interface or a username, and which allows you and the CLI to discriminate among a collection of statements.

For example, the following list shows the statements available at the top level of configuration mode:

```
user@host# set?
Possible completions:
> accounting-options  Accounting data configuration
+ apply-groups        Groups from which to inherit configuration data
> chassis             Chassis configuration
> class-of-service    Class-of-service configuration
> firewall            Define a firewall configuration
> forwarding-options  Configure options to control packet sampling
> groups              Configuration groups
> interfaces          Interface configuration
> policy-options      Routing policy option configuration
> protocols           Routing protocol configuration
> routing-instances   Routing instance configuration
> routing-options     Protocol-independent routing option configuration
> snmp               Simple Network Management Protocol
> system              System parameters
```

An angle bracket (>) before the statement name indicates that it is a container statement and that you can define other statements at levels below it. If there is no angle bracket (>) before the statement name, the statement is a leaf statement; you cannot define other statements at hierarchy levels below it.

A plus sign (+) before the statement name indicates that it can contain a set of values. To specify a set, include the values in brackets. For example:

```
[edit]
user@host# set policy-options community my-as1-transit members [65535:10 65535:11]
```

In some statements, you can include an identifier. For some identifiers, such as interface names, you must specify the identifier in a precise format. For example, the interface name so-0/0/0 refers to a SONET/SDH interface that is on the Flexible PIC Concentrator (FPC) in slot 0, in the first PIC location, and in the first port on the Physical Interface Card (PIC). For other identifiers, such as interface descriptive text and policy and firewall term names, you can specify any name, including special characters, spaces, and tabs.

You must enclose in quotation marks (double quotes) identifiers and any strings that include a space or tab character or any of the following characters:

() [] { } ! @ # \$ % ^ & | ' = ?

If you do not type an option for a statement that requires one, a message indicates the type of information required. In this example, you need to type an area number to complete the command:

```
[edit]
user@host# set protocols ospf area<Enter>
^
syntax error, expecting <identifier>
```

Related Documentation

- [Displaying the Current Junos OS Configuration on page 497](#)

Deleting a Statement from a Junos OS Configuration

To delete a statement or identifier from a Junos OS configuration, use the **delete** configuration mode command. Deleting a statement or an identifier effectively "unconfigures" the functionality associated with that statement or identifier, returning that functionality to its default condition.

```
user@host# delete <statement-path> <identifier>
```

When you delete a statement, the statement and all its subordinate statements and identifiers are removed from the configuration.

For statements that can have more than one identifier, when you delete one identifier, only that identifier is deleted. The other identifiers in the statement remain.

To delete the entire hierarchy starting at the current hierarchy level, do not specify a statement or an identifier in the **delete** command. When you omit the statement or identifier, you are prompted to confirm the deletion:

```
[edit]
user@host# delete
Delete everything under this level? [yes, no] (no)
Possible completions:
no    Don't delete everything under this level
yes   Delete everything under this level
Delete everything under this level? [yes, no] (no)
```

NOTE: You cannot delete multiple statements or identifiers within a hierarchy using a single delete command. You must delete each statement or identifier individually using multiple delete commands. For example, consider the following configuration at the [edit system] hierarchy level:

```
system {
  host-name host-211;
  domain-name domain-122;
  backup-router 192.168.71.254;
  arp;
  authentication-order [ radius password tacplus ];
}
```

To delete the domain-name, host-name, and backup-router from the configuration, you cannot issue a single delete command:

```
user@host> delete system hostname host-211 domain-name domain-122 backup-router
192.168.71.254
```

You can only delete each statement individually:

```
user@host delete system host-name host-211
user@host delete system domain-name domain-122
user@host delete system backup-router 192.168.71.254
```

Related Documentation

- [Example: Deleting a Statement from the Junos OS Configuration on page 471](#)
- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)
- [Copying a Junos OS Statement in the Configuration on page 473](#)

Example: Deleting a Statement from the Junos OS Configuration

The following example shows how to delete the **ospf** statement, effectively unconfiguring OSPF on the router:

```
[edit]
```

```

user@host# set protocols ospf area 0.0.0.0 interface so-0/0/0 hello-interval 5
[edit]
user@host# show
protocols {
  ospf {
    area 0.0.0.0 {
      interface so-0/0/0 {
        hello-interval 5;
      }
    }
  }
}
[edit]
user@host# delete protocols ospf
[edit]
user@host# show
[edit]
user@host#

```

Delete all statements from the current level down:

```

[edit]
user@host# edit protocols ospf area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@host# set interface so-0/0/0 hello-interval 5
[edit protocols ospf area 0.0.0.0]
user@host# delete
Delete everything under this level? [yes, no] (no) yes
[edit protocols ospf area 0.0.0.0]
user@host# show
[edit]
user@host#

```

Unconfigure a particular property:

```

[edit]
user@host# set interfaces so-3/0/0 speed 100mb
[edit]
user@host# show
interfaces {
  so-3/0/0 {
    speed 100mb;
  }
}
[edit]
user@host# delete interfaces so-3/0/0 speed
[edit]
user@host# show
interfaces {
  so-3/0/0;
}

```

- [Example: Using Global Replace in a Junos OS Configuration—Using the upto Option on page 608](#)
- [Deleting a Statement from a Junos OS Configuration on page 470](#)

Copying a Junos OS Statement in the Configuration

When you have many similar statements in a Junos configuration, you can add one statement and then make copies of that statement. Copying a statement duplicates that statement and the entire hierarchy of statements configured under that statement. Copying statements is useful when you are configuring many physical or logical interfaces of the same type.

To make a copy of an existing statement in the configuration, use the configuration mode **copy** command:

```
user@host# copy existing-statement to new-statement
```

Immediately after you have copied a portion of the configuration, the configuration might not be valid. You must check the validity of the new configuration, and if necessary, modify either the copied portion or the original portion for the configuration to be valid.

Related Documentation

- [Example: Copying a Statement in the Junos Configuration on page 473](#)
- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)
- [Examples: Re-Using Configuration on page 476](#)

Example: Copying a Statement in the Junos Configuration

This example shows how you can create one virtual connection (VC) on an interface by copying an existing VC.

- [Requirements on page 473](#)
- [Overview on page 474](#)
- [Configuration on page 474](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you begin this example, configure the following initial configuration.

```
[edit interfaces]
user@host# show
at-1/0/0 {
  description "PAIX to MAE West"
  encapsulation atm-pvc;
  unit 61 {
    point-to-point;
    vci 0.61;
    family inet {
      address 10.0.1.1/24;
    }
  }
}
```

To quickly configure the *initial configuration* for this example, copy the following commands, paste it into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste this command into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces at-1/0/0 description "PAIX to MAE West"
set interfaces at-1/0/0 encapsulation atm-pvc
set interfaces at-1/0/0 unit 61 point-to-point
set interfaces at-1/0/0 unit 61 vci 0.61
set interfaces at-1/0/0 unit 61 family inet address 10.0.1.1/24
```

Overview

Copying statements is useful when you are configuring many physical or logical interfaces of the same type. You can add one statement and then make copies of that statement. Copying a statement duplicates that statement and the entire hierarchy of statements configured under that statement. In the case of this example, we are adding a virtual connection that is very similar to a virtual connection already configured.

Configuration

CLI Quick Configuration

Start at the **[edit interfaces at-1/0/0]** hierarchy level.

```
copy unit 61 to unit 62
set unit 62 vci 0.62
edit unit 62
replace pattern 10.0.1.1 with 10.0.2.1
```

Configuring by Copying

Step-by-Step Procedure

To configure by copying a configuration:

1. Go to the **[edit interfaces at-1/0/0]** hierarchy level and copy unit 61.

```
[edit interfaces at-1/0/0]
user@host# copy unit 61 to unit 62
```

2. Take a look at the new configuration and see what you need to change to make the configuration valid..

```
user@host# show interfaces at-1/0/0
description "PAIX to MAE West"
encapsulation atm-pvc;
unit 61 {
  point-to-point;
  vci 0.61;
  family inet {
    address 10.0.1.1/24;
  }
}
unit 62 {
  point-to-point;
  vci 0.61;
  family inet {
    address 10.0.1.1/24;
  }
}
```

```
}
```

3. Change the configuration to make it valid.

In this example you want to reconfigure the virtual circuit identifier (VCI) and virtual path identifier (VPI).

```
[edit interfaces at-1/0/0]
user@host# set unit 62 vci 0.62
```

You also want to replace the IP address of the new interface with its own IP address.

```
[edit interfaces at-1/0/0]
user@host# edit unit 62
user@host# replace pattern 10.0.1.1 with 10.0.2.1
```

Results

```
[edit]
show interfaces
at-1/0/0 {
  description "PAIX to MAE West"
  encapsulation atm-pvc;
  unit 61 {
    point-to-point;
    vci 0.61;
    family inet {
      address 10.0.1.1/24;
    }
  }
  unit 62 {
    point-to-point;
    vci 0.62;
    family inet {
      address 10.0.2.1/24;
    }
  }
}
```

Related Documentation • [Copying a Junos OS Statement in the Configuration on page 473](#)

Issuing Relative Junos OS Configuration Mode Commands

The **top** or **up** command followed by another configuration command, including **edit**, **insert**, **delete**, **deactivate**, **annotate**, or **show** enables you to quickly move to the top of the hierarchy or to a level above the area you are configuring.

To issue configuration mode commands from the top of the hierarchy, use the **top** command; then specify a configuration command. For example:

```
[edit interfaces fxp0 unit 0 family inet]
user@host# top edit system login
[edit system login]
user@host#
```

To issue configuration mode commands from a location higher up in the hierarchy, use the **up** configuration mode command; specify the number of levels you want to move up the hierarchy and then specify a configuration command. For example:

```
[edit protocols bgp]
user@host# up 2 activate system
```

Renaming an Identifier in a Junos OS Configuration

When modifying a Junos configuration, you can rename an identifier that is already in the configuration. You can do this either by deleting the identifier (using the **delete** command) and then adding the renamed identifier (using the **set** and **edit** commands), or you can rename the identifier using the **rename** configuration mode command:

```
user@host# rename <statement-path> identifier1 to identifier2
```

**Related
Documentation**

- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)
- [Examples: Re-Using Configuration on page 476](#)
- [Inserting a New Identifier in a Junos OS Configuration on page 481](#)

Examples: Re-Using Configuration

If you need to make changes to the configuration of a device, you can always remove the original configuration settings using the **delete** command and add your new configuration settings using the **set** command. There are, however, other ways of modifying a configuration that are more efficient and easier to use.

This example shows how to use the following configuration mode commands to update an existing configuration:

- **rename**—Rename an existing configuration setting, such as an interface name. This can be useful when you are adding new interfaces to a device.
 - **copy**—Copy a configuration setting and the entire hierarchy of statements configured under that setting. Copying configuration statements is useful when you are configuring many physical or logical interfaces of the same type.
 - **replace**—Make global changes to text patterns in the configuration. For example, if you consistently misspell a word common to the description statement for all of the interfaces on your device, you can fix this mistake with a single command.
- [Requirements on page 477](#)
 - [Overview on page 477](#)
 - [Configuration on page 477](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Overview

In the course of the first example in this topic, you will make the following configuration changes:

- Create a new interface with a description that contains a typing error.
- Copy the configuration from the interface that you created to create a new interface.
- Rename one of the interfaces that you created.
- Fix the typing error in the description for the interfaces that you created.

In the second, shorter example, you will experiment with some of the same commands under slightly different circumstances.

Configuration

CLI Quick Configuration

This example does not use commands that are suitable for this section.

Using the Copy, Rename, and Replace Commands to Modify a Loopback Interface Configuration

Step-by-Step Procedure

CAUTION: If your configuration uses any of the loopback interface unit numbers used in this example, you must substitute different loopback interface unit numbers that you are not using in your device's configuration in the following steps to avoid adversely impacting the operational status of your device.

To create and modify a configuration of a loopback interface using the **copy**, **rename**, and **replace** commands:

1. Create a new loopback interface unit number and include a description.
The mistakes in the spelling of *loopback* in the description are intentional.
[edit]
user@host# **set interfaces lo0 unit 100 description "this is a lopbck interface"**
2. Display the configuration for the loopback interface you have just added.
[edit]
user@host# **show interfaces lo0 unit 100 description "this is a lopbck interface";**
3. Duplicate the loopback interface you have just created, warts and all, from unit 100 to unit 101.

```
[edit]
user@host# copy interfaces lo0 unit 100 to unit 101
```

4. Display the configurations for loopback interfaces lo0 unit 100 and lo0 unit 101.

```
[edit]
user@host# show interfaces lo0 unit 100
description "this is a lopbck interface";
[edit]
user@host# show interfaces lo0 unit 101
description "this is a lopbck interface";
```

The **copy** command duplicates an interface including any child statements such as **description**.

5. Rename the loopback interface lo0 unit 100 to loopback interface lo0 unit 102.

```
[edit]
user@host# rename interfaces lo0 unit 100 to unit 102
```

6. Display the configuration for loopback interface lo0 unit 100.

```
[edit]
user@host# show interfaces lo0 unit 100
[edit]
user@host#
```

You should not see any results from this command. The loopback interface lo0 unit 100 is now gone. The **rename** command replaces the configuration statement indicated with the new configuration.

7. Fix the misspelling of the word *loopback* in the descriptions for loopback interfaces lo0 unit 101 and lo0 unit 102.

```
[edit]
user@host# replace pattern lopbck with loopback
```

8. Display the configuration for loopback interfaces lo0 unit 101 and lo0 102 to verify that the word *loopback* is spelled correctly now.

```
[edit]
user@host# show interfaces lo0 unit 101
description "this is a loopback interface";
[edit]
user@host# show interfaces lo0 unit 102
description "this is a loopback interface";
```

The **replace** command replaces all instances of the pattern specified in the command, unless limited in some way. The next example in this topic shows one way to limit the effect of the **replace** command.

9. From configuration mode, use the **rollback** command to put the device's configuration back to the state it was in before you executed the previous steps.

```
[edit]
user@host# rollback
```

Results From configuration mode, use the **show interfaces lo0 unit 101** and **show interfaces lo0 unit 102** commands to ensure that the device's configuration is back to the state it was in before you executed the steps in this example.

```
[edit]
user@host: show interfaces lo0 unit 101
[edit]
user@host#
```

You should not see any results from this command.

```
[edit]
user@host# show interfaces lo0 unit 102
[edit]
user@host#
```

You should not see any results from this command.

Compare the Copy Command at the Top-Level Configuration Hierarchy Level

Step-by-Step Procedure The previous example shows the **copy**, **rename**, and **replace** commands at the **[edit interfaces interface-name unit logical-interface-number]** hierarchy level. This example shows how some of these commands work at the top level of the CLI configuration mode hierarchy.

The following example requires you to navigate to various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

1. Create an Ethernet interface.

```
[edit]
user@host# set interfaces et-2/0/0 unit 0 family inet address 192.0.2.2
```

2. Copy the interface you just created to another interface.

```
[edit]
user@host# copy interfaces et-2/0/0 to et-2/1/0
```

Compare this **copy** command to the one in Step 3 in the first example, where the **copy** command takes the keyword **unit** before the value to be copied. Notice that the keyword **interfaces** is not repeated after the preposition **to** and before the value to be copied. This happens in some top-level statements with the **copy** command.

TIP: Similarly, in the **rename** command, you do not repeat the keyword part of the statement before the new identifier in some top-level statements.

3. Show your configuration so far.

```
[edit]
user@host# show interfaces
et-2/0/0 {
  unit 0 {
```

```
        family inet {
            address 192.0.2.2/32;
        }
    }
}
et-2/1/0 {
    unit 0 {
        family inet {
            address 192.0.2.2/32;
        }
    }
}
```

4. Replace the address for et-2/1/0 with another IP address.

```
[edit interfaces et-2/1/0 unit 0 family inet]
user@host# replace pattern 192.0.2.2 with 192.0.2.40
```

Notice that if you want to change only a specific occurrence of a pattern instead of all of them (as you did in Step 7 in the first example), you need to drill down to that specific hierarchy level before using the **replace** command.

5. Show your interfaces again.

```
[edit]
user@host# show interfaces
et-2/0/0 {
    unit 0 {
        family inet {
            address 192.0.2.2/32;
        }
    }
}
et-2/1/0 {
    unit 0 {
        family inet {
            address 192.0.2.40/32;
        }
    }
}
```

6. From configuration mode, use the **rollback** command to put the device's configuration back to the state it was in before you executed the previous steps.

```
[edit]
user@host# rollback
```

Results From configuration mode, use the **show interfaces et-2/0/0** and **show interfaces et-2/1/0** commands to ensure that the device's configuration is back to the state it was in before you executed the steps in this example.

```
[edit]
user@host# show interfaces et-2/0/0
[edit]
user@host#
```

You should not see any results from this command.

```
[edit]
user@R1# show interfaces et-2/1/0
[edit]
user@host#
```

You should not see any results from this command.

Inserting a New Identifier in a Junos OS Configuration

When configuring a device running Junos OS, you can enter most statements and identifiers in any order. Regardless of the order in which you enter the configuration statements, the CLI always displays the configuration in a strict order. However, there are a few cases where the ordering of the statements matters because the configuration statements create a sequence that is analyzed in order.

For example, in a routing policy or firewall filter, you define terms that are analyzed sequentially. Also, when you create a named path in dynamic MPLS, you define an ordered list of the transit routers in the path, starting with the first transit router and ending with the last one.

To modify a portion of the configuration in which the statement order matters, use the **insert** configuration mode command:

```
user@host# insert <statement-path> identifier1 (before | after) identifier2
```

If you do not use the **insert** command, but instead simply configure the identifier, it is placed at the end of the list of similar identifiers.

Related Documentation

- [Renaming an Identifier in a Junos OS Configuration on page 476](#)
- [Examples: Re-Using Configuration on page 476](#)
- [Example: Inserting a New Identifier in a Junos Configuration on page 481](#)
- [Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration on page 489](#)

Example: Inserting a New Identifier in a Junos Configuration

This example shows the use of the **insert** command.

Whereas a term added using the **set** command is placed at the end of the existing list of terms, you use the **insert** command to add a term in the order you specify. Specifying the order of statement is important in the cases in which the order of the statements matters because the configuration statements create a sequence that is analyzed in order.

Also notice, as shown in this example, that you must create the term before you can place it using the **insert** command.

- [Requirements on page 482](#)
- [Overview on page 483](#)
- [Configuration on page 483](#)

Requirements

Before you can insert a term, you must configure an initial policy. To quickly configure the initial policy for this example, copy the following commands, paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit policy-options]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-statement statics term term1 from route-filter 192.168.0.0/16 orlonger
set policy-statement statics term term1 from route-filter 224.0.0.0/3 orlonger
set policy-statement statics term term1 then reject
set policy-statement statics term term2 from protocol direct
set policy-statement statics term term2 then reject
set policy-statement statics term term3 from protocol static
set policy-statement statics term term3 then reject
set policy-statement statics term term4 then accept
```

Now check that you have the hierarchy correctly configured.

```
[edit policy-options]
user@host# show
policy-statement statics {
  term term1 {
    from {
      route-filter 192.168.0.0/16 orlonger;
      route-filter 224.0.0.0/3 orlonger;
    }
    then reject;
  }
  term term2 {
    from protocol direct;
    then reject;
  }
  term term3 {
    from protocol static;
    then reject;
  }
  term term4 {
    then accept;
  }
}
```

Overview

When configuring a device running Junos OS, you can enter most statements and identifiers in any order. However, there are a few cases, such as in routing policies or firewall filters, in which the order of the statements matters because the configuration statements create a sequence that is analyzed in order.

To modify a portion of the configuration in which the statement order matters, you must use the **insert** configuration mode command. If you use the **set** command instead, the added statement or identifier will be in the wrong place sequentially. The only other way to get the terms of the command in the correct order is to dismantle the configuration and start over.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit policy-options] hierarchy level, and then enter commit from configuration mode.

```
[edit]
user@host# rename policy-options policy-statement statics term term4 to term term6
[edit]
user@host# set policy-options policy-statement statics term term4 from protocol local
[edit]
user@host# set policy-options policy-statement statics term term4 then reject
[edit]
user@host# set policy-options policy-statement statics term term5 from protocol
aggregate
[edit]
user@host# set policy-options policy-statement statics term term5 then reject
[edit]
user@host# insert policy-options policy-statement statics term term4 after term term3
[edit]
user@host# insert policy-options policy-statement statics term term5 after term term4
```

Configuring to Insert Terms

Step-by-Step Procedure

1. Determine in what order the terms in your configuration need to go—the original terms and the new terms you plan to add.

In the original configuration, the policy is named **statics** and there are four terms. Each of the first three terms matches on a different match criteria and the resulting matches are rejected. The last term accepts all the rest of the traffic.

In this example, you need to add two terms that weed out additional types of traffic. Both of these terms need to go before the last term in the original configuration.

2. Rename original term4 to term6.

```
[edit]
user@host# rename policy-options policy-statement statics term term4 to term
term6
```

This step preserves the original last term, now renamed term6, as the last term.

3. Create a new term4.

```
[edit]
user@host# set policy-options policy-statement statics term term4 from protocol
local
user@host# set policy-options policy-statement statics term term4 then reject
```

A new term is added that matches traffic from local system addresses and rejects it.

4. Create new term5.

```
[edit]
user@host# set policy-options policy-statement statics term term5 from protocol
aggregate
user@host# set policy-options policy-statement statics term term5 then reject
```

A new term is added that matches traffic from aggregate routes and rejects it.

5. Insert term4 after term3.

```
[edit]
user@host# insert policy-options policy-statement statics term term4 after term
term3
```

6. Insert term5 after term4.

```
[edit]
user@host# insert policy-options policy-statement statics term term5 after term
term4
```

Results

```
[edit]
user@host# show policy-options policy-statement statics
term term1 {
  from {
    route-filter 192.168.0.0/16 orlonger;
    route-filter 224.0.0.0/3 orlonger;
  }
  then reject;
}
term term2 {
  from protocol direct;
  then reject;
}
term term3 {
  from protocol static;
  then accept;
}
term term4 {
  from protocol local;
  then reject;
}
term term5 {
  from protocol aggregate;
  then reject;
}
```

```
term term6 {
  then accept;
}
```

Related Documentation

- [Inserting a New Identifier in a Junos OS Configuration on page 481](#)
- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)

Example: Using the Wildcard Command with the Range Option

- [Requirements on page 485](#)
- [Overview on page 485](#)
- [Configuration on page 486](#)
- [Verification on page 488](#)

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, T Series or EX Series device
- Junos OS Release 12.1 or later running on the device

Overview

The **range** option with the **wildcard** command enables you to specify ranges in **activate**, **deactivate**, **delete**, **protect**, **set**, **show**, and **unprotect** commands. You can use ranges to specify a range of interfaces, logical units, VLANs, and other numbered elements. The **wildcard range** option expands the command you entered into multiple commands, each of which corresponds to one item in the range.

The **wildcard range** option enables you to configure multiple configuration statements using a single **set** command, instead of configuring each of them individually. For example, to configure 24 Gigabit Ethernet interfaces with different port numbers, you can use a single **wildcard range set** command instead of 24 individual **set interfaces** commands.

Similarly, to deactivate a group of 30 logical interfaces, you can use the **wildcard range deactivate** command instead of deactivating each logical interface individually.

You can use **wildcard range** with the **active**, **deactivate**, **delete**, **protect**, **set**, **show**, and **unprotect** configuration commands:

```
user@host# wildcard range ?
```

Possible completions:

activate	Remove the inactive tag from a statement
deactivate	Add the inactive tag to a statement
delete	Delete a data element
protect	Protect the statement
set	Set a parameter
show	Show a parameter
unprotect	Unprotect the statement

You can also specify all configuration hierarchy levels and their child configuration statements in the CLI by using **wildcard range** with the **set** option:

Possible completions:

```
> > access           Network access configuration
> > access-profile    Access profile for this instance
> > accounting-options Accounting data configuration
> > applications      Define applications by protocol characteristics
...
```

Configuration

The following examples show how to configure multiple configuration statements in a single step by using the **range** option with the **wildcard** configuration command:

- [Using the Range Option for Configuring a Series of Named Identifiers for a Configuration Statement on page 486](#)
- [Specifying Multiple Ranges in the Syntax on page 486](#)
- [Specifying a Range and Unique Numbers In the Syntax on page 487](#)
- [Excluding Some Values from a Range on page 487](#)
- [Specifying a Range with a Step Number on page 488](#)

Using the Range Option for Configuring a Series of Named Identifiers for a Configuration Statement

Step-by-Step Procedure

You can configure a series of identifiers for a configuration statement, by specifying a numerical range of values for the identifiers.

- To configure a series of the same type of interface with different port numbers (0 through 23), specify the range for the port numbers by using the following format:

```
[edit]
user@host# wildcard range set interfaces ge-0/0/[0-23] unit 0 family vpls
```

Results Expands to 24 different **set** commands to configure interfaces with port numbers ranging from 0 through 23:

```
[edit]
user@host# set interfaces ge-0/0/0 unit 0 family vpls
user@host# set interfaces ge-0/0/1 unit 0 family vpls
user@host# set interfaces ge-0/0/2 unit 0 family vpls
...
user@host# set interfaces ge-0/0/23 unit 0 family vpls
```

Specifying Multiple Ranges in the Syntax

Step-by-Step Procedure

You can have multiple ranges specified in a **wildcard range** command. Each range must be separated by a comma. You can also have overlapping ranges.

- To specify more than one range in the syntax, include the minimum and maximum values for each range, separated by a comma.

```
[edit]
```

```
user@host# wildcard range protect event-options policy p[1-3,5-7,6-9]
```

Results Expands to the following **set** commands:

```
[edit]
user@host# set protect event-options policy p1
user@host# set protect event-options policy p2
user@host# set protect event-options policy p3
user@host# set protect event-options policy p5
user@host# set protect event-options policy p6
user@host# set protect event-options policy p7
user@host# set protect event-options policy p8
user@host# set protect event-options policy p9
```

Specifying a Range and Unique Numbers In the Syntax

Step-by-Step Procedure You can also specify a combination of a range and unique numbers in the syntax of the **wildcard range** command.

- To specify a range and unique numbers, separate them with a comma.

```
[edit]
user@host# wildcard range protect event-options policy p[1-3,5,7,10]
```

Results Expands to the following **set** commands:

```
[edit]
user@host# set protect event-options policy p1
user@host# set protect event-options policy p2
user@host# set protect event-options policy p3
user@host# set protect event-options policy p5
user@host# set protect event-options policy p7
user@host# set protect event-options policy p10
```

Excluding Some Values from a Range

Step-by-Step Procedure You can exclude certain values from a range by marking the numbers or the range of numbers to be excluded by using an exclamation mark.

- To exclude certain values from a range, include the portion to be excluded with **!** in the syntax.

```
[edit]
user@host# wildcard range protect event-options policy p[1-5,!3-4]
```

Results Expands to the following **set** commands:

```
[edit]
user@host# set protect event-options policy p1
user@host# set protect event-options policy p2
user@host# set protect event-options policy p5
```

Specifying a Range with a Step Number

- Step-by-Step Procedure** You can provide a step number for a range to have a constant interval in the range.
- To provide a step, include the step value in the syntax preceded by a forward slash (/).
- ```
[edit]
user@host# wildcard range protect event-options policy p[1-10/2]
```

**Results** Expands to the following **set** commands:

```
[edit]
user@host# set protect event-options policy p1
user@host# set protect event-options policy p3
user@host# set protect event-options policy p5
user@host# set protect event-options policy p7
user@host# set protect event-options policy p9
```

### Verification

Confirm that the configuration is working properly.

- [Checking the Configuration on page 488](#)

### Checking the Configuration

---

**Purpose** Check the configuration created using the **wildcard range** option. The following sample shows output for the configuration described in “[Using the Range Option for Configuring a Series of Named Identifiers for a Configuration Statement](#)” on page 486.

**Action** user@host> show configuration interfaces

```

ge-0/0/0 {
 unit 0 {
 family vpls;
 }
}
ge-0/0/1 {
 unit 0 {
 family vpls;
 }
}
ge-0/0/2 {
 unit 0 {
 family vpls;
 }
}
ge-0/0/3 {
 unit 0 {
 family vpls;
 }
}
...
ge-0/0/23 {
 unit 0 {
 family vpls;
 }
}

```

**Meaning** The output indicates that 24 Gigabit Ethernet interfaces ranging from **ge-0/0/0** through **ge-0/0/23** are created.

**Related Documentation** • [Using Wildcard Characters in Interface Names on page 601](#)

## Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration

In a Junos configuration, you can deactivate statements and identifiers so that they do not take effect when you issue the **commit** command. Any deactivated statements and identifiers are marked with the **inactive** tag. They remain in the configuration, but are not activated when you issue a **commit** command.

To deactivate a statement or identifier, use the **deactivate** configuration mode command:

```
user@host# deactivate(statement | identifier)
```

To reactivate a statement or identifier, use the **activate** configuration mode command:

```
user@host# activate (statement | identifier)
```

In both commands, the **statement** and **identifier** you specify must be at the current hierarchy level. When you deactivate a statement, that specific statement is completely ignored and is not applied at all when you issue a **commit** command.

To disable a statement, use the **disable** configuration mode command:

In some portions of the configuration hierarchy, you can include a **disable** statement to disable functionality. One example is disabling an interface by including the **disable** statement at the **[edit interface *interface-name*]** hierarchy level. When you disable a functionality, it is activated when you issue a **commit** command but is treated as though it is down or administratively disabled.

**Related  
Documentation**

- [Example: Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration on page 490](#)
- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)

---

## Example: Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration

---

This example shows a common use case in which the **deactivate** and **activate** configuration mode commands are used. It involves dual Routing Engines, master and backup, that have graceful Routing Engine switchover (GRES) configured. The software on both Routing Engines needs to be upgraded. This can easily be accomplished by deactivating GRES, updating the Routing Engines, and then reactivating GRES.

**NOTE:** You can also perform a similar upgrade using the same setup except that nonstop active routing (NSR) is configured instead of GRES. You would need to deactivate NSR and then upgrade the Routing Engines before reactivating NSR.

- 
- [Requirements on page 490](#)
  - [Overview on page 490](#)
  - [Configuration on page 491](#)

### Requirements

This example requires the use of a router with dual Routing Engines that can be upgraded.

Before you begin this example, make sure that you have GRES configured.

### Overview

In this example, there are two Routing Engines. GRES is configured, and the Routing Engines need to be upgraded. To accomplish the upgrading, you need to deactivate the GRES feature, upgrade each of the Routing Engines, and then activate GRES again.

## Configuration

### Configuring the Deactivation and Reactivation of GRES

#### Step-by-Step Procedure

To deactivate and reactivate GRES for Routing Engine upgrade:

1. Show that GRES is enabled for the router.

```
[edit]
user@host# show chassis
redundancy {
 graceful-switchover;
}
fpc 2 {
 pic 0 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}
```

2. Deactivate GRES.

```
[edit]
user@host# deactivate chassis redundancy graceful-switchover
user@host# commit
```

3. Show that GRES is deactivated.

```
[edit]
user@host# show chassis
redundancy {
 inactive: graceful-switchover;
}
fpc 2 {
 pic 0 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}
```

4. Upgrade the Routing Engines one by one.

For instructions on upgrading Junos OS on dual Routing Engines, see tasks 2 and 3 in [“Installing the Software Package on a Router with Redundant Routing Engines” on page 58](#).

5. Reactivate GRES.

```
[edit]
user@host# activate chassis redundancy graceful-switchover
user@host# commit
```

**Results** Verify that GRES feature is activated again.

```
[edit]
user@host# show chassis
```

```
redundancy {
 graceful-switchover;
}
fpc 2 {
 pic 0 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}
```

---

## Adding Comments in a Junos OS Configuration

You can include comments in a Junos configuration to describe any statement in the configuration. You can add comments interactively in the CLI and by editing the ASCII configuration file.

When configuring interfaces, you can add comments about the interface by including the **description** statement at the **[edit interfaces *interface-name*]** hierarchy level. Any comments you include appear in the output of the **show interfaces** commands. For more information about the **description** statement, see the *Junos OS Network Interfaces Library for Routing Devices*.

- [Adding Comments in the CLI on page 492](#)
- [Adding Comments in a File on page 493](#)

### Adding Comments in the CLI

When you add comments in configuration mode, they are associated with a statement at the current level. Each statement can have one single-line comment associated with it. Before you can associate a comment with a statement, the statement must exist. The comment is placed on the line preceding the statement.

To add comments to a configuration, use the **annotate** configuration mode command:

```
user@host# annotate statement "comment-string"
```

***statement*** is the configuration statement to which you are attaching the comment; it must be at the current hierarchy level. If a comment for the specified ***statement*** already exists, it is deleted and replaced with the new comment.

***comment-string*** is the text of the comment. The comment text can be any length, and you must type it on a single line. If the comment contains spaces, you must enclose it in quotation marks. In the comment string, you can include the comment delimiters ***/\* \*/*** or ***#***. If you do not specify any, the comment string is enclosed with the ***/\* \*/*** comment delimiters.

To delete an existing comment, specify an empty comment string:

```
user@host# annotate statement ""
```

If you add comments with the **annotate** command, you can view the comments within the configuration by entering the **show** configuration mode command or the **show configuration** operational mode command.

**NOTE:** The Junos OS supports annotation up to the last level in the configuration hierarchy, including oneliners. However, annotation of parts (the child statements or identifiers within the oneliner) of the oneliner is not supported. For example, in the following sample configuration hierarchy, annotation is supported up to the level 1 parent hierarchy, but not supported for the metric child statement:

```
[edit protocols]
 isis {
 interface ge-0/0/0.0 {
 level 1 metric 10;
 }
 }
}
```

## Adding Comments in a File

When you edit the ASCII configuration file and add comments, they can be one or more lines and must precede the statement they are associated with. If you place the comments in other places in the file, such as on the same line following a statement or on a separate line following a statement, they are removed when you use the **load** command to open the configuration into the CLI.

The following excerpt from a configuration example illustrates how to place and how not to place comments in a configuration file:

```
/* This comment goes with routing-options */
routing-options {
 /* This comment goes with routing-options traceoptions */
 traceoptions {
 /* This comment goes with routing-options traceoptions tracefile */
 tracefile rpd size 1m files 10;
 /* This comment goes with routing-options traceoptions traceflag task */
 traceflag task;
 /* This comment goes with routing-options traceoptions traceflag general */
 traceflag general;
 }
 autonomous-system 10458; /* This comment is dropped */
}
routing-options {
 rib-groups {
 ifrg {
 import-rib [inet.0 inet.2];
 /* A comment here is dropped */
 }
 dvmrp-rib {
 import-rib inet.2;
 export-rib inet.2;
 }
 }
}
```

```
 /* A comment here is dropped */
 }
 /* A comment here is dropped */
}
/* A comment here is dropped */
}
```

When you include comments in the configuration file directly, you can format comments in the following ways:

- Start the comment with a `/*` and end it with a `*/`. The comment text can be on a single line or can span multiple lines.
- Start the comment with a `#` and end it with a new line (carriage return).

**Related  
Documentation**

- [Adding Junos OS Configuration Statements and Identifiers on page 469](#)
- [Example: Including Comments in a Junos OS Configuration by Using the CLI on page 494](#)

---

## Example: Including Comments in a Junos OS Configuration by Using the CLI

---

Adding comments to a Junos OS configuration makes the configuration file readable and more readily understood by users. Using the Junos OS CLI, you can include comments as you configure by using the **annotate** statement. In this example, comments are added by using the CLI for an already existing configuration:

- [Requirements on page 494](#)
- [Overview on page 495](#)
- [Configuration on page 495](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you add a comment, you must configure the following hierarchy on the router.

To quickly configure the *initial configuration* for this example, copy the following command, paste it into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste this command into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols ospf area 0.0.0.0 interface so-0/0/0.0 hello-interval 5
```

Now, check that you have this hierarchy configured.

```
user@host# show protocols
ospf {
 area 0.0.0.0 {
 interface so-0/0/0 {
 hello-interval 5;
 }
 }
}
```

```
}
```

## Overview

When you add comments by using the CLI, you do so in configuration mode using the **annotate** statement. Each comment you add is associated with a statement at the current level. Each statement can have one single-line comment associated with it.

To configure the **annotate** statement, move to the level of the statement with which you want to associate a comment. To view the comments, go to the top of the configuration hierarchy and use the **show** command.

## Configuration

### CLI Quick Configuration

To quickly configure the *comments* for this example, copy the following commands, paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste the commands into the CLI, starting at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
edit protocols ospf
annotate area 0.0.0.0 "Backbone area configuration added June 15, 1998"
edit area 0.0.0.0
annotate interface so-0/0/0.0 "Interface from router sj1 to router sj2"
```

Notice that the commands are moving you down the hierarchy as you annotate different sections of the hierarchy.

### Including Comments in the CLI Configuration Mode

### Step-by-Step Procedure

This procedure assumes that you have already configured the initial configuration.

To add comments to a configuration:

1. Move to the first hierarchy level to which you need to add a comment.  

```
[edit]
user@host# edit protocols ospf
```
2. Add a comment to the **area** configuration statement by using the **annotate** statement.  

```
[edit protocols ospf]
user@host# annotate area 0.0.0.0 "Backbone area configuration added June 15, 1998"
```
3. Move down a level to the **interface** configuration statement.  

```
[edit protocols ospf]
user@host# edit area 0.0.0.0
```
4. Add a comment to interface so-0/0/0.0 by using the **annotate** statement.  

```
[edit protocols ospf area 0.0.0.0]
user@host# annotate interface so-0/0/0.0 "Interface from router sj1 to router sj2"
```

## Results

---

Move to the top of the hierarchy and use the **show** command to see the comments you added. The comments precede the statement they are associated with.

```
[edit]
user@host# show protocols
ospf {
 /* Backbone area configuration added June 15, 1998 */
 area 0.0.0.0 {
 /* Interface from router sj1 to router sj2 */
 interface so-0/0/0.0 {
 hello-interval 5;
 }
 }
}
```

After you have confirmed that the configuration is correct, enter the **commit** command.

**Related Documentation** • [Adding Comments in a Junos OS Configuration on page 492](#)

## Updating the configure private Configuration

---

When you are in configure private mode, you must work with a copy of the most recently committed shared configuration. If the global configuration changes, you can issue the **update** command to update your private candidate configuration. When you do this, your private candidate configuration contains a copy of the most recently committed configuration with your private changes merged in. For example:

```
[edit]
user@host# update
[edit]
user@host#
```

**NOTE:** Merge conflicts can occur when you issue the **update** command.

You can also issue the **rollback** command to discard your private candidate configuration changes and obtain the most recently committed configuration:

```
[edit]
user@host# rollback
[edit]
user@host#
```

**Related Documentation** • [Forms of the configure Command on page 465](#)

## Displaying the Current Junos OS Configuration

To display the current configuration for a device running Junos OS, use the **show** configuration mode command. This command displays the configuration at the current hierarchy level or at the specified level.

```
user@host# show <statement-path>
```

The configuration statements appear in a fixed order, interfaces appear alphabetically by type, and then in numerical order by slot number, PIC number, and port number. Note that when you configure the router, you can enter statements in any order.

You also can use the CLI operational mode **show configuration** command to display the last committed current configuration, which is the configuration currently running on the router:

```
user@host> show configuration
```

When you show a configuration, a timestamp at the top of the configuration indicates when the configuration was last changed:

```
Last commit: 2006-07-18 11:21:58 PDT by echen
version 8.3
```

If you have omitted a required statement at a particular hierarchy level, when you issue the **show** command in configuration mode, a message indicates which statement is missing. As long as a mandatory statement is missing, the CLI continues to display this message each time you issue a **show** command. For example:

```
[edit]
user@host# show
protocols {
 pim {
 interface so-0/0/0 {
 priority 4;
 version 2;
 # Warning: missing mandatory statement(s): 'mode'
 }
 }
}
```

When you issue the **show configuration** command with the **| display set** pipe option to view the configuration as **set** commands, those portions of the configuration that you do not have permissions to view are substituted with the text **ACCESS-DENIED**.

Unsupported statements included in the CLI configuration are displayed with the “unsupported” text in the configuration. For example, if a statement is configured on an unsupported platform, the CLI displays a message that the statement is ignored in the configuration because it is configured on an unsupported platform. When you issue the **show** command with the **| display xml** option, you can see the **unsupported="unsupported"** attribute for configuration that is unsupported.

The “unsupported” attribute included in text configuration or XML configuration is provided to scripts when the **unsupported="unsupported"** attribute is included in the **<get-configuration>** RPC call.

**Related  
Documentation**

- [Example: Displaying the Current Junos OS Configuration on page 498](#)
- [Displaying set Commands from the Junos OS Configuration on page 501](#)

---

## Example: Displaying the Current Junos OS Configuration

The following example shows how you can display the current Junos configuration.

**Set a** configuration:

```
[edit]
user@host# set protocols ospf area 0.0.0.0 interface so-0/0/0 hello-interval 5
```

**To display the current configuration:**

```
[edit]
user@host# show
protocols {
 ospf {
 area 0.0.0.0 {
 interface so-0/0/0 {
 hello-interval 5;
 }
 }
 }
}
```

Display a particular hierarchy in the configuration:

```
[edit]
user@host# show protocols ospf area 0.0.0.0
interface so-0/0/0 {
 hello-interval 5;
}
```

Move down a level and display the configuration at that level:

```
[edit]
user@host# edit protocols ospf area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@host# show
interface so-0/0/0 {
 hello-interval 5;
}
```

**Set and commit a configuration:**

```
[edit]
user@host# set protocols ospf area 0.0.0.0 interface so-0/0/0 hello-interval 5
[edit]
user@host# commit
commit complete
```

```
[edit]
user@host# quit
exiting configuration mode
```

Display the last committed configuration:

```
user@host> show configuration
Last commit: 2006-08-10 11:21:58 PDT by user
version 8.3
protocols {
 ospf {
 area 0.0.0.0 {
 interface so-0/0/0 {
 hello-interval 5;
 }
 }
 }
}
```

**Related Documentation**

## Displaying Additional Information About the Junos OS Configuration

In configuration mode only, to display additional information about the configuration, use the **display detail** command after the pipe ( | ) in conjunction with a **show** command. The additional information includes the help string that explains each configuration statement and the permission bits required to add and modify the configuration statement.

```
user@host# show <hierarchy-level> | display detail
```

For example:

```
[edit]
user@host# show | display detail
##
version: Software version information
require: system
##
version "3.4R1 [tlim]";
system {
 ##
 ## host-name: Host name for this router
 ## match: ^[:alnum:]._-]+$
 ## require: system
 ##
}
host-name router-name;
##
domain-name: Domain name for this router
match: ^[:alnum:]._-]+$
require: system
##
domain-name isp.net;
##
```

```
backup-router: Address of router to use while booting
##

- [Displaying set Commands from the Junos OS Configuration on page 501](#)

## Displaying set Commands from the Junos OS Configuration

In configuration mode, you can display the configuration as a series of configuration mode commands required to re-create the configuration. This is useful if you are not familiar

with how to use configuration mode commands or if you want to cut, paste, and edit the displayed configuration.

To display the configuration as a series of configuration mode commands, which are required to re-create the configuration from the top level of the hierarchy as **set** commands, issue the **show** configuration mode command with the **display set** option:

```
user@host# show | display set
```

This topic contains the following examples:

- [Example: Displaying set Commands from the Configuration on page 502](#)
- [Example: Displaying Required set Commands at the Current Hierarchy Level on page 502](#)
- [Example: Displaying set Commands with the match Option on page 503](#)

### Example: Displaying set Commands from the Configuration

Display the **set** commands from the configuration at the **[edit interfaces]** hierarchy level:

```
[edit interfaces fe-0/0/0]
user@host# show
unit 0 {
 family inet {
 address 192.107.1.230/24;
 }
 family iso;
 family mpls;
}
inactive: unit 1 {
 family inet {
 address 10.0.0.1/8;
 }
}
user@host# show | display set
set interfaces fe-0/0/0 unit 0 family inet address 192.107.1.230/24
set interfaces fe-0/0/0 unit 0 family iso
set interfaces fe-0/0/0 unit 0 family mpls
set interfaces fe-0/0/0 unit 1 family inet address 10.0.0.1/8
deactivate interfaces fe-0/0/0 unit 1
```

To display the configuration as a series of configuration mode commands required to re-create the configuration from the current hierarchy level, issue the **show** configuration mode command with the **display set relative** option:

```
user@host# show | display set relative
```

### Example: Displaying Required set Commands at the Current Hierarchy Level

Display the configuration as a series of configuration mode commands required to re-create the configuration from the current hierarchy level:

```
[edit interfaces fe-0/0/0]
user@host# show
unit 0 {
 family inet {
```

```

 address 192.107.1.230/24;
 }
 family iso;
 family mpls;
}
inactive: unit 1 {
 family inet {
 address 10.0.0.1/8;
 }
}
user@host# show | display set relative
set unit 0 family inet address 192.107.1.230/24
set unit 0 family iso
set unit 0 family mpls
set unit 1 family inet address 10.0.0.1/8
deactivate unit 1

```

To display the configuration as **set** commands and search for text matching a regular expression by filtering output, specify the **match** option after the pipe ( | ):

```
user@host# show | display set | match regular-expression
```

### Example: Displaying set Commands with the match Option

Display IP addresses associated with an interface:

```

xe-2/3/0 {
 unit 0 {
 family inet {
 address 192.107.9.106/30;
 }
 }
}
so-5/1/0 {
 unit 0 {
 family inet {
 address 192.107.9.15/32 {
 destination 192.107.9.192;
 }
 }
 }
}
lo0 {
 unit 0 {
 family inet {
 address 127.0.0.1/32;
 }
 }
}
user@host# show interfaces | display set | match address
set interfaces xe-2/3/0 unit 0 family inet address 192.168.9.106/30
set interfaces so-5/1/0 unit 0 family inet address 192.168.9.15/32 destination 192.168.9.192
set interfaces lo0 unit 0 family inet address 127.0.0.1/32

```

**Related Documentation**

- [Displaying the Current Junos OS Configuration on page 497](#)

## Displaying Users Currently Editing the Junos OS Configuration

---

To display the users currently editing the configuration, use the **status** configuration mode command:

```
user@host# status
Users currently editing the configuration:
rchen terminal p0 (pid 55691) on since 2006-03-01 13:17:25 PST
[edit interfaces]
```

The system displays who is editing the configuration (**rchen**), where the user is logged in (**terminal p0**), the date and time the user logged in (**2006-03-01 13:17:25 PST**), and what level of the hierarchy the user is editing (**[edit interfaces]**).

If you issue the **status** configuration mode command and a user has scheduled a candidate configuration to become active for a future time, the system displays who scheduled the commit (**root**), where the user is logged in (**terminal d0**), the date and time the user logged in (**2002-10-31 14:55:15 PST**), and that a commit is pending (**commit at**).

```
[edit]
user@host# status
Users currently editing the configuration:
root terminal d0 (pid 767) on since 2002-10-31 14:55:15 PST, idle 00:03:09
commit at
```

For information about how to schedule a commit, see [“Scheduling a Junos OS Commit Operation” on page 513](#).

If you issue the **status** configuration mode command and a user is editing the configuration in configure exclusive mode, the system displays who is editing the configuration (**root**), where the user is logged in (**terminal d0**), the date and time the user logged in (**2002-11-01 13:05:11 PST**), and that a user is editing the configuration in configure exclusive mode (**exclusive [edit]**).

```
[edit]
user@host# status
Users currently editing the configuration:
root terminal d0 (pid 2088) on since 2002-11-01 13:05:11 PST
exclusive [edit]
```

## Verifying a Junos OS Configuration

---

To verify that the syntax of a Junos configuration is correct, use the configuration mode **commit check** command:

```
[edit]
user@host# commit check
configuration check succeeds
[edit]
```

user@host#

If the **commit check** command finds an error, a message indicates the location of the error.

## Junos OS Commit Model for Router or Switch Configuration

---

The router or switch configuration is saved using a commit model—a candidate configuration is modified as desired and then committed to the system. When a configuration is committed, the router or switch checks the configuration for syntax errors, and if no errors are found, the configuration is saved as **juniper.conf.gz** and activated. The formerly active configuration file is saved as the first rollback configuration file (**juniper.conf.1.gz**), and any other rollback configuration files are incremented by 1. For example, **juniper.conf.1.gz** is incremented to **juniper.conf.2.gz**, making it the second rollback configuration file. The router or switch can have a maximum of 49 rollback configurations (numbered 1 through 49) saved on the system.

On the router or switch, the active configuration file and the first three rollback files (**juniper.conf.gz.1**, **juniper.conf.gz.2**, **juniper.conf.gz.3**) are located in the **/config** directory. If the file **rescue.conf.gz** is saved on the system, this file should also be saved in the **/config** directory. The factory default files are located in the **/etc/config** directory.

There are two mechanisms used to propagate the configurations between Routing Engines within a router or switch:

- **Synchronization**—Propagates a configuration from one Routing Engine to a second Routing Engine within the same router or switch chassis.

**NOTE:** The QFX3500 switch has only one Routing Engine.

To synchronize configurations, use the **commit synchronize** CLI command. If one of the Routing Engines is locked, the synchronization fails. If synchronization fails because of a locked configuration file, you can use the **commit synchronize force** command. This command overrides the lock and synchronizes the configuration files.

- **Distribution**—Propagates a configuration across the routing plane on a multichassis router or switch. Distribution occurs automatically. There is no user command available to control the distribution process. If a configuration is locked during a distribution of a configuration, the locked configuration does not receive the distributed configuration file, so the synchronization fails. You need to clear the lock before the configuration and resynchronize the routing planes.

**NOTE:** When you use the **commit synchronize force** CLI command on a multichassis platform, the forced synchronization of the configuration files does not affect the distribution of the configuration file across the routing plane. If a configuration file is locked on a router or switch remote from the router or switch where the command was issued, the synchronization fails on the remote router or switch. You need to clear the lock and reissue the **synchronize** command.

**Related  
Documentation**

- [commit on page 662](#)

---

## Committing a Junos OS Configuration

---

To save Junos OS configuration changes to the configuration database and to activate the configuration on the router, use the **commit** configuration mode command. You can issue the **commit** command from any hierarchy level:

```
[edit]
user@host# commit
commit complete
[edit]
user@host#
```

When you enter the **commit** command, the configuration is first checked for syntax errors (**commit check**). Then, if the syntax is correct, the configuration is activated and becomes the current, operational router configuration.

You can issue the **commit** command from any hierarchy level.

A configuration commit can fail for any of the following reasons:

- The configuration includes incorrect syntax, which causes the commit check to fail.

- The candidate configuration that you are trying to commit is larger than 700 MB.
- The configuration is locked by a user who entered the **configure exclusive** command.

If the configuration contains syntax errors, a message indicates the location of the error, and the configuration is not activated. The error message has the following format:

```
[edit edit-path]
'offending-statement;'
error-message
```

For example:

```
[edit firewall filter login-allowed term allowed from]
'icmp-type [echo-request echo-reply];'
keyword 'echo-reply' unrecognized
```

You must correct the error before recommitting the configuration. To return quickly to the hierarchy level where the error is located, copy the path from the first line of the error and paste it at the configuration mode prompt at the **[edit]** hierarchy level.

The uncommitted, candidate configuration file is `/var/run/db/juniper.db`. It is limited to 700 MB. If the commit fails with a message **configuration database size limit exceeded**, view the file size from configuration mode by entering the command **run file list /var/run/db detail**. You can simplify the configuration and reduce the file size by creating configuration groups with wildcards or defining less specific match policies in your firewall filters.

**NOTE:** CLI commit-time warnings displayed for configuration changes at the **[edit interfaces]** hierarchy level are removed and are logged as system log messages.

This is also applicable to VRRP configuration at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family (*inet* | *inet6*) address *address*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family (*inet* | *inet6*) address *address*]**

When you commit a configuration, you commit the entire configuration in its current form. If more than one user is modifying the configuration, committing it saves and activates the changes of all the users.

**NOTE:**

- If you are using Junos OS in a Common Criteria environment, system log messages are created whenever a secret attribute is changed (for example, password changes or changes to the RADIUS shared secret). These changes are logged during the following configuration load operations:

load merge  
load replace  
load override  
load update

For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*.

- We do not recommend performing a commit operation on the backup Routing Engine when graceful Routing Engine switchover is enabled on the router.

**NOTE:** If you configure the same IP address for a management interface or internal interface such as fxp0 and an external physical interface such as ge-0/0/1, when graceful Routing Engine switchover (GRES) is enabled, the CLI displays an appropriate commit error message that identical addresses have been found on the private and public interfaces. In such cases, you must assign unique IP addresses for the two interfaces that have duplicate addresses.

The management Ethernet interface used for the TX Matrix Plus router, T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers, is em0. Junos OS automatically creates the router's management Ethernet interface, em0.

## Committing a Junos OS Configuration and Exiting Configuration Mode

To save Junos OS configuration changes, activate the configuration on the device and exit configuration mode, using the **commit and-quit** configuration mode command. This command succeeds only if the configuration contains no errors.

```
[edit]
user@host# commit and-quit
commit complete
```

```

exiting configuration mode
user@host>

```

**NOTE:** We do not recommend performing a commit operation on the backup Routing Engine when graceful Routing Engine switchover is enabled on the router.

Documentation**

- [Activating a Junos OS Configuration but Requiring Confirmation on page 512](#)

## Commit Operation When Multiple Users Configure the Software

Up to 32 users can be in configuration mode simultaneously, and they all can be making changes to the configuration. All changes made by all users are visible to everyone editing the configuration—the changes become visible as soon as the user presses the Enter key at the end of a command that changes the configuration, such as **set**, **edit**, or **delete**.

When any of the users editing the configuration issues a **commit** command, all changes made by all users are checked and activated.

If you enter configuration mode with the **configure private** command, each user has a private candidate configuration to edit somewhat independently of other users. When you commit the configuration, only your own changes get committed. To synchronize your copy of the configuration after other users have committed changes, you can run the **update** command in configuration mode. A commit operation also updates all of the private candidate configurations. For example, suppose user X and user Y are both in **configure private** mode, and user X commits a configuration change. When user Y performs a subsequent commit operation and then views the new configuration, the new configuration seen by user Y includes the changes made by user X.

If you enter configuration mode with the **configure exclusive** command, you lock the candidate configuration for as long as you remain in configuration mode, allowing you to make changes without interference from other users. Other users can enter and exit configuration mode, but they cannot commit the configuration. This is true even if the other users entered configuration mode before you enter the **configure exclusive** command. For example, suppose user X is already in the **configure private** or **configure** mode. Then suppose user Y enters the **configure exclusive** mode. User X cannot commit any changes to the configuration, even if those changes were entered before user Y logged in. If user Y exits **configure exclusive** mode, user X can then commit the changes made in **configure private** or **configure** mode.

## Activating a Junos OS Configuration but Requiring Confirmation

---

When you commit the current candidate configuration, you can require an explicit confirmation for the commit to become permanent. This is useful if you want to verify that a configuration change works correctly and does not prevent access to the router. If the change prevents access or causes other errors, the router automatically returns to the previous configuration and restores access after the rollback confirmation timeout passes. This feature is called automatic rollback.

To commit the current candidate configuration but require an explicit confirmation for the commit to become permanent, use the **commit confirmed** configuration mode command:

```
[edit]
user@host# commit confirmed
commit confirmed will be automatically rolled back in 10 minutes unless confirmed
commit complete
#commit confirmed will be rolled back in 10 minutes
[edit]
user@host#
```

Once you have verified that the change works correctly, you can keep the new configuration active by entering a **commit** or **commit check** command within 10 minutes of the **commit confirmed** command. For example:

```
[edit]
user@host# commit check
commit confirmed will be automatically rolled back in 10 minutes unless confirmed
commit complete
#commit confirmed will be rolled back in 10 minutes
[edit]
user@host#
```

If the commit is not confirmed within a certain time (10 minutes by default), Junos OS automatically rolls back to the previous configuration and a broadcast message is sent to all logged-in users.

To show when a rollback is scheduled after a **commit confirmed** command, enter the **show system commit** command. For example:

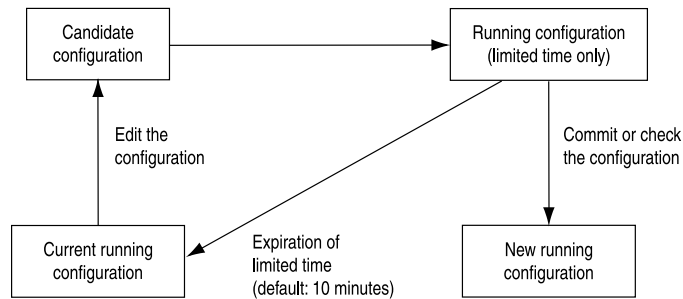

```
user@host>show system commit
0 2005-01-05 15:00:37 PST by root via cli commit confirmed, rollback in 3mins
```

Like the **commit** command, the **commit confirmed** command verifies the configuration syntax and reports any errors. If there are no errors, the configuration is activated and begins running on the router.

Figure 14 illustrates how the **commit confirmed** command works.

Figure 14: Confirm a Configuration

To change the amount of time before you have to confirm the new configuration, specify the number of minutes when you issue the command:

```

[edit]
user@host# commit confirmed minutes
commit complete
[edit]
user@host#

```

In Junos OS Release 11.4 and later, you can also use the **commit confirmed** command in the **[edit private]** configuration mode.

#### Related Documentation

- [Scheduling a Junos OS Commit Operation on page 513](#)
- [Committing a Junos OS Configuration on page 508](#)

## Scheduling a Junos OS Commit Operation

You can schedule when you want your candidate configuration to become active. To save Junos OS configuration changes and activate the configuration on the router at a future time or upon reboot, use the **commit at** configuration mode command, specifying **reboot** or a future time at the **[edit]** hierarchy level:

```

[edit]
user@host # commit at string

```

Where **string** is **reboot** or the future time to activate the configuration changes. You can specify time in two formats:

- A time value in the form **hh:mm[:ss]** (hours, minutes, and optionally seconds)—Commit the configuration at the specified time, which must be in the future but before 11:59:59 PM on the day the **commit at** configuration mode command is issued. Use 24-hour time for the **hh** value; for example, **04:30:00** is 4:30:00 AM, and **20:00** is 8:00 PM. The time is interpreted with respect to the clock and time zone settings on the router.
- A date and time value in the form **yyyy-mm-dd hh:mm[:ss]** (year, month, date, hours, minutes, and, optionally, seconds)—Commit the configuration at the specified day and time, which must be after the **commit at** command is issued. Use 24-hour time for the **hh** value. For example, **2003-08-21 12:30:00** is 12:30 PM on August 21, 2003. The time is interpreted with respect to the clock and time zone settings on the router.

Enclose the **string** value in quotation marks (" "). For example, **commit at "18:00:00"**. For date and time, include both values in the same set of quotation marks. For example, **commit at "2005-03-10 14:00:00"**.

A commit check is performed immediately when you issue the **commit at** configuration mode command. If the result of the check is successful, then the current user is logged out of configuration mode, and the configuration data is left in a read-only state. No other commit can be performed until the scheduled commit is completed.

**NOTE:** If Junos OS fails before the configuration changes become active, all configuration changes are lost.

You cannot enter the **commit at** configuration command after you issue the **request system reboot** command.

You cannot enter the **request system reboot** command once you schedule a commit operation for a specific time in the future.

You cannot commit a configuration when a scheduled commit is pending. For information about how to cancel a scheduled configuration by means of the **clear** command, see the [CLI Explorer](#).

**NOTE:** We do not recommend performing a commit operation on the backup Routing Engine when graceful Routing Engine switchover is enabled on the router.

---

## Monitoring the Junos OS Commit Process

To monitor the Junos commit process, use the **display detail** command after the pipe with the **commit** command:

```
user@host# commit | display detail
```

For example:

```
[edit]
user@host# commit | display detail
2003-09-22 15:39:39 PDT: exporting juniper.conf
2003-09-22 15:39:39 PDT: setup foreign files
2003-09-22 15:39:39 PDT: propagating foreign files
2003-09-22 15:39:39 PDT: complete foreign files
2003-09-22 15:39:40 PDT: copying configuration to juniper.data+
2003-09-22 15:39:40 PDT: dropping unchanged foreign files
2003-09-22 15:39:40 PDT: daemons checking new configuration
2003-09-22 15:39:41 PDT: commit wrapup...
```

```

2003-09-22 15:39:42 PDT: activating '/var/etc/ntp.conf'
2003-09-22 15:39:42 PDT: activating '/var/etc/kmd.conf'

```

**Related  
Documentation**

- [Committing a Junos OS Configuration on page 508](#)
- [Adding a Comment to Describe the Committed Configuration on page 515](#)

## Adding a Comment to Describe the Committed Configuration

You can include a comment that describes changes to the committed configuration. To do so, include the `commit comment` statement. The comment can be as long as 512 bytes and you must type it on a single line.

```

[edit]
user@host# commit comment comment-string

```

*comment-string* is the text of the comment.

**NOTE:** You cannot include a comment with the `commit check` command.

To add a comment to the `commit` command, include the `comment` statement after the `commit` command:

```

[edit]
user@host# commit comment "add user joe"
commit complete
[edit]
user@host#

```

To add a comment to the **commit confirmed** command, include the **comment** statement after the **commit confirmed** command:

```
[edit]
user@host# commit confirmed comment "add customer to port 27"
commit confirmed will be automatically rolled back in 10 minutes unless confirmed
commit complete
[edit]
user@host#
```

To view these commit comments, issue the **show system commit** operational mode command.

In Junos OS Release 11.4 and later, you can also use the **commit confirmed** command in the **[edit private]** configuration mode.

  - [Backing Up the Committed Configuration on the Alternate Boot Drive on page 516](#)

---

## Backing Up the Committed Configuration on the Alternate Boot Drive

---

After you commit the configuration and are satisfied that it is running successfully, you should issue the **request system snapshot** command to back up the new software onto the **/altconfig** file system. If you do not issue the **request system snapshot** command, the configuration on the alternate boot drive will be out of sync with the configuration on the primary boot drive.

The **request system snapshot** command backs up the root file system to **/altroot**, and **/config** to **/altconfig**. The root and **/config** file systems are on the router's flash drive, and the **/altroot** and **/altconfig** file systems are on the router's hard disk (if available).

**NOTE:** For more information about backing up the file system on an ACX Series Universal Access Router, see *Understanding System Snapshot on an ACX Series Router*.

After you issue the **request system snapshot** command, you cannot return to the previous version of the software because the running and backup copies of the software are identical.

## Junos OS Batch Commits Overview

---

Junos OS provides a batch commit feature that aggregates or merges multiple configuration edits from different CLI sessions or users and adds them to a batch commit queue. A batch commit server running on the device takes one or more jobs from the batch commit queue, applies the configuration changes to the shared configuration database, and then commits the configuration changes in a single commit operation.

Batches are prioritized by the commit server based on priority of the batch specified by the user or the time when the batch job is added. When one batch commit is complete, the next set of configuration changes are aggregated and loaded into the batch queue for the next session of the batch commit operation. Batches are created until there are no commit entries left in the queue directory.

When compared to the regular commit operation where all commits are independently committed sequentially, batch commits save time and system resources by committing multiple small configuration edits in a single commit operation.

Batch commits are performed from the **[edit batch]** configuration mode. The commit server properties can be configured at the **[edit system commit server]** hierarchy level.

## Aggregation and Error Handling

When there is a load-time error in one of the aggregated jobs, the commit job that encounters the error is discarded and the remaining jobs are aggregated and committed.

For example, if there are five commit jobs (**commit-1**, **commit-2**, **commit-3**, **commit-4**, and **commit-5**) being aggregated, and **commit-3** encounters an error while loading, **commit-3** is discarded and **commit-1**, **commit-2**, **commit-4**, and **commit-5** are aggregated and committed.

If there is an error during the commit operation when two or more jobs are aggregated and committed, the aggregation is discarded and each of those jobs is committed individually like a regular commit operation.

For example, if there are five commit jobs (**commit-1**, **commit-2**, **commit-3**, **commit-4**, and **commit-5**) that are aggregated and if there is a commit error caused because of **commit-3**, the aggregation is discarded, **commit-1**, **commit-2**, **commit-3**, **commit-4**, and **commit-5** are committed individually, and the CLI reports a commit error for **commit-3**.

### Related Documentation

- [Example: Configuring Batch Commit Server Properties on page 517](#)

## Example: Configuring Batch Commit Server Properties

This example shows how to configure batch commit server properties to manage batch commit operations.

- [Requirements on page 517](#)
- [Overview on page 518](#)
- [Configuration on page 518](#)
- [Verification on page 520](#)

## Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Router
- Junos OS Release 12.1 or later running on the device

## Overview

You can control how the batch commit queue is handled by the commit server by configuring the server properties at the **[edit system commit server]** hierarchy level. This enables you to control how many commit jobs are aggregated or merged into a single batch commit, the maximum number of jobs that can be added to the queue, days to keep batch commit error logs, interval between two batch commits, and tracing operations for batch commit operations.

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level. You can configure the commit server properties from either the regular **[edit]** mode or the **[edit batch]** mode.

**Device R0**

```
set system commit server maximum-aggregate-pool 4
set system commit server maximum-entries 500
set system commit server commit-interval 5
set system commit server days-to-keep-error-logs 30
set system commit server traceoptions file commitd_nov
set system commit server traceoptions flag all
```

### Configuring the Commit Server Properties

#### Step-by-Step Procedure

1. (Optional) Configure the number of commit transactions to aggregate or merge in a single commit operation.

The default value for **maximum-aggregate-pool** is 5.

**NOTE:** Setting **maximum-aggregate-pool** to 1 commits each of the jobs individually.

In this example, the number of commit transactions is set to 4 indicating that four different commit jobs are aggregated into a single commit before the commit operation is initiated.

```
[edit system commit server]
user@R0# set maximum-aggregate-pool 4
```

2. (Optional) Configure the maximum number of jobs allowed in a batch.

This limits the number of commits jobs that are added to the queue.

```
[edit system commit server]
user@R0# set maximum-entries 500
```

**NOTE:** If you set **maximum-entries** to 1, the commit server cannot add more than one job to the queue, and the CLI displays an appropriate message when you try to commit more than one job.

3. (Optional) Configure the time (in seconds) to wait before starting the next batch commit operation.

```
[edit system commit server]
user@R0# set commit-interval 5
```

4. (Optional) Configure the number of days to keep error logs.

The default value is 30 days.

```
[edit system commit server]
user@R0# set days-to-keep-error-logs 30
```

5. (Optional) Configure tracing operations to log batch commit events.

In this example, the filename for logging batch commit events is **commitd\_nov**, and all traceoption flags are set.

```
[edit system commit server]
user@R0# set traceoptions commitd_nov
user@R0# set traceoptions flag all
```

**Results** From configuration mode, confirm your configuration by entering the **show system commit server** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show system commit server
maximum-aggregate-pool 4;
maximum-entries 500;
commit-interval 5;
days-to-keep-error-logs 30;
traceoptions {
 file commitd_nov;
 flag all;
}
```

### Committing the Configuration from Batch Configuration Mode

**Step-by-Step Procedure** To commit the configuration from the **[edit batch]** mode, do one of the following:

- Log in to the device and enter **commit**.

```
[edit batch]
user@R0# commit
Added to commit queue request-id: 1000
```

- To assign a higher priority to a batch commit job, issue the **commit** command with the **priority** option.

```
[edit batch]
user@R0# commit priority
Added to commit queue request-id: 1001
```

- To commit a configuration without aggregating the configuration changes with other commit jobs in the queue, issue the **commit** command with the **atomic** option.

```
[edit batch]
user@R0# commit atomic
Added to commit queue request-id: 1002
```

- To commit a configuration without aggregating the configuration changes with other commit jobs in the queue, and issuing a higher priority to the commit job, issue the **commit** command with the **atomic priority** option.

[edit batch]

user@R0# **commit atomic priority**

Added to commit queue request-id: 1003

## Verification

Confirm that the configuration is working properly.

- [Checking the Batch Commit Server Status on page 520](#)
- [Checking the Batch Commit Status on page 520](#)
- [Viewing the Patch Files in a Batch Commit Job on page 521](#)
- [Viewing the Trace Files for Batch Commit Operations on page 523](#)

---

### Checking the Batch Commit Server Status

**Purpose** Check the status of the batch commit server.

**Action** user@R0> **show system commit server**  
Commit server status : Not running

By default, the status of the commit server is **Not running**. The commit server starts running only when a batch commit job is added to the queue.

When a batch commit job is added to the queue, the status of the commit server changes to **Running**.

user@R0> **show system commit server**

Commit server status : Running  
Jobs in process:  
1003 1004 1005

**Meaning** The **Jobs in process** field lists the commit IDs of jobs that are in process.

---

### Checking the Batch Commit Status

**Purpose** Check the commit server queue for the status of the batch commits.

**Action** user@R0> show system commit server queue

```
Pending commits:
 Id: 1005
 Last Modified: Tue Nov 1 23:56:43 2011

Completed commits:
 Id: 1000
 Last Modified: Tue Nov 1 22:46:43 2011
 Status: Successfully committed 1000

 Id: 1002
 Last Modified: Tue Nov 1 22:50:35 2011
 Status: Successfully committed 1002

 Id: 1004
 Last Modified: Tue Nov 1 22:51:48 2011
 Status: Successfully committed 1004

 Id: 1007
 Last Modified: Wed Nov 2 01:08:04 2011
 Status: Successfully committed 1007

 Id: 1009
 Last Modified: Wed Nov 2 01:16:45 2011
 Status: Successfully committed 1009

 Id: 1010
 Last Modified: Wed Nov 2 01:19:25 2011
 Status: Successfully committed 1010

 Id: 1011
 Last Modified: Wed Nov 2 01:28:16 2011
 Status: Successfully committed 1011

Error commits:
 Id: 1008
 Last Modified: Wed Nov 2 01:08:18 2011
 Status: Error while committing 1008
```

**Meaning** **Pending commits** displays commit jobs that are added to the commit queue but are not committed yet. **Completed commits** displays the list of commit jobs that are successful. **Error commits** are commits that failed because of an error.

### Viewing the Patch Files in a Batch Commit Job

**Purpose** View the timestamps, patch files, and the status of each of the commit jobs. Patch files show the configuration changes that occur in each commit operation that is added to the batch commit queue.

**Action** 1. Issue the **show system commit server queue patch** command to view the patches for all commit operations.

```
user@R0> show system commit server queue patch
Pending commits:
 none
```

## Completed commits:

```
Id: 1000
Last Modified: Tue Nov 1 22:46:43 2011
Status: Successfully committed 1000
```

## Patch:

```
[edit groups]
 re1 { ... }
+ GRP-DHCP-POOL-NOACCESS {
+ access {
+ address-assignment {
+ pool <*> {
+ family inet {
+ dhcp-attributes {
+ maximum-lease-time 300;
+ grace-period 300;
+ domain-name verizon.net;
+ name-server {
+ 4.4.4.1;
+ 4.4.4.2;
+ }
+ }
+ }
+ }
+ }
+ }
+ }
```

```
Id: 1002
Last Modified: Tue Nov 1 22:50:35 2011
Status: Successfully committed 1002
```

## Patch:

```
[edit]
+ snmp {
+ community abc;
+ }
```

```
Id: 1010
Last Modified: Wed Nov 2 01:19:25 2011
Status: Successfully committed 1010
```

## Patch:

```
[edit system syslog]
 file test { ... }
+ file j {
+ any any;
+ }
```

## Error commits:

```
Id: 1008
Last Modified: Wed Nov 2 01:08:18 2011
Status: Error while committing 1008
```

## Patch:

```
[edit system]
+ radius-server {
+ 10.1.1.1 port 222;
+ }
```

The output shows the changes in configuration for each commit job ID.

- To view the patch for a specific commit job ID, issue the **show system commit server queue patch id <id-number>** command.

```
user@R0> show system commit server queue patch id 1000
```

```
Completed commits:
```

```
Id: 1000
```

```
Last Modified: Tue Nov 1 22:46:43 2011
```

```
Status: Successfully committed 1000
```

```
Patch:
```

```
[edit system]
```

```
+ radius-server {
```

```
+ 192.168.69.162 secret teH.bTc/RVbPM;
```

```
+ 192.168.64.10 secret teH.bTc/RVbPM;
```

```
+ 192.168.60.52 secret teH.bTc/RVbPM;
```

```
+ 192.168.60.55 secret teH.bTc/RVbPM;
```

```
+ 192.168.4.240 secret teH.bTc/RVbPM;
```

```
+ }
```

**Meaning** The output shows the patch created for a commit job. The + or - sign indicates the changes in the configuration for a specific commit job.

### Viewing the Trace Files for Batch Commit Operations

**Purpose** View the trace files for batch commit operations. You can use the trace files for troubleshooting purposes.

- Action**
- Issue the **file show /var/log/<filename>** command to view all entries in the log file.

```
user@R0> file show /var/log/commitd_nov
```

The output shows commit server event logs and other logs for batch commits.

```
Nov 1 22:46:43 Successfully committed 1000
```

```
Nov 1 22:46:43 pausing after commit for 0 seconds
```

```
...
```

```
Nov 1 22:46:43 Done working on queue
```

```
...
```

```
Nov 1 22:47:17 maximum-aggregate-pool = 5
```

```
Nov 1 22:47:17 maximum-entries= 0
```

```
Nov 1 22:47:17 asynchronous-prompt = no
```

```
Nov 1 22:47:17 commit-interval = 0
```

```
Nov 1 22:47:17 days-to-keep-error-logs = -1
```

```
...
```

```
Nov 1 22:47:17 Added to commit queue request-id: 1001
```

```
Nov 1 22:47:17 Commit server status=running
```

```
Nov 1 22:47:17 No need to pause
```

```
...
```

```
Nov 1 22:47:18 Error while committing 1001
```

```
Nov 1 22:47:18 doing rollback
```

```
...
```

- To view log entries only for successful batch commit operations, issue the **file show /var/log/<filename>** command with the **| match committed** pipe option.

```
user@R0> file show /var/log/commitd_nov | match committed
```

The output shows batch commit job IDs for successful commit operations.

```
Nov 1 22:46:43 Successfully committed 1000
Nov 1 22:50:35 Successfully committed 1002
Nov 1 22:51:48 Successfully committed 1004
Nov 2 01:08:04 Successfully committed 1007
Nov 2 01:16:45 Successfully committed 1009
Nov 2 01:19:25 Successfully committed 1010
Nov 2 01:28:16 Successfully committed 1011
```

- To view log entries only for failed batch commit operations, issue the **file show** `/var/log/<filename>` command with the **| match "Error while"** pipe option.

```
user@R0> file show/var/log/commitd_nov | match "Error while"
```

The output shows commit job IDs for failed commit operations.

```
Nov 1 22:47:18 Error while committing 1001
Nov 1 22:51:10 Error while committing 1003
Nov 1 22:52:15 Error while committing 1005
...
```

- To view log entries only for commit server events, issue the **file show** `/var/log/<filename>` command with the **| match "commit server"** pipe option.

```
user@R0> file show/var/log/commitd_nov | match "commit server"
```

The output shows commit server event logs.

```
Nov 1 22:46:39 Commit server status=running

## Understanding How the Junos OS Configuration Is Stored

When you edit a configuration, you work in a copy of the current configuration to create a candidate configuration. The changes you make to the candidate configuration are visible in the CLI immediately, so if multiple users are editing the configuration at the same time, all users can see all changes.

To have a candidate configuration take effect, you *commit* the changes. At this point, the candidate file is checked for proper syntax, activated, and marked as the current, operational software configuration file. If multiple users are editing the configuration, when you commit the candidate configuration, all changes made by all the users take effect.

In addition to saving the current configuration, the CLI saves the current operational version and the previous 49 versions of committed configurations. The most recently committed configuration is version 0, which is the current operational version and the

default configuration that the system returns to if you roll back to a previous configuration. The oldest saved configuration is version 49.

By default, Junos OS saves the current configuration and three previous versions of the committed configuration on the CompactFlash card. The currently operational Junos OS configuration is stored in the file **juniper.conf.gz**, and the last three committed configurations are stored in the files **juniper.conf.1.gz**, **juniper.conf.2.gz**, and **conf.3.gz**. These four files are located in the router or switch's CompactFlash card in the directory **/config**.

The remaining 46 previous versions of committed configurations, the files **juniper.conf.4** through **juniper.conf.49**, are stored in the directory **/var/db/config** on the hard disk.

---

## Comparing Configuration Changes with a Prior Version

---

In configuration mode only, when you have made changes to the configuration and want to compare the candidate configuration with a prior version, you can use the **compare** command to display the configuration. The **compare** command compares the candidate configuration with either the current committed configuration or a configuration file and displays the differences between the two configurations. To compare configurations, specify the **compare** command after the pipe:

```
[edit]
user@host# show | compare (filename) rollback n
```

**filename** is the full path to a configuration file. The file must be in the proper format: a hierarchy of statements.

**n** is the index into the list of previously committed configurations. The most recently saved configuration is number 0, and the oldest saved configuration is number 49. If you do not specify arguments, the candidate configuration is compared against the active configuration file (**/config/juniper.conf**).

The comparison output uses the following conventions:

- Statements that are only in the candidate configuration are prefixed with a plus sign (+).
- Statements that are only in the comparison file are prefixed with a minus sign (-).
- Statements that are unchanged are prefixed with a single blank space ( ).

The following example shows various changes, then a comparison of the candidate configuration with the active configuration, showing only the changes made at the **[edit protocols bgp]** hierarchy level:

```
[edit]
user@host# edit protocols bgp
[edit protocols bgp]
user@host# show
group my-group {
 type internal;
 hold-time 60;
 advertise-inactive;
 allow 1.1.1.1/32;
}
group fred {
 type external;
 peer-as 33333;
 allow 2.2.2.2/32;
}
group test-peers {
 type external;
 allow 3.3.3.3/32;
}
[edit protocols bgp]
user@host# set group my-group hold-time 90
[edit protocols bgp]
user@host# delete group my-group advertise-inactive
[edit protocols bgp]
user@host# set group fred advertise-inactive
[edit protocols bgp]
user@host# delete group test-peers
[edit protocols bgp]
user@host# show | compare
[edit protocols bgp group my-group]
- hold-time 60;
+ hold-time 90;
- advertise-inactive;
[edit protocols bgp group fred]
+ advertise-inactive;
[edit protocols bgp]
- group test-peers {
 - type external;
 - allow 3.3.3.3/32;
}
[edit protocols bgp]
user@host# show
group my-group {
 type internal;
 hold-time 90;
 allow 1.1.1.1/32;
}
group fred {
 type external;
 advertise-inactive;
 peer-as 33333;
```

```
 allow 2.2.2.2/32;
}
```

---

## Understanding the `show | compare | display xml` Command Output

---

The **`compare | display xml`** filter compares the candidate configuration with the current committed configuration and displays the differences between the two configurations in XML. To compare configurations, enter **`compare | display xml`** after the pipe ( `|` ) symbol in either operational or configuration mode.

Example in operational mode:

```
user@host> show configuration | compare | display xml
```

Example in configuration mode:

```
[edit]
user@host# show | compare | display xml
```

You can enter a specific configuration hierarchy immediately preceding the **`compare`** filter, for example, **`show configuration system syslog | compare | display xml`**. In configuration mode, you can navigate to a hierarchy where the command is applied.

The differences from the compare filter function are output in XML. The **`configuration`** tag starts the output. The context for changes is established with hierarchy name tags relative to the root of the compare. For element changes, an **`operation`** attribute are output in the tag where a change occurs. This attribute has the value **`create`**, **`delete`**, or **`merge`**. For metadata changes, the metadata name is specified. For example, if a statement is marked inactive, the **`inactive="inactive"`** attribute and value are output. The `nc` namespace is used when necessary to indicate that an attribute is in the NETCONF namespace rather than the Junos OS namespace.

The following sections explain the XML that is generated for particular types of configuration changes. The corresponding text changes are shown for comparison.

- [Adding a Statement \(create Operation\) on page 529](#)
- [Deleting a Statement \(delete Operation\) on page 529](#)
- [Changing a Statement \(delete and create Operations\) on page 530](#)
- [Changing Metadata \(inactive Attribute and Operation\) on page 531](#)
- [Adding an Annotation \(comment Tag and create Operation\) on page 532](#)
- [Changing an Annotation \(comment Tag, and delete and create Operations\) on page 532](#)
- [Adding a Statement Inside a Container \(create Operation, and insert and key Attributes\) on page 533](#)
- [Changing the Order Inside a Container \(merge Operation, and insert and key Attributes\) on page 534](#)

## Adding a Statement (create Operation)

The following example shows the addition of IPv4 address 2.2.2.2 to unit 1. The tags through **name** provide the context for the addition. The **operation="create"** attribute indicates that a **unit** statement was created and is defined by the configuration within the **unit** tag.

```
[edit interfaces ge-0/0/0]
user@host> show configuration | compare
[edit interfaces ge-0/0/0]
+ unit 1 {
+ family inet {
+ address 2.2.2.2/32;
+ }
+ }

[edit interfaces ge-0/0/0]
user@host# show | compare | display xml
<configuration>
 <interfaces>
 <interface>
 <name>ge-0/0/0</name>
 <unit nc:operation="create">
 <name>1</name>
 <family>
 <inet>
 <address>
 <name>2.2.2.2/32</name>
 </address>
 </inet>
 </family>
 </unit>
 </interface>
 </interfaces>
</configuration>
```

## Deleting a Statement (delete Operation)

The following example shows the deletion of a simple statement in the configuration hierarchy. The tags through **system** provide the context for the deletion. The **operation="delete"** attribute indicates that the **services** statement was deleted. The configuration following the **services** statement was deleted though is not output.

```
[edit system]
user@host> show configuration | compare
[edit system]
- services {
- ftp;
- }

[edit system]
user@host# show | compare | display xml
<configuration>
 <system>
 <services operation="delete"/>
 </system>
</configuration>
```

The following example shows the deletion of unit 1 from the ge-0/0/0 interface. The configuration following the **unit** statement was deleted though is not output.

```
[edit interfaces ge-0/0/0]
user@host> show configuration | compare
[edit interfaces ge-0/0/0]
- unit 1 {
- family inet {
- address 2.2.2.2/32;
- }
- }

[edit interfaces ge-0/0/0]
user@host# show | compare | display xml
<configuration>
 <interfaces>
 <interface>
 <name>ge-0/0/0</name>
 <unit nc:operation="delete">
 <name>1</name>
 </unit>
 </interface>
 </interfaces>
</configuration>
```

The following example shows the deletion of the **apply-groups** configuration. The groups that are deleted are not output.

```
[edit]
user@host# delete apply-groups

[edit]
user@host> show configuration | compare
[edit]
- apply-groups [g1 g2 g3];

[edit]
user@host# show | compare | display xml
<configuration>
 <apply-groups operation="delete"/>
</configuration>
```

## Changing a Statement (delete and create Operations)

The following example shows a change in a statement in the hierarchy. The tags through **system** provide the context for the change. The **operation="delete"** attribute indicates that the **host-name** statement was deleted. The configuration following the **host-name** statement was deleted though is not output. The **operation="create"** attribute indicates that a **host-name** statement was created and is defined by the configuration within the **host-name** tag.

```
[edit system]
user@host> show configuration | compare
[edit system]
- host-name router1;
+ host-name router2;

[edit system]
user@host# show | compare | display xml
```

```

<configuration>
 <system>
 <host-name nc:operation="delete"/>
 <host-name nc:operation="create">router2</host-name>
 </system>
</configuration>

```

## Changing Metadata (inactive Attribute and Operation)

The following example shows the inactivation of a statement in the hierarchy. The tags through **system** provide the context for the change. The **inactive="inactive"** attribute indicates that the **syslog** statement was inactivated.

```

[edit system]
user@host> show configuration | compare
[edit system]
! inactive: syslog { ... }

[edit system]
user@host# show | compare | display xml
<configuration>
 <system>
 <syslog inactive="inactive"/>
 </system>
</configuration>

```

The following example shows the addition of an inactive **syslog** statement. The **operation="create"** attribute indicates that the **syslog** statement was created and is defined by the configuration within the **syslog** tag. The **inactive="inactive"** attribute indicates that the **syslog** statement was inactivated.

```

[edit system]
user@host> show configuration | compare
[edit system]
+ inactive: syslog {
+ file foo {
+ any any;
+ }
+ }

[edit system]
user@host# show | compare | display xml
<configuration>
 <system>
 <syslog nc:operation="create"
 inactive="inactive">
 <file>
 <name>foo</name>
 <contents>
 <name>any</name>
 <any/>
 </contents>
 </file>
 </syslog>
 </system>
</configuration>

```

## Adding an Annotation (comment Tag and create Operation)

The following example shows the addition of a comment to a statement. The tags through **syslog** provide the context for the annotation. The **operation="create"** attribute for the **junos:comment** tag indicates that a comment was added to the **[edit system syslog]** hierarchy.

```
[edit system]
user@host> show configuration | compare
[edit system]
+ /* my-comments-simple */
 syslog { ... }

[edit system]
user@host# show | compare | display xml
<configuration>
 <system>
 <junos:comment nc:operation="create">/* my-comments-simple
 */</junos:comment>
 <syslog/>
 </system>
</configuration>
```

The following example shows the addition of a comment to a statement. The tags through **syslog** provide the context for the annotation. The **operation="create"** attribute for the **junos:comment** tag indicates that a comment was added to the **[edit system syslog]** hierarchy for the statement output within the **syslog** tag.

```
[edit system syslog]
user@host> show configuration | compare
+ /* my-comments-ele */
 file f1 { ... }

[edit system syslog]
user@host# show | compare | display xml
<configuration>
 <system>
 <syslog>
 <junos:comment nc:operation="create">/* my-comments-elem
 */</junos:comment>
 <file>
 <name>f1</name>
 </file>
 </syslog>
 </system>
</configuration>
```

## Changing an Annotation (comment Tag, and delete and create Operations)

The following example shows the change of a comment for a statement. The tags through **system** provide the context for the annotation. The **operation="delete"** attribute for the **junos:comment** tag indicates that a comment was deleted from the **[edit system]** hierarchy at the **syslog** statement. The **operation="create"** attribute for the **junos:comment** tag

indicates that a comment was added to the **[edit system]** hierarchy for the **syslog** statement.

```
[edit system]
user@host> show configuration | compare
- /* my-comments-1 */
+ /* my-comments-2 */
 syslog { ... }

[edit system]
user@host# show | compare | display xml
<configuration>
 <system>
 <junos:comment nc:operation="delete"/>
 <junos:comment nc:operation="create">/* my-comments-2
*/</junos:comment>
 <syslog/>
 </system>
</configuration>
```

### Adding a Statement Inside a Container (create Operation, and insert and key Attributes)

The following example shows the addition of a **file** statement at the **[edit system syslog]** hierarchy. The tags through **syslog** provide the context for the addition. The **operation="create"** attribute for the **file** tag indicates that a **file** statement was added. The **yang:insert="after"** attribute indicates that the file was added after the position indicated by the **yang:key="[name='file-1']"** attribute. The **file-1** value represents the position within the existing **file** statements, where one is the first file. In this example, the new **file** statement was added after the first file.

```
[edit system syslog]
user@host> show configuration | compare
[edit system syslog]
 file file-1 { ... }
+ file file-2 {
+ any any;
+ }

[edit system syslog]
user@host# show | compare | display xml
<configuration>
 <system>
 <syslog>
 <file nc:operation="create"
 yang:insert="after"
 yang:key="[name='file-1']">
 <name>file-2</name>
 <contents>
 <name>any</name>
 <any/>
 </contents>
 </file>
 </syslog>
 </system>
</configuration>
```

## Changing the Order Inside a Container (merge Operation, and insert and key Attributes)

The following example shows the change in order of **file** statements at the **[edit system syslog]** hierarchy. The tags through **syslog** provide the context for the change. The **operation="merge"** attribute for the **file** tag indicates that an existing **file** statement was moved. The **yang:insert="after"** attribute indicates that the file was moved after the file in the position indicated by the **yang:key="[name='file-1']"** attribute. The **file-1** value represents a position within the existing **file** statements, where one is the first file. The value at the **name** tag, **file-3**, represents a position within the existing file statements. In this example, the **file** statement in the third position was moved after the first file.

```
[edit system syslog]
user@host> show configuration | compare
[edit system syslog]
 file f1 { ... }
! file f3 { ... }

[edit system syslog]
user@host# show | compare | display xml
<configuration>
 <system>
 <syslog>
 <file nc:operation="merge"
 yang:insert="after"
 yang:key="[name='file-1']">
 <name>file-3</name>
 </file>
 </syslog>
 </system>
 </configuration>
```

## Returning to the Most Recently Committed Junos OS Configuration

---

To return to the most recently committed configuration and load it into configuration mode without activating it, use the **rollback** configuration mode command:

```
[edit]
user@host# rollback

load complete
```

To activate the configuration to which you rolled back, use the **commit** command:

```
[edit]
user@host# rollback
load complete
[edit]
user@host# commit
```

- Related Documentation**
- [Rolling Back Junos OS Configuration Changes on page 444](#)
  - [Returning to a Previously Committed Junos OS Configuration on page 535](#)
  - [Understanding How the Junos OS Configuration Is Stored on page 525](#)

## Returning to a Previously Committed Junos OS Configuration

This topic explains how you can return to a configuration prior to the most recently committed one, and contains the following sections:

- [Returning to a Configuration Prior to the One Most Recently Committed on page 535](#)
- [Displaying Previous Configurations on page 535](#)
- [Comparing Configuration Changes with a Prior Version on page 536](#)
- [Creating and Returning to a Rescue Configuration on page 538](#)
- [Saving a Configuration to a File on page 539](#)

### Returning to a Configuration Prior to the One Most Recently Committed

To return to a configuration prior to the most recently committed one, include the configuration number, 0 through 49, in the **rollback** command. The most recently saved configuration is number 0 (which is the default configuration to which the system returns), and the oldest saved configuration is number 49.

```
[edit]
user@host# rollback number
load complete
```

### Displaying Previous Configurations

To display previous configurations, including the rollback number, date, time, the name of the user who committed changes, and the method of commit, use the **rollback ?** command.

```
[edit]
user@host# rollback ?

| Pipe through a command
[edit]

```

## Comparing Configuration Changes with a Prior Version

In configuration mode only, when you have made changes to the configuration and want to compare the candidate configuration with a prior version, you can use the **compare** command to display the configuration. The **compare** command compares the candidate configuration with either the current committed configuration or a configuration file and displays the differences between the two configurations. To compare configurations, specify the **compare** command after the pipe:

```

[edit]
user@host# show | compare (filename| rollback n)

```

**filename** is the full path to a configuration file. The file must be in the proper format: a hierarchy of statements.

*n* is the index into the list of previously committed configurations. The most recently saved configuration is number 0, and the oldest saved configuration is number 49. If you do not specify arguments, the candidate configuration is compared against the active configuration file (`/config/juniper.conf`).

The comparison output uses the following conventions:

- Statements that are only in the candidate configuration are prefixed with a plus sign (+).
- Statements that are only in the comparison file are prefixed with a minus sign (-).
- Statements that are unchanged are prefixed with a single blank space ( ).

The following example shows various changes, then a comparison of the candidate configuration with the active configuration, showing only the changes made at the **[edit protocols bgp]** hierarchy level:

```
[edit]
user@host# edit protocols bgp
[edit protocols bgp]
user@host# show
group my-group {
 type internal;
 hold-time 60;
 advertise-inactive;
 allow 1.1.1.1/32;
}
group fred {
 type external;
 peer-as 33333;
 allow 2.2.2.2/32;
}
group test-peers {
 type external;
 allow 3.3.3.3/32;
}
[edit protocols bgp]
user@host# set group my-group hold-time 90
[edit protocols bgp]
user@host# delete group my-group advertise-inactive

## Creating and Returning to a Rescue Configuration

A rescue configuration allows you to define a known working configuration or a configuration with a known state that you can roll back to at any time. This alleviates the necessity of having to remember the rollback number with the **rollback** command. You use the rescue configuration when you need to roll back to a known configuration or as a last resort if your router or switch configuration and the backup configuration files become damaged beyond repair.

To save the most recently committed configuration as the rescue configuration so that you can return to it at any time, issue the **request system configuration rescue save** command:

```
user@host> request system configuration rescue save
```

To return to the rescue configuration, use the **rollback rescue** configuration mode command:

```
[edit]
user@host# rollback rescue
load complete
```

**NOTE:** If the rescue configuration does not exist, or if the rescue configuration is not a complete, viable configuration, then the rollback command fails, an error message appears, and the current configuration remains active.

To activate the rescue configuration that you have loaded, use the **commit** command:

```
[edit]
user@host# rollback rescue
load complete
[edit]
user@host# commit
```

To delete an existing rescue configuration, issue the **request system configuration rescue delete** command:

```
user@host> request system configuration rescue delete
user@host>
```

For more information about the **request system configuration rescue delete** and **request system configuration rescue save** commands, see the [CLI Explorer](#).

## Saving a Configuration to a File

Save Junos OS configuration to a file so that you can edit it with a text editor of your choice. You can save your current configuration to an ASCII file, which saves the configuration in its current form, including any uncommitted changes. If more than one user is modifying the configuration, all changes made by all users are saved.

To save software configuration changes to an ASCII file, use the **save** configuration mode command:

```
[edit]
user@host# save filename
[edit]
user@host#
```

The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.

By default, the configuration is saved to a file in your home directory, which is on the flash drive.

When you issue this command from anywhere in the hierarchy (except the top level), a **replace** tag is automatically included at the beginning of the file. You can use the **replace** tag to control how a configuration is loaded from a file.

```
user@host> file show /var/home/user/myconf
replace:
protocols {
 bgp {
 disable;
 group int {
 type internal;
 }
 }
 isis {
 disable;
 interface all {
 level 1 disable;
 }
 interface fxp0.0 {
 disable;
 }
 }
 ospf {
 traffic-engineering;
 reference-bandwidth 4g;
 ...
 }
}
```

```
}
```

## Saving a Configuration to a File

Save Junos OS configuration to a file so that you can edit it with a text editor of your choice. You can save your current configuration to an ASCII file, which saves the configuration in its current form, including any uncommitted changes. If more than one user is modifying the configuration, all changes made by all users are saved.

To save software configuration changes to an ASCII file, use the **save** configuration mode command:

```
[edit]
user@host# save filename
[edit]
user@host#
```

The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.

By default, the configuration is saved to a file in your home directory, which is on the flash drive.

When you issue this command from anywhere in the hierarchy (except the top level), a **replace** tag is automatically included at the beginning of the file. You can use the **replace** tag to control how a configuration is loaded from a file.

```
user@host> file show /var/home/user/myconf
replace:
protocols {
 bgp {
 disable;
 group int {
 type internal;
 }
 }
 isis {
 disable;
 interface all {
 level 1 disable;
 }
 interface fxp0.0 {
 disable;
 }
 }
 ospf {
 traffic-engineering;
```

```

 reference-bandwidth 4g;
 ...
}
}

```

## Additional Details About Specifying Junos OS Statements and Identifiers

This topic provides more detailed information about CLI container and leaf statements so that you can better understand how you must specify them when creating ASCII configuration files. It also describes how the CLI performs type checking to verify that the data you entered is in the correct format.

- [Specifying Statements on page 541](#)
- [Performing CLI Type Checking on page 543](#)

### Specifying Statements

Statements are shown one of two ways, either with braces or without:

- Statement name and identifier, with one or more lower level statements enclosed in braces:

```

statement-name1 identifier-name {
 statement-name2;
 additional-statements;
}

```

- Statement name, identifier, and a single identifier:

```

statement-name identifier-name1 identifier-name2;

```

The **statement-name** is the name of the statement.

The **identifier-name** is a name or other string that uniquely identifies an instance of a statement. An identifier is used when a statement can be specified more than once in a configuration.

When specifying a statement, you must specify either a statement name or an identifier name, or both, depending on the statement hierarchy.

You specify identifiers in one of the following ways:

- **identifier-name**—The **identifier-name** is a keyword used to uniquely identify a statement when a statement can be specified more than once in a statement.
- **identifier-name value**—The **identifier-name** is a keyword, and the **value** is a required option variable.
- **identifier-name [value1 value2 value3 ...]**—The **identifier-name** is a keyword that accepts multiple values. The brackets are required when you specify a set of values; however, they are optional when you specify only one value.

The following examples illustrate how statements and identifiers are specified in the configuration:

```
protocol { # Top-level statement (statement-name).
 ospf { # Statement under "protocol" (statement-name).
 area 0.0.0.0 { # OSPF area "0.0.0.0" (statement-name identifier-name),
 interface so-0/0/0 { # which contains an interface named "so-0/0/0."
 hello-interval 25; # Identifier and value (identifier-name value).
 priority 2; # Identifier and value (identifier-name value).
 disable; # Flag identifier (identifier-name).
 }
 interface so-0/0/1; # Another instance of "interface," named so-0/0/1,
 } # this instance contains no data, so no braces
 } # are displayed.
}

policy-options { # Top-level statement (statement-name).
 term term1 { # Statement under "policy-options"
 # (statement-name value).
 from { # Statement under "term" (statement-name).
 route-filter 10.0.0.0/8 orlonger reject; # One identifier ("route-filter")
 with
 route-filter 127.0.0.0/8 orlonger reject; # multiple values.
 route-filter 128.0.0.0/16 orlonger reject;
 route-filter 149.20.64.0/24 orlonger reject;
 route-filter 172.16.0.0/12 orlonger reject;
 route-filter 191.255.0.0/16 orlonger reject;
 }
 then { # Statement under "term" (statement-name).
 next term; # Identifier (identifier-name).
 }
 }
}
```

When you create an ASCII configuration file, you can specify statements and identifiers in one of the following ways. However, each statement has a preferred style, and the CLI uses that style when displaying the configuration in response to a configuration mode **show** command.

- Statement followed by identifiers:

```
statement-name identifier-name [...] identifier-name value [...];
```

- Statement followed by identifiers enclosed in braces:

```
statement-name {
 identifier-name;
 [...]
 identifier-name value;
 [...]
}
```

- For some repeating identifiers, you can use one set of braces for all the statements:

```
statement-name {
 identifier-name value1;
 identifier-name value2;
}
```

## Performing CLI Type Checking

When you specify identifiers and values, the CLI performs type checking to verify that the data you entered is in the correct format. For example, for a statement in which you must specify an IP address, the CLI requires you to enter an address in a valid format. If you have not, an error message indicates what you need to type. [Table 60](#) lists the data types the CLI checks.

**Table 60: CLI Configuration Input Types**

| Data Type                                                                                                   | Format                                                                                         | Examples                                                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Physical interface name (used in the <code>[edit interfaces]</code> hierarchy)                              | <i>type-fpc/pic/port</i>                                                                       | Correct: so-0/0/1<br>Incorrect: so-0                                                                                                                                                                              |
| Full interface name                                                                                         | <i>type-fpc/pic/port&lt;:channel&gt;.logical</i>                                               | Correct: so-0/0/1.0<br>Incorrect: so-0/0/1                                                                                                                                                                        |
| Full or abbreviated interface name (used in places other than the <code>[edit interfaces]</code> hierarchy) | <i>type-&lt;fpc&lt;/pic/port&gt;&gt;&lt;&lt;:channel&gt;.logical&gt;</i>                       | Correct: so, so-1, so-1/2/3:4.5                                                                                                                                                                                   |
| IP address                                                                                                  | <i>0xhex-bytesoctet&lt;.octet&lt;.octet.&lt;octet&gt;&gt;&gt;</i>                              | Correct: 1.2.3.4, 0x01020304, 128.8.1, 128.8<br><br>Sample translations:<br><br>1.2.3 becomes 1.2.3.0<br>0x01020304 becomes 1.2.3.4<br>0x010203 becomes 0.1.2.3                                                   |
| IP address (destination prefix) and prefix length                                                           | <i>0xhex-bytes&lt;/length&gt;octet&lt;octet&lt;.octet.&lt;octet&gt;&gt;&gt;&lt;/length&gt;</i> | Correct: 10/8, 128.8/16, 1.2.3.4/32, 1.2.3.4<br><br>Sample translations:<br><br>1.2.3 becomes 1.2.3.0/32<br>0x01020304 becomes 1.2.3.4/32<br>0x010203 becomes 0.1.2.3/32<br>default becomes 0.0.0.0/0             |

**Related Documentation** • [Entering and Exiting the Junos OS CLI Configuration Mode on page 462](#)

## Loading a Configuration from a File

You can create a file, copy the file to the local router, and then load the file into the CLI. After you have loaded the file, you can commit it to activate the configuration on the router, or you can edit the configuration interactively using the CLI and commit it at a later time.

You can also create a configuration while typing at the terminal and then load it. Loading a configuration from the terminal is generally useful when you are cutting existing portions of the configuration and pasting them elsewhere in the configuration.

To load an existing configuration file that is located on the router, use the **load** configuration mode command:

```
[edit]
user@host# load (factory-default | merge | override | patch | replace | set | update)
filename <relative>
```

For information about specifying the filename, see [“Specifying Filenames and URLs” on page 576](#).

To load a configuration from the terminal, use the following version of the **load** configuration mode command. Press Ctrl-d to end the input.

```
[edit]
user@host# load (factory-default | merge | override | patch | replace | set | update)
terminal <relative>
```

To replace an entire configuration, specify the **override** option at any level of the hierarchy. A **load override** operation completely replaces the current candidate configuration with the file you are loading. Thus, if you saved a complete configuration, use this option.

An **override** operation discards the current candidate configuration and loads the configuration in **filename** or the configuration that you type at the terminal. When you use the **override** option and commit the configuration, all system processes reparse the configuration. For an example, see [Figure 15](#).

To replace portions of a configuration, specify the **replace** option. The **load replace** operation looks for **replace:** tags that you added to the loaded file, and replaces the parts of the candidate configuration with whatever is specified after the tag. This is useful when you want more control over exactly what is being changed. For this operation to work, you must include **replace:** tags in the file or configuration you type at the terminal. The software searches for the **replace:** tags, deletes the existing statements of the same name, if any, and replaces them with the incoming configuration. If there is no existing statement of the same name, the **replace** operation adds to the configuration the statements marked with the **replace:** tag. For an example, see [Figure 16](#).

If, in an **override** or **merge** operation, you specify a file or type text that contains **replace:** tags, the **replace:** tags are ignored and the **override** or **merge** operation is performed.

If you are performing a **replace** operation and the file you specify or text you type does not contain any **replace:** tags, the **replace** operation is effectively equivalent to a **merge** operation. This might be useful if you are running automated scripts and cannot know in advance whether the scripts need to perform a **replace** or a **merge** operation. The scripts can use the **replace** operation to cover either case.

The **load merge** operation adds the saved file to the existing candidate configuration. This is useful if you are adding new configuration sections. For example, suppose that you are adding a BGP configuration to the **[edit protocols]** hierarchy level, where there was no BGP configuration before, you can use the **load merge** operation to combine the saved file configuration to the existing candidate configuration. If the existing configuration and the incoming configuration contain conflicting statements, the statements in the incoming configuration override those in the existing configuration.

To replace only the configuration that has changed, specify the **update** option at any level of the hierarchy. The **load update** operation compares the candidate configuration and the file you are loading, and only changes the parts of the candidate configuration that are different from the new configuration. You would use this, for example, if there is an existing BGP configuration and the file you are loading changes it in some way.

To change part of the configuration with a patch file, specify the **patch** option. The **load patch** operation loads a file or terminal input that contains configuration changes. First, on a device that already has the configuration changes, you type the **show | compare** command to output the differences between two configurations. Then you can load the differences on another router. The advantage of the **load patch** command is that it saves you from having to copy snippets from different hierarchy levels into a text file prior to loading them into the target device. This might be a useful time saver if you are configuring several devices with the same options. For example, suppose that you configure a routing policy on router1 and you want to replicate the policy configuration on router2, router3, and router4. You can use the **load patch** operation.

First, run the **show | compare** command.

```
user@router1# show | compare rollback 3
[edit protocols ospf]
+ export default-static;
- export static-default
[edit policy-options]
+ policy-statement default-static {
```

```
+ from protocol static;
+ then accept;
+ }
```

Copy the output of the **show | compare** command to the clipboard, making sure to include the hierarchy levels. On router2, router3, and router4, type **load patch terminal** and paste the output. Press Enter and then press Ctrl-d to end the operation. If the patch input specifies different values for an existing statement, the patch input overrides the existing statement.

To use the **merge**, **replace**, **set**, or **update** option without specifying the full hierarchy level, specify the **relative** option. For example:

```
[edit system]
user@host# show static-host-mapping
bob sysid 987.654.321ab
[edit system]
user@host# load replace terminal relative
[Type ^D at a new line to end input]
replace: static-host-mapping {
 bob sysid 0123.456.789bc;
}
load complete
[edit system]
user@host# show static-host-mapping
bob sysid 0123.456.789bc;
```

To load a configuration that contains the **set** configuration mode command, specify the **set** option. This option executes the configuration instructions line by line as they are stored in a file or from a terminal. The instructions can contain any configuration mode command, such as **set**, **edit**, **exit**, and **top**. For an example, see [Figure 19](#).

To copy a configuration file from another network system to the local router, you can use the SSH and Telnet utilities, as described in the [CLI Explorer](#).

**NOTE:** If you are using Junos OS in a Common Criteria environment, system log messages are created whenever a secret attribute is changed (for example, password changes or changes to the RADIUS shared secret). These changes are logged during the following configuration load operations:

```
load merge
load replace
load override
load update
```

For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*.

## Creating and Returning to a Rescue Configuration

A rescue configuration allows you to define a known working configuration or a configuration with a known state that you can roll back to at any time. This alleviates the necessity of having to remember the rollback number with the **rollback** command. You use the rescue configuration when you need to roll back to a known configuration or as a last resort if your router or switch configuration and the backup configuration files become damaged beyond repair.

To save the most recently committed configuration as the rescue configuration so that you can return to it at any time, issue the **request system configuration rescue save** command:

```
user@host> request system configuration rescue save
```

To return to the rescue configuration, use the **rollback rescue** configuration mode command:

```
[edit]
user@host# rollback rescue
load complete
```

**NOTE:** If the rescue configuration does not exist, or if the rescue configuration is not a complete, viable configuration, then the **rollback** command fails, an error message appears, and the current configuration remains active.

To activate the rescue configuration that you have loaded, use the **commit** command:

```
[edit]
user@host# rollback rescue
load complete
[edit]
user@host# commit
```

To delete an existing rescue configuration, issue the **request system configuration rescue delete** command:

```
user@host> request system configuration rescue delete
user@host>
```

For more information about the **request system configuration rescue delete** and **request system configuration rescue save** commands, see the [CLI Explorer](#).

### Related Documentation

- [Comparing Configuration Changes with a Prior Version on page 526](#)
- [Saving a Configuration to a File on page 539](#)

## Compressing the Current Configuration File

By default, the current operational configuration file is compressed and is stored in the file **juniper.conf.gz** the **/config** file system, along with the last three committed versions

of the configuration. If you have large networks, the current configuration file might exceed the available space in the **/config** file system. Compressing the current configuration file enables the file to fit in the file system, typically reducing the size of the file by 90 percent. You might want to compress your current operation configuration files when they reach 3 megabytes (MB) in size.

When you compress the current configuration file, the names of the configuration files change. To determine the size of the files in the **/config** file system, issue the **file list /config detail** command.

**NOTE:** We recommend that you compress the configuration files (this is the default) to minimize the amount of disk space that they require.

- If you want to compress the current configuration file, include the **compress-configuration-files** statement at the **[edit system]** hierarchy level:  

```
[edit system]
compress-configuration-files;
```
- Commit the current configuration file to include the **compression-configuration-files** statement. Commit the configuration again to compress the current configuration file:

```
[edit system]
user@host# set compress-configuration-files
user@host# commit
commit complete
user@host# commit
commit complete
```

- If you do not want to compress the current operational configuration file, include the **no-compress-configuration-files** statement at the **[edit system]** hierarchy level:  

```
[edit system]
no-compression-configuration-files;
```
- Commit the current configuration file to include the **no-compress-configuration-files** statement. Commit the configuration again to uncompress the current configuration file:

```
[edit system]
user@host# commit
commit complete
user@host# commit
commit complete
```

## Example: Protecting the Junos OS Configuration from Modification or Deletion

---

This example shows how to use the **protect** and **unprotect** commands in the configuration mode to protect and unprotect the CLI configuration.

- [Requirements on page 551](#)
- [Overview on page 551](#)
- [Protecting a Parent-Level Hierarchy on page 552](#)
- [Protecting a Child Hierarchy on page 552](#)
- [Protecting a Configuration Statement Within a Hierarchy on page 552](#)
- [Protecting a List of Identifiers for a Configuration Statement on page 553](#)
- [Protecting an Individual Member from a Homogenous List on page 553](#)
- [Unprotecting a Configuration on page 554](#)
- [Verification on page 554](#)

### Requirements

This example uses the following hardware and software components:

- A M Series, MX Series, PTX Series, or T Series device
- Junos OS 11.2 or later running on all devices

### Overview

The Junos OS enables you to protect the device configuration from being modified or deleted by other users. This can be accomplished by using the **protect** command in the configuration mode of the CLI. Likewise, you can also unprotect a protected configuration by using the **unprotect** command.

These commands can be used at any level of the configuration hierarchy—a top-level parent hierarchy or a configuration statement or an identifier within the lowest level of the hierarchy.

If a configuration hierarchy is protected, users cannot perform the following activities:

- Deleting or modifying a hierarchy or a statement or identifier within the protected hierarchy
- Inserting a new configuration statement or an identifier within the protected hierarchy
- Renaming a statement or identifier within the protected hierarchy
- Copying a configuration into a protected hierarchy
- Activating or deactivating statements within a protected hierarchy
- Annotating a protected hierarchy

## Protecting a Parent-Level Hierarchy

- Step-by-Step Procedure** To protect a configuration at the top level of the hierarchy:
- Identify the hierarchy that you want to protect and issue the **protect** command for the hierarchy at the **[edit]** hierarchy level.
- For example, if you want to protect the entire **[edit access]** hierarchy level, issue the following command:
- ```
[edit]
user@host# protect access
```
- Results** Protects all elements under the parent hierarchy.

NOTE:

- If you issue the **protect** command for a hierarchy that is not used in the configuration, the Junos OS CLI displays the following error message:
- ```
[edit]
user@host# protect access
warning: statement not found
```
- 

## Protecting a Child Hierarchy

- Step-by-Step Procedure** To protect a child hierarchy contained within a parent hierarchy:
- Navigate to the parent container hierarchy. Use the **protect** command for the hierarchy at the parent level.
- For example, if you want to protect the **[edit system syslog console]** hierarchy level, use the following command at the **[edit system syslog]** hierarchy level.
- ```
[edit system syslog]
user@host# protect console
```
- Results** Protects all elements under the child hierarchy.

Protecting a Configuration Statement Within a Hierarchy

- Step-by-Step Procedure** To protect a configuration statement within a hierarchy level:
- Navigate to the hierarchy level containing the statement that you want to protect and issue the **protect** command for the hierarchy.
- For example, if you want to protect the **host-name** statement under the **[edit system]** hierarchy level, issue the following command:
- ```
[edit system]
user@host# protect host-name
```

## Protecting a List of Identifiers for a Configuration Statement

**Step-by-Step Procedure** Some configuration statements can take multiple values. For example, the **address** statement at the **[edit system login deny-sources]** hierarchy level can take a list of hostnames, IPv4 addresses, or IPv6 addresses. Suppose you have the following configuration:

```
[edit system login]
deny-sources {
 address [172.17.28.19 172.17.28.20 172.17.28.21 172.17.28.22];
}
```

- To protect all the addresses for the **address** statement, issue the following command at the **[edit]** level:

```
[edit]
user@host# protect system login deny-sources address
```

**Results** All the addresses ([172.17.28.19 172.17.28.20 172.17.28.21 172.17.28.22]) for the **address** statement are protected.

## Protecting an Individual Member from a Homogenous List

**Step-by-Step Procedure** Suppose you have the following configuration:

```
[edit groups]
test1 {
 system {
 name-server {
 10.1.2.1;
 10.1.2.2;
 10.1.2.3;
 10.1.2.4;
 }
 }
}
```

- To protect one or more individual addresses for the **name-server** statement, issue the following command at the **[edit]** level:

```
[edit]
user@host# protect groups test1 system name-server 10.1.2.1
user@host# protect groups test1 system name-server 10.1.2.4
```

**Results** Addresses 10.1.2.1 and 10.1.2.4 are protected.

## Unprotecting a Configuration

- Step-by-Step Procedure** Suppose you have the following configuration at the **[edit system]** hierarchy level:
- ```
protect: system {
  host-name bigping;
  domain-search 10.1.2.1;
  login {
    deny-sources {
      protect: address [ 172.17.28.19 172.17.28.173 172.17.28.0 174.0.0.0 ];
    }
  }
}
```
- To unprotect the entire **[edit system]** hierarchy level, issue the following command at the **[edit]** level:

```
[edit]
user@host# unprotect system
```
- Results** The entire **system** hierarchy level is unprotected.

Verification

Verify That a Hierarchy Is Protected Using the show Command

- Purpose** To check that a configuration hierarchy is protected.
- Action** In the configuration mode, issue the **show** command at the **[edit]** hierarchy level to see all the configuration hierarchies and configuration statements that are protected.

NOTE: All protected hierarchies or statements are prefixed with a **protect:** string.

```
...
protect: system {
  host-name bigping;
  domain-search 10.1.2.1;
  login {
    deny-sources {
      protect: address [ 172.17.28.19 172.17.28.173 172.17.28.0 174.0.0.0 ];
    }
  }
}
...
```

Verify That a Hierarchy Is Protected by Attempting to Modify a Configuration

- Purpose** To verify that a configuration is protected by trying to modify the configuration using the **activate**, **copy**, **insert**, **rename**, and **delete** commands.

Action To verify that a configuration is protected:

1. Try using the **activate**, **copy**, **insert**, **rename**, and **delete** commands for a top-level hierarchy or a child-level hierarchy or a statement within the hierarchy.

For a protected hierarchy or statement, the Junos OS displays an appropriate warning that the command has not executed. For example:

```
protect: system {
  host-name a;
  inactive: domain-search [ a b ];
}
```

2. To verify that the hierarchy is protected, try issuing the **activate** command for the **domain-search** statement:

```
[edit system]
```

```
user@host# activate system domain-search
```

The Junos OS CLI displays an appropriate message:

```
warning: [system] is protected, 'system domain-search' cannot be activated
```

Verify Usage of the protect Command

Purpose To view the **protect** commands used for protecting a configuration.

- Action**
1. Navigate to the required hierarchy.
 2. Issue the **show | display set relative** command.

```
user@host> show | display set relative
set system host-name bigping
set system domain-search 10.1.2.1
set system login deny-sources address 172.17.28.19
set system login deny-sources address 172.17.28.173
set system login deny-sources address 172.17.28.0
set system login deny-sources address 174.0.0.0
protect system login deny-sources address
protect system
```

View the Configuration in XML

Purpose To check if the protected hierarchies or statements are also displayed in the XML. Protected hierarchies, statements, or identifiers are displayed with the **| display xml** attribute in the XML.

Action To view the configuration in XML:

1. Navigate to the hierarchy you want to view and issue the **show** command with the pipe symbol and option **| display xml**:

[edit system]

```
user@host# show | display xml
[edit]
user@host# show system | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/11.2IO/junos">
  <configuration junos:changed-seconds="1291279234"
junos:changed-localtime="2010-12-02 00:40:34 PST">
    <system protect="protect">
      <host-name>bigping</host-name>
      <domain-search>10.1.2.1</domain-search>
      <login>
        <message>

          \jnpr

          \tUNAUTHORIZED USE OF THIS ROUTER
          \tIS STRICTLY PROHIBITED!

        </message>
        <class>
          <name>a</name>
          <allow-commands>commit-synchronize</allow-commands>
          <deny-commands>commit</deny-commands>
        </class>
        <deny-sources>
          <address protect="protect">172.17.28.19</address>
          <address protect="protect">172.17.28.173</address>
          <address protect="protect">172.17.28.0</address>
          <address protect="protect">174.0.0.0</address>
        </deny-sources>
      </login>
      <syslog>
        <archive>
        </archive>
      </syslog>
    </system>
  </configuration>
  <cli>
    <banner>[edit]</banner>
  </cli>
</rpc-reply>
```

NOTE: Loading an XML configuration with the `unprotect="unprotect"` tag unprotects an already protected hierarchy. For example, suppose you load the following XML hierarchy:

```
<protocols unprotect="unprotect">
  <ospf>
    <area>
      <name>0.0.0.0</name>
      <interface>
        <name>all</name>
      </interface>
```

```
</area>
</ospf>
</protocols>
```

The `[edit protocols]` hierarchy becomes unprotected if it is already protected.

Synchronizing Routing Engines

If your router has two Routing Engines, you can manually direct one Routing Engine to synchronize its configuration with the other by issuing the **commit synchronize** command. The Routing Engine on which you execute this command (requesting Routing Engine) copies and loads its candidate configuration to the other (responding Routing Engine). Both Routing Engines then perform a syntax check on the candidate configuration file being committed. If no errors are found, the configuration is activated and becomes the current operational configuration on both Routing Engines.

The **commit synchronize** command does not work if the responding Routing Engine has uncommitted configuration changes. However, you can enforce commit synchronization on the Routing Engines by using the **force** option. When you issue the **commit synchronize** command with the **force** option from one Routing Engine, the configuration sessions on the other Routing Engine will be terminated and its configuration synchronized with that on the Routing Engine from which you issued the command.

NOTE: We recommend that you use the **force** option only if you are unable to resolve the issues that caused the **commit synchronize** command to fail.

For example, if you are logged in to **re1** (requesting Routing Engine) and you want **re0** (responding Routing Engine) to have the same configuration as **re1**, issue the **commit synchronize** command on **re1**. **re1** copies and loads its candidate configuration to **re0**. Both Routing Engines then perform a syntax check on the candidate configuration file being committed. If no errors are found, **re1**'s candidate configuration is activated and becomes the current operational configuration on both Routing Engines.

NOTE: When you issue the **commit synchronize** command, you must use the groups **re0** and **re1**. For information about how to use the **apply-groups** statement, see [“Applying a Junos OS Configuration Group” on page 617](#).

The responding Routing Engine must be running Junos OS Release 5.0 or later.

To synchronize a Routing Engine's current operational configuration file with the other, log in to the Routing Engine from which you want to synchronize and issue the **commit synchronize** command:

```
[edit]
user@host# commit synchronize
commit complete
[edit]
user@host#
```

NOTE: You can also add the **commit synchronize** statement at the **[edit system]** hierarchy level so that a **commit** command automatically invokes a **commit synchronize** command by default. For more information, see the *Administration Guide for Security Devices*.

To enforce a **commit synchronize** on the Routing Engines, log in to the Routing Engine from which you want to synchronize and issue the **commit synchronize** command with the **force** option:

```
[edit]
user@host# commit synchronize force
re0:
re1:
commit complete
re0:
commit complete
[edit]
user@host#
```

NOTE:

- If you have nonstop routing enabled on your router, you must enter the **commit synchronize** command from the master Routing Engine after you make any changes to the configuration. If you enter this command on the backup Routing Engine, Junos OS displays a warning and commits the configuration.
- Starting with Junos OS Release 9.3, accounting of backup Routing Engine events or operations is not supported on accounting servers such as TACACS+ or RADIUS. Accounting is only supported for events or operations on a master Routing Engine.

For the **commit** synchronization process, the master Routing Engine commits the configuration and sends a copy of the configuration to the backup Routing Engine. Then the backup Routing Engine loads and commits the configuration. So, the **commit** synchronization between the master and backup Routing Engines takes place one Routing Engine at a time. If the configuration has a large text size or many **apply-groups**, **commit** times can be longer than desired.

You can use the **commit fast-synchronize** statement to have the synchronization between the master and backup Routing Engines occur simultaneously instead of sequentially. This can reduce the time needed for synchronization because the commits on the master and backup Routing Engines occur in parallel.

Include the **fast-synchronize** statement at the **[edit system]** hierarchy level to have synchronize occur simultaneously between the master and the backup Routing Engines:

```
[edit system]
commit fast-synchronize
```

NOTE:

- If commit fails on either Routing Engine, the commit process is rolled back on the other Routing Engine as well. This ensures that both Routing Engines have the same configuration.
- When the **fast-synchronize** statement is configured, the commits on the master Routing Engine and the backup Routing Engine run in parallel. In this process, the configuration is validated only on the Routing Engine where you execute the **commit** command. Therefore, it is recommended not to include too many configuration details in groups like **re0** and **re1**, because the configuration specified in group **re0** is applied only if the current Routing Engine is in slot 0. Likewise, the configuration specified in group **re1** is applied only if the current Routing Engine is in slot 1.
- Ensure that the Junos OS software version running on both the Routing Engines is the same.

Configuring Multiple Routing Engines to Synchronize Committed Configurations Automatically

If your router or switch has multiple Routing Engines, you can manually direct one Routing Engine to synchronize its configuration with the others by issuing the **commit synchronize** command.

To make the Routing Engines synchronize automatically whenever a configuration is committed, include the **commit synchronize** statement at the **[edit system]** hierarchy level:

```
[edit system]
commit synchronize;
```

The Routing Engine on which you execute the **commit** command (requesting Routing Engine) copies and loads its candidate configuration to the other (responding) Routing Engines. All Routing Engines then perform a syntax check on the candidate configuration file being committed. If no errors are found, the configuration is activated and becomes the current operational configuration on all Routing Engines.

For the commit synchronization process, the master Routing Engine commits the configuration and sends a copy of the configuration to the backup Routing Engine. Then the backup Routing Engine loads and commits the configuration. So, the commit synchronization between the master and backup Routing Engines takes place one Routing Engine at a time. If the configuration has a large text size or many apply-groups, commit times can be longer than desired.

You can use the **commit fast-synchronize** statement to have the synchronization between the master and backup Routing Engines occur simultaneously instead of sequentially. This can reduce the time needed for synchronization because the commits on the master and backup Routing Engines occur in parallel.

Include the **fast-synchronize** statement at the **[edit system]** hierarchy level to have synchronize occur simultaneously between the master and the backup Routing Engines:

```
[edit system]
commit fast-synchronize
```

NOTE:

- If commit fails on either Routing Engine, the commit process is rolled back on the other Routing Engine as well. This ensures that both Routing Engines have the same configuration.
- When the **fast-synchronize** statement is configured, the commits on the master Routing Engine and the backup Routing Engine run in parallel. In this process, the configuration is validated only on the Routing Engine where you execute the commit command. Therefore, it is recommended not to include too many configuration details in groups like **re0** and **re1**, because the configuration specified in group **re0** is applied only if the current Routing Engine is in slot 0. Likewise, the configuration specified in group **re1** is applied only if the current Routing Engine is in slot 1.
- Ensure that the Junos OS software version running on both the Routing Engines is same.

Overview of Junos OS CLI Operational Mode Commands

This topic provides an overview of Junos OS CLI operational mode commands and contains the following sections:

- [CLI Command Categories on page 563](#)
- [Commonly Used Operational Mode Commands on page 565](#)

CLI Command Categories

When you log in to a device running Junos OS and the CLI starts, there are several broad groups of CLI commands:

- Commands for controlling the CLI environment—Some set commands in the **set** hierarchy configure the CLI display screen. For information about these commands, see [“Understanding the Junos OS CLI Modes, Commands, and Statement Hierarchies” on page 423](#).
- Commands for monitoring and troubleshooting—The following commands display information and statistics about the software and test network connectivity. Detailed command descriptions are provided in the *Junos OS Interfaces Command Reference*.
 - **clear**—Clear statistics and protocol database information.
 - **mtrace**—Trace mtrace packets from source to receiver.
 - **monitor**—Perform real-time debugging of various software components, including the routing protocols and interfaces.
 - **ping**—Determine the reachability of a remote network host.
 - **show**—Display the current configuration and information about interfaces, routing protocols, routing tables, routing policy filters, system alarms, and the chassis.
 - **test**—Test the configuration and application of policy filters and autonomous system (AS) path regular expressions.
 - **traceroute**—Trace the route to a remote network host.
- Commands for connecting to other network systems—The **ssh** command opens Secure Shell connections, and the **telnet** command opens telnet sessions to other hosts on the network. For information about these commands, see the [CLI Explorer](#).
- Commands for copying files—The **copy** command copies files from one location on the router or switch to another, from the router or switch to a remote system, or from a remote system to the router or switch. For information about these commands, see the [CLI Explorer](#).
- Commands for restarting software processes—The commands in the **restart** hierarchy restart the various Junos OS processes, including the routing protocol, interface, and SNMP. For information about these commands, see the [CLI Explorer](#).
- A command—**request**—for performing system-level operations, including stopping and rebooting the router or switch and loading Junos OS images. For information about this command, see the [CLI Explorer](#).
- A command—**start**—to exit the CLI and start a UNIX shell. For information about this command, see the [CLI Explorer](#).
- A command—**configure**—for entering configuration mode, which provides a series of commands that configure Junos OS, including the routing protocols, interfaces, network management, and user access. For information about the CLI configuration commands, see [“Understanding Junos OS CLI Configuration Mode” on page 456](#).
- A command—**quit**—to exit the CLI. For information about this command, see the [CLI Explorer](#).
- For more information about the CLI operational mode commands, see the [CLI Explorer](#).

Commonly Used Operational Mode Commands

Table 61 lists some operational commands you may find useful for monitoring router or switch operation. For a complete description of operational commands, see the Junos OS command references.

NOTE: The QFX3500 switch does not support the IS-IS, OSPF, BGP, MPLS, and RSVP protocols.

Table 61: Commonly Used Operational Mode Commands

Items to Check	Description	Command
Software version	Versions of software running on the router or switch	show version
Log files	Contents of the log files	monitor
	Log files and their contents and recent user logins	show log
Remote systems	Host reachability and network connectivity	ping
	Route to a network system	traceroute
Configuration	Current system configuration	show configuration
Manipulate files	List of files and directories on the router or switch	file list
	Contents of a file	file show
Interface information	Detailed information about interfaces	show interfaces
Chassis	Chassis alarm status	show chassis alarms
	Information currently on craft display	show chassis craft-interface
	Router or switch environment information	show chassis environment
	Hardware inventory	show chassis hardware
Routing table information	Information about entries in the routing tables	show route
Forwarding table information	Information about data in the kernel's forwarding table	show route forwarding-table
IS-IS	Adjacent routers or switches	show isis adjacency
OSPF	Display standard information about OSPF neighbors	show ospf neighbor
BGP	Display information about BGP neighbors	show bgp neighbor

Table 61: Commonly Used Operational Mode Commands (*continued*)

Items to Check	Description	Command
MPLS	Status of interfaces on which MPLS is running	show mpls interface
	Configured LSPs on the router or switch, as well as all ingress, transit, and egress LSPs	show mpls lsp
	Routes that form a label-switched path	show route label-switched-path
RSVP	Status of interfaces on which RSVP is running	show rsvp interface
	Currently active RSVP sessions	show rsvp session
	RSVP packet and error counters	show rsvp statistics

Junos OS Operational Mode Commands That Combine Other Commands

In some cases, some Junos OS operational commands are created from a combination of other operational commands. These commands can be useful shortcuts for collecting information about the device, as shown in [Figure 20](#).

Figure 20: Commands That Combine Other Commands

The **request support information** command provides output from a combination of other operational commands.

```

user@host> request support information

root@host> show system uptime

Current time: 2007-02-16 13:10:08 PST
System booted: 2007-02-02 09:21:50 PST (2w0d 03:48 ago)
Protocols started: 2007-02-02 09:24:42 PST (2w0d 03:45 ago)
Last configured: 2007-02-16 03:04:58 PST (10:05:10 ago) by root
1:10PM up 14 days, 3:48, 2 users, load averages: 0.01, 0.02, 0.00

root@host> show version detail

Hostname: host

Related Documentation

- [Overview of Junos OS CLI Operational Mode Commands on page 563](#)
- [Understanding the Brief, Detail, Extensive, and Terse Options of Junos OS Operational Commands on page 567](#)

Understanding the Brief, Detail, Extensive, and Terse Options of Junos OS Operational Commands

The Junos OS operational mode commands can include **brief**, **detail**, **extensive**, or **terse** options. You can use these options to control the amount of information you want to view.

1. Use the **?** prompt to list options available for the command. For example:

```

user@host> show interfaces fe-1/1/1 ?
Possible completions:
<[Enter]>      Execute this command
brief          Display brief output
descriptions   Display interface description strings
detail         Display detailed output
extensive      Display extensive output
media          Display media information
snmp-index     SNMP index of interface
statistics     Display statistics and detailed output
terse          Display terse output
|              Pipe through a command

```

2. Choose the option you wish to use with the command. (See [Figure 21.](#))

Figure 21: Command Output Options

Command output with the **brief** option.

```

user@host> show interfaces fe-1/1/1 brief
Physical interface: fe-1/1/1, Enabled, Physical link is Down
Link-level type: Ethernet, MTU: 1514, Speed: 100mbps, Loopback:
Disabled, Source filtering: Disabled,
Flow control: Enabled
Device flags : Present Running Down
Interface flags: Hardware-Down SNMP-Traps Internal: 0x4000
Link flags : None

```

Command output with the **terse** option.

```

user@host> show interfaces fe-1/1/1 terse
Interface      Admin Link Proto  Local      Remote
fe-1/1/1       up      down

```

Command output with the **extensive** option.

```

user@host> show interfaces fe-1/1/1 extensive
Physical interface: fe-1/1/1, Enabled, Physical link is Down
Interface index: 141, SNMP ifIndex: 33, Generation: 24
Link-level type: Ethernet, MTU: 1514, Speed: 100mbps, Loopback:
Disabled, Source filtering: Disabled,
Flow control: Enabled
Device flags : Present Running Down
Interface flags: Hardware-Down SNMP-Traps Internal: 0x4000
Link flags : None
CoS queues : 4 supported, 4 maximum usable queues
Hold-times : Up 0 ms, Down 0 ms
Current address: 00:90:69:d0:f8:9e, Hardware address: 00:90:69:d0:f8:9e
Last flapped : 2007-02-02 09:26:25 PST (2w0d 03:40 ago)
Statistics last cleared: Never
Traffic statistics:
Input bytes :                0                0 bps
Output bytes :                0                0 bps
Input packets:                0                0 pps
Output packets:              0                0 pps

- [Controlling the Scope of an Operational Mode Command on page 568](#)

Controlling the Scope of an Operational Mode Command

The Junos OS CLI operational commands include options that you can use to identify specific components on a device running Junos OS. For example:

1. Type the **show interfaces** command to display information about all interfaces on the router.

```

user@host> show interfaces
Physical interface: so-0/0/0, Enabled, Physical link is Up
Interface index: 128, SNMP ifIndex: 23
Link-level type: PPP, MTU: 4474, Clocking: Internal, SONET mode, Speed: OC3,
Loopback: None, FCS: 16, Payload scrambler: Enabled
Device flags : Present Running
Interface flags: Point-To-Point SNMP-Traps Internal: 0x4000
Link flags : Keepalives
Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
Keepalive: Input: 13861 (00:00:05 ago), Output: 13891 (00:00:01 ago)
LCP state: Opened
NCP state: inet: Opened, inet6: Not-configured, iso: Opened, mppls:
Not-configured
CHAP state: Closed
PAP state: Closed

```

```

CoS queues      : 4 supported, 4 maximum usable queues
Last flapped    : 2008-06-02 17:16:14 PDT (1d 14:21 ago)
Input rate      : 40 bps (0 pps)
Output rate     : 48 bps (0 pps)

```

---(more)---

2. To display information about a specific interface, type that interface as a command option:

```

user@host> show interfaces fe-0/1/3
Physical interface: fe-0/1/3, Enabled, Physical link is Up
  Interface index: 135, SNMP ifIndex: 30
  Link-level type: Ethernet, MTU: 1514, Speed: 100mbps, MAC-REWRITE Error:
None,
  Loopback: Disabled, Source filtering: Disabled, Flow control: Enabled
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Link flags     : None
  CoS queues     : 4 supported, 4 maximum usable queues
  Current address: 00:05:85:8f:c8:22, Hardware address: 00:05:85:8f:c8:22
  Last flapped   : 2008-06-02 17:16:15 PDT (1d 14:28 ago)
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  Active alarms  : None
  Active defects : None

user@host>

```

Operational Mode Commands on a TX Matrix Router or TX Matrix Plus Router

When you issue operational mode commands on the TX Matrix router, CLI command options allow you to restrict the command output to show only a component of the routing matrix rather than the routing matrix as a whole.

These are the options shown in the CLI:

- **scc**—The TX Matrix router (or switch-card chassis)
- **sfc**—The TX Matrix Plus router (also referred to as or switch-fabric chassis)
- **lcc number**—A specific router in a routing matrix based on a TX Matrix router or a TX Matrix Plus router.
- **all-lcc**—All T640 routers (in a routing matrix based on a TX Matrix router) or all T1600 routers or T4000 routers (in a routing matrix based on a TX Matrix Plus router).

If you specify none of these options, then the command applies by default to the whole routing matrix.

Examples of Routing Matrix Command Options

The following output samples, using the **show version** command, demonstrate some different options for viewing information about the routing matrix.

```

user@host> show version ?
Possible completions:
  <[Enter]>      Execute this command
  all-lcc       Show software version on all LCC chassis

```

brief	Display brief output
detail	Display detailed output
lcc	Show software version on specific LCC (0..3)
scc	Show software version on the SCC
	Pipe through a command

Sample Output: No Routing Matrix Options Specified

```

Monitoring Who Uses the Junos OS CLI

Depending upon how you configure Junos OS, multiple users can log in to the router, use the CLI, and configure or modify the software configuration.

If, when you enter configuration mode, another user is also in configuration mode, a notification message is displayed that indicates who the user is and what portion of the configuration the person is viewing or editing:

```
user@host> configure
Entering configuration mode
```

```
Users currently editing the configuration:
  root terminal d0 (pid 4137) on since 2008-04-09 23:03:07 PDT, idle 7w6d 08:22
    [edit]
The configuration has been changed but not committed

[edit]
user@host#
```

Interface Naming Conventions Used in the Junos OS Operational Commands

This topic explains the interface naming conventions used in the Junos OS operational commands, and contains the following sections:

- [Physical Part of an Interface Name on page 572](#)
- [Logical Part of an Interface Name on page 572](#)
- [Channel Identifier Part of an Interface Name on page 573](#)

Physical Part of an Interface Name

The physical interface naming conventions for Junos OS platforms is as follows:

- On SRX devices, the unique name of each network interface has the following format to identify the physical device that corresponds to a single physical network connector:

type-slot/pim-or-ioc/port

- On other platforms, when you display information about an interface, you specify the interface type, the slot in which the Flexible PIC Concentrator (FPC) is installed, the slot on the FPC in which the PIC is located, and the configured port number.

In the physical part of the interface name, a hyphen (-) separates the media type from the FPC number, and a slash (/) separates the FPC, PIC, and port numbers:

type-fpc/pic/port

NOTE: Exceptions to the ***type-fpc/pic/port*** physical description include the aggregated Ethernet and aggregated SONET/SDH interfaces, which use the syntax ***aenumber*** and ***asnumber***, respectively.

Logical Part of an Interface Name

The logical unit part of the interface name corresponds to the logical unit number, which can be a number from 0 through 16,384. In the virtual part of the name, a period (.) separates the port and logical unit numbers:

- SRX devices:

type-slot/pim-or-ioc/port:channel.unit

- Other platforms:

type-fpc/pic/port.logical

Channel Identifier Part of an Interface Name

The channel identifier part of the interface name is required only on channelized interfaces. For channelized interfaces, channel 0 identifies the first channelized interface. For channelized intelligent queuing (IQ) interfaces, channel 1 identifies the first channelized interface.

NOTE: Depending on the type of channelized interface, up to three levels of channelization can be specified. For more information, see the *Junos Network Interfaces Configuration Guide*.

A colon (:) separates the physical and virtual parts of the interface name:

- SRX devices:

type-slot/pim-or-ioc/port:channel
type-slot/pim-or-ioc/port:channel:channel
type-slot/pim-or-ioc/port:channel:channel:channel

- Other platforms:

type-fpc/pic/port:channel
type-fpc//pic/port:channel:channel
type-fpc/pic/port:channel:channel:channel

Viewing Files and Directories on a Device Running Junos OS

Junos OS stores information in files on the device, including configuration files, log files, and router software files. This topic shows some examples of operational commands that you can use to view files and directories on a device running Junos OS.

Sections include:

- [Directories on the Router or Switch on page 573](#)
- [Listing Files and Directories on page 574](#)
- [Specifying Filenames and URLs on page 576](#)

Directories on the Router or Switch

Table 62 lists some standard directories on a device running Junos OS.

Table 62: Directories on the Router

Directory	Description
<code>/config</code>	This directory is located on the device's router's internal flash drive. It contains the active configuration (juniper.conf) and rollback files 1, 2, and 3.
<code>/var/db/config</code>	This directory is located on the router's device's hard drive and contains rollback files 4 through 49.
<code>/var/tmp</code>	This directory is located on the device's hard drive. It holds core files from the various processes on the Routing Engines. Core files are generated when a particular process crashes and are used by Juniper Networks engineers to diagnose the reason for failure.
<code>/var/log</code>	This directory is located on the device's hard drive. It contains files generated by both the device's logging function as well as the traceoptions command.
<code>/var/home</code>	This directory is located on the device's hard drive. It contains a subdirectory for each configured user on the device. These individual user directories are the default file location for many Junos OS commands.
<code>/altroot</code>	This directory is located on the device's hard drive and contains a copy of the root file structure from the internal flash drive. This directory is used in certain disaster recovery modes where the internal flash drive is not operational.
<code>/altconfig</code>	This directory is located on the device's hard drive and contains a copy of the <code>/config</code> file structure from the internal flash drive. This directory is also used in certain disaster recovery modes when the internal flash drive is not operational.

Listing Files and Directories

You can view the device's directory structure as well as individual files by issuing the **file** command in operational mode.

- To get help about the **file** command, type the following:

```

user@host> file ?
Possible completions:
<[Enter]>      Execute this command
archive       Archives files from the system
checksum      Calculate file checksum
compare       Compare files
copy          Copy files (local or remote)
delete        Delete files from the system
list          List file information
rename        Rename files
show          Show file contents
source-address Local address to use in originating the connection
|            Pipe through a command
user@host> file

```

Help shows that the **file** command includes several options for manipulating files.

2. Use the **list** option to see the directory structure of the device. For example, to show the files located in your home directory on the device:

```
user@host> file list
.ssh/
common
```

The default directory for the **file list** command is the home directory of the user logged in to the device. In fact, the user's home directory is the default directory for most of Junos OS commands requiring a filename.

3. To view the contents of other file directories, specify the directory location. For example:

```
user@host> file list /config
juniper.conf
juniper.conf.1.gz
juniper.conf.2.gz
juniper.conf.3.gz
```

4. You can also use the device's context-sensitive help system to locate a directory. For example:

```
user@host> file list /?
Possible completions:
<[Enter]>      Execute this command
<path>        Path to list

...

```

Specifying Filenames and URLs

In some CLI commands and configuration statements—including **file copy**, **file archive**, **load**, **save**, **set system login user *username* authentication *load-key-file***, and **request system software add**—you can include a filename. On a routing matrix, you can include chassis information as part of the filename (for example, **lcc0**, **lcc0-re0**, or **lcc0-re1**).

You can specify a filename or URL in one of the following ways:

- **filename**—File in the user's current directory on the local flash drive. You can use wildcards to specify multiple source files or a single destination file. Wildcards are not supported in Hypertext Transfer Protocol (HTTP) or FTP.

NOTE: Wildcards are supported only by the **file** (**compare** | **copy** | **delete** | **list** | **rename** | **show**) commands. When you issue the **file show** command with a wildcard, it must resolve to one filename.

- **path/filename**—File on the local flash disk.
- **/var/filename** or **/var/path/filename**—File on the local hard disk. You can also specify a file on a local Routing Engine for a specific T640 router on a routing matrix:

```
user@host> file delete lcc0-re0:/var/tmp/junk
```
- **a:filename** or **a:path/filename**—File on the local drive. The default path is / (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format.
- **hostname:/path/filename**, **hostname:filename**, **hostname:path/filename**, or **scp://hostname/path/filename**—File on an scp/ssh client. This form is not available in the worldwide version of Junos OS. The default path is the user's home directory on the remote system. You can also specify **hostname** as **username@hostname**.
- **ftp://hostname/path/filename**—File on an FTP server. You can also specify **hostname** as **username@hostname** or **username:password@hostname**. The default path is the user's home directory. To specify an absolute path, the path must start with **%2F**; for example, **ftp://hostname/%2Fpath/filename**. To have the system prompt you for the password, specify **prompt** in place of the password. If a password is required, and you do not specify the password or **prompt**, an error message is displayed:

```
user@host> file copy ftp://username@ftp.hostname.net//filename
file copy ftp.hostname.net: Not logged in.

user@host> file copy ftp://username:prompt@ftp.hostname.net//filename
Password for username@ftp.hostname.net:
```
- **http://hostname/path/filename**—File on an HTTP server. You can also specify **hostname** as **username@hostname** or **username:password@hostname**. If a password is required and you omit it, you are prompted for it.
- **re0:/path/filename** or **re1:/path/filename**—File on a local Routing Engine. You can also specify a file on a local Routing Engine for a specific T640 router on a routing matrix:

```
user@host> show log lcc0-re1:chassisd
```

Documentation

- [Displaying Junos OS Information on page 577](#)

Displaying Junos OS Information

You can display Junos OS version information and other status to determine if the version of Junos OS that you are running supports particular features or hardware.

To display Junos OS information:

1. Make sure you are in operational mode.
2. To display brief information and status for the kernel and Packet Forwarding Engine, enter the **show version brief** command. This command shows version information for Junos OS packages installed on the router. For example:

```
user@host> show version brief
Hostname: host
Model: m7i
JUNOS Base OS boot [9.1R1.8]
JUNOS Base OS Software Suite [9.1R1.8]
JUNOS Kernel Software Suite [9.1R1.8]
JUNOS Crypto Software Suite [9.1R1.8]
JUNOS Packet Forwarding Engine Support (M/T Common) [9.1R1.8]
JUNOS Packet Forwarding Engine Support (M7i/M10i) [9.1R1.8]
JUNOS Online Documentation [9.1R1.8]
JUNOS Routing Software Suite [9.1R1.8]
```

```
user@host>
```

If the **Junos Crypto Software Suite** is listed, the router has Canada and USA encrypted Junos OS. If the **Junos Crypto Software Suite** is not listed, the router is running worldwide nonencrypted Junos OS.

3. To display detailed version information, enter the **show version detail** command. This command display shows the hostname and version information for Junos OS packages installed on your router. It also includes the version information for each software process. For example:

```
user@host> show version detail

Hostname: host
Model: m20
JUNOS Base OS boot [8.4R1.13]
JUNOS Base OS Software Suite [8.4R1.13]
JUNOS Kernel Software Suite [8.4R1.13]
JUNOS Crypto Software Suite [8.4R1.13]
JUNOS Packet Forwarding Engine Support (M/T Common) [8.4R1.13]
JUNOS Packet Forwarding Engine Support (M20/M40) [8.4R1.13]
JUNOS Online Documentation [8.4R1.13]

Managing Programs and Processes Using Junos OS Operational Mode Commands

This topic shows some examples of Junos operational commands that you can use to manage programs and processes on a device running Junos OS.

Sections include:

- [Showing Software Processes on page 580](#)
- [Restarting the Junos OS Process on page 581](#)
- [Stopping Junos OS on page 582](#)
- [Rebooting Junos OS on page 583](#)

Showing Software Processes

To verify system operation or to begin diagnosing an error condition, you may need to display information about software processes running on the device.

To show software processes:

1. Make sure you are in operational mode.
2. Type the **show system processes extensive** command. This command shows the CPU utilization on the device and lists the processes in order of CPU utilization. For example:

```
user@host> show system processes extensive
```

```
Last pid: 28689; load averages: 0.01, 0.00, 0.00 up 56+06:16:13 04:52:04
73 processes: 1 running, 72 sleeping
```

```
Mem: 101M Active, 101M Inact, 98M Wired, 159M Cache, 69M Buf, 286M Free
Swap: 1536M Total, 1536M Free
```

PID	USERNAME	PRI	NICE	SIZE	RES	STATE	TIME	WCPU	CPU	COMMAND
3365	root	2	0	21408K	4464K	select	511:23	0.00%	0.00%	chassisd
3508	root	2	0	3352K	1168K	select	32:45	0.00%	0.00%	l2ald
3525	root	2	0	3904K	1620K	select	13:40	0.00%	0.00%	dcd
5532	root	2	0	11660K	2856K	kqread	10:36	0.00%	0.00%	rpd
3366	root	2	0	2080K	828K	select	8:33	0.00%	0.00%	alarmd

---(more)---

Table 63 lists and describes the output fields included in this example. The fields are listed in alphabetical order.

Table 63: show system process extensive Command Output Fields

Field	Description
COMMAND	Command that is running.
CPU	Raw (unweighted) CPU usage. The value of this field is used to sort the processes in the output.
last pid	Last process identifier assigned to the process.
load averages	Three load averages, followed by the current time.
Mem	Information about physical and virtual memory allocation.
NICE	UNIX “nice” value. The nice value allows a process to change its final scheduling priority.
PID	Process identifier.
PRI	Current kernel scheduling priority of the process. A lower number indicates a higher priority.
processes	Number of existing processes and the number of processes in each state (sleeping , running , starting , zombies , and stopped).
RES	Current amount of resident memory, in KB.
SIZE	Total size of the process (text , data , and stack), in KB.
STATE	Current state of the process (sleep , wait , run , idle , zombi , or stop).
Swap	Information about physical and virtual memory allocation.
USERNAME	Owner of the process.
WCPU	Weighted CPU usage.

Restarting the Junos OS Process

To correct an error condition, you might need to restart a software process running on the device. You can use the **restart** command to force a restart of a software process.

CAUTION: Do not restart a software process unless specifically asked to do so by your Juniper Networks customer support representative. Restarting a software process during normal operation of a device could cause interruption of packet forwarding and loss of data.

To restart a software process:

1. Make sure you are in operational mode.
2. Type the following command:

```
user@host> restart process-name < (immediately | gracefully | soft) >
```

- **process-name** is the name of the process that you want to restart. For example, **routing** or **class-of-service**. You can use the command completion feature of Junos OS to see a list of software processes that you can restart using this command.
- **gracefully** restarts the software process after performing clean-up tasks.
- **immediately** restarts the software process without performing any clean-up tasks.
- **soft** rereads and reactivates the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant.

The following example shows how to restart the routing process:

```
user@host> restart routing
Routing protocol daemon started, pid 751
```

When a process restarts, the process identifier (PID) is updated. (See [Figure 22](#).)

Figure 22: Restarting a Process

PID	USERNAME	PRI	NICE	SIZE	RES	STATE	TIME	WCPU	CPU	COMMAND
546	root	10	0	9096K	1720K	nanslp	0:21	0.00%	0.00%	chassisd
685	root	2	0	12716K	3840K	kqread	0:01	0.00%	0.00%	rpdp
553	root	2	0	8792K	1544K	select	0:01	0.00%	0.00%	mib2d

PID before restart

547	root	2	0	7732K	888K	select	0:00	0.00%	0.00%	alarmd
545	root	2	0	10292K	2268K	select	0:00	0.00%	0.00%	dcd
1	root	10	0	816K	520K	wait	0:00	0.00%	0.00%	init
550	root	2	-12	1308K	692K	select	0:00	0.00%	0.00%	ntpd
758	root	32	0	21716K	832K	RUN	0:00	0.00%	0.00%	top
560	root	2	0	8208K	1088K	select	0:00	0.00%	0.00%	rmopd
561	root	2	0	8188K	1156K	select	0:00	0.00%	0.00%	cosd
559	root	2	0	1632K	840K	select	0:00	0.00%	0.00%	ilmid
573	lab	2	0	7480K	2580K	select	0:00	0.00%	0.00%	cli
751	root	2	0	12716K	3944K	kqread	0:00	0.00%	0.00%	rpdp
558	root	2	20	8708K	1880K	select	0:00	0.00%	0.00%	sampld
555	root	2	0	1856K	932K	select	0:00	0.00%	0.00%	vrpd
686	root	2	0	7808K	940K	select	0:00	0.00%	0.00%	apsd

PID after restart

Stopping Junos OS

To avoid damage to the file system and to prevent loss of data, you must always gracefully shut down Junos OS before powering off the device.

NOTE: SRX Series Services Gateway devices for the branch and EX Series Ethernet Switches support resilient dual-root partitioning.

If you are unable to shut down a device gracefully because of unexpected circumstances such as a power outage or a device failure, resilient dual-root partitioning prevents file corruption and enables a device to remain operational. In addition, it enables a device to boot transparently from the second root partition if the system fails to boot from the primary root partition.

Resilient dual-root partitioning serves as a backup mechanism for providing additional resiliency to a device when there is an abnormal shutdown. However, it is not an alternative to performing a graceful shutdown under normal circumstances.

To stop Junos OS:

1. Make sure you are in operational mode.
2. Enter the **request system halt** command. This command stops all system processes and halts the operating system. For example:

```
user@host> request system halt
Halt the system? [yes,no] (no) yes
shutdown: [pid 3110]
Shutdown NOW!
*** FINAL System shutdown message from root@host ***
System going down IMMEDIATELY
user@host> Dec 17 17:28:40 init: syslogd (PID 2514) exited with status=0 Normal
Exit
Waiting (max 60 seconds) for system process `bufdaemon' to stop...stopped
Waiting (max 60 seconds) for system process `syncer' to stop...stopped
syncing disks... 4
done
Uptime: 3h31m41s
ata0: resetting devices.. done
The operating system has halted.
Please press any key to reboot.
```

Rebooting Junos OS

After a software upgrade or to recover (occasionally) from an error condition, you must reboot Junos OS.

To reboot Junos OS:

1. Make sure you are in operational mode.
2. Enter the **request system reboot** command. This command displays the final stages of the system shutdown and executes the reboot. Reboot requests are recorded to the system log files, which you can view with the **show log messages** command. For example:

```
user@host> request system reboot
Reboot the system? [yes,no] (no) yes
```

```
shutdown: [pid 845]
Shutdown NOW!
*** FINAL System shutdown message from root@host ***
System going down IMMEDIATELY
user@host> Dec 17 17:34:20 init: syslogd (PID 409) exited with status=0 Normal
Exit
Waiting (max 60 seconds) for system process `bufdaemon' to stop...stopped
Waiting (max 60 seconds) for system process `syncer' to stop...stopped
syncing disks... 10 6
done
Uptime: 2m45s
ata0: resetting devices.. done
Rebooting...
```

Using the Junos OS CLI Comment Character # for Operational Mode Commands

The comment character in Junos OS enables you to copy operational mode commands that include comments from a file and paste them into the CLI. A pound sign (#) at the beginning of the command-line indicates a comment line. This is useful for describing frequently used operational mode commands; for example, a user's work instructions on how to monitor the network. To add a comment to a command file, the first character of the line must be #. When you start a command with #, the rest of the line is disregarded by Junos OS.

To add comments in operational mode, start with a # and end with a new line (carriage return):

```
user@host> # comment-string
```

comment-string is the text of the comment. The comment text can be any length, but each comment line must begin with a #.

Example: Using Comments in Junos OS Operational Mode Commands

The following example shows how to use comments in a file:

```
#Command 1: Show the router version
show version
#Command 2: Show all router interfaces
show interfaces terse
```

The following example shows how to copy and paste contents of a file into the CLI:

```
user@host> #Command 1: Show the router version
user@host> show version
Hostname: myhost
Model: m5
```

```

Filtering Command Output

- [Using the Pipe \(| \) Symbol to Filter Junos OS Command Output on page 587](#)
- [Using Regular Expressions with the Pipe \(| \) Symbol to Filter Junos OS Command Output on page 588](#)
- [Filtering Operational Mode Command Output in a QFabric System on page 589](#)
- [Pipe \(| \) Filter Functions in the Junos OS Command-Line Interface on page 590](#)

Using the Pipe (|) Symbol to Filter Junos OS Command Output

The Junos OS enables you to filter command output by adding the pipe (|) symbol when you enter a command.

For example:

```
user@host> show rip neighbor ?
Possible completions:
<[Enter]>      Execute this command
<name>         Name of RIP neighbor
instance       Name of RIP instance
logical-system Name of logical system, or 'all'
|              Pipe through a command
```

The following example lists the filters that can be used with the pipe symbol (|):

```
user@host> show interfaces | ?
user@host> show interfaces | ?
Possible completions:
append      Append output text to file
count       Count occurrences
display     Show additional kinds of information
except      Show only text that does not match a pattern
find        Search for first occurrence of pattern
hold        Hold text without exiting the --More-- prompt
last        Display end of output only
match       Show only text that matches a pattern
no-more     Don't paginate output
refresh     Refresh a continuous display of the command
request     Make system-level requests
resolve     Resolve IP addresses
save        Save output text to file
tee         Write to standard output and file
trim        Trim specified number of columns from start of line
```

For the **show configuration** command only, an additional compare filter is available:

```
user@host> show configuration | ?
Possible completions:
  compare          Compare configuration changes with prior version
  ...
```

You can enter any of the pipe filters in conjunction. For example:

```
user@host> command | match regular-expression | save filename
```

NOTE: This topic describes *only* the filters that can be used for operational mode command output. For information about filters that can be used in configuration mode, see the *Junos OS Administration Library for Routing Devices*.

Using Regular Expressions with the Pipe (|) Symbol to Filter Junos OS Command Output

The **except**, **find**, and **match** filters used with the pipe symbol employ regular expressions to filter output. Juniper Networks uses the regular expressions as defined in POSIX 1003.2. If the regular expressions contain spaces, operators, or wildcard characters, enclose the expression in quotation marks.

Table 64: Common Regular Expression Operators in Operational Mode Commands

Operator	Function
	Indicates that a match can be one of the two terms on either side of the pipe.
^	Used at the beginning of an expression, denotes where a match should begin.
\$	Used at the end of an expression, denotes that a term must be matched exactly up to the point of the \$ character.
[]	Specifies a range of letters or digits to match. To separate the start and end of a range, use a hyphen (-).
()	Specifies a group of terms to match.

For example, if a command produces the following output:

```

12
22
321
4

```

a pipe filter of **| match 2** displays the following output:

```

12
22
321

```

and a pipe filter of **| except 1** displays the following output:

```

22
4

```

- [Pipe \(| \) Filter Functions in the Junos OS Command-Line Interface on page 590](#)

Filtering Operational Mode Command Output in a QFabric System

When you issue an operational mode command in a QFabric system, the output generated can be fairly extensive because of the number of components contained within the system. To make the output more accessible, you can filter the output by appending the **| filter** option to the end of most Junos OS commands.

1. To filter operational mode command output and limit it to a Node group, include the **| filter node-group *node-group-name*** option at the end of your Junos OS operational mode command.

```
root@qfabric> show interfaces terse | filter node-group NW-NG-0
```

Interface	Admin	Link	Proto	Local	Remote
NW-NG-0:dsc	up	up			
NW-NG-0:em0	up	up			
NW-NG-0:em1	up	up			
NW-NG-0:gre	up	up			
NW-NG-0:ipip	up	up			
NW-NG-0:lo0	up	up			
NW-NG-0:lo0.16384	up	up	inet	127.0.0.1	--> 0/0
NW-NG-0:lo0.16385	up	up	inet		
NW-NG-0:lsi	up	up			
NW-NG-0:mtun	up	up			
NW-NG-0:pimd	up	up			
NW-NG-0:pime	up	up			
NW-NG-0:tap	up	up			
Node01:ge-0/0/10	up	up			
Node01:ge-0/0/40	up	up			
Node01:ge-0/0/41	up	up			
vlan	up	up			

2. To filter operational mode command output and limit it to a set of Node groups, include the **| filter node-group** option at the end of your Junos OS operational mode command and specify the list of Node group names in brackets.

```
root@qfabric> show ethernet-switching interfaces | filter node-group [NW-NG-0 RSNG-1]
```

Interface	State	VLAN members	Tag	Tagging	Blocking
NW-NG-0:ae0.0	up	v200	200	tagged	unblocked
		v50	50	tagged	unblocked
		v51	51	tagged	unblocked
		v52	52	tagged	unblocked
		v53	53	tagged	unblocked
RSNG-1:ae0.0	up	v200	200	untagged	unblocked
RSNG-1:ae47.0	up	v50	50	tagged	unblocked
		v51	51	tagged	unblocked
		v52	52	tagged	unblocked
		v53	53	tagged	unblocked

- [Refreshing the Output of a Command on page 597](#)

Comparing Configurations and Displaying the Differences in Text

The **compare** filter compares the candidate configuration with either the current committed configuration or a configuration file and displays the differences between

the two configurations with text characters. To compare configurations, enter **compare** after the pipe (|) symbol:

```
[edit]
user@host# show | compare [filename] rollback n]
```

filename is the full path to a configuration file.

n is the index into the list of previously committed configurations. The most recently saved configuration is 0. If you do not specify arguments, the candidate configuration is compared against the active configuration file (**/config/juniper.conf**).

The comparison output uses the following conventions:

- Statements that are only in the candidate configuration are prefixed with a plus sign (+).
- Statements that are only in the comparison file are prefixed with a minus sign (-).
- Statements that are unchanged are prefixed with a single blank space ().

For example:

```
user@host> show configuration system | compare rollback 9
[edit system]
+ host-name device;
+ backup-router 192.168.71.254;
- ports {
-     console log-out-on-disconnect;
- }
[edit system name-server]
+ 172.17.28.11;
  172.17.28.101 { ... }
[edit system name-server]
  172.17.28.101 { ... }
+ 172.17.28.100;
+ 172.17.28.10;
[edit system]
- scripts {
-     commit {
-         allow-transients;
-     }
- }
+ services {
+     ftp;
+     rlogin;
+     rsh;
+     telnet;
+ }
```

Starting with Junos OS Release 8.3, output from the **show | compare** command has been enhanced to more accurately reflect configuration changes. This includes more intelligent handling of order changes in lists. For example, consider names in a group that are reordered as follows:

```
groups {      groups {
group_xmp;    group_xmp;
group_cmp;    group_grp:
group_grp;    group_cmp;
}             }
```

In previous releases, output from the **show | compare** command looked like the following:

```
[edit groups]
- group_xmp;
- group_cmp;
- group_grp;
+ group_xmp;
+ group_grp;
+ group_cmp;
```

Now, output from the **show | compare** command looks like the following:

```
[edit groups]
group_xmp {...}
! group_grp {...}
```

Comparing Configurations and Displaying the Differences in XML

The **compare | display xml** filter compares the candidate configuration with the current committed configuration and displays the differences between the two configurations in XML. To compare configurations, enter **compare | display xml** after the pipe (|) symbol in either operational or configuration mode.

Example in operational mode:

```
user@host> show configuration | compare | display xml
```

Example in configuration mode:

```
[edit]
user@host# show | compare | display xml
```

You can enter a specific configuration hierarchy prior to **| compare**. In configuration mode, you can navigate to a hierarchy where the command is applied.

For a description of the XML output, see [“Understanding the show | compare | display xml Command Output” on page 528](#).

Counting the Number of Lines of Output

To count the number of lines in the output from a command, enter **count** after the pipe symbol (|). For example:

```
user@host> show configuration | count
Count: 269 lines
```

Displaying Output in XML Tag Format

To display command output in XML tag format, enter **display xml** after the pipe symbol (|).

The following example displays the **show cli directory** command output as XML tags:

```
user@host> show cli directory | display xml
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/7.5I0/junos">
  <cli>
    <working-directory>/var/home/user</working-directory>
  </cli>
```

```

    <cli>
      <banner></banner>
    </cli>
  </rpc-reply>

```

To display the change in the candidate and active configurations in XML tag format, see [“Comparing Configurations and Displaying the Differences in XML” on page 592](#)

Displaying Output in JSON Format

To display command output in JavaScript Object Notation (JSON) format, enter **display json** after the pipe symbol (|).

The following example displays the **show cli directory** command output in JSON format:

```
user@host> show cli directory | display json
```

```

{
  "cli" : [
    {
      "working-directory" : [
        {
          "data" : "/var/home/username"
        }
      ]
    }
  ]
}

```

Displaying the RPC tags for a Command

To display the remote procedure call (RPC) XML tags for an operational mode command, enter **display xml rpc** after the pipe symbol (|).

The following example displays the RPC tags for the **show route** command:

```

user@host> show route | display xml rpc
<rpc-reply xmlns:junos="http://xml.juniper.net/junos/10.1I0/junos">
  <rpc>
    <get-route-information>
    </get-route-information>
  </rpc>
  <cli>
    <banner></banner>
  </cli>
</rpc-reply>

```

Ignoring Output That Does Not Match a Regular Expression

To ignore text that matches a regular expression, specify the **except** command after the pipe symbol (|). If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For information on common regular expression operators, see [“Using Regular Expressions with the Pipe \(| \) Symbol to Filter Junos OS Command Output” on page 588](#).

The following example displays all users who are logged in to the router, except for the user **root**:

```
user@host> show system users | except root
 8:28PM up 1 day, 13:59, 2 users, load averages: 0.01, 0.01, 0.00
USER   TTY FROM                LOGIN@  IDLE WHAT
user   p0  device1.example.com  7:25PM    - cli
```

Displaying Output from the First Match of a Regular Expression

To display output starting with the first occurrence of text matching a regular expression, enter **find** after the pipe symbol (|). If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For information on common regular expression operators, see [“Using Regular Expressions with the Pipe \(| \) Symbol to Filter Junos OS Command Output” on page 588](#).

The following example displays the routes in the routing table starting at IP address **208.197.169.0**:

```
user@host> show route | find 208.197.169.0
208.197.169.0/24    *[Static/5] 1d 13:22:11
                  > to 192.168.4.254 via so-3/0/0.0
224.0.0.5/32      *[OSPF/10] 1d 13:22:12, metric 1
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
47.0005.80ff.f800.0000.0108.0001.1921.6800.4015.00/160
                  *[Direct/0] 1d 13:22:12
                  > via lo0.0
```

The following example displays the first CCC entry in the forwarding table:

```
user@host> show route forwarding-table | find ccc
Routing table: ccc
MPLS:
Interface.Label   Type RtRef Nexthop          Type Index NhRef Netif
default           perm  0          10.0.16.2                rjct   3    1
0                 user  0          10.0.16.2                recv   5    2
1                 user  0          10.0.16.2                recv   5    2
32769             user  0          10.0.16.2                ucst   45   1 fe-0/0/0.534
fe-0/0/0. (CCC)   user  0          10.0.16.2                indr   44   2
                                     Push 32768, Push
```

Retaining Output After the Last Screen

To not return immediately to the CLI prompt after viewing the last screen of output, enter **hold** after the pipe symbol (|). The following example prevents returning to the CLI prompt after you have viewed the last screen of output from the **show log log-file-1** command:

```
user@host> show log log-file-1 | hold
```

This filter is useful when you want to scroll or search through output.

Displaying Output Beginning with the Last Entries

To display text starting from the end of the output, enter **last <lines>** after the pipe symbol (|).

The following example displays the last entries in **log-file-1** file:

```
user@host> show log log-file-1 | last
```

This filter is useful for viewing log files in which the end of the file contains the most recent entries.

NOTE: When the number of lines requested is less than the number of lines that the screen length setting permits you to display, Junos returns as many lines as permitted by the screen length setting. That is, if your screen length is set to 20 lines and you have requested only the last 10 lines, Junos returns the last 19 lines instead of the last 10 lines.

Displaying Output That Matches a Regular Expression

To display output that matches a regular expression, enter **match *regular-expression*** after the pipe symbol (|). If the regular expression contains any spaces, operators, or wildcard characters, enclose it in quotation marks. For information on common regular expression operators, see [“Using Regular Expressions with the Pipe \(| \) Symbol to Filter Junos OS Command Output” on page 588](#).

The following example matches all the Asynchronous Transfer Mode (ATM) interfaces in the configuration:

```
user@host> show configuration | match at-
at-2/1/0 {
at-2/1/1 {
at-2/2/0 {
at-5/2/0 {
at-5/3/0 {
```

Preventing Output from Being Paginated

By default, if output is longer than the length of the terminal screen, you are provided with a **---(more)---** message to display the remaining output. To display the remaining output, press the Spacebar.

To prevent the output from being paginated, enter **no-more** after the pipe symbol (|).

The following example displays output from the **show configuration** command all at once:

```
user@host> show configuration | no-more
```

This feature is useful, for example, if you want to copy the entire output and paste it into an e-mail.

Sending Command Output to Other Users

To display command output on the terminal of a specific user logged in to your router, or on the terminals of all users logged in to your router, enter **request message (all | user *account@terminal*)** after the pipe symbol (|).

If you are troubleshooting your router and, for example, talking with a customer service representative on the phone, you can use the **request message** command to send your representative the command output you are currently viewing on your terminal.

The following example sends the output from the **show interfaces** command you enter on your terminal to the terminal of the user **root@tty1**:

```
user@host> show interfaces | request message user root@tty1
```

The user **root@tty1** sees the following output appear on the terminal screen:

```
Message from user@host on /dev/tty0 at 10:32 PST...
Physical interface: dsc, Enabled, Physical link is Up
  Interface index: 5, SNMP ifIndex: 5
  Type: Software-Pseudo, MTU: Unlimited...
```

Resolving IP Addresses

In operational mode only, if the output of a command displays an unresolved IP address, you can enter **| resolve** after the command to display the name associated with the IP address. The **resolve** filter enables the system to perform a reverse DNS lookup of the IP address. If DNS is not enabled, the lookup fails and no substitution is performed.

To perform a reverse DNS lookup of an unresolved IP address, enter **resolve <full-names>** after the pipe symbol (**|**). If you do not specify the **full-names** option, the name is truncated to fit whatever field width limitations apply to the IP address.

The following example performs a DNS lookup on any unresolved IP addresses in the output from the **show ospf neighbors** command:

```
user@host> show ospf neighbors | resolve
```

Saving Output to a File

When command output is lengthy, when you need to store or analyze the output, or when you need to send the output in an e-mail or by FTP, you can save the output to a file. By default, the file is placed in your home directory on the router.

To save command output to a file, enter **save filename** after the pipe symbol (**|**).

The following example saves the output from the **request support information** command to a file named **my-support-info.txt**:

```
user@host> request support information | save my-support-info.txt
Wrote 1143 lines of output to 'my-support-info.txt'
user@host>
```

Appending Output to a File

When command output is displayed, you can either save the output to a file, which overwrites the existing contents of that file or you can append the output text to a specific file.

To append the command output to the file, enter **append filename** after the pipe symbol (**|**).

The following example appends the output from the **request support information** command to a file named **my-support-info.txt**:

```
user@host> request support information | append my-support-info.txt
Wrote 2247 lines of output to 'my-support-info.txt'
user@host>
```

Displaying Output on Screen and Writing to a File

When command output is displayed, you can also write the output to a file. To both display the output and write it to a file, enter **tee filename** after the pipe symbol (**|**).

The following example displays the output from the **show interfaces ge-* terse** command (displaying information about the status of the gigabit Ethernet interfaces on the device) and diverts the output to a file called **ge-interfaces.txt**:

```
user@host> show interfaces ge-* terse | tee ge-interfaces.txt
Interface           Admin Link Proto  Local           Remote
ge-0/1/0             up    down
ge-0/1/1             up    up
ge-0/1/2             up    down
ge-0/1/3             up    up
```

Unlike the UNIX **tee** command, only an error message is displayed if the file cannot be opened (instead of displaying the output and then the error message).

```
user@host> show interfaces ge-* terse | tee /home/user/test.txt
error: tee failed: file /home/user/test.txt could not be opened

user@host>
```

Trimming Output by Specifying the Starting Column

Output appears on the terminal screen in terms of rows and columns. The first alphanumeric character starting at the left of the screen is in column 1, the second character is in column 2, and so on. To display output starting from a specific column (thus trimming the leftmost portion of the output), enter **trim columns** after the pipe symbol (**|**). The **trim** filter is useful for trimming the date and time from the beginning of system log messages.

The following example displays output from the **show system storage** command, filtering out the first 10 columns:

```
user@host> show system storage | trim 11
```

NOTE: The **trim** command does not accept negative values.

Refreshing the Output of a Command

You can run an operational mode command with the **| refresh** pipe option to refresh the output displayed on the screen periodically. The default refresh occurs every second. However, you can also explicitly specify a refresh interval from 1 through 604800 seconds.

For example, to refresh the output of the **show interfaces** command every five seconds, you would run the following command:

```
user@host > show interfaces | refresh 5
```

Using Keyboard Sequences to Move Around and Edit the Junos OS CLI

You can use keyboard sequences in the Junos OS command-line interface (CLI) to move around and edit the command line. You can also use keyboard sequences to scroll through a list of recently executed commands. [Table 65](#) lists some of the CLI keyboard sequences. They are the same as those used in Emacs.

Table 65: CLI Keyboard Sequences

Category	Action	Keyboard Sequence
Move the Cursor	Move the cursor back one character.	Ctrl+b
	Move the cursor back one word.	Esc+b or Alt+b
	Move the cursor forward one character.	Ctrl+f
	Move the cursor forward one word.	Esc+f or Alt+f
	Move the cursor to the beginning of the command line.	Ctrl+a
	Move the cursor to the end of the command line.	Ctrl+e
Delete Characters	Delete the character before the cursor.	Ctrl+h, Delete, or Backspace
	Delete the character at the cursor.	Ctrl+d
	Delete all characters from the cursor to the end of the command line.	Ctrl+k
	Delete all characters on the command line.	Ctrl+u or Ctrl+x
	Delete the word before the cursor.	Ctrl+w, Esc+Backspace, or Alt+Backspace
	Delete the word after the cursor.	Esc+d or Alt+d
Insert Recently Deleted Text	Insert the most recently deleted text at the cursor.	Ctrl+y
Redraw the Screen	Redraw the current line.	Ctrl+l

Table 65: CLI Keyboard Sequences (*continued*)

Category	Action	Keyboard Sequence
Display Previous Command Lines	Scroll backward through the list of recently executed commands.	Ctrl+p
	Scroll forward through the list of recently executed commands.	Ctrl+n
	Search the CLI history in reverse order for lines matching the search string.	Ctrl+r
	Search the CLI history by typing some text at the prompt, followed by the keyboard sequence. The CLI attempts to expand the text into the most recent word in the history for which the text is a prefix.	Esc+/ sequence
Display Previous Command Words	Scroll backward through the list of recently entered words in a command line.	Esc+. or Alt+.
Repeat Keyboard Sequences	Specify the number of times to execute a keyboard sequence. <i>number</i> can be from 1 through 9 and <i>sequence</i> is the keyboard sequence that you want to execute.	Esc+ <i>number</i> sequence or Alt+ <i>number</i> sequence

 - [Using Global Replace in a Junos OS Configuration on page 603](#)

Using Wildcard Characters in Interface Names

You can use wildcard characters in the Junos OS operational commands to specify groups of interface names without having to type each name individually. [Table 66](#) lists the available wildcard characters. You must enclose all wildcard characters except the asterisk (*) in quotation marks (" ").

Table 66: Wildcard Characters for Specifying Interface Names

Wildcard Character	Description
* (asterisk)	Match any string of characters in that position in the interface name. For example, so* matches all SONET/SDH interfaces.
"[<i>character</i> < <i>character</i> ...>]"	Match one or more individual characters in that position in the interface name. For example, so-"[03]"* matches all SONET/SDH interfaces in slots 0 and 3.

Table 66: Wildcard Characters for Specifying Interface Names (*continued*)

Wildcard Character	Description
"[!character<character...>]"	Match all characters except the ones included in the brackets. For example, so- "[!03]" * matches all SONET/SDH interfaces except those in slots 0 and 3.
"[character1-character2]"	Match a range of characters. For example, so- "[0-3]" * matches all SONET/SDH interfaces in slots 0, 1, 2, and 3.
"[!character1-character2]"	Match all characters that are not in the specified range of characters. For example, so- "[!0-3]" * matches all SONET/SDH interfaces in slots 4, 5, 6, and 7.

 - [Using Global Replace in a Junos OS Configuration on page 603](#)

Common Regular Expressions to Use with the replace Command

Table 67: Common Regular Expressions to Use with the replace Command

Operator	Function
	Indicates that a match can be one of the two terms on either side of the pipe.
^	Used at the beginning of an expression, denotes where a match should begin.
\$	Used at the end of an expression, denotes that a term must be matched exactly up to the point of the \$ character.
[]	Specifies a range of letters or digits to match. To separate the start and end of a range, use a hyphen (-).
()	Specifies a group of terms to match. Stored as numbered variables. Use for back references as \1 \2 \9.
*	0 or more terms.
+	One or more terms.
.	Any character except for a space (" ").
\	A backslash escapes special characters to suppress their special meaning. For example, \. matches . (period symbol).
\n	Back reference. Matches the <i>n</i> th group.
&	Back reference. Matches the entire match.

Table 68 lists some replacement examples.

Table 68: Replacement Examples

Command	Result
<code>replace pattern myrouter with router1</code>	Match: <code>myrouter</code> Result: <code>router1</code>
<code>replace pattern "192.168\.(.*)/24" with "10.2.1/28"</code>	Match: <code>192.168.3.4/24</code> Result: <code>10.2.3.4/28</code>
<code>replace pattern "1.1" with "abc&def"</code>	Match: <code>1.1</code> Result: <code>abc1.1def</code>
<code>replace pattern 1.1 with "abc\&def"</code>	Match: <code>1#1</code> Result: <code>abc&def</code>

- [Example: Using Global Replace in a Junos OS Configuration—Using the \n Back Reference on page 604](#)

Using Global Replace in the Junos OS Configuration

You can make global changes to variables and identifiers in the Junos OS configuration by using the **replace** configuration mode command. This command replaces a pattern in a configuration with another pattern. For example, you can use this command to find and replace all occurrences of an interface name when a PIC is moved to another slot in the router.

```
user@host# replace pattern pattern1 with pattern2 <upto n>
```

pattern *pattern1* is a text string or regular expression that defines the identifiers and values you want to replace in the configuration.

pattern2 is a text string or regular expression that replaces the identifiers and values located with *pattern1*.

Juniper Networks uses standard UNIX-style regular expression syntax (as defined in POSIX 1003.2). If the regular expression contains spaces, operators, or wildcard characters, enclose the expression in quotation marks. Greedy qualifiers (match as much as possible) are supported. Lazy qualifiers (match as little as possible) are not.

The **upto *n*** option specifies the number of objects replaced. The value of *n* controls the total number of objects that are replaced in the configuration (not the total number of times the pattern occurs). Objects at the same hierarchy level (siblings) are replaced first. Multiple occurrences of a pattern within a given object are considered a single replacement. For example, if a configuration contains a **010101** text string, the command

replace pattern 01 with pattern 02 upto 2 replaces 010101 with 020202 (instead of 020201). Replacement of 010101 with 020202 is considered a single replacement ($n = 1$), not three separate replacements ($n = 3$).

If you do not specify an **upto** option, all identifiers and values in the configuration that match *pattern1* are replaced.

The **replace** command is available in configuration mode at any hierarchy level. All matches are case-sensitive.

Example: Using Global Replace in a Junos OS Configuration—Using the \n Back Reference

This example shows how you can use a backreference to replace a pattern.

- [Requirements on page 604](#)
- [Overview on page 605](#)
- [Configuration on page 605](#)

Requirements

No special configuration beyond device initiation is required before configuring this example.

Before you begin, configure the following:

```
[edit]
user@host# show interfaces
xe-0/0/0 {
    unit 0;
}
fe-3/0/1 {
    vlan-tagging;
    unit 0 {
        description "inet6 configuration. IP: 2000::c0a8::1bf5";
        vlan-id 100;
        family inet {
            address 17.10.1.1/24;
        }
    }
}
```

```

    family inet6 {
        address 2000::c0a8:1bf5/3;
    }
}

```

To quickly configure this initial configuration, copy the following commands and paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level:

```

set interfaces xe-0/0/0 unit 0
set interfaces fe-3/0/1 vlan-tagging
set interfaces fe-3/0/1 unit 0 description "inet6 configuration IP: 2000::c0a8:1bf5"
set interfaces fe-3/0/1 unit 0 vlan-id 100
set interfaces fe-3/0/1 unit 0 family inet address 17.10.1.1/24
set interfaces fe-3/0/1 unit 0 family inet6 address 2000::c0a8:1bf5/3

```

Overview

One of the most useful features of regular expressions is the backreference. Backreferences provide a convenient way to identify a repeated character or substring within a string. Once you find the pattern, you can repeat it without writing it again. You refer to the previously captured pattern with just `\#` (where `#` is a numeral that indicates the number of times you want the pattern matched).

You can use backreferences to recall, or find, data and replace it with something else. In this way you can reformat large sets of data with a single replace command, thus saving you the time it would take to look for and replace the pattern manually.

Configuration

Configuring a Replacement Using a Backreference in the Command

Step-by-Step Procedure

To replace a pattern in a Junos OS configuration using a backreference:

- Use the **replace** command.

```

[edit]
user@host# replace pattern pattern1 with pattern2

```

In this case, we want to replace `:.1bf5` with `1bf5`.

```

[edit]
user@host# replace pattern "(.*)1bf5" with "\11bf5"

```

Notice the backreference (`\1`), which indicates the pattern should be searched for and replaced only once.

Results

Here is the resulting configuration:

```

[edit]
user@host# show interfaces
xe-0/0/0 {

```

```

    unit 0;
  }
  fe-3/0/1 {
    vlan-tagging;
    unit 0 {
      description "inet6 configuration. IP: 2000::c0a8:1bf5";
      vlan-id 100;
      family inet {
        address 17.10.1.1/24;
      }
      family inet6 {
        address 2000::c0a8:1bf5/3;
      }
    }
  }
}

```

In this example, the pattern 2000::c0a8:1bf5 is replaced with 2000::c0a8:1bf5 once.

 - [Using Global Replace in a Junos OS Configuration on page 603](#)

Example: Using Global Replace in a Junos OS Configuration—Replacing an Interface Name

This example shows how to replace an interface name globally in a configuration by using the **replace** command.

Using the **replace** command can be a faster and better way to change a configuration. For example, a PIC might be moved to another slot in a router, which changes the interface name. With one command you can update the whole configuration. Or you might want to quickly extend the configuration with other similar configurations, for example, similar interfaces. By using a combination of the **copy** and **replace** commands, you can add to a configuration and then replace certain aspects of the newly copied configurations. The **replace** command works with regular expressions. Regular expressions are quick, flexible, and ubiquitous. You can fashion just about any pattern you might need to search for, and most programming languages support regular expressions.

- [Requirements on page 606](#)
- [Overview on page 607](#)
- [Configuration on page 607](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before you begin, configure the following hierarchy on the router. To quickly configure this hierarchy, see “[CLI Quick Configuration](#)” on page 495 .

```
user@host# show interfaces
```

```

so-0/0/0 {
  dce;
}
user@host# show protocols
ospf {
  area 0.0.0.0 {
    interface so-0/0/0.0 {
      hello-interval 5;
    }
  }
}

```

Overview

This example shows how to replace an interface name globally in a configuration by using the **replace** command. It is a simple example.

The previous configuration is the starting point for this configuration update. In the course of this example, you change the name of the initial interface throughout the configuration with one command.

Configuration

CLI Quick Configuration To quickly configure the initial configuration for this example, copy the following commands, paste them into a text file, remove any line breaks and change any details necessary to match your network configuration, copy and paste these commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.:

```

set interfaces so-0/0/0 dce
set protocols ospf area 0.0.0.0 interface so-0/0/0.0 hello-interval 5

```

Configuring an Interface Name Change

Step-by-Step Procedure To change an interface name:

1. Make sure that you are at the top of the configuration mode hierarchy.

```
user@host# top
```
2. Replace so-0/0/0 with so-1/1/0 using the **replace** command, which uses the **pattern** keyword.

```
user@host# replace pattern so-0/0/0 with so-1/1/0
```

Results

After making the required changes, verify the configuration by using the **show interfaces** and **show protocols** configuration mode commands.

```

[edit]
user@host# show interfaces
so-1/1/0 {
  dce;
}
user@host# show protocols

```

```
ospf {
  area 0.0.0.0 {
    interface so-1/1/0.0 {
      hello-interval 5;
    }
  }
}
```

After you have confirmed that the configuration is correct, enter the **commit** command.

Related Documentation

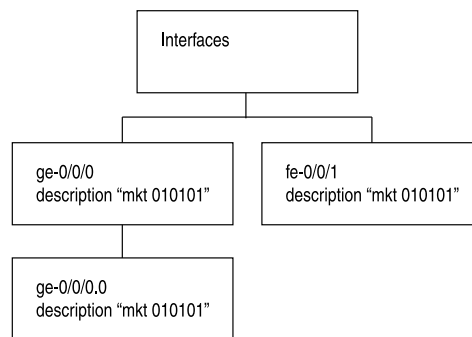

- [Example: Using Global Replace in a Junos OS Configuration—Using the upto Option on page 608](#)
- [Using Global Replace in a Junos OS Configuration on page 603](#)
- [Examples: Re-Using Configuration on page 476](#)

Example: Using Global Replace in a Junos OS Configuration—Using the upto Option

Consider the hierarchy shown in [Figure 23](#). The text string **010101** appears in three places: the description sections of **ge-0/0/0**, **ge-0/0/0.0**, and **fe-0/0/1**. These three instances are three objects. The following example shows how you can use the **upto** option to perform replacements in a JUNOS configuration:

Figure 23: Replacement by Object

Current Configuration:

user@host > **replace pattern 01 with pattern 02 upto 2**

Resulting Configuration:

g017228

An **upto 2** option in the **replace** command converts **01** to **02** for two object instances. The objects under the main interfaces **ge-0/0/0** and **fe-0/0/1** will be replaced first (since these are siblings in the hierarchy level). Because of the **upto 2** restriction, the **replace** command replaces patterns in the first and second instance in the hierarchy (siblings), but not the third instance (child of the first instance).

```

user@host# show interfaces
ge-0/0/0 {
  description "mkt 010101"; #First instance in the hierarchy
  unit 0 {
    description "mkt 010101"; #Third instance in the hierarchy (child of the first
    instance)
  }
}
fe-0/0/1 {
  description "mkt 010101"; #second instance in the hierarchy (sibling of the first
  instance)
  unit 0 {
    family inet {
      address 200.200.20.2/24;
    }
  }
}
[edit]
user@host# replace pattern 01 with 02 upto 2
[edit]
user@host# commit
commit complete

[edit]
user@host# show interfaces
ge-0/0/0 {
  description "mkt 020202"; #First instance in the hierarchy
  unit 0 {
    description "mkt 010101"; #Third instance in the hierarchy (child of the first
    instance)
  }
}
fe-0/0/1 {
  description "mkt 020202"; #second instance in the hierarchy (sibling of the first
  instance)
  unit 0 {
    family inet {
      address 200.200.20.2/24;
    }
  }
}

```

Related Documentation • [Using Global Replace in a Junos OS Configuration on page 603](#)

Using Regular Expressions to Delete Related Items from a Junos OS cConfiguration

The Junos OS command-line interface (CLI) enables you to delete related configuration items simultaneously, such as channelized interfaces or static routes, by using a single

command and regular expressions. Deleting a statement or an identifier effectively “unconfigures” the functionality associated with that statement or identifier, returning that functionality to its default condition.

You can only delete certain parts of the configuration where you normally put multiple items, for example, interfaces. However, you cannot delete “groups” of different items; for example:

```
user@host# show system services
ftp;
rlogin;
rsh;
ssh {
    root-login allow;
}
telnet;
[edit]
user@host# wildcard delete system services *
syntax error.
```

When you delete a statement, the statement and all its subordinate statements and identifiers are removed from the configuration.

To delete related configuration items, issue the **wildcard** configuration mode command with the **delete** option and specify the statement path, the items to be summarized with a regular expression, and the regular expression.

```
user@host# wildcard delete <statement-path> <identifier> <regular-expression>
```

NOTE: When you use the **wildcard** command to delete related configuration items, the regular expression must be the final statement.

If the Junos OS matches more than eight related items, the CLI displays only the first eight items.

Deleting Interfaces from the Configuration

Delete multiple T1 interfaces in the range from t1-0/0/0:0 through t1-0/0/0:23:

```
user@host# wildcard delete interfaces t1-0/0/0:.*
matched: t1-0/0/0:0
matched: t1-0/0/0:1
matched: t1-0/0/0:2
Delete 3 objects? [yes,no] (no) no
```

**Deleting Routes from
the Configuration**

Delete static routes in the range from 172.0.0.0 to 172.255.0.0:

```
user@host# wildcard delete routing-options static route 172.*
matched: 172.16.0.0/12
matched: 172.16.14.0/24
matched: 172.16.100.0/24
matched: 172.16.128.0/19
matched: 172.16.160.0/24
matched: 172.17.12.0/23
matched: 172.17.24.0/23
matched: 172.17.28.0/23
...
Delete 13 objects? [yes,no] (no)
```

Understanding Junos OS Configuration Groups

This topic provides an overview of the configuration groups feature and the inheritance model in Junos OS, and contains the following sections:

- [Configuration Groups Overview on page 614](#)
- [Inheritance Model on page 614](#)
- [Configuring Configuration Groups on page 614](#)

Configuration Groups Overview

The configuration groups feature in Junos OS enables you to create a group containing configuration statements and to direct the inheritance of that group's statements in the rest of the configuration. The same group can be applied to different sections of the configuration, and different sections of one group's configuration statements can be inherited in different places in the configuration.

Configuration groups enable you to create smaller, more logically constructed configuration files, making it easier to configure and maintain Junos OS. For example, you can group statements that are repeated in many places in the configuration, such as when configuring interfaces, and thereby limit updates to just the group.

You can also use wildcards in a configuration group to allow configuration data to be inherited by any object that matches a wildcard expression.

The configuration group mechanism is separate from the grouping mechanisms used elsewhere in the configuration, such as BGP groups. Configuration groups provide a generic mechanism that can be used throughout the configuration but that are known only to the Junos OS CLI. The individual software processes that perform the actions directed by the configuration receive the expanded form of the configuration—they have no knowledge of configuration groups.

Inheritance Model

Configuration groups use true inheritance, which involves a dynamic, ongoing relationship between the source of the configuration data and the target of that data. Data values changed in the configuration group are automatically inherited by the target. The target does not need to contain the inherited information, although the inherited values can be overridden in the target without affecting the source from which they were inherited.

This inheritance model allows you to see only the instance-specific information without seeing the inherited details. A command pipe in configuration mode allows you to display the inherited data.

Configuring Configuration Groups

For areas of your configuration to inherit configuration statements, you must first put the statements into a configuration group and then apply that group to the levels in the configuration hierarchy that require the statements.

To configure configuration groups and inheritance, you can include the **groups** statement at the **[edit]** hierarchy level:

```
[edit]
groups {
  group-name {
    configuration-data;
  }
}
```

Include the **apply-groups [group-names]** statement anywhere in the configuration where the configuration statements contained in a configuration group are needed.

**Related
Documentation**

- [Creating a Junos OS Configuration Group on page 615](#)

Creating the Junos OS Configuration Group

To create a configuration group, include the **groups** statement at the **[edit]** hierarchy level:

```
[edit]
groups {
  group-name {
    configuration-data;
  }
  lccn-re0 {
    configuration-data;
  }
  lccn-re1 {
    configuration-data;
  }
}
```

group-name is the name of a configuration group. You can configure more than one configuration group by specifying multiple **group-name** statements. However, you cannot use the prefix **junos-** in a group name because it is reserved for use by Junos OS. Similarly, the configuration group **juniper-ais** is reserved exclusively for Juniper Advanced Insight Solutions (AIS)-related configuration. For more information on the **juniper-ais** configuration group, see the [Juniper Networks Advanced Insight Solutions Guide](#).

One reason for the naming restriction is a configuration group called **junos-defaults**. This preset configuration group is applied to the configuration automatically. You cannot modify or remove the **junos-defaults** configuration group. For more information about the Junos default configuration group, see [“Using Junos OS Defaults Groups” on page 640](#).

On routers that support multiple Routing Engines, you can also specify two special group names:

- **re0**—Configuration statements applied to the Routing Engine in slot 0.
- **re1**—Configuration statements applied to the Routing Engine in slot 1.

The configuration specified in group **re0** is only applied if the current Routing Engine is in slot 0; likewise, the configuration specified in group **re1** is only applied if the current Routing Engine is in slot 1. Therefore, both Routing Engines can use the same configuration file, each using only the configuration statements that apply to it. Each **re0** or **re1** group contains at a minimum the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group also should contain the configuration for the backup router and static routes.

In addition, the TX Matrix router supports group names for the Routing Engines in each T640 router attached to the routing matrix. Providing special group names for all Routing Engines in the routing matrix allows you to configure the individual Routing Engines in each T640 router differently. Parameters that are not configured at the **[edit groups]** hierarchy level apply to all Routing Engines in the routing matrix.

configuration-data contains the configuration statements applied elsewhere in the configuration with the **apply-groups** statement. To have a configuration inherit the statements in a configuration group, include the **apply-groups** statement. For information about the **apply-groups** statement, see [“Applying a Junos OS Configuration Group” on page 617](#).

The group names for Routing Engines on the TX Matrix router have the following formats:

- **lccn-re0**—Configuration statements applied to the Routing Engine in slot 0 in a specified T640 router.
- **lccn-re1**—Configuration statements applied to the Routing Engine in slot 1 in a specified T640 router.

n identifies the T640 router and can be from 0 through 3. For example, to configure Routing Engine 1 properties for **lcc3**, you include statements at the **[edit groups lcc3-re1]** hierarchy level. For information about the TX Matrix router and routing matrix, see the *Administration Guide for Security Devices*.

NOTE: The management Ethernet interface used for the TX Matrix Plus router, T1600 routers in a routing matrix, and PTX Series Packet Transport Switches, is **em0**. Junos OS automatically creates the router's management Ethernet interface, **em0**.

Related Documentation

- [Applying a Junos OS Configuration Group on page 617](#)
- [Using Junos OS Defaults Groups on page 640](#)
- [Understanding Junos OS Configuration Groups on page 614](#)
- [Disabling Inheritance of a Junos OS Configuration Group on page 620](#)
- [Using Wildcards with Configuration Groups on page 622](#)
- [Example: Configuring Sets of Statements with Configuration Groups on page 625](#)

Applying the Junos OS Configuration Group

To have the Junos OS configuration inherit the statements from a configuration group, include the **apply-groups** statement:

```
apply-groups [ group-names ];
```

If you specify more than one group name, list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.

For routers that support multiple Routing Engines, you can specify **re0** and **re1** group names. The configuration specified in group **re0** is only applied if the current Routing Engine is in slot 0; likewise, the configuration specified in group **re1** is only applied if the current Routing Engine is in slot 1. Therefore, both Routing Engines can use the same configuration file, each using only the configuration statements that apply to it. Each **re0** or **re1** group contains at a minimum the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group also should contain the configuration for the backup router and static routes.

NOTE: The management Ethernet interface used for the TX Matrix Plus router, T1600 routers in a routing matrix, and PTX Series Packet Transport Switches, is **em0**.

You can include only one **apply-groups** statement at each specific level of the configuration hierarchy. The **apply-groups** statement at a specific hierarchy level lists the configuration groups to be added to the containing statement's list of configuration groups.

Values specified at the specific hierarchy level override values inherited from the configuration group.

Groups listed in nested **apply-groups** statements take priority over groups in outer statements. In the following example, the BGP neighbor **10.0.0.1** inherits configuration data from group **one** first, then from groups **two** and **three**. Configuration data in group **one** overrides data in any other group. Data from group **ten** is used only if a statement is not contained in any other group.

```
apply-groups [ eight nine ten ];
protocols {
  apply-groups seven;
  bgp {
    apply-groups [ five six ];
    group some-bgp-group {
      apply-groups four;
      neighbor 10.0.0.1 {
        apply-groups [ one two three ];
      }
    }
  }
}
```

When you configure a group defined for the root level—that is, in the default logical system—you cannot successfully apply that group to a nondefault logical system under the `[edit logical-systems logical-system-name]` hierarchy level. Although the router accepts the commit if you apply the group, the configuration group does not take effect for the nondefault logical system. You can instead create an additional configuration group at the root level and apply it within the logical system. Alternatively, you can modify the original group so that it includes configuration for both the default and nondefault logical system hierarchy levels.

Related Documentation

- [Disabling Inheritance of a Junos OS Configuration Group on page 620](#)
- [Creating a Junos OS Configuration Group on page 615](#)
- [Using Wildcards with Configuration Groups on page 622](#)
- [Example: Configuring Sets of Statements with Configuration Groups on page 625](#)

Example: Configuring and Applying Junos OS Configuration Groups

In this example, the SNMP configuration is divided between the group **basic** and the normal configuration hierarchy.

There are a number of advantages to placing the system-specific configuration (SNMP contact) into a configuration group and thus separating it from the normal configuration hierarchy—the user can replace (using the **load replace** command) either section without discarding data from the other.

In addition, setting a contact for a specific box is now possible because the group data would be hidden by the router-specific data.

```
[edit]
groups {
  basic { # User-defined group name
    snmp { # This group contains some SNMP data
      contact "My Engineering Group";
      community BasicAccess {
        authorization read-only;
      }
    }
  }
}
apply-groups basic; # Enable inheritance from group "basic"
snmp { # Some normal (non-group) configuration
  location "West of Nowhere";
}
```

This configuration is equivalent to the following:

```
[edit]
snmp {
  location "West of Nowhere";
  contact "My Engineering Group";
}
```

```
community BasicAccess {
  authorization read-only;
}
}
```

For information about how to disable inheritance of a configuration group, see [“Disabling Inheritance of a Junos OS Configuration Group” on page 620](#).

Example: Creating and Applying Configuration Groups on a TX Matrix Router

The following example shows how to configure and apply configuration groups on a TX Matrix Router:

```
[edit]
groups {
  re0 { # Routing Engine 0 on TX Matrix router
    system {
      host-name hostname;
      backup-router ip-address;
    }
    interfaces {
      fxp0 {
        unit 0 {
          family inet {
            address ip-address;
          }
        }
      }
    }
  }
  re1 { # Routing Engine 1 on TX Matrix router
    system {
      host-name hostname;
      backup-router ip-address;
    }
    interfaces {
      fxp0 {
        unit 0 {
```

```
        family inet {
            address ip-address;
        }
    }
}
}
lcc0-re0 { # Routing Engine 0 on T640 router numbered 0
    system {
        host-name hostname;
        backup-router ip-address;
    }
    interfaces {
        fxp0 {
            unit 0 {
                family inet {
                    address ip-address;
                }
            }
        }
    }
}
lcc0-re1 { # Routing Engine 1 on T640 router numbered 0
    system {
        host-name hostname;
        backup-router ip-address;
    }
    interfaces {
        fxp0 {
            unit 0 {
                family inet {
                    address ip-address;
                }
            }
        }
    }
}

Disabling Inheritance of a Junos OS Configuration Group

To disable inheritance of a configuration group at any level except the top level of the hierarchy, include the **apply-groups-except** statement:

```
apply-groups-except [ group-names ];
```

This statement is useful when you use the **apply-group** statement at a specific hierarchy level but also want to override the values inherited from the configuration group for a specific parameter.

Example: Disabling Inheritance on Interface so-1/1/0

In the following example, the **apply-groups** statement is applied globally at the interfaces level. The **apply-groups-except** statement is also applied at interface **so-1/1/0** so that it uses the default values for the **hold-time** and **link-mode** statements.

```
[edit]
groups { # "groups" is a top-level statement
  global { # User-defined group name
    interfaces {
      <*> {
        hold-time down 640;
        link-mode full-duplex;
      }
    }
  }
}
apply-groups global;
interfaces {
  so-1/1/0 {
    apply-groups-except global; # Disables inheritance from group "global"
    # so-1/1/0 uses default value for "hold-time"
    # and "link-mode"
  }
}
```

For information about applying a configuration group, see [“Applying a Junos OS Configuration Group” on page 617](#).

Configuration groups can add some confusion regarding the actual values used by the router, because configuration data can be inherited from configuration groups. To view the actual values used by the router, use the **display inheritance** command after the pipe (|) in a **show** command. This command displays the inherited statements at the level at which they are inherited and the group from which they have been inherited.

```
[edit]
user@host# show | display inheritance
snmp {
  location "West of Nowhere";
  ##
  ## 'My Engineering Group' was inherited from group 'basic'
  ##
  contact "My Engineering Group";
  ##
  ## 'BasicAccess' was inherited from group 'basic'
  ##
  community BasicAccess {
    ##
    ## 'read-only' was inherited from group 'basic'
    ##
    authorization read-only;
  }
}
```

To display the expanded configuration (the configuration, including the inherited statements) without the **##** lines, use the **except** command after the pipe in a **show** command:

```
[edit]
user@host# show | display inheritance | except ##
snmp {
  location "West of Nowhere";
  contact "My Engineering Group";
  community BasicAccess {
    authorization read-only;
  }
}
```

NOTE: Using the `display inheritance | except ##` option removes all the lines with `##`. Therefore, you might also not be able to view information about passwords and other important data where `##` is used. To view the complete configuration details with all the information without just the comments marked with `##`, use the `no-comments` option with the `display inheritance` command:

```
[edit]
user@host# show | display inheritance no-comments
snmp {
  location "West of Nowhere";
  contact "My Engineering Group";
  community BasicAccess {
    authorization read-only;
  }
}
```

- [Understanding Junos OS Configuration Groups on page 614](#)

Using Wildcards with Configuration Groups

You can use wildcards to identify names and allow one statement to provide data for a variety of statements. For example, grouping the configuration of the **sonet-options** statement over all SONET/SDH interfaces or the dead interval for OSPF over all Asynchronous Transfer Mode (ATM) interfaces simplifies configuration files and eases their maintenance.

Using wildcards in normal configuration data is done in a style that is consistent with that used with traditional UNIX shell wildcards. In this style, you can use the following metacharacters:

- Asterisk (`*`)—Matches any string of characters.
- Question mark (`?`)—Matches any single character.
- Open bracket (`[`)—Introduces a character class.
- Close bracket (`]`)—Indicates the end of a character class. If the close bracket is missing, the open bracket matches a `[` rather than introduce a character class.

- A character class matches any of the characters between the square brackets. Within a configuration group, an interface name that includes a character class must be enclosed in quotation marks.
- Hyphen (-)—Specifies a range of characters.
- Exclamation point (!)—The character class can be complemented by making an exclamation point the first character of the character class. To include a close bracket (]) in a character class, make it the first character listed (after the !, if any). To include a minus sign, make it the first or last character listed.

Wildcarding in configuration groups follows the same rules, but any term using a wildcard pattern must be enclosed in angle brackets *<pattern>* to differentiate it from other wildcarding in the configuration file.

```
[edit]
groups {
  sonet-default {
    interfaces {
      <so-*> {
        sonet-options {
          payload-scrambler;
          rfc-2615;
        }
      }
    }
  }
}
```

Wildcard expressions match (and provide configuration data for) existing statements in the configuration that match their expression only. In the previous example, the expression *<so-*>* passes its **sonet-options** statement to any interface that matches the expression *so-**.

The following example shows how to specify a range of interfaces:

```
[edit]
groups {
  gigabit-ethernet-interfaces {
    interfaces {
      "<ge-1/2/[5-8]>" {
        description "These interfaces reserved for Customer ABC";
      }
    }
  }
}
```

Angle brackets allow you to pass normal wildcarding through without modification. In any matching within the configuration, whether it is done with or without wildcards, the first item encountered in the configuration that matches is used. In the following example, data from the wildcarded BGP groups is inherited in the order in which the groups are listed. The preference value from *<*a*>* overrides the preference in *<*b*>*, just as the **p** value from *<*c*>* overrides the one from *<*d*>*. Data values from any of these groups override the data values from **abcd**.

```
[edit]
user@host# show
groups {
  one {
    protocols {
      bgp {
        group <*a*> {
          preference 1;
        }
        group <*b*> {
          preference 2;
        }
        group <*c*> {
          out-delay 3;
        }
        group <*d*> {
          out-delay 4;
        }
        group abcd {
          preference 10;
          hold-time 10;
          out-delay 10;
        }
      }
    }
  }
}
protocols {
  bgp {
    group abcd {
      apply-groups one;
    }
  }
}
[edit]
user@host# show | display inheritance
protocols {
  bgp {
    group abcd {
      ##
      ## '1' was inherited from group 'one'
      ##
      preference 1;
      ##
      ## '10' was inherited from group 'one'
      ##
      hold-time 10;
      ##
      ## '3' was inherited from group 'one'
      ##
      out-delay 3;
    }
  }
}
```

 - [Creating a Junos OS Configuration Group on page 615](#)
 - [Understanding Junos OS Configuration Groups on page 614](#)

Example: Configuring Sets of Statements with Configuration Groups

When sets of statements exist in configuration groups, all values are inherited. For example:

```
[edit]
user@host# show
groups {
  basic {
    snmp {
      interface so-1/1/1.0;
    }
  }
}
apply-groups basic;
snmp {
  interface so-0/0/0.0;
}
[edit]
user@host# show | display inheritance
snmp {
  ##
  ## 'so-1/1/1.0' was inherited from group 'basic'
  ##
  interface [ so-0/0/0.0 so-1/1/1.0 ];
}
```

For sets that are not displayed within brackets, all values are also inherited. For example:

```
[edit]
user@host# show
groups {
  worldwide {
    system {
      name-server {
        10.0.0.100;
        10.0.0.200;
      }
    }
  }
}
apply-groups worldwide;
system {
  name-server {
    10.0.0.1;
    10.0.0.2;
  }
}
```

```
}
[edit]
user@host# show | display inheritance
system {
  name-server {
    ##
    ## '10.0.0.100' was inherited from group 'worldwide'
    ##
    10.0.0.100;
    ##
    ## '10.0.0.200' was inherited from group 'worldwide'
    ##
    10.0.0.200;
    10.0.0.1;
    10.0.0.2;
  }
}
```

Example: Configuring Interfaces Using Junos OS Configuration Groups

You can use configuration groups to separate the common interface media parameters from the interface-specific addressing information. The following example places configuration data for ATM interfaces into a group called **atm-options**:

```
[edit]
user@host# show
groups {
  atm-options {
    interfaces {
      <at-*> {
        atm-options {
          vpi 0 maximum-vcs 1024;
        }
        unit <*> {
          encapsulation atm-snap;
          point-to-point;
          family iso;
        }
      }
    }
  }
}
apply-groups atm-options;
interfaces {
  at-0/0/0 {
    unit 100 {
      vci 0.100;
      family inet {
        address 10.0.0.100/30;
      }
    }
  }
}
```

```

    }
  }
  unit 200 {
    vci 0.200;
    family inet {
      address 10.0.0.200/30;
    }
  }
}
[edit]
user@host# show | display inheritance
interfaces {
  at-0/0/0 {
    ##
    ## "atm-options" was inherited from group "atm-options"
    ##
    atm-options {
      ##
      ## "1024" was inherited from group "atm-options"
      ##
      vpi 0 maximum-vcs 1024;
    }
    unit 100 {
      ##
      ## "atm-snap" was inherited from group "atm-options"
      ##
      encapsulation atm-snap;
      ##
      ## "point-to-point" was inherited from group "atm-options"
      ##
      point-to-point;
      vci 0.100;
      family inet {
        address 10.0.0.100/30;
      }
      ##
      ## "iso" was inherited from group "atm-options"
      ##
      family iso;
    }
    unit 200 {
      ##
      ## "atm-snap" was inherited from group "atm-options"
      ##
      encapsulation atm-snap;
      ##
      ## "point-to-point" was inherited from group "atm-options"
      ##
      point-to-point;
      vci 0.200;
      family inet {
        address 10.0.0.200/30;
      }
      ##
      ## "iso" was inherited from group "atm-options"
    }
  }
}

```

```
        ##
        family iso;
    }
}
[edit]
user@host# show | display inheritance | except ##
interfaces {
  at-0/0/0 {
    atm-options {
      vpi 0 maximum-vcs 1024;
    }
    unit 100 {
      encapsulation atm-snap;
      point-to-point;
      vci 0.100;
      family inet {
        address 10.0.0.100/30;
      }
      family iso;
    }
    unit 200 {
      encapsulation atm-snap;
      point-to-point;
      vci 0.200;
      family inet {
        address 10.0.0.200/30;
      }
      family iso;
    }
  }
}
```

- [Example: Configuring a Consistent IP Address for the Management Interface on page 628](#)

Example: Configuring a Consistent IP Address for the Management Interface

On routers with multiple Routing Engines, each Routing Engine is configured with a separate IP address for the management interface (**fxp0**). To access the master Routing Engine, you must know which Routing Engine is active and use the appropriate IP address.

Optionally, for consistent access to the master Routing Engine, you can configure an additional IP address and use this address for the management interface regardless of which Routing Engine is active. This additional IP address is active only on the management interface for the master Routing Engine. During switchover, the address moves to the new master Routing Engine.

In the following example, address **10.17.40.131** is configured for both Routing Engines and includes a **master-only** statement. With this configuration, the **10.17.40.131** address is active only on the master Routing Engine. The address remains consistent regardless of which Routing Engine is active. Address **10.17.40.132** is assigned to **fxp0** on **re0**, and **10.17.40.133** is assigned to **fxp0** on **re1**.

```
[edit groups re0 interfaces fxp0]
unit 0 {
  family inet {
    address 10.17.40.131/25 {
      master-only;
    }
    address 10.17.40.132/25;
  }
}
[edit groups re1 interfaces fxp0]
unit 0 {
  family inet {
    address 10.17.40.131/25 {
      master-only;
    }
    address 10.17.40.133/25;
  }
}
```

This feature is available on all routers that include dual Routing Engines. On a routing matrix composed of the TX Matrix router, this feature is applicable to the switch-card chassis (SCC) only. Likewise, on a routing matrix composed of a TX Matrix Plus router, this feature is applicable to the switch-fabric chassis (SFC) only.

NOTE:

- If you configure the same IP address for a management interface or internal interface such as **fxp0** and an external physical interface such as **ge-0/0/1**, when graceful Routing Engine switchover (GRES) is enabled, the CLI displays an appropriate commit error message that identical addresses have been found on the private and public interfaces. In such cases, you must assign unique IP addresses for the two interfaces that have duplicate addresses.
- The management Ethernet interface used for the TX Matrix Plus router, T1600 routers in a routing matrix, and PTX Series Packet Transport Routers, is **em0**. Junos OS automatically creates the router's management Ethernet interface, **em0**.

- [Creating a Junos OS Configuration Group on page 615](#)
- [Example: Configuring Interfaces Using Junos OS Configuration Groups on page 626](#)

Example: Configuring Peer Entities

In this example, we create a group **some-isp** that contains configuration data relating to another Internet service provider (ISP). We can then insert **apply-group** statements at any point to allow any location in the configuration hierarchy to inherit this data.

```
[edit]
user@host# show
groups {
  some-isp {
    interfaces {
      <xe-*> {
        gigether-options {
          flow-control;
        }
      }
    }
    protocols {
      bgp {
        group <*> {
          neighbor <*> {
            remove-private;
          }
        }
      }
      pim {
        interface <*> {
          version 1;
        }
      }
    }
  }
}
interfaces {
  xe-0/0/0 {
    apply-groups some-isp;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
protocols {
  bgp {
    group main {
      neighbor 10.254.0.1 {
        apply-groups some-isp;
      }
    }
  }
  pim {
    interface xe-0/0/0.0 {
      apply-groups some-isp;
    }
  }
}
```

```

    }
  }
}
[edit]
user@host# show | display inheritance
interfaces {
  xe-0/0/0 {
    ##
    ## "gigether-options" was inherited from group "some-isp"
    ##
    gigether-options {
      ##
      ## "flow-control" was inherited from group "some-isp"
      ##
      flow-control;
    }
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
protocols {
  bgp {
    group main {
      neighbor 10.254.0.1 {
        ##
        ## "remove-private" was inherited from group "some-isp"
        ##
        remove-private;
      }
    }
  }
  pim {
    interface xe-0/0/0.0 {
      ##
      ## "1" was inherited from group "some-isp"
      ##
      version 1;
    }
  }
}

```

- [Establishing Regional Configurations on page 631](#)

Establishing Regional Configurations

In this example, one group is populated with configuration data that is standard throughout the company, while another group contains regional deviations from this standard:

```
[edit]
user@host# show
groups {
  standard {
    interfaces {
      <t3-*> {
        t3-options {
          compatibility-mode larscom subrate 10;
          idle-cycle-flag ones;
        }
      }
    }
  }
  northwest {
    interfaces {
      <t3-*> {
        t3-options {
          long-buildout;
          compatibility-mode kentrox;
        }
      }
    }
  }
}
apply-groups standard;
interfaces {
  t3-0/0/0 {
    apply-groups northwest;
  }
}
[edit]
user@host# show | display inheritance
interfaces {
  t3-0/0/0 {
    ##
    ## "t3-options" was inherited from group "northwest"
    ##
    t3-options {
      ##
      ## "long-buildout" was inherited from group "northwest"
      ##
      long-buildout;
      ##
      ## "kentrox" was inherited from group "northwest"
      ##
      compatibility-mode kentrox;
      ##
      ## "ones" was inherited from group "standard"
      ##
      idle-cycle-flag ones;
    }
  }
}
```

Configuring Wildcard Configuration Group Names

Wildcards are configuration group names that use special characters to create a pattern that can be applied to multiple statements. Wildcards are useful for copying one set of configuration options to a large number of different configuration groups. It is important to set up your wildcard name properly to ensure that the wildcard configuration options get copied to the appropriate configuration groups.

In this example, you configure different values for the `<*-major>` and `<*-minor>` wildcard groups under the `label-switched-path` statement. The asterisk (*) character represents a section of the wildcard name that can match any string of characters. For example the configuration options under `label-switched-path <*-major>` are passed onto `label-switched-path metro-major` and any other `label-switched-path` configuration group containing `-major` in its name.

```
[edit]
user@host# show
groups {
  mpls-conf {
    protocols {
      mpls {
        label-switched-path <*-major> {
          retry-timer 5;
          bandwidth 155m;
          optimize-timer 60;
        }
        label-switched-path <*-minor> {
          retry-timer 15;
          bandwidth 64k;
          optimize-timer 120;
        }
      }
    }
  }
}
apply-groups mpls-conf;
protocols {
  mpls {
    label-switched-path metro-major {
      to 10.0.0.10;
    }
    label-switched-path remote-minor {
      to 10.0.0.20;
    }
  }
}
[edit]
user@host# show | display inheritance
protocols {
```

```

mpls {
  label-switched-path metro-major {
    to 10.0.0.10;
    ##
    ## "5" was inherited from group "mpls-conf"
    ##
    retry-timer 5;
    ## "155m" was inherited from group "mpls-conf"
    ##
    bandwidth 155m;
    ##
    ## "60" was inherited from group "mpls-conf"
    ##
    optimize-timer 60;
  }
  label-switched-path remote-minor {
    to 10.0.0.20;
    ##
    ## "15" was inherited from group "mpls-conf"
    ##
    retry-timer 15;
    ##
    ## "64k" was inherited from group "mpls-conf"
    ##
    bandwidth 64k;
    ##
    ## "120" was inherited from group "mpls-conf"
    ##
    optimize-timer 120;
  }
}

```

Related Documentation

- [Using Wildcards with Configuration Groups on page 622](#)

Example: Referencing the Preset Statement From the Junos OS defaults Group

The following example is a preset statement from the Junos defaults group that is available for FTP in a stateful firewall:

```

[edit]
groups {
  junos-defaults {
    applications {
      application junos-ftp {# Use FTP default configuration
        application-protocol ftp;
        protocol tcp;
        destination-port 21;
      }
    }
  }
}

```

To reference a preset Junos default statement from the Junos defaults group, include the **junos-default-name** statement at the applicable hierarchy level. For example, to

reference the Junos default statement for FTP in a stateful firewall, include the **junos-ftp** statement at the **[edit services stateful-firewall rule my-rule term my-term from applications]** hierarchy level:

```
[edit]
services {
  stateful-firewall {
    rule my-rule {
      term my-term {
        from {

        }
      }
    }
  }
}
```

Related Documentation

- [Example: Viewing Default Statements That Have Been Applied to the Configuration on page 635](#)
- [Using Junos OS Defaults Groups on page 640](#)
- [Understanding Junos OS Configuration Groups on page 614](#)
- [Creating a Junos OS Configuration Group on page 615](#)

Example: Viewing Default Statements That Have Been Applied to the Configuration

To view the Junos defaults that have been applied to the configuration, issue the **show | display inheritance defaults** command. For example, to view the inherited Junos defaults at the **[edit system ports]** hierarchy level:

```
user@host# show system ports | display inheritance defaults
## ## 'console' was inherited from group 'junos-defaults'
## 'vt100' was inherited from group 'junos-defaults'
## console type vt100;
```

If you choose not to use existing Junos default statements, you can create your own configuration groups manually.

To view the complete configuration information without the comments marked with **##**, use the **no-comments** option with the **display inheritance** command.

- [Configuring Configuration Groups on page 614](#)

Using Conditions to Apply Configuration Groups Overview

You can use the **when** statement at the **[edit groups group-name]** hierarchy level to define conditions under which a configuration group should be applied.

You can configure a group to be applied based on the type of chassis, model, or Routing Engine, virtual chassis member, cluster node, and start and optional end time of day or date.

For example, you could use the **when** statement to create a generic configuration group for each type of node and then apply the configuration based on certain node properties, such as chassis or model.

Related Documentation

- [Example: Configuring Conditions for Applying Configuration Groups on page 636](#)

Example: Configuring Conditions for Applying Configuration Groups

This example shows how to configure conditions under which a specified configuration group is to be applied.

- [Requirements on page 636](#)
- [Overview on page 636](#)
- [Configuration on page 637](#)

Requirements

No special configuration beyond device initialization is required before you configure this example.

Overview

You can configure your group configuration data at the **[edit groups group-name]** hierarchy level, then use the **when** statement to have the group applied based on conditions including: type of chassis, model, routing-engine, virtual chassis member, cluster node, and start and optional end time of day or date.

If you specify multiple conditions in a single configuration group, all conditions must be met before the configuration group is applied.

You can specify the start time or the time duration for the configuration group to be applied. If only the start time is specified, the configuration group is applied at the specified time and it remains in effect until the time is changed. If the end time is specified, then on each day, the applied configuration group is started and stopped at the specified times.

This example sets conditions in a configuration group, **test1**, such that this group is applied only when all of the following conditions are met: the router is a model MX240 router with chassis type LCC0, with a Routing Engine operating as RE0, is member0 of the virtual

chassis on node0, and the configuration group will only be in effect from 9:00 a.m. until 5:00 p.m. each day.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set groups test1 when model mx240
set groups test1 when chassis lcc0
set groups test1 when routing-engine re0
set groups test1 when member member0
set groups test1 when node node0
set groups test1 when time 9 to 5
```

Step-by-Step Procedure To configure conditions for configuration group **test1**:

1. Set the condition that identifies the model MX240 router.

```
[edit groups test1 when]
user@host# set model mx240
```
2. Set the condition that identifies the chassis type as LCC0.

```
[edit groups test1 when]
user@host# set chassis lcc0
```
3. Set the condition that identifies the Routing Engine operating as RE0.

```
[edit groups test1 when]
user@host# set routing-engine re0
```
4. Set the condition that identifies the virtual chassis **member0**.

```
[edit groups test1 when]
user@host# set member member0
```
5. Set the condition that identifies the cluster **node0**.

```
[edit groups test1 when]
user@host# set node node0
```
6. Set the condition that applies the group only between the hours of 9:00 a.m. and 5:00 p.m. daily.

```
[edit groups test1 when]
user@host# set time 9 to 5
```

NOTE: The syntax for specifying the time is: `time <start-time> [to <end-time>]` using the time format `yyyy-mm-dd.hh:mm`, `hh:mm`, or `hh`.

7. Commit the configuration.

```
user@host# commit
```

Results From configuration mode, confirm your configuration by entering the **show groups test1** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show groups test1
when {
  time 9 to 5;
  chassis lcc0;
  model mx240;
  routing-engine re0;
  member member0;
  node node0;
}
```

Verification

Confirm that the configuration is working properly.

- [Checking Group Inheritance with Conditional Data on page 638](#)

Checking Group Inheritance with Conditional Data

Purpose Verify that conditional data from a configuration group is inherited when applied.

Action The **show | display inheritance** operational command can be issued with the **when** data to display the conditional inheritance. Using this example, you could issue one of these commands to determine that the conditional data was inherited:

```
user@host> show | display inheritance when model mx240
user@host> show | display inheritance when chassis lcc0
user@host> show | display inheritance when routing-engine re0
user@host> show | display inheritance when member member0
user@host> show | display inheritance when node node0
user@host> show | display inheritance when time 9 to 5
```

- [Using Conditions to Apply Configuration Groups Overview on page 636](#)

Improving Commit Time When Using Configuration Groups

Configuration groups are used for applying configurations across other hierarchies without re-entering configuration data. Some configuration groups specify every configuration detail. Other configuration groups make use of wildcards to configure ranges of data, without detailing each configuration line. Some configurations have an inheritance path that includes a long string of configurations to be applied.

When a configuration that uses configuration groups is committed, the commit process expands and reads all of the configuration data of the group into memory in order to

apply the configurations as intended. The commit performance can be negatively impacted if many configuration groups are being applied, especially if the configuration groups use wildcards extensively.

If your system uses many configuration groups that use wildcards, you can configure the **persist-groups-inheritance** statement at the **[edit system commit]** hierarchy level to improve commit time performance.

Using this option allows the system to build the inheritance path for each configuration group inside the database, instead of in the process memory. This can improve commit time performance. However, it can also increase the database size by up to 22 percent.

**Related
Documentation**

- [Example: Improving Commit Time When Using Configuration Groups on page 639](#)
- *persist-groups-inheritance*

Example: Improving Commit Time When Using Configuration Groups

This example shows how to use the **persist-groups-inheritance** configuration statement to improve commit time performance when committing configurations that make use of many configuration groups that are created using wildcards.

- [Requirements on page 639](#)
- [Overview on page 639](#)
- [Configuration on page 640](#)
- [Verification on page 640](#)

Requirements

This example uses the following hardware and software components:

- One Juniper Networks M Series, MX Series, or T Series router that uses a number of configuration groups created with wildcards.
- Junos OS Release 13.2 or later.

Overview

When committing a configuration that uses configuration groups, at the time of commit, all of the inheritance paths of the configuration groups must be fully expanded into memory to apply the configurations as intended. This can negatively impact commit performance if there are many configuration groups and they are configured using wildcards.

To improve commit performance, you can configure **persist-groups-inheritance** at the **[edit system commit]** hierarchy level. Configuring this option causes the configuration groups to be expanded into the database instead of into the process memory at commit time.

Configuration

Configuring Persist Groups Inheritance

Step-by-Step Procedure

To configure **persist-groups-inheritance**:

1. Set the **persist-groups-inheritance** option.

```
[edit system commit]  
user@host# set persist-groups-inheritance
```
2. Commit the configuration.

```
[edit system commit]  
user@host# commit
```

Verification

Verifying the Configuration

Purpose Verify that **persist-groups-inheritance** is configured.

Action To confirm the configuration, use the **show system commit** command.

```
[edit ]  
user@host# show system commit  
persist-groups-inheritance
```

Related Documentation

- [Improving Commit Time When Using Configuration Groups on page 638](#)
- *persist-groups-inheritance*

Using Junos OS Defaults Groups

Junos OS provides a hidden and immutable configuration group called **junos-defaults** that is automatically applied to the configuration of your router. The **junos-defaults** group contains preconfigured statements that contain predefined values for common applications. Some of the statements must be referenced to take effect, such as definitions for applications (for example, FTP or telnet settings). Other statements are applied automatically, such as terminal settings.

NOTE: Many identifiers included in the **junos-defaults** configuration group begin with the name **junos-**. Because identifiers beginning with the name **junos-** are reserved for use by Juniper Networks, you cannot define any configuration objects using this name.

You cannot include **junos-defaults** as a configuration group name in an **apply-groups** statement.

To view the full set of available preset statements from the Junos defaults group, issue the **show groups junos-defaults** configuration mode command at the top level of the configuration. The following example displays a partial list of Junos defaults groups:

```
user@host# show groups junos-defaults
# Make vt100 the default for the console port
system {
  ports {
    console type vt100;
  }
}
applications {
  # File Transfer Protocol
  application junos-ftp {
    application-protocol ftp;
    protocol tcp;
    destination-port 21;
  }
  # Trivial File Transfer Protocol
  application junos-tftp {
    application-protocol tftp;
    protocol udp;
    destination-port 69;
  }
  # RPC port mapper on TCP
  application junos-rpc-portmap-tcp {
    application-protocol rpc-portmap;
    protocol tcp;
    destination-port 111;
  }
  # RPC port mapper on UDP
}
```

To reference statements available from the **junos-defaults** group, include the selected **junos- *default-name*** statement at the applicable hierarchy level.

Related Documentation

- [Creating a Junos OS Configuration Group on page 615](#)

Set Up Routing Engine Configuration Groups

In a router with two Routing Engines, one configuration should be shared between both Routing Engines. This ensures that both Routing Engine configurations are identical. Within this configuration, create two Routing Engine groups, one for each Routing Engine. Within these groups, you specify the Routing Engine–specific parameters.

For more information about creating configuration groups, see *CLI User Guide*.

For more information about the initial configuration for redundant Routing Engine systems and the re0 group, see *Junos OS High Availability Library for Routing Devices*.

1. Create the configuration group **re0**. The **re0** group is a special group designator that is only used by **RE0** in a redundant routing platform.

```
[edit]
root# set groups re0
```

2. Navigate to the **groups re0** level of the configuration hierarchy.

```
[edit]
root# edit groups re0
```

3. Specify the router hostname.

```
[edit groups re0]
root# set system host-name host-name
```

NOTE: The hostname specified in the router configuration is not used by the DNS server to resolve to the correct IP address. This hostname is used to display the name of the Routing Engine in the CLI. For example, the hostname appears at the command-line prompt when the user is logged in to the CLI:

```
user-name@host-name>
```

4. Configure the IP address and prefix length for the router Ethernet interface.
 - For all devices *except* the TX Matrix Plus router, T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- For TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix only, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces em0 unit 0 family inet address address/prefix-length
```

To use **em0** as an out-of-band management Ethernet interface, you must configure its logical port, **em0.0**, with a valid IP address.

- For a T1600 standalone router (not connected to a TX Matrix Plus router and not in a routing matrix):

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

5. Return to the top level of the hierarchy.

```
[edit groups re0]
root# top
```

6. Create the configuration group **re1**.

```
[edit]
root# set groups re1
```

7. Navigate to the **groups re1** level of the configuration hierarchy.

```
[edit]
root# edit groups re1
```

8. Specify the router hostname.

```
[edit groups re1]
root# set system host-name host-name
```

9. Configure the IP address and prefix length for the router Ethernet interface.

- For all devices *except* the TX Matrix Plus router, T1600 or T4000 routers in a routing matrix, and PTX Series Packet Transport Routers:

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

- For TX Matrix Plus router, and T1600 or T4000 routers in a routing matrix only:

```
[edit]
root@# set interfaces em0 unit 0 family inet address address/prefix-length
```

To use **em0** as an out-of-band management Ethernet interface, you must configure its logical port, **em0.0**, with a valid IP address.

- For a T1600 standalone router (not connected to a TX Matrix Plus router, and not in a routing matrix):

```
[edit]
root@# set interfaces fxp0 unit 0 family inet address address/prefix-length
```

10. Return to the top level of the hierarchy.

```
[edit groups re0]
root# top
```

11. Specify the group application order.

```
[edit]
root# set apply-groups [ re0 re1 ]
```

Controlling the CLI Environment

- [Controlling the Junos OS CLI Environment on page 645](#)
- [Setting the Junos OS CLI Screen Length and Width on page 647](#)
- [Example: Controlling the CLI Environment on page 648](#)
- [Example: Enabling Configuration Breadcrumbs on page 654](#)

Controlling the Junos OS CLI Environment

In operational mode, you can control the Junos OS command-line interface (CLI) environment. For example, you can specify the number of lines that are displayed on the screen or your terminal type. The following output lists the options that you can use to control the CLI environment:

```
user@host>set cli ?
Possible completions:
complete-on-space  Set whether typing space completes current word
directory          Set working directory
idle-timeout       Set maximum idle time before login session ends
logical-system     Set default logical system
prompt            Set CLI command prompt string
restart-on-upgrade Set whether CLI prompts to restart after software upgrade

screen-length      Set number of lines on screen
screen-width       Set number of characters on a line
terminal          Set terminal type
timestamp          Timestamp CLI output
```

NOTE: When you use SSH to log in to the router or log in from the console when its terminal type is already configured, your terminal type, screen length, and screen width are already set.

This chapter discusses the following topics:

- [Setting the Terminal Type on page 646](#)
- [Setting the CLI Prompt on page 646](#)
- [Setting the CLI Directory on page 646](#)
- [Setting the CLI Timestamp on page 646](#)

- [Setting the Idle Timeout on page 646](#)
- [Setting the CLI to Prompt After a Software Upgrade on page 646](#)
- [Setting Command Completion on page 647](#)
- [Displaying CLI Settings on page 647](#)

Setting the Terminal Type

To set the terminal type, use the **set cli terminal** command:

```
user@host> set cli terminal terminal-type
```

The terminal type can be one of the following: **ansi**, **vt100**, **small-xterm**, or **xterm**.

Setting the CLI Prompt

The default CLI prompt is **user@host>**. To change this prompt, use the **set cli prompt** command. If the prompt string contains spaces, enclose the string in quotation marks (" ").

```
user@host> set cli prompt string
```

Setting the CLI Directory

To set the current working directory, use the **set cli directory** command:

```
user@host> set cli directory directory
```

directory is the pathname of working directory.

Setting the CLI Timestamp

By default, CLI output does not include a timestamp. To include a timestamp in CLI output, use the **set cli timestamp** command:

```
user@host> set cli timestamp [format time-date-format | disable]
```

If you do not specify a timestamp format, the default format is **Mmm dd hh:mm:ss** (for example, Feb 08 17:20:49). Enclose the format in single quotation marks (').

Setting the Idle Timeout

By default, an individual CLI session never times out after extended times, unless the **idle-timeout** statement has been included in the user's login class configuration. To set the maximum time an individual session can be idle before the user is logged off the router, use the **set cli idle-timeout** command:

```
user@host> set cli idle-timeout timeout
```

timeout can be 0 through 100,000 minutes. Setting **timeout** to 0 disables the timeout.

Setting the CLI to Prompt After a Software Upgrade

By default, the CLI prompts you to restart after a software upgrade. To disable the prompt for an individual session, use the **set cli restart-on-upgrade off** command:

```
user@host> set cli restart-on-upgrade off
```

To reenable the prompt, use the **set cli restart-on-upgrade on** command:

```
user@host> set cli restart-on-upgrade on
```

Setting Command Completion

By default, you can press Tab or the Spacebar to have the CLI complete a command.

To have the CLI allow only a tab to complete a command, use the **set cli complete-on-space off** command:

```
user@host> set cli complete-on-space off
Disabling complete-on-space
user@host>
```

To reenable the use of both spaces and tabs for command completion, use the **set cli complete-on-space on** command:

```
user@host> set cli complete-on-space on
Enabling complete-on-space
user@host>
```

Displaying CLI Settings

To display the current CLI settings, use the **show cli** command:

```
user@host> show cli
CLI screen length set to 24
CLI screen width set to 80
CLI complete-on-space set to on
```

NOTE: In Junos OS Release 13.3 and later, the value of screen width is 0 or in the range of 40 through 1024.

- Related Documentation**
- [Example: Controlling the CLI Environment on page 648](#)

Setting the Junos OS CLI Screen Length and Width

You can set the Junos OS command-line interface (CLI) screen length and width according to your specific requirements. This topic contains the following sections:

- [Setting the Screen Length on page 647](#)
- [Setting the Screen Width on page 648](#)

Setting the Screen Length

The default CLI screen length is 24 lines. To change the length, use the **set cli screen-length** command:

```
user@host> set cli screen-length length
```

Setting the screen length to 0 lines disables the display of output one screen at a time. Disabling this UNIX **more**-type interface can be useful when you are issuing CLI commands from scripts.

Setting the Screen Width

The value of CLI screen width is **0** or in the range of **40** through **1024**. The default CLI screen width is 80 characters. To change the width, use the **set cli screen-width** command:

```
user@host> set cli screen-width width
```

NOTE: In Junos OS Release 13.2 and earlier, the value of *width* is in the range of 0 through 1024.

Related Documentation

- [Example: Controlling the CLI Environment on page 648](#)
- [Controlling the Junos OS CLI Environment on page 645](#)

Example: Controlling the CLI Environment

The following example shows you how to change the default CLI environment.

Changing the CLI environment is all about customizing the CLI window to fit your personal preferences. Use the settings discussed in this topic to make the CLI window look and behave according to what you find most convenient and efficient.

- [Requirements on page 648](#)
- [Overview on page 649](#)
- [Configuration on page 649](#)

Requirements

No special configuration beyond device initialization is required before configuring this example.

Before starting this example, check what the default settings are. Use the **show cli** operational mode command.

```
user@host> show cli
CLI complete-on-space set to on
CLI idle-timeout disabled
CLI restart-on-upgrade set to on
CLI screen length set to 66
CLI screen width set to 80
CLI terminal is 'xterm'
```

Is the prompt set to your *username@routename*? If not, exit the CLI and enter the operational mode again.

Is the CLI screen length set to 66 and the CLI screen width set to 80? If so, you can start the example. Otherwise, make these changes to the CLI settings:

```

user@host> set cli screen-length 66
Screen length set to 66 lines long
user@host> set cli screen-width 80
Screen width set to 80 columns wide

```

Overview

To see a list of CLI environmental settings that you can change, use the **set cli ?** command.

```

user@host> set cli ?
Possible completions:
  complete-on-space  Set whether typing space completes current word
  directory           Set working directory
  idle-timeout        Set maximum idle time before login session ends
  logical-system      Set default logical system
  prompt             Set CLI command prompt string
  restart-on-upgrade  Set whether CLI prompts to restart after software upgrade
  screen-length       Set number of lines on screen
  screen-width        Set number of characters on a line
  terminal            Set terminal type
  timestamp           Timestamp CLI output

```

This example focuses on three of these commands: **set cli screen-length**, **set cli screen-width**, and **set cli prompt**.

Configuration

This configuration example has the following sections:

- [Configuring the CLI Prompt on page 650](#)
- [Configuring CLI Width on page 650](#)
- [Configuring CLI Length on page 651](#)
- [Return to the Default CLI Prompt on page 653](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands and paste them in a text file, remove any line breaks, change the values used to match your network configuration, and then copy and paste the commands into the CLI at the operational command prompt.

```

set cli prompt "router1-san-jose> "
set cli screen-width 110
set cli screen-length 45

```

NOTE: In Junos OS Release 13.3 and later, the value of screen width is 0 or in the range of 40 through 1024.

Configuring the CLI Prompt

Step-by-Step Procedure The default CLI prompt is your *username@hostname*. But you can have any prompt you find useful.

To configure a different CLI prompt:

- Use the following operational mode command where *string* is the exact text you want to see at the command line.

```
set cli prompt "string"
```

For example, if "*string*" is "router1-san-jose> ", the command is as follows:

```
set cli prompt "router1-san-jose> "
router1-san-jose>
```

Configuring CLI Width

Step-by-Step Procedure How do you know what width works best for you? This example discusses how CLI width can affect what you see.

To configure a new default CLI width:

- See what the current defaults are for the CLI environment.

```
router1-san-jose> show cli
CLI complete-on-space set to on
CLI idle-timeout disabled
CLI restart-on-upgrade set to on
CLI screen length set to 66
CLI screen width set to 80
CLI terminal is 'xterm'
router1-san-jose>
```

NOTE: In Junos OS Release 13.3 and later, the value of *width* is 0 or in the range of 40 through 1024.

- Look at the following output for the operational command **show class-of-service forwarding-class**.

The output from this command is wider than some and so illustrates a common problem with viewing output. If, for example, you have a relatively narrow window, command output might show up in overrun lines.

```
router1-san-jose> show class-of-service forwarding-class
Forwarding class  ID  Queue  Restricted queue  Fabric
priority Policing priority SPU priority
premium-rate      0   0      0                low
normal
medium-rate       1   1      1                low
normal
low-rate          2   2      2                low
normal
```

```

NC          3      3      3      low
normal
tunnel-rate 4      4      0      low
normal

```

The lines look to be intermingled and it is hard to read across to find the information you might be seeking.

3. Change the window width to 110 columns.

Notice how the output of this command is much easier to read in the wider format:

```
router1-san-jose> set cli screen-width 110
```

```
router1-san-jose> show class-of-service forwarding-class
```

Forwarding class	ID	Queue	Restricted queue	Fabric priority	Policing priority	SPU priority
premium-rate	0	0	0	low	normal	low
medium-rate	1	1	1	low	normal	low
low-rate	2	2	2	low	normal	low
NC	3	3	3	low	normal	low
tunnel-rate	4	4	0	low	normal	low

Configuring CLI Length

Step-by-Step Procedure

You can configure the length of the CLI screen in a similar fashion as you did the width.

To configure a new default CLI length:

1. See what the current defaults are for the CLI environment.

```

router1-san-jose> show cli
CLI complete-on-space set to on
CLI idle-timeout disabled
CLI restart-on-upgrade set to on
CLI screen length set to 66
CLI screen width set to 80
CLI terminal is 'xterm'
router1-san-jose>

```

2. Look at the following output for the operational command **show version**.

```

Makefile                                sync-dpm-sb.manifest
build                                  sync-equilibrium-sb.manifest
etc                                   sync-equilibrium2-sb.manifest
include                               sync-hellopics-sb.manifest

router1-san-jose>

```

With a shorter sscreen, you can easily see where the current output begins and ends.

Return to the Default CLI Prompt

Step-by-Step Procedure

To go back to the default prompt:

1. Exit the CLI.

```

router1-san-jose> exit
%

```
2. Enter the CLI operational mode again.

```

% cli
user@host>

```

- Related Documentation**

 - [Controlling the Junos OS CLI Environment on page 645](#)

Example: Enabling Configuration Breadcrumbs

The output of **show configuration** operational mode command and **show configuration** mode commands can be configured to display configuration breadcrumbs that indicate the exact location in the hierarchy of the output being viewed.

Before enabling the configuration breadcrumbs feature, check the output of the **show configuration** command.

```
user@host> show configuration
```

```
...
    }
  }
}
fe-4/1/2 {
  description "FA4/1/2: mxvj1-mr6 (64.12.137.160/27) (T=bb1an, bbmail,
bbowmtc)";
  unit 0 {
    family inet {
      filter {
        output 151mj;
      }
      address 64.12.137.187/27 {
        vrrp-group 1 {
          virtual-address 64.12.137.189;
        }
      }
    }
  }
}
---(more 18%)-----
```

In the output, there is no clear indication about the section of the configuration being viewed.

To enable the configuration breadcrumbs feature:

1. Define a class at the **[edit system login]** hierarchy level.

```
[edit system login]
user@host# set class breadclass idle-timeout 10
```

2. Add a user to the defined login class to enable the breadcrumbs output view when this user enters the **show configuration** operational mode command.

```
[edit system login user user1]
user@host# set class breadclass
```

3. Configure the **configuration-breadcrumbs** statement at the **[edit system login class <class name>]** hierarchy level.

```
[edit system login class breadclass]
user@host# set configuration-breadcrumbs
```

4. Confirm the configuration.

```
[edit]
user@host# commit
```

On enabling configuration breadcrumbs in the CLI, User1 (the user added to the login class) can verify the feature in the output by entering the **show configuration** command.

```
user1@host> show configuration
```

```
...
    }
  }
}
fe-4/1/2 {
  description "FA4/1/2: mxvj1-mr6 (64.12.137.160/27) (T=bb1an, bbmail,
bbowmtc)";
  unit 0 {
    family inet {
      filter {
        output 151mj;
      }
      address 64.12.137.187/27 {
        vrrp-group 1 {
          virtual-address 64.12.137.189;
---(more 18%)---[groups main interfaces fe-4/1/2 unit 0 family inet address
64.12.137.187/27 vrrp-group 1]---
```

The new output indicates the exact location of the configuration hierarchy being viewed. User1 is currently viewing the interface configuration of a group.

NOTE: If you are enabling configuration breadcrumbs for your own user account, you should log out and log in again to see the changes.

apply-groups

Syntax	<code>apply-groups [<i>group-names</i>];</code>
Hierarchy Level	All hierarchy levels
Release Information	Statement introduced before Junos OS Release 7.4.
Description	<p>Apply a configuration group to a specific hierarchy level in a configuration, to have a configuration inherit the statements in the configuration group.</p> <p>You can specify more than one group name. You must list them in order of inheritance priority. The configuration data in the first group takes priority over the data in subsequent groups.</p>
Options	<i>group-names</i> —One or more names specified in the groups statement.
Required Privilege Level	<code>configure</code> —To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• Applying a Junos OS Configuration Group on page 617• groups on page 674

apply-groups-except

Syntax	<code>apply-groups-except [<i>group-names</i>];</code>
Hierarchy Level	All hierarchy levels except the top level
Release Information	Statement introduced before Junos OS Release 7.4.
Description	Disable inheritance of a configuration group.
Options	<i>group-names</i> —One or more names specified in the groups statement.
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• groups on page 674• Disabling Inheritance of a Junos OS Configuration Group on page 620

activate

Syntax	<code>activate (<i>statement</i> <i>identifier</i>)</code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Remove the inactive: tag from a statement, effectively adding the statement or identifier back to the configuration. Statements or identifiers that have been activated take effect when you next issue the commit command.
Options	<p><i>identifier</i>—Identifier from which you are removing the inactive tag. It must be an identifier at the current hierarchy level.</p> <p><i>statement</i>—Statement from which you are removing the inactive tag. It must be a statement at the current hierarchy level.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• deactivate on page 670• Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration on page 489

annotate

Syntax `annotate statement "comment-string"`

Release Information Command introduced before Junos OS Release 7.4.

Description Add comments to a configuration. You can add comments only at the current hierarchy level.

Any comments you add appear only when you view the configuration by entering the [show](#) command in configuration mode or the **show configuration** command in operational mode.

NOTE: The Junos OS supports annotation up to the last level in the configuration hierarchy, including oneliners. However, annotation of parts (child statements or identifiers within a oneliner) of the oneliner is not supported. For example, in the following sample configuration hierarchy, annotation is supported up to the oneliner level 1, but not supported for the metric child statement and its attribute *10*:

```
[edit protocols]
  isis {
    interface ge-0/0/0.0 {
      level 1 metric 10;
    }
  }
}
```

Options *comment-string*—Text of the comment. You must enclose it in quotation marks. In the comment string, you can include the comment delimiters `/* */` or `#`. If you do not specify any, the comment string is enclosed with the `/* */` comment delimiters. If a comment for the specified *statement* already exists, it is deleted and replaced with the new comment.

statement—Statement to which you are attaching the comment.

Required Privilege Level `configure`—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.

- [Adding Comments in a Junos OS Configuration on page 492](#)

commit

Syntax commit <<at <"string">> <and-quit> <check> <comment <"comment-string">>
 <confirmed> <display detail> <fast-synchronize> <minutes> <peers-synchronize >
 <synchronize <force> <scripts>>

Release Information Command introduced before Junos OS Release 7.4.
 Command introduced in Junos OS Release 11.1 for the QFX Series.
 Option **fast-synchronize** added in Junos OS Release 12.2.
 Option **synchronize scripts** introduced in Junos OS Release 13.2.
 Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
 Option **peers-synchronize** introduced in Junos OS Release 14.2R6.

Description Commit the set of changes to the database and cause the changes to take operational effect.

NOTE: The **fast-synchronize** option is not supported in a QFX Series Virtual Chassis.

NOTE: Beginning in Junos OS 12.3, it is possible that FPCs brought offline using the **request chassis fpc slot fpc-slot offline** operational-mode CLI command can come online during a configuration commit or power-supply replacement procedure. As an alternative, use the **set fpc fpc-slot power off** configuration-mode command at the [edit chassis] hierarchy level to ensure that the FPCs remain offline.

Options **at <"string">**—(Optional) Save software configuration changes and activate the configuration at a future time, or upon reboot.

string is **reboot** or the future time to activate the configuration changes. Enclose the **string** value (including **reboot**) in quotation marks (" "). You can specify time in two formats:

- A time value in the form **hh:mm[:ss]** (hours, minutes, and optionally seconds)—Commit the configuration at the specified time, which must be in the future but before 11:59:59 PM on the day the **commit at** configuration command is issued. Use 24-hour time for the **hh** value; for example, **04:30:00** is 4:30:00 AM, and **20:00** is 8:00 PM. The time is interpreted with respect to the clock and time zone settings on the router.
- A date and time value in the form **yyyy-mm-dd hh:mm[:ss]** (year, month, date, hours, minutes, and, optionally, seconds)—Commit the configuration at the specified day and time, which must be after the **commit at** command is issued. Use 24-hour time for the **hh** value. For example, **2003-08-21 12:30:00** is 12:30 PM on August 21, 2003. The time is interpreted with respect to the clock and time zone settings on the router.

For example, **commit at "18:00:00"**. For date and time, include both values in the same set of quotation marks. For example, **commit at "2005-03-10 14:00:00"**.

A *commit check* is performed when you issue the **commit at** configuration mode command. If the result of the check is successful, then the current user is logged out of configuration mode, and the configuration data is left in a read-only state. No other commit can be performed until the scheduled commit is completed.

NOTE: If Junos OS fails before the configuration changes become active, all configuration changes are lost.

You cannot enter the **commit at** configuration command when there is a pending reboot.

You cannot enter the **request system reboot** command once you schedule a commit operation for a specific time in the future.

You cannot commit a configuration when a scheduled commit is pending. For information about how to use the **clear** command to cancel a scheduled configuration, see the [CLI Explorer](#).

and-quit—(Optional) Commit the configuration and, if the configuration contains no errors and the commit succeeds, exit from configuration mode.

check—(Optional) Verify the syntax of the configuration, but do not activate it.

comment <*comment-string*>—(Optional) Add a comment that describes the committed configuration. The comment can be as long as 512 bytes and must be typed on a single line. You cannot include a comment with the **commit check** command. Enclose *comment-string* in quotation marks (" "). For example, **commit comment "Includes changes recommended by SW Lab"**.

confirmed <*minutes*>—(Optional) Require that the commit be confirmed within the specified amount of time. To confirm a commit, enter either a **commit** or **commit check** command. If the commit is not confirmed within the time limit, the configuration rolls back automatically to the precommit configuration and a broadcast message is sent to

all logged-in users. To show when a rollback is scheduled, enter the **show system commit** command. The allowed range is 1 through 65,535 minutes, and the default is 10 minutes.

In Junos OS Release 11.4 and later, you can also use the **commit confirmed** command in the **[edit private]** configuration mode.

display detail—(Optional) Monitors the commit process.

NOTE: In Junos OS Release 10.4 and later, if the number of commit details or messages exceeds a page when used with the **| display detail** pipe option, the more pagination option on the screen is no longer available. Instead, the messages roll up on the screen by default, just like using the **commit** command with the **| no more** pipe option.

fast-synchronize—(Optional) Configure the commits to run in parallel on both the master and backup Routing Engines to reduce the time taken for commit synchronization.

NOTE: The **fast-synchronize** statement is not supported on QFX Series devices when used in a Virtual Chassis.

peers-synchronize—(Optional) Automatically synchronizes and commits MC-LAG configurations across the peers. The local peer (the requesting peer) on which you enable the **peers-synchronize** statement copies and loads its configuration to the remote (the responding) peer. Each peer then performs a syntax check on the configuration file being committed. If no errors are found, the configuration is activated and becomes the current operational configuration on both peers.

synchronize <force> <scripts>—(Optional) If your router has two Routing Engines, you can manually direct one Routing Engine to synchronize its configuration with the other by issuing the **commit synchronize** command. The Routing Engine on which you execute this command (the request Routing Engine) copies and loads its candidate configuration to the other Routing Engine (the responding Routing Engine). Both Routing Engines then perform a syntax check on the candidate configuration file being committed. If no errors are found, the configuration is activated and becomes the current operational configuration on both Routing Engines.

It can happen that the **commit synchronize** command is initiated at the same time from both Routing Engines, which causes the process to hang. As of Junos OS Release 15.1, this is a temporary (20 seconds) anomaly, after which the user can try the **commit synchronize** command again.

The **commit synchronize** command does not work if the responding Routing Engine has uncommitted configuration changes. However, you can enforce commit synchronization on the Routing Engines by using the **force** option. When you issue the **commit synchronize** command with the **force** option from one Routing Engine, the configuration sessions on

the other Routing Engine are terminated and its configuration synchronized with that on the Routing Engine from which you issued the command.

When you issue the **commit synchronize** command with the **scripts** option, the device synchronizes all commit, event, lib, op, and SNMP scripts from the requesting Routing Engine to the responding Routing Engine and also commits and synchronizes the configuration. If the commit check operation fails for the requesting Routing Engine, the process stops, and the scripts are not copied to the responding Routing Engine. If the commit check or commit operation fails for the responding Routing Engine, the scripts are still synchronized, since the synchronization occurs prior to the commit check operation on the responding Routing Engine.

If the **load-scripts-from-flash** statement is configured for the requesting Routing Engine, the device synchronizes the scripts from flash memory on the requesting Routing Engine to flash memory on the responding Routing Engine. Otherwise, the device synchronizes the scripts from the hard disk on the requesting Routing Engine to the hard disk on the responding Routing Engine. The device synchronizes all scripts regardless of whether they are enabled in the configuration or have been updated since the last synchronization.

NOTE: When you issue the **commit synchronize** command, you must use the **apply-groups re0** and **re1** commands. For information about how to use groups, see [“Disabling Inheritance of a Junos OS Configuration Group” on page 620](#).

The responding Routing Engine must use Junos OS Release 5.0 or later.

Required Privilege Level

configure—To enter configuration mode.

NOTE: If you are using Junos OS in a Common Criteria environment, system log messages are created whenever a secret attribute is changed (for example, password changes or changes to the RADIUS shared secret). These changes are logged during the following configuration load operations:

```
load merge
load replace
load override
load update
```

For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*

commit-interval (Batch Commits)

Syntax	<code>commit-interval <i>number-of-seconds-between-commits</i>;</code>
Hierarchy Level	[edit system commit server], [edit system commit synchronize server]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	For Junos OS batch commits, specify the time interval (in seconds) between two commit operations.
Options	<p><i>number-of-seconds-between-commits</i>—Time interval (in seconds) between two commit operations.</p> <p>Range: 1 through 30 seconds.</p> <p>Default: 5 seconds.</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Batch Commit Server Properties on page 517

configuration-breadcrumbs

Syntax	configuration-breadcrumbs;
Hierarchy Level	[edit system login class]
Release Information	Statement introduced in Junos OS Release 12.2.
Description	Enable the configuration breadcrumbs view in the CLI to display the location in the configuration hierarchy.
Required Privilege Level	admin—To view this statement in the configuration. admin-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Enabling Configuration Breadcrumbs on page 654• <i>Defining Junos OS Login Classes</i>• <i>class</i>• <i>login</i>

copy

Syntax	<code>copy <i>existing-statement</i> to <i>new-statement</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Make a copy of an existing statement in the configuration.
Options	<i>existing-statement</i> —Statement to copy. <i>new-statement</i> —Copy of the statement.
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• Copying a Junos OS Statement in the Configuration on page 473

days-to-keep-error-logs (Batch Commits)

Syntax	<code>days-to-keep-error-logs <i>days-to-keep-error-log-entries</i>;</code>
Hierarchy Level	[edit system commit server], [edit system commit synchronize server]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	For Junos OS batch commits, specify the number of days to keep the error logs.
Options	<i>days-to-keep-error-log-entries</i> —Number of days to keep the error logs. Range: 1 through 366 days Default: 1 day
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Batch Commit Server Properties on page 517

deactivate

Syntax	<code>deactivate (<i>statement</i> <i>identifier</i>)</code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Add the inactive: tag to a statement, effectively commenting out the statement or identifier from the configuration. Statements or identifiers marked as inactive do not take effect when you issue the commit command.
Options	<p><i>identifier</i>—Identifier to which you are adding the inactive: tag. It must be an identifier at the current hierarchy level.</p> <p><i>statement</i>—Statement to which you are adding the inactive: tag. It must be a statement at the current hierarchy level.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• activate on page 660• delete on page 671• Deactivating and Reactivating Statements and Identifiers in a Junos OS Configuration on page 489.

delete

Syntax	<code>delete <statement-path> <identifier></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Delete a statement or identifier. All subordinate statements and identifiers contained within the specified statement path are deleted with it.</p> <p>Deleting a statement or an identifier effectively “unconfigures” or disables the functionality associated with that statement or identifier.</p> <p>If you do not specify <i>statement-path</i> or <i>identifier</i>, the entire hierarchy, starting at the current hierarchy level, is removed.</p>
Options	<p><i>statement-path</i>—(Optional) Path to an existing statement or identifier. Include this if the statement or identifier to be deleted is not at the current hierarchy level.</p> <p><i>identifier</i>—(Optional) Name of the statement or identifier to delete.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• deactivate on page 670• Deleting a Statement from a Junos OS Configuration on page 470

edit

Syntax	<code>edit <i>statement-path</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Move inside the specified statement hierarchy. If the statement does not exist, it is created.</p> <p>You cannot use the edit command to change the value of identifiers. You must use the set command.</p>
Options	<i>statement-path</i> —Path to the statement.
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• set on page 689• Displaying the Current Junos OS Configuration on page 497

exit

Syntax	exit <configuration-mode>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Exit the current level of the statement hierarchy, returning to the level prior to the last edit command, or exit from configuration mode. The quit and exit commands are synonyms.
Options	<p>none—Return to the previous edit level. If you are at the top of the statement hierarchy, exit configuration mode.</p> <p>configuration-mode—(Optional) Exit from configuration mode.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• top on page 700• up on page 703• Displaying the Current Junos OS Configuration on page 497

groups

```
Syntax  groups {
        group-name {
            configuration-data;
            when {
                chassis chassis-id;
                member member-id;
                model model-id;
                node node-id;
                peers [ names of peers ]
                routing-engine routing-engine-id;
                time <start-time> [to <end-time>];
            }
            conditional-data;
        }
        lccn-re0 {
            configuration-data;
        }
        lccn-re1 {
            configuration-data;
        }
    }
```

Hierarchy Level [edit]

Release Information Statement introduced before Junos OS Release 7.4.

Description Create a configuration group.

Options —

group-name—Name of the configuration group. To configure multiple groups, specify more than one **group-name**.

configuration-data—The configuration statements that are to be applied elsewhere in the configuration with the **apply-groups** statement, to have the target configuration inherit the statements in the group.

when conditional-data—Option introduced in Junos 11.3. The conditional statements that are to be applied when this configuration group is applied.

On routers that support multiple Routing Engines, you can also specify two special group names:

re0—Configuration statements that are to be applied to the Routing Engine in slot 0.

re1—Configuration statements that are to be applied to the Routing Engine in slot 1.

The configuration specified in group **re0** is applied only if the current Routing Engine is in slot 0; likewise, the configuration specified in group **re1** is applied only if the current Routing Engine is in slot 1. Therefore, both Routing Engines can use the same configuration file, each using only the configuration statements that apply to it. Each

re0 or **re1** group contains at a minimum the configuration for the hostname and the management interface (**fxp0**). If each Routing Engine uses a different management interface, the group also should contain the configuration for the backup router and static routes.

(Routing matrix only) The TX Matrix router supports group names for the Routing Engines in each connected T640 router in the following formats:

NOTE: The management Ethernet interface used for the TX Matrix Plus router, T1600 routers in a routing matrix, and PTX Series Packet Transport Routers, is **em0**. Junos OS automatically creates the router's management Ethernet interface, **em0**.

- **lccn-re0**—Configuration statements applied to the Routing Engine in slot 0 of the specified T640 router that is connected to a TX Matrix router.
 - **lccn-re1**—Configuration statements applied to the specified to the Routing Engine in slot 1 of the specified T640 router that is connected to a TX Matrix router.
- n* identifies the T640 router and can be from 0 through 3.

The remaining statements are explained separately.

Required Privilege Level configure—To enter configuration mode.

help

Syntax	<code>help <(apropos <i>string</i> reference <<i>statement-name</i>> syslog <<i>syslog-tag</i>> tip cli <i>number</i> topic <<i>word</i>>)></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Display help about available configuration statements or general information about getting help.
Options	<p>apropos <i>string</i>—(Optional) Display statement names and help text that matches the string specified. If the string contains spaces, enclose it in quotation marks (" "). You can also specify a regular expression for the string, using standard UNIX-style regular expression syntax.</p> <p>reference <<i>statement-name</i>>—(Optional) Display summary information for the statement. This information is based on summary descriptions that appear in the Junos configuration guides.</p> <p>syslog <<i>syslog-tag</i>>—(Optional) Display information about system log messages.</p> <p>tip cli <i>number</i>—(Optional) Display a tip about using the CLI. Specify the number of the tip you want to view.</p> <p>topic <<i>word</i>>—(Optional) Display usage guidelines for a topic or configuration statement. This information is based on subjects that appear in the Junos configuration guides.</p> <p>Entering the help command without an option provides introductory information about how to use the help command.</p>
Required Privilege Level	configure—To enter configuration mode.
Related Documentation	<ul style="list-style-type: none">• Getting Online Help from the Junos OS Command-Line Interface on page 447

insert

Syntax	insert < <i>statement-path</i> > <i>identifier1</i> (before after) <i>identifier2</i>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Insert an identifier in to an existing hierarchy.
Options	<p>after—Place <i>identifier1</i> after <i>identifier2</i>.</p> <p>before—Place <i>identifier1</i> before <i>identifier2</i>.</p> <p><i>identifier1</i>—Existing identifier.</p> <p><i>identifier2</i>—New identifier to insert.</p> <p><i>statement-path</i>—(Optional) Path to the existing identifier.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• Inserting a New Identifier in a Junos OS Configuration on page 481

load

Syntax	load (factory-default merge override patch replace set update) load (<i>filename</i> terminal) <relative>
QFX Series	load (dhcp-snooping <i>filename</i>)
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 11.1 for the QFX Series. Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
Description	Load a configuration from an ASCII configuration file, from terminal input, or from the factory default. Your current location in the configuration hierarchy is ignored when the load operation occurs.

NOTE: **load** can be run from configuration mode only.

Options **dhcp-snooping**—(QFX Series switches) Loads DHCP snooping entries.

factory-default—Loads the factory configuration. The factory configuration contains the manufacturer's suggested configuration settings. The factory configuration is the router or switch's first configuration and is loaded when the router or switch is first installed and powered on.

NOTE: To load the factory default configuration, you must first **unprotect** any protected hierarchies in the configuration.

filename—Name of the file to load. For information about specifying the filename, see [“Specifying Filenames and URLs” on page 576](#).

merge—Combine the configuration that is currently shown in the CLI with the configuration.

override—Discard the entire configuration that is currently shown in the CLI and load the entire configuration. Marks every object as changed.

patch—Change part of the configuration and mark only those parts as changed.

replace—Look for a **replace** tag in *filename*, delete the existing statement of the same name, and replace it with the configuration.

set—Merge a set of commands with an existing configuration. This option executes the configuration instructions line by line as they are stored in a file or from a terminal. The instructions can contain any configuration mode command, such as **set**, **edit**, **exit**, and **top**.

relative—(Optional) Execute set of commands until the current edit point.

terminal—Use the text you type at the terminal as input to the configuration. Type Ctrl+d to end terminal input.

update—Discard the entire configuration that is currently shown in the CLI, and load the entire configuration. Marks changed objects only.

NOTE: If you are using Junos OS in a Common Criteria environment, system log messages are created whenever a secret attribute is changed (for example, password changes or changes to the RADIUS shared secret). These changes are logged during the following configuration load operations:

```
load merge
load replace
load override
load update
```

For more information, see the *Secure Configuration Guide for Common Criteria and Junos-FIPS*.

Required Privilege Level configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.

maximum-aggregate-pool (Batch Commits)

Syntax	<code>maximum-aggregate-pool <i>maximum-number-of-commits-to-aggregate</i>;</code>
Hierarchy Level	[edit system commit server], [edit system commit synchronize server]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	For Junos OS batch commits, specify the maximum number of individual commit operations that are aggregated or merged into a single commit operation.
Options	<p><i>maximum-number-of-commits-to-aggregate</i>—Maximum number of individual commit operations that are aggregated or merged into a single commit operation.</p> <p>Range: 1 through 4294967295</p> <p>Default: 5</p>
Required Privilege Level	<p>system—To view this statement in the configuration.</p> <p>system-control—To add this statement to the configuration.</p>
Related Documentation	<ul style="list-style-type: none"> • Example: Configuring Batch Commit Server Properties on page 517

maximum-entries (Batch Commits)

Syntax	<code>maximum-entries <i>number-of-entries</i>;</code>
Hierarchy Level	[edit system commit server], [edit system commit synchronize server]
Release Information	Statement introduced in Junos OS Release 12.1.
Description	For Junos OS batch commits, specify the maximum number of commit jobs that are included in the commit queue.
Options	<i>number-of-entries</i> —Maximum number of commit jobs that are included in the commit queue.
Required Privilege Level	system—To view this statement in the configuration. system-control—To add this statement to the configuration.
Related Documentation	<ul style="list-style-type: none">• Example: Configuring Batch Commit Server Properties on page 517

protect

Syntax	<code>protect (hierarchy statement identifier)</code>
Release Information	Command introduced in Junos OS Release 11.2.
Description	Protect a hierarchy, statement, or identifier from modification or deletion.
Options	none
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• Example: Protecting the Junos OS Configuration from Modification or Deletion on page 551

quit

Syntax	quit <configuration-mode>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Exit the current level of the statement hierarchy, returning to the level prior to the last edit command, or exit from configuration mode. The quit and exit commands are synonyms.
Options	<p>none—Return to the previous edit level. If you are at the top of the statement hierarchy, exit configuration mode.</p> <p>configuration-mode—(Optional) Exit from configuration mode.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• top on page 700• up on page 703• Displaying the Current Junos OS Configuration on page 497

rename

Syntax `rename <statement-path> identifier1 to identifier2`

Release Information Command introduced before Junos OS Release 7.4.

Description Rename an existing configuration statement or identifier.

Options *identifier1*—Existing identifier to rename.

identifier2—New name of identifier.

statement-path—(Optional) Path to an existing statement or identifier.

NOTE: For example, to rename interface `ge-0/0/0.0` to `ge-0/0/10.0` at the following hierarchy level:

```
logical-systems {
  logical-system-abc {
    (...)
    protocols {
      ospf {
        area 0.0.0.0 {
          interface ge-0/1/0.0;
```

Issue the following command:

```
rename logical-systems logical-system-abc protocols ospf area 0.0.0.0 interface
ge-0/1/0.0.0 to interface ge-0/1/10.0
```

Required Privilege Level `configure`—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.

Related Documentation

- [Renaming an Identifier in a Junos OS Configuration on page 476](#)

replace

Syntax	replace pattern <i>pattern1</i> with <i>pattern2</i> <upto <i>n</i> >
Release Information	Command introduced in Junos OS Release 7.6.
Description	Replace identifiers or values in a configuration. For more information, refer to KB30332 .
Options	<p><i>pattern1</i>—Text string or regular expression that defines the identifiers or values you want to match.</p> <p><i>pattern2</i>—Text string or regular expression that replaces the identifiers and values located with <i>pattern1</i>.</p> <p>Juniper Networks uses standard UNIX-style regular expression syntax (as defined in POSIX 1003.2). If the regular expression contains spaces, operators, or wildcard characters, enclose the expression in quotation marks. Greedy qualifiers (match as much as possible) are supported. Lazy qualifiers (match as little as possible) are not.</p> <p>upto <i>n</i>—Number of objects replaced. The value of <i>n</i> controls the total number of objects that are replaced in the configuration (not the total number of times the pattern occurs). Objects at the same hierarchy level (siblings) are replaced first. Multiple occurrences of a pattern within a given object are considered a single replacement. If you do not specify an upto option, all identifiers and values in the configuration that match <i>pattern1</i> are replaced.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• Using Global Replace in a Junos OS Configuration on page 603

rollback

Syntax	<code>rollback <number rescue></code>
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p>
Description	<p>Return to a previously committed configuration. The software saves the last 50 committed configurations, including the rollback number, date, time, and name of the user who issued the commit configuration command.</p> <p>The currently operational Junos OS configuration is stored in the file juniper.conf, and the last three committed configurations are stored in the files juniper.conf.1, juniper.conf.2, and juniper.conf.3. These four files are located in the directory /config, which is on the router's flash drive. The remaining 46 previous committed configurations, the files juniper.conf.4 through juniper.conf.49, are stored in the directory /var/db/config, which is on the router's hard disk.</p> <p>During rollback, the configuration you specify is loaded from the associated file. Only objects in the rollback configuration that differ from the previously loaded configuration are marked as changed (equivalent to load update).</p>
Options	<p>none (Optional)—Return to the most recently saved configuration.</p> <p>number—(Optional) Configuration to return to. The range of values is from 0 through 49. The most recently saved configuration is number 0, and the oldest saved configuration is number 49. The default is 0.</p> <p>rescue—(Optional) Return to the rescue configuration.</p>
Required Privilege Level	rollback—To roll back to configurations other than the one most recently committed.
Related Documentation	<ul style="list-style-type: none"> • Returning to a Previously Committed Junos OS Configuration on page 535 • Creating and Returning to a Rescue Configuration on page 538

run

Syntax	<code>run <i>command</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Run a top-level CLI command without exiting from configuration mode.
Options	<i>command</i> —CLI top-level command.
Required Privilege Level	configure—To enter configuration mode.
Related Documentation	<ul style="list-style-type: none">• Understanding Junos OS CLI Configuration Mode on page 456

save

Syntax	<code>save <i>filename</i></code>
QFX Series	<code>save (dhcp-snooping <i>filename</i>)</code>
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.</p>
Description	<p>Save the configuration to an ASCII file. The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.</p> <p>When saving a file to a remote system, the software uses the scp/ssh protocol.</p>
Options	<p><i>filename</i>—Name of the saved file. You can specify a filename in one of the following ways:</p> <ul style="list-style-type: none"> • <i>filename</i>—File in the user's home directory (the current directory) on the local flash drive. • <i>path/filename</i>—File on the local flash drive. • <i>/var/filename</i> or <i>/var/path/filename</i>—File on the local hard disk. • <i>a:filename</i> or <i>a:path/filename</i>—File on the local drive. The default path is / (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format. • <i>hostname:/path/filename</i>, <i>hostname:filename</i>, <i>hostname:path/filename</i>, or <i>scp://hostname/path/filename</i>—File on an scp/ssh client. This form is not available in the worldwide version of Junos OS. The default path is the user's home directory on the remote system. You can also specify <i>hostname</i> as <i>username@hostname</i>. • <i>ftp://hostname/path/filename</i>—File on an FTP server. You can also specify <i>hostname</i> as <i>username @hostname</i> or <i>username:password @hostname</i>. The default path is the user's home directory. To specify an absolute path, the path must start with the string %2F; for example, <i>ftp://hostname/%2Fpath/filename</i>. To have the system prompt you for the password, specify <i>prompt</i> in place of the password. If a password is required, and you do not specify the password or <i>prompt</i>, an error message is displayed: <pre> user@host> file copy ftp://username@ftp.hostname.net//filename file copy ftp.hostname.net: Not logged in. user@host> file copy ftp://username:prompt@ftphostname.net//filename </pre> <p>Password for <i>username@ftp.hostname.net</i>:</p> • <i>http://hostname/path/filename</i>—File on a Hypertext Transfer Protocol (HTTP) server. You can also specify <i>hostname</i> as <i>username@hostname</i> or <i>username:password@hostname</i>. If a password is required and you omit it, you are prompted for it. • <i>re0:/path/filename</i> or <i>re1:/path/filename</i>—File on a local Routing Engine.

Required Privilege Level configure—To enter configuration mode.

server (Batch Commits)

Syntax

```
server {  
    commit-interval <number-of-seconds-between-commits>;  
    days-to-keep-error-logs <days-to-keep-error-log-entries>;  
    maximum-aggregate-pool <maximum-number-of-commits-to-aggregate>;  
    maximum-entries <number-of-entries>;  
    traceoptions {  
        file filename;  
        files number;  
        flag (all | batch | commit-server | configuration);  
        size maximum-file-size;  
        (world-readable | no-world-readable);  
    }  
}
```

Hierarchy Level [edit system commit]

Release Information Statement introduced in Junos OS Release 12.1.

Description Configure the system commit to occur in batches. Configure parameters for aggregating and saving batch commits.

Options [commit-interval](#)—Configure the interval between commits.

[days-to-keep-error-logs](#)—Configure the number of days to keep log entries.

[maximum-aggregate-pool](#)—Configure the maximum number of commits to aggregate together.

[maximum-entries](#) —Configure the maximum number of commit entries.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Related Documentation

- [Example: Configuring Batch Commit Server Properties on page 517](#)

set

Syntax	<code>set <<i>statement-path</i>> <i>identifier</i></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Create a statement hierarchy and set identifier values. This is similar to edit except that your current level in the hierarchy does not change.
Options	<p><i>identifier</i>—Name of the statement or identifier to set.</p> <p><i>statement-path</i>—(Optional) Path to an existing statement hierarchy level. If that hierarchy level does not exist, it is created.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• edit on page 672• Displaying the Current Junos OS Configuration on page 497

show

Syntax	<code>show <statement-path> <identifier></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Display the current configuration.
Options	<p><code>none</code>—Display the entire configuration at the current hierarchy level.</p> <p><code>identifier</code>—(Optional) Display the configuration for the specified identifier.</p> <p><code>statement-path</code>—(Optional) Display the configuration for the specified statement hierarchy path.</p>
Required Privilege Level	<code>configure</code> —To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• show display inheritance on page 694• show display omit on page 695• show display set on page 696• show display set relative on page 697• show groups junos-defaults on page 698• Displaying the Current Junos OS Configuration on page 497

show configuration

Syntax	<code>show configuration</code> <code><statement-path></code>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Display the configuration that currently is running on the router or switch, which is the last committed configuration.
Options	<p>none—Display the entire configuration.</p> <p>statement-path—(Optional) Display one of the following hierarchies in a configuration. (Each statement-path option has additional suboptions not described here. See the appropriate feature guide or EX Series switch documentation for more information.)</p> <ul style="list-style-type: none"> • access—Network access configuration. • access-profile—Access profile configuration. • accounting-options—Accounting data configuration. • applications—Applications defined by protocol characteristics. • apply-groups—Groups from which configuration data is inherited. • chassis—Chassis configuration. • chassis network-services—Current running mode. • class-of-service—Class-of-service configuration. • diameter—Diameter base protocol layer configuration. • ethernet-switching-options—(EX Series switch only) Ethernet switching configuration. • event-options—Event processing configuration. • firewall—Firewall configuration. • forwarding-options—Options that control packet sampling. • groups—Configuration groups. • interfaces—Interface configuration. • jsrc—JSRC partition configuration. • jsrc-partition—JSRC partition configuration. • logical-systems—Logical system configuration. • poe—(EX Series switch only) Power over Ethernet configuration. • policy-options—Routing policy option configuration. • protocols—Routing protocol configuration.

- **routing-instances**—Routing instance configuration.
- **routing-options**—Protocol-independent routing option configuration.
- **security**—Security configuration.
- **services**—Service PIC applications configuration.
- **snmp**—Simple Network Management Protocol configuration.
- **system**—System parameters configuration.
- **virtual-chassis**—(EX Series switch only) Virtual Chassis configuration.
- **vlan**—(EX Series switch only) VLAN configuration.

Additional Information The portions of the configuration that you can view depend on the user class that you belong to and the corresponding permissions. If you do not have permission to view a portion of the configuration, the text **ACCESS-DENIED** is substituted for that portion of the configuration. If you do not have permission to view authentication keys and passwords in the configuration, because the **secret** permission bit is not set for your user account, the text **SECRET-DATA** is substituted for that portion of the configuration. If an identifier in the configuration contains a space, the identifier is displayed in quotation marks.

Likewise, when you issue the **show configuration** command with the **| display set** pipe option to view the configuration as **set** commands, those portions of the configuration that you do not have permissions to view are substituted with the text **ACCESS-DENIED**.

show | display inheritance

Syntax show | display inheritance <brief | defaults | no-comments | terse>

Release Information Command introduced before Junos OS Release 7.4.

Description Show the inherited configuration data and information about the source group from which the configuration has been inherited. Show interface ranges configuration data in expanded format and information about the source interface-range from which the configuration has been expanded

```
user@host# show system ports | display inheritance defaults
## 'console' was inherited from group 'junos-defaults'
## 'vt100' was inherited from group 'junos-defaults'
## console type vt100;
```

```
user@host# show system login class readonly | display inheritance
## 'interface' was inherited from group global'
## 'network' was inherited from group global'
## 'routing' was inherited from group global'
## 'system' was inherited from group global'
## 'trace' was inherited from group global'
## 'view' was inherited from group global'
##
permissions [ interface network routing system trace view ];
```

```
user@host# show system login class readonly | display inheritance no-comments
permissions [ interface network routing system trace view ];
```

- Options**
- **brief**—Display brief output for the command.
 - **defaults**—Display the Junos OS defaults that have been applied to the configuration.
 - **no-comments**—Display configuration information without inline comments marked with ##.
 - **terse**—Display terse output with inheritance details as inline comment.

status

Syntax	status
Release Information	Command introduced before Junos OS Release 7.4.
Description	Display the users currently editing the configuration.
Required Privilege Level	configure—To enter configuration mode. <ul style="list-style-type: none">• “Displaying Users Currently Editing the Junos OS Configuration” on page 504.

top

Syntax	<code>top <configuration-command></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Return to the top level of configuration command mode, which is indicated by the [edit] banner.
Options	<i>configuration-command</i> —(Optional) Issue configuration mode commands from the top of the hierarchy.
Required Privilege Level	configure—To enter configuration mode.
Related Documentation	<ul style="list-style-type: none">• Displaying the Current Junos OS Configuration on page 497• exit on page 673• up on page 703

tracoptions (Batch Commits)

Syntax	<pre>tracoptions { file <i>filename</i>; files <i>number</i>; flag (all batch commit-server configuration); size <i>maximum-file-size</i>; (world-readable no-world-readable); }</pre>
Hierarchy Level	<pre>[edit system commit server], [edit system commit synchronize server]</pre>
Release Information	Statement introduced in Junos OS Release 12.1.
Description	For Junos OS batch commits, configure tracing operations.
Options	file <i>name</i> —Name of the file to receive the output of the tracing operation.

NOTE: If you configure **tracoptions** and do not explicitly specify a **filename** for logging the events, the batch commit events are logged in the **commitd** file (**var/log/commitd**) by default.

files *number*—Maximum number of trace files.

flag *flag*—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. You can include the following flags:

- **all**—All tracing operations flags.
- **batch**—Tracing operations for batch events.
- **commit-server**—Tracing operations for commit server events.
- **configuration**—Tracing operations for the reading of configuration.

size—Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB).

world-readable | no-world-readable—**readable**—Grant all users permission to read archived log files, or restrict the permission only to the root user and users who have the Junos OS maintenance permission.

Required Privilege Level	<pre>system—To view this statement in the configuration. system-control—To add this statement to the configuration.</pre>

update

Syntax update

Release Information Command introduced in Junos OS Release 7.5.

Description Update private candidate configuration with a copy of the most recently committed configuration, including your private changes.

NOTE: The **update** command is available only when you are in configure private mode.

Required Privilege Level configure—To enter configuration mode.

Related Documentation

- [Updating the configure private Configuration on page 496.](#)

when

Syntax	<pre> when { chassis <i>chassis-id</i>; member <i>member-id</i>; model <i>model-id</i>; node [<i>names of peers</i>]<i>node-id</i>; peers [<i>names of peers</i>]; routing-engine <i>routing-engine-id</i>; time <<i>start-time</i>> [to <<i>end-time</i>>]; } </pre>
Hierarchy Level	[edit groups <i>group-name</i>]
Release Information	<p>Statement introduced in Junos OS Release 11.3.</p> <p>peers option added in Junos OS Release 14.2R6 for the MX Series.</p> <p>peers option added in Junos OS Release 15.1X53-D60 for the QFX Series.</p>
Description	<p>Define conditions under which the configuration group should be applied. Conditions include the type of chassis, model, or Routing Engine, virtual chassis member, cluster node, and start and optional end time of day. If you specify multiple conditions in a single configuration group, all conditions must be met before the configuration group is applied.</p>
Options	<p>chassis <i>chassis-id</i>—Specify the chassis type of the router. Valid types include SCC0, SCC1, LCC0, LCC1 ... LCC3.</p> <p>member <i>member-id</i>—Specify the name of the member of the virtual chassis.</p> <p>model <i>model-id</i>—Specify the model name of the router, such as m7i or tx100.</p> <p>node <i>node-id</i>—Specify the cluster node.</p> <p>peers [<i>names of peers</i>]—Specify the names of the MC-LAG peers participating in commit synchronization.</p> <p>routing-engine <i>routing-engine-id</i>—Specify the type of Routing Engine, re0 or re1.</p> <p>time <<i>start-time</i>> [to <<i>end-time</i>>]—Specify the start time or time duration for this configuration group to be applied. If only the start time is specified, the configuration group is applied at the specified time and remains in effect until the time is changed. If the end time is specified, then on each day, the applied configuration group is started and stopped at the specified times. The syntax for specifying the time is: time <<i>start-time</i>> [to <<i>end-time</i>>] using the time format yyyy-mm-dd.hh:mm, hh:mm, or hh.</p>
Required Privilege Level	configure—To enter configuration mode.

wildcard delete

Syntax	<code>wildcard delete <statement-path> <identifier> <regular-expression></code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Delete a statement or identifier. All subordinate statements and identifiers contained within the specified statement path are deleted with it.</p> <p>Deleting a statement or an identifier effectively “unconfigures” or disables the functionality associated with that statement or identifier.</p> <p>If you do not specify <i>statement-path</i> or <i>identifier</i>, the entire hierarchy starting at the current hierarchy level is removed.</p>
Options	<p><i>identifier</i>—(Optional) Name of the statement or identifier to delete.</p> <p><i>regular-expression</i>—(Optional) The pattern based on which you want to delete multiple items. When you use the wildcard command to delete related configuration items, the <i>regular-expression</i> must be the final statement.</p> <p><i>statement-path</i>—(Optional) Path to an existing statement or identifier. Include this if the statement or identifier to be deleted is not at the current hierarchy level.</p>
Required Privilege Level	configure—To enter configuration mode. Other required privilege levels depend on where the statement is located in the configuration hierarchy.

CHAPTER 31

Junos OS CLI Environment Commands

- `set cli complete-on-space`
- `set cli directory`
- `set cli idle-timeout`
- `set cli prompt`
- `set cli restart-on-upgrade`
- `set cli screen-length`
- `set cli screen-width`
- `set cli terminal`
- `set cli timestamp`
- `set date`
- `show cli`
- `show cli`
- `show cli authorization`
- `show cli directory`
- `show cli history`

set cli complete-on-space

Syntax	set cli complete-on-space (off on)
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Set the command-line interface (CLI) to complete a partial command entry when you type a space or a tab. This is the default behavior of the CLI.
Options	off —Turn off command completion. on —Allow either a space or a tab to be used for command completion.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>CLI User Interface Overview</i>• show cli on page 720
List of Sample Output	set cli complete-on-space on page 710
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli complete-on-space

In the following example, pressing the Spacebar changes the partial command entry from **com** to **complete-on-space**. The example shows how adding the keyword **off** at the end of the command disables command completion.

```
user@host> set cli com<Space>
user@host>set cli complete-on-space off
Disabling complete-on-space
```

set cli directory

Syntax	set cli directory <i>directory</i>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Set the current working directory.
Options	<i>directory</i> —Pathname of the working directory.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>CLI User Interface Overview</i>• <i>show cli directory</i>
List of Sample Output	set cli directory on page 711
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli directory

```
user@host> set cli directory /var/tmp
Current directory: /var/tmp
```

set cli idle-timeout

Syntax	set cli idle-timeout < <i>minutes</i> >
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Set the maximum time that an individual session can be idle before the user is logged off the router or switch.
Options	<i>minutes</i> —(Optional) Maximum idle time. The range of values, in minutes, is 0 through 100,000. If you do not issue this command, and the user's login class does not specify this value, the user is never forced off the system after extended idle times. Setting the value to 0 disables the timeout.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>CLI User Interface Overview</i>• show cli on page 720
List of Sample Output	set cli idle-timeout on page 712
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli idle-timeout

```
user@host> set cli idle-timeout 60
Idle timeout set to 60 minutes
```

set cli prompt

Syntax	set cli prompt <i>string</i>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Set the prompt so that it is displayed within the CLI.
Options	<i>string</i> —CLI prompt string. To include spaces in the prompt, enclose the string in quotation marks. By default, the string is <i>username@hostname</i> .
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>CLI User Interface Overview</i>• show cli on page 720
List of Sample Output	set cli prompt on page 713
Output Fields	When you enter this command, the new CLI prompt is displayed.

Sample Output

set cli prompt

```
user@host> set cli prompt lab1-router>
lab1-router>
```

set cli restart-on-upgrade

Syntax	set cli restart-on-upgrade string (off on)
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	For an individual session, set the CLI to prompt you to restart the router or switch after upgrading the software.
Options	off —Disables the prompt. on —Enables the prompt.
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• <i>CLI User Interface Overview</i>• show cli on page 720
List of Sample Output	set cli restart-on-upgrade on page 714
Output Fields	When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli restart-on-upgrade

```
user@host> set cli restart-on-upgrade on
Enabling restart-on-upgrade
```

set cli screen-length

Syntax	set cli screen-length <i>length</i>
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Set terminal screen length.</p> <pre>user@host> set cli screen-length 75 Screen Length set to 75</pre>
Options	<p><i>length</i>—Number of lines of text that the terminal screen displays. The range of values, in number of lines, is 24 through 100,000. The default is 24.</p> <p>The point at which the ---(more)--- prompt appears on the screen is a function of this setting and the settings for the set cli screen-width and set cli terminal commands.</p>
Required Privilege Level	view
Related Documentation	<ul style="list-style-type: none">• Setting the Screen Length on page 647• Setting the Junos OS CLI Screen Length and Width on page 647• set cli screen-width on page 716• set cli terminal on page 717• show cli on page 722

set cli screen-width

Syntax `set cli screen-width <width>`

Release Information Command introduced before Junos OS Release 7.4.

Description Set the terminal screen width.

```
user@host> set cli screen-width 132
Screen width set to 132
```

Options *width*—Number of characters in a line. The value is **0** or in the range of **40** through **1024**. The default value is **80**.

NOTE: In Junos OS Release 13.2 and earlier, the value of *width* is in the range of **0** through **1024**.

show cli

List of Syntax	Syntax on page 720 Syntax (QFX Series and OCX Series) on page 720
Syntax	show cli
Syntax (QFX Series and OCX Series)	show cli <authorization> <directory> <history <i>count</i> >
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches. Command introduced in Junos OS Release 11.1 for the QFX Series. Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.
Description	Display configured CLI settings.
Options	This command has no options.
Required Privilege Level	view
List of Sample Output	show cli on page 721
Output Fields	Table 69 lists the output fields for the show cli command. Output fields are listed in the approximate order in which they appear.

Table 69: show cli Output Fields

Field Name	Field Description
CLI complete-on-space	Capability to complete a partial command entry when you type a space or a tab: on or off .
CLI idle-timeout	Maximum time that an individual session can be idle before the user is logged out from the router or switch. When this feature is enabled, the number of minutes is displayed. Otherwise, the state is disabled .
CLI restart-on-upgrade	CLI is set to prompt you to restart the router or switch after upgrading the software: on or off .
CLI screen-length	Number of lines of text that the terminal screen displays.
CLI screen-width	Number of characters in a line on the terminal screen.
CLI terminal	Terminal type.
CLI is operating in	Mode: enhanced .
CLI timestamp	Date and time format for the timestamp. If the timestamp is not set, the state is disabled .
CLI working directory	Pathname of the working directory.

Sample Output

show cli

```
user@host> show cli
CLI complete-on-space set to on
CLI idle-timeout disabled
CLI restart-on-upgrade set to on
CLI screen-length set to 47
CLI screen-width set to 132
CLI terminal is 'vt100'
CLI is operating in enhanced mode
CLI timestamp disabled
CLI working directory is '/var/tmp'
```

show cli

Syntax	show cli
Release Information	Command introduced before Junos OS Release 7.4.
Description	<p>Display configured CLI settings.</p> <pre>user@host> show cli CLI complete-on-space set to on CLI idle-timeout disabled CLI restart-on-upgrade set to on CLI screen-length set to 47 CLI screen-width set to 132 CLI terminal is 'vt100' CLI is operating in enhanced mode CLI timestamp disabled CLI working directory is '/var/tmp'</pre>

show cli authorization

Syntax show cli authorization

Release Information Command introduced before Junos OS Release 7.4.

Description Display the permissions for the current user.

```
user@host> show cli authorization
Current user: 'root' login: 'boojum' class '(root)'
Permissions:
Permissions:
  admin      -- Can view user accounts
  admin-control-- Can modify user accounts
  clear      -- Can clear learned network info
  configure  -- Can enter configuration mode
  control    -- Can modify any config
  edit       -- Can edit full files
  field      -- Can use field debug commands
  floppy     -- Can read and write the floppy
  interface  -- Can view interface configuration
  interface-control-- Can modify interface configuration
  network    -- Can access the network
  reset      -- Can reset/restart interfaces and daemons
  routing    -- Can view routing configuration
  routing-control-- Can modify routing configuration
  shell      -- Can start a local shell
  snmp       -- Can view SNMP configuration
  snmp-control-- Can modify SNMP configuration
  system     -- Can view system configuration
  system-control-- Can modify system configuration
  trace      -- Can view trace file settings
  trace-control-- Can modify trace file settings
  view       -- Can view current values and statistics
  maintenance -- Can become the super-user
  firewall   -- Can view firewall configuration
  firewall-control-- Can modify firewall configuration
  secret     -- Can view secret statements
  secret-control-- Can modify secret statements
  rollback   -- Can rollback to previous configurations
  security   -- Can view security configuration
  security-control-- Can modify security configuration
  access     -- Can view access configuration
  access-control-- Can modify access configuration
  view-configuration-- Can view all configuration (not including secrets)
  flow-tap   -- Can view flow-tap configuration
  flow-tap-control-- Can modify flow-tap configuration
  idp-profiler-operation-- Can Profiler data
  pgcp-session-mirroring-- Can view pgcp session mirroring configuration
  pgcp-session-mirroring-control-- Can modify pgcp session mirroring configuration
  storage    -- Can view fibre channel storage protocol configuration
  storage-control-- Can modify fibre channel storage protocol configuration
  all-control -- Can modify any configuration
```

CHAPTER 32

Junos OS CLI Operational Mode Commands

- `configure`
- `file`
- `help`
- `|` (pipe)
- `request`
- `request system commit server pause`
- `request system commit server queue cleanup`
- `request system commit server start`
- `restart`
- `set`
- `show system commit server queue`
- `show system commit server status`

configure

Syntax	configure <batch> <dynamic> <exclusive> <private>
Release Information	Command introduced before Junos OS Release 7.4. Command introduced in Junos OS Release 9.0 for EX Series switches.
Description	Enter configuration mode. When this command is entered without any optional keywords, everyone can make configuration changes and commit all changes made to the configuration.
Options	<p>none—Enter configuration mode.</p> <p>batch—(Optional) Work in the batch commit mode where commit operations are executed in batches.</p> <p>dynamic—(Optional) Configure routing policies and certain routing policy objects in a dynamic database that is not subject to the same verification required in the standard configuration database. As a result, the time it takes to commit changes to the dynamic database is much shorter than for the standard configuration database. You can then reference these policies and policy objects in routing policies you configure in the standard database.</p> <p>exclusive—(Optional) Lock the candidate configuration for as long as you remain in configuration mode, allowing you to make changes without interference from other users. Other users can enter and exit configuration mode, but they cannot change the configuration.</p> <p>private—(Optional) Allow multiple users to edit different parts of the configuration at the same time and to commit only their own changes, or to roll back without interfering with one another's changes. You cannot commit changes in configure private mode when another user is in configure exclusive mode.</p>
Additional Information	For more information about the different methods of entering configuration mode and the restrictions that apply, see the <i>Junos OS Administration Library for Routing Devices</i> .
Required Privilege Level	configure
Related Documentation	<ul style="list-style-type: none"> • show configuration on page 691
List of Sample Output	configure on page 729
Output Fields	When you enter this command, you are placed in configuration mode and the system prompt changes from <i>hostname></i> to <i>hostname#</i> .

Sample Output

configure

```
user@host> configure
Entering configuration mode
[edit]
user@host#
```

file

Syntax	file <archive checksum compare copy delete list rename show source address>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Archive files from the device, copy files to and from the router or switch, calculate the file checksum, compare files, delete a file from the device, list files on the device, rename a file, show file contents, or show the local address to initiate a connection.
Options	<p>archive (Optional)—Archive, and optionally compress, one or multiple local system files as a single file, locally or at a remote location.</p> <p>checksum (Optional)—Calculate the Message Digest 5 (MD5) checksum of a file.</p> <p>compare (Optional)—Compare two local files and describe the differences between them in default, context, or unified output styles.</p> <p>copy (Optional)—Copy files from one place to another on the local switch or between the local switch and a remote system.</p> <p>delete (Optional)—Delete a file on the local switch.</p> <p>list (Optional)—Display a list of files on the local switch.</p> <p>rename (Optional)—Rename a file on the local switch.</p> <p>show (Optional)—Display the contents of a file.</p> <p>source address (Optional)—Specify the source address of the local file.</p>
Required Privilege Level	maintenance

help

Syntax	<code>help < (apropos <i>string</i> reference <<i>statement-name</i>> syslog <<i>syslog-tag</i>> tip cli <i>number</i> topic <<i>word</i>>)></code>
Release Information	Command introduced before Junos OS Release 7.4. apropos option added in Junos OS Release 8.0.
Description	Display help about available operational commands, configuration statements, or general information about getting help. Entering the help command without an option provides introductory information about how to use the help and ? commands.
Options	<p>apropos <i>string</i>—(Optional) Display command names and help text that matches the string specified. If the string contains spaces, enclose it in quotation marks (" "). You can also specify a regular expression for the string, using standard UNIX-style regular expression syntax.</p> <p>reference <<i>statement-name</i>>—(Optional) Display summary information for a configuration statement. This information is based on summary descriptions that appear in the Junos configuration guides.</p> <p>syslog <<i>syslog-tag</i>>—(Optional) Display information about system log messages.</p> <p>tip cli <i>number</i>—(Optional) Display a tip about using the CLI. Specify the number of the tip you want to view.</p> <p>topic <<i>word</i>>—(Optional) Display usage guidelines for a topic or configuration statement. This information is based on subjects that appear in the Junos configuration guides.</p>
Required Privilege Level	None
Related Documentation	<ul style="list-style-type: none"> • Getting Online Help from the Junos OS Command-Line Interface on page 447

| (pipe)

Syntax	(compare count display (changed commit-scripts detail set inheritance json omit xml) except <i>pattern</i> find <i>pattern</i> hold last <i>lines</i> match <i>pattern</i> no-more refresh <i>interval</i> request message (all <i>account@terminal</i>) resolve <full-names> save <i>filename</i> append <i>filename</i> tee trim <i>columns</i>)
Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>display commit-scripts option added in Junos OS Release 7.4.</p> <p>tee option added in Junos OS Release 14.1.</p> <p>display json option added in Junos OS Release 14.2.</p> <p>compare display xml option added in Junos OS Release 15.1.</p>
Description	Filter the output of an operational mode or a configuration mode command.
Options	<p>append <i>filename</i>—Append the output to a file.</p> <p>compare (<i>filename</i> rollback <i>n</i>)—Compare configuration changes with another configuration file. In operational mode, use the show configuration command. In configuration mode, use the show command. See “Comparing Configurations and Displaying the Differences in Text” on page 590</p> <p>compare display xml—Compare configuration changes with the active configuration and display them in XML format. In operational mode, use the show configuration command. In configuration mode, use the show command. See “Understanding the show compare display xml Command Output” on page 528.</p> <p>count—Display the number of lines in the output.</p> <p>display—Display additional information about the configuration contents.</p> <p>changed—Tag changes with junos:changed attribute (XML only).</p> <p>commit-scripts—(Configuration mode only) Display all statements that are in a configuration, including statements that were generated by transient changes. For more information, see the <i>Automation Scripting Feature Guide</i>.</p> <p>detail—(Configuration mode only) Display configuration data detail.</p> <p>inheritance <brief default no-comments groups terse>—(Configuration mode only) Display inherited configuration data and source group.</p> <p>json—Display the output for operational commands and configuration data in JavaScript Object Notation (JSON) format.</p> <p>omit—(Configuration mode only) Display configuration statements omitted by the apply-flags omit configuration statement.</p> <p>set—Display the configuration as a series of configuration mode commands required to re-create the configuration.</p>

xml—(Operational mode only) Display the command output as Junos XML protocol (Extensible Markup Language [XML]) tags.

except *pattern*—Ignore text matching a regular expression when searching the output. If the regular expression contains spaces, operators, or wildcard characters, enclose it in quotation marks.

find *pattern*—Display the output starting at the first occurrence of text matching a regular expression. If the regular expression contains spaces, operators, or wildcard characters, enclose it in quotation marks (" ").

hold—Hold text without exiting the **--More--** prompt.

last *lines*—Display the last number of lines you want to view from the end of the configuration. However, when the number of lines requested is less than the number of lines that the screen length setting permits you to display, Junos returns as many lines as permitted by the screen length setting. For more information on using the **last *lines*** option, see [“Displaying Output Beginning with the Last Entries” on page 594](#).

match *pattern*—Search for text matching a regular expression. If the regular expression contains spaces, operators, or wildcard characters, enclose it in quotation marks.

no-more—Display output all at once rather than one screen at a time.

resolve—(Operational mode only) Convert IP addresses into Domain Name System (DNS) names. Truncates to fit original size unless **full-names** is specified. To prevent the names from being truncated, use the **full-names** option.

refresh *interval*—Refresh the display of the command according to the interval specified. The screen gets refreshed periodically to show you the current output of the command until you quit the command. The default refresh interval is one second. However, you can also explicitly specify a value from 1 through 604800 for the refresh interval.

request message (all | *account@terminal*)—Display command output on the terminal of a specific user logged in to your router, or on the terminals of all users logged in to your router.

save *filename*—Save the output to a file or URL. For information about specifying the filename, see [“Specifying Filenames and URLs” on page 576](#).

tee—Allows you to both display the command output on screen and write it to a file. Unlike the UNIX **tee** command, if the file cannot be opened, just an error message is displayed.

trim *columns*—Trim specified number of columns from the start line. Only positive values are accepted. An error message appears if a negative value is given.

request

Syntax request <chassis | ipsec switch | message | mpls | routing-engine | security | services | system | flow-collector | support information>

Release Information Command introduced before Junos OS Release 7.4.

Description Stop or reboot router components, switch between primary and backup components, display messages, and display system information.

CAUTION: Halt the backup Routing Engine before you remove it or shut off the power to the router; otherwise, you might need to reinstall the Junos OS.

NOTE: If your router contains two Routing Engines and you want to shut the power off to the router or remove a Routing Engine, you must first halt the backup Routing Engine (if it has been upgraded) and then the master Routing Engine. To halt a Routing Engine, enter the `request system halt` command. You can also halt both Routing Engines at the same time by issuing the `request system halt both-routing-engines` command.

If you want to reboot a router that has two Routing Engines, reboot the backup Routing Engine (if you have upgraded it) and then the master Routing Engine.

NOTE: If you reboot the TX Matrix router, all the T640 master Routing Engines connected to the TX Matrix router reboot. If you halt both Routing Engines on a TX Matrix router, all the T640 Routing Engines connected to the TX Matrix router are also halted. Likewise, if you reboot the TX Matrix Plus router, all the T1600 or T4000 master Routing Engines connected to the TX Matrix Plus router reboot. If you halt both Routing Engines on a TX Matrix Plus router, all the T1600 or T4000 Routing Engines connected to the TX Matrix Plus router are also halted.

NOTE: If you insert a Flexible PIC Concentrator (FPC) into your router, you may need to issue the `request chassis fpc` command (or press the online button) to bring the FPC online. This applies to FPCs in M20, M40, M40e, M160, M320, and T Series routers. For command usage, see the `request chassis fpc` command description in the [CLI Explorer](#).

Additional Information Most **request** commands are described in the *Junos System Basics and Services Command Reference*. The following **request** commands are described in the *Junos Interfaces Command Reference*: **request ipsec switch** and **request services**.

request system commit server pause

Syntax `request system commit server pause`

Release Information Command introduced in Junos OS Release 12.1.

Description Pause the commit server.

NOTE: If you issue this command when a commit job is in process, the batch commit server pauses only after the current commit job is completed.

Options This command has no options.

Required Privilege Level view

Related Documentation • [Example: Configuring Batch Commit Server Properties on page 517](#)

Sample Output

When you enter the `request system commit server pause` command, you are provided feedback on the status of your request.

`request system commit server pause`

```
user@host> request system commit server pause
```

```
Successfully paused the commit server.
```

request system commit server queue cleanup

Syntax	request system commit server queue cleanup <id <i>commit-id</i>> <job-status (error pending success)>
Release Information	Command introduced in Junos OS Release 12.1.
Description	Clean up the batch commit queue.
Options	id <i>commit-id</i> —(Optional) Clean up batch commit operation status messages for a specific commit ID. job-status —(Optional) Clean up batch commit operation status messages for the following: <ul style="list-style-type: none">• error—Clean up status messages for batch commit operations that have errors.• pending—Clean up status messages for batch commit operations that are pending.• success—Clean up status messages for batch commit operations that are successful.

Release Information	<p>Command introduced before Junos OS Release 7.4.</p> <p>Command introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Command introduced in Junos OS Release 11.1 for the QFX Series.</p> <p>Command introduced in Junos OS Release 12.2 for ACX Series routers.</p>

Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Options added:

- **dynamic-flow-capture** in Junos OS Release 7.4.
- **dls** in Junos OS Release 7.5.
- **event-processing** in Junos OS Release 7.5.
- **ppp** in Junos OS Release 7.5.
- **l2ald** in Junos OS Release 8.0.
- **link-management** in Release 8.0.
- **pgcp-service** in Junos OS Release 8.4.
- **sbc-configuration-process** in Junos OS Release 9.5.
- **services pgcp gateway** in Junos OS Release 9.6.
- **sfc** and **all-sfc** for the TX Matrix Router in Junos OS Release 9.6.

Description Restart a Junos OS process.

CAUTION: Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router or switch to drop calls and interrupt transmission, resulting in possible loss of data.

Options **none**—Same as **gracefully**.

adaptive-services—(Optional) Restart the configuration management process that manages the configuration for stateful firewall, Network Address Translation (NAT), intrusion detection services (IDS), and IP Security (IPsec) services on the Adaptive Services PIC.

all-chassis—(TX Matrix and TX Matrix Plus routers only) (Optional) Restart the software process on all chassis.

all-lcc—(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process on all T640 routers connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process on all T1600 routers connected to the TX Matrix Plus router.

all-members—(MX Series routers only) (Optional) Restart the software process for all members of the Virtual Chassis configuration.

all-sfc—(TX Matrix Plus routers only) (Optional) For a TX Matrix Plus router, restart the software processes for the TX Matrix Plus router (or switch-fabric chassis).

ancpd-service—(Optional) Restart the Access Node Control Protocol (ANCP) process, which works with a special Internet Group Management Protocol (IGMP) session to collect outgoing interface mapping events in a scalable manner.

application-identification—(Optional) Restart the process that identifies an application using intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports.

audit-process—(Optional) Restart the RADIUS accounting process that gathers statistical data that can be used for general network monitoring, analyzing, and tracking usage patterns, for billing a user based on the amount of time or type of services accessed.

auto-configuration—(Optional) Restart the Interface Auto-Configuration process.

autoinstallation—(EX Series switches only) (Optional) Restart the autoinstallation process.

captive-portal-content-delivery—(Optional) Restart the HTTP redirect service by specifying the location to which a subscriber's initial Web browser session is redirected, enabling initial provisioning and service selection for the subscriber.

ce-l2tp-service—(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Universal Edge Layer 2 Tunneling Protocol (L2TP) process, which establishes L2TP tunnels and Point-to-Point Protocol (PPP) sessions through L2TP tunnels.

chassis-control—(Optional) Restart the chassis management process.

class-of-service—(Optional) Restart the class-of-service (CoS) process, which controls the router's or switch's CoS configuration.

clksyncd-service—(Optional) Restart the external clock synchronization process, which uses synchronous Ethernet (SyncE).

database-replication—(EX Series switches and MX Series routers only) (Optional) Restart the database replication process.

datapath-trace-service—(Optional) Restart the packet path tracing process.

dhcp—(EX Series switches only) (Optional) Restart the software process for a Dynamic Host Configuration Protocol (DHCP) server. A DHCP server allocates network IP addresses and delivers configuration settings to client hosts without user intervention.

dhcp-service—(Optional) Restart the Dynamic Host Configuration Protocol process.

dialer-services—(EX Series switches only) (Optional) Restart the ISDN dial-out process.

diameter-service—(Optional) Restart the diameter process.

disk-monitoring—(Optional) Restart disk monitoring, which checks the health of the hard disk drive on the Routing Engine.

dls—(QFX Series only) (Optional) Restart the data link switching (DLSw) service.

dot1x-protocol—(EX Series switches only) (Optional) Restart the port-based network access control process.

dynamic-flow-capture—(Optional) Restart the dynamic flow capture (DFC) process, which controls DFC configurations on Monitoring Services III PICs.

ecc-error-logging—(Optional) Restart the error checking and correction (ECC) process, which logs ECC parity errors in memory on the Routing Engine.

ethernet-connectivity-fault-management—(Optional) Restart the process that provides IEEE 802.1ag Operation, Administration, and Management (OAM) connectivity fault management (CFM) database information for CFM maintenance association end points (MEPs) in a CFM session.

ethernet-link-fault-management—(EX Series switches and MX Series routers only)
(Optional) Restart the process that provides the OAM link fault management (LFM) information for Ethernet interfaces.

ethernet-switching—(EX Series switches only) (Optional) Restart the Ethernet switching process.

event-processing—(Optional) Restart the event process (eventd).

fibre-channel—(QFX Series only) (Optional) Restart the Fibre Channel process.

firewall—(Optional) Restart the firewall management process, which manages the firewall configuration and enables accepting or rejecting packets that are transiting an interface on a router or switch.

general-authentication-service—(EX Series switches and MX Series routers only)
(Optional) Restart the general authentication process.

gracefully—(Optional) Restart the software process.

iccp-service—(Optional) Restart the Inter-Chassis Communication Protocol (ICCP) process.

idp-policy—(Optional) Restart the intrusion detection and prevention (IDP) protocol process.

immediately—(Optional) Immediately restart the software process.

interface-control—(Optional) Restart the interface process, which controls the router's or switch's physical interface devices and logical interfaces.

ipsec-key-management—(Optional) Restart the IPsec key management process.

isdn-signaling—(QFX Series only) (Optional) Restart the ISDN signaling process, which initiates ISDN connections.

kernel-replication—(Optional) Restart the kernel replication process, which replicates the state of the backup Routing Engine when graceful Routing Engine switchover (GRES) is configured.

l2-learning—(Optional) Restart the Layer 2 address flooding and learning process.

l2cpd-service—(Optional) Restart the Layer 2 Control Protocol process, which enables features such as Layer 2 protocol tunneling and nonstop bridging.

l2tp-service— (M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Layer 2 Tunneling Protocol (L2TP) process, which sets up client services for establishing Point-to-Point Protocol (PPP) tunnels across a network and negotiating Multilink PPP if it is implemented.

l2tp-universal-edge— (MX Series routers only) (Optional) Restart the L2TP process, which establishes L2TP tunnels and PPP sessions through L2TP tunnels.

lACP— (Optional) Restart the Link Aggregation Control Protocol (LACP) process. LACP provides a standardized means for exchanging information between partner systems on a link to allow their link aggregation control instances to reach agreement on the identity of the LAG to which the link belongs, and then to move the link to that LAG, and to enable the transmission and reception processes for the link to function in an orderly manner.

lcc number— (TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process for a specific T640 router that is connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

license-service— (EX Series switches only) (Optional) Restart the feature license management process.

link-management— (TX Matrix and TX Matrix Plus routers and EX Series switches only) (Optional) Restart the Link Management Protocol (LMP) process, which establishes and maintains LMP control channels.

lldpd-service— (EX Series switches only) (Optional) Restart the Link Layer Discovery Protocol (LLDP) process.

local— (MX Series routers only) (Optional) Restart the software process for the local Virtual Chassis member.

local-policy-decision-function— (Optional) Restart the process for the Local Policy Decision Function, which regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

mac-validation— (Optional) Restart the Media Access Control (MAC) validation process, which configures MAC address validation for subscriber interfaces created on demux interfaces in dynamic profiles on MX Series routers.

member *member-id*— (MX Series routers only) (Optional) Restart the software process for a specific member of the Virtual Chassis configuration. Replace ***member-id*** with a value of 0 or 1.

mib-process— (Optional) Restart the Management Information Base (MIB) version II process, which provides the router's MIB II agent.

mobile-ip— (Optional) Restart the Mobile IP process, which configures Junos OS Mobile IP features.

moundd-service— (EX Series switches and MX Series routers only) (Optional) Restart the service for NFS mount requests.

mpls-traceroute— (Optional) Restart the MPLS Periodic Traceroute process.

mspd— (Optional) Restart the Multiservice process.

multicast-snooping— (EX Series switches and MX Series routers only) (Optional) Restart the multicast snooping process, which makes Layer 2 devices, such as VLAN switches, aware of Layer 3 information, such as the media access control (MAC) addresses of members of a multicast group.

named-service— (Optional) Restart the DNS Server process, which is used by a router or a switch to resolve hostnames into addresses.

network-access-service— (QFX Series only) (Optional) Restart the network access process, which provides the router's Challenge Handshake Authentication Protocol (CHAP) authentication service.

nfsd-service— (Optional) Restart the Remote NFS Server process, which provides remote file access for applications that need NFS-based transport.

packet-triggered-subscribers— (Optional) Restart the packet-triggered subscribers and policy control (PTSP) process, which allows the application of policies to dynamic subscribers that are controlled by a subscriber termination device.

peer-selection-service— (Optional) Restart the Peer Selection Service process.

pgcp-service— (Optional) Restart the pgcpd service process running on the Routing Engine. This option does not restart pgcpd processes running on mobile station PICs. To restart pgcpd processes running on mobile station PICs, use the **services pgcp gateway** option.

pgm— (Optional) Restart the process that implements the Pragmatic General Multicast (PGM) protocol for assisting in the reliable delivery of multicast packets.

pic-services-logging— (Optional) Restart the logging process for some PICs. With this process, also known as fsad (the file system access daemon), PICs send special logging information to the Routing Engine for archiving on the hard disk.

pki-service—(Optional) Restart the PKI Service process.

ppp—(Optional) Restart the Point-to-Point Protocol (PPP) process, which is the encapsulation protocol process for transporting IP traffic across point-to-point links.

ppp-service—(Optional) Restart the Universal edge PPP process, which is the encapsulation protocol process for transporting IP traffic across universal edge routers.

pppoe—(Optional) Restart the Point-to-Point Protocol over Ethernet (PPPoE) process, which combines PPP that typically runs over broadband connections with the Ethernet link-layer protocol that allows users to connect to a network of hosts over a bridge or access concentrator.

protected-system-domain-service—(Optional) Restart the Protected System Domain (PSD) process.

redundancy-interface-process—(Optional) Restart the ASP redundancy process.

remote-operations—(Optional) Restart the remote operations process, which provides the ping and traceroute MIBs.

root-system-domain-service—(Optional) Restart the Root System Domain (RSD) service.

routing—(ACX Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the routing protocol process.

routing <logical-system *logical-system-name*>—(Optional) Restart the routing protocol process, which controls the routing protocols that run on the router or switch and maintains the routing tables. Optionally, restart the routing protocol process for the specified logical system only.

sampling—(Optional) Restart the sampling process, which performs packet sampling based on particular input interfaces and various fields in the packet header.

sbc-configuration-process—(Optional) Restart the session border controller (SBC) process of the border signaling gateway (BSG).

scc—(TX Matrix routers only) (Optional) Restart the software process on the TX Matrix router (or switch-card chassis).

sdk-service—(Optional) Restart the SDK Service process, which runs on the Routing Engine and is responsible for communications between the SDK application and Junos OS. Although the SDK Service process is present on the router, it is turned off by default.

secure-neighbor-discovery—(QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the secure Neighbor Discovery Protocol (NDP) process, which provides support for protecting NDP messages.

sfc *number*—(TX Matrix Plus routers only) (Optional) Restart the software process on the TX Matrix Plus router (or switch-fabric chassis). Replace *number* with 0.

service-deployment—(Optional) Restart the service deployment process, which enables Junos OS to work with the Session and Resource Control (SRC) software.

services—(Optional) Restart a service.

services pgcp gateway gateway-name—(Optional) Restart the pgcpd process for a specific border gateway function (BGF) running on an MS-PIC. This option does not restart the pgcpd process running on the Routing Engine. To restart the pgcpd process on the Routing Engine, use the **pgcp-service** option.

sflow-service—(EX Series switches only) (Optional) Restart the flow sampling (sFlow technology) process.

snmp—(Optional) Restart the SNMP process, which enables the monitoring of network devices from a central location and provides the router's or switch's SNMP master agent.

soft—(Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.

static-subscribers—(Optional) Restart the static subscribers process, which associates subscribers with statically configured interfaces and provides dynamic service activation and activation for these subscribers.

statistics-service—(Optional) Restart the process that manages the Packet Forwarding Engine statistics.

subscriber-management—(Optional) Restart the Subscriber Management process.

subscriber-management-helper—(Optional) Restart the Subscriber Management Helper process.

tunnel-oamd—(Optional) Restart the Tunnel OAM process, which enables the Operations, Administration, and Maintenance of Layer 2 tunneled networks. Layer 2 protocol tunneling (L2PT) allows service providers to send Layer 2 protocol data units (PDUs) across the provider's cloud and deliver them to Juniper Networks EX Series Ethernet Switches that are not part of the local broadcast domain.

usb-control—(MX Series routers) (Optional) Restart the USB control process.

vrrp—(ACX Series routers, EX Series switches, and MX Series routers only) (Optional) Restart the Virtual Router Redundancy Protocol (VRRP) process, which enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts.

web-management—(QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the Web management process.

Required Privilege Level reset

List of Sample Output [restart interfaces on page 750](#)

Output Fields When you enter this command, you are provided feedback on the status of your request.

Sample Output

restart interfaces

```
user@host> restart interfaces
interfaces process terminated
interfaces process restarted
```

set

Syntax	<code>set <statement-path> identifier</code>
Release Information	Command introduced before Junos OS Release 7.4.
Description	Create a statement hierarchy and set identifier values. This is similar to edit except that your current level in the hierarchy does not change.
Options	<p><i>identifier</i>—Name of the statement or identifier to set.</p> <p><i>statement-path</i>—(Optional) Path to an existing statement hierarchy level. If that hierarchy level does not exist, it is created.</p>
Required Privilege Level	configure—To enter configuration mode, but other required privilege levels depend on where the statement is located in the configuration hierarchy.
Related Documentation	<ul style="list-style-type: none">• edit on page 672• Displaying the Current Junos OS Configuration on page 497

show system commit server queue

Syntax `show system commit server queue`
`<id commit-id>`
`<job-status (all| error| pending| success)>`
`<patch (none | id commit-id) | (job-status (all | error | pending | success))>`

Release Information Command introduced in Junos OS Release 12.1.

Description Display the status of commit server queue transactions.

NOTE: Only 50 successful commit jobs are stored in the database and displayed in the output. When the fifty-first job is committed, the first job is deleted from the database and is no longer displayed in the output.

Options `id commit-id`—(Optional) Display the batch commit operation status messages for a specific commit ID.

`job-status`—(Optional) Display batch commit operation status messages for the following batch commit statuses:

- `all`—Status messages for all batch commit operations.
- `error`—Status messages for batch commit operations that have errors.
- `pending`—Status messages for batch commit operations that are pending.
- `success`—Status messages for batch commit operations that are successful.

`patch (none | id commit-id) | job-status (all | error | pending | success)`—(Optional) Display the patch file containing the configuration changes for all batch commit operations, a specific batch commit ID, or a specific job status.

Required Privilege Level view

J-Web User Guide for Security Devices

PART 6

Overview

- [Understanding the J-Web User Interface on page 761](#)

Understanding the J-Web User Interface

- [J-Web Overview on page 761](#)
- [Starting the J-Web User Interface on page 762](#)
- [Understanding the J-Web Interface Layout on page 762](#)
- [Getting Help in the J-Web User Interface on page 765](#)

J-Web Overview

The J-Web interface allows you to monitor, configure, troubleshoot, and manage the routing platform by means of a Web browser enabled with Hypertext Transfer Protocol (HTTP) or HTTP over Secure Sockets Layer (HTTPS). J-Web provides access to all the configuration statements supported by the routing platform, so you can fully configure it without using the Junos OS CLI.

You can perform the following tasks with the J-Web interface:

- **Monitoring**—Display the current configuration and information about the system, interfaces, chassis, routing protocols, routing tables, routing policy filters, and other features.
- **Configuring**—The J-Web interface provides the following different configuration methods:
 - Configure the routing platform quickly and easily without configuring each statement individually.
 - Edit a graphical version of the Junos OS CLI configuration statements and hierarchy.
 - Edit the configuration in a text file.
 - Upload a configuration file.

The J-Web interface also allows you to manage configuration history and set a rescue configuration.

- **Troubleshooting**—Troubleshoot routing problems by running the ping or traceroute diagnostic tool. The diagnostic tools also allow you to capture and analyze routing platform control traffic.

- Maintaining—Manage log, temporary, and core (crash) files and schedule reboots on the routing platforms.
- Configuring and monitoring events—Filter and view system log messages that record events occurring on the router. You can configure files to log system log messages and also assign attributes, such as severity levels, to messages.

Starting the J-Web User Interface

Before you start the user interface, you must perform the initial device configuration described in the Getting Started Guide for your device. After the initial configuration, you use your username and password, and the hostname or IP address of the device, to start the user interface.

To start the J-Web user interface:

1. Launch your HTTP-enabled or HTTPS-enabled Web browser.

To use HTTPS, you must have installed the certificate provided by the device.

NOTE: If the device is running the worldwide version of the Junos OS and you are using the Microsoft Internet Explorer Web browser, you must disable the Use SSL 3.0 option in the Web browser to access the device.

2. Type **http://** or **https://** in your Web browser followed by the hostname or IP address of the device, and press Enter.

The J-Web login page appears.

3. Type your username and password, and click **Log In**.

To correct or change the username or password you typed, click **Reset**, type the new entry or entries, and click **Log In**.

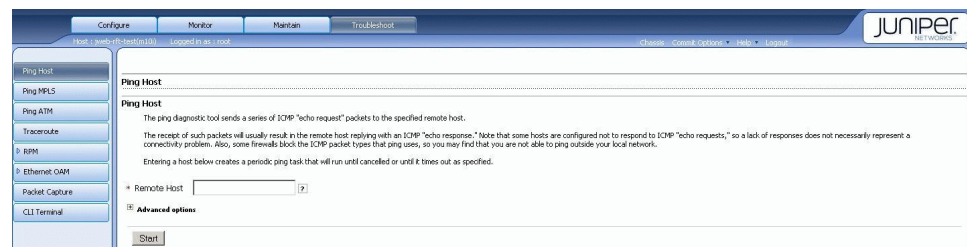

NOTE: The default username is **root** with no password. You must change this during initial configuration or the system does not accept the configuration.

To explicitly terminate a J-Web session at any time, click **Logout** in the top pane.

Understanding the J-Web Interface Layout

Each page of the J-Web interface is divided into the following panes, as shown in [Figure 24](#).

Figure 24: J-Web Layout

- Top pane—Displays identifying information and links.
- Main pane—Location where you monitor, configure, troubleshoot, and manage the Juniper Networks device by entering information in text boxes, making selections, and clicking buttons.
- Side pane—Displays subtasks of the Configure, Monitor, Maintain, or Troubleshoot task currently displayed in the main pane. For the configuration editor, this pane displays the hierarchy of configuration statements committed on the router. Click an item to access it in the main pane.

Top Pane

The top pane comprises the elements shown in Figure 25.

Figure 25: Top Pane Elements

- *hostname – model*—Hostname and model of the Juniper Networks device.
- Logged in as: *username*—Username you used to log in to the device.
- Chassis—The chassis view of the device.
- Commit Options
 - Commit—Commits the candidate configuration. Changes made by other users as well as changes made in other J-Web sessions will be committed.
 - Compare—Displays the differences between the committed and uncommitted configuration on the device.
 - Discard—Discards the candidate configuration. Changes made by other users as well as changes made in other J-Web sessions will be discarded.
 - Preference—Enables you to select preferences for committing configuration. **Commit Check** only validates the configuration and reports errors. **Commit** validates and commits the configuration specified on every J-Web page.
- Help
 - Help Contents—Link to context-sensitive help information.

- **About**—Link to information about the J-Web interface, such as the version number.
- **Logout**—Ends your current login session with the Juniper Networks device and returns you to the login page.
- **Taskbar**—Menu of J-Web tasks. Click a J-Web task to access it.
 - **Configure**—Configure the device by using Configuration pages or the configuration editor, and view configuration history.
 - **Monitor**—View information about configuration and hardware on the device.
 - **Maintain**—Manage files and licenses, upgrade software, and reboot the device.
 - **Troubleshoot**—Troubleshoot network connectivity problems.

Main Pane

The main pane comprises the elements shown in [Figure 26](#).

Figure 26: Main Pane Elements

- **Help (?) icon**—Displays useful information when you move the cursor over the question mark. This help displays field-specific information, such as the definition, format, and valid range of the field.
- **Red asterisk (*)**—Indicates a required field.

Side Pane

The side pane comprises the elements shown in [Figure 27](#).

Figure 27: Side Pane Elements

- Subtask—Displays options related to the selected task in the J-Web taskbar.
- Configuration hierarchy—For the J-Web configuration editor, displays the hierarchy of committed statements in the device configuration.
 - Click **Expand all** to display the entire hierarchy.
 - Click **Hide all** to display only the statements at the top level.
 - Click plus signs (+) to expand individual items.
 - Click minus signs (–) to hide individual items.

Getting Help in the J-Web User Interface

To get Help in the J-Web user interface, use the following methods:

- Field-sensitive Help—Move the cursor over the question mark (?) next to the field for which you want more information. Typically, this Help includes one line of information about what this field does or what you must enter in a given text box. For example, Help for the Peer Autonomous System Number text box states, “The value should be a number between 1 and 65535.”
- Context-sensitive Help—Click **Help** in the taskbar to open a separate page displaying the summary of all the fields on that page. To exit Help, close the page.
- Wizard Help (SRX100, SRX110, SRX210, SRX220, SRX240, SRX550, and SRX650)—Use the Firewall Policy, VPN, and NAT wizards to perform basic configurations. Click a field in a wizard page to display information about that field in the lower-left corner of the wizard page.

PART 7

Configuring and Managing a Device Using J-Web

- [Installing J-Web on page 769](#)
- [Configuring Secure Web Access to a Device on page 771](#)
- [Configuring a Device Using J-Web on page 775](#)
- [Managing J-Web Sessions and Users on page 785](#)

Installing J-Web

- J-Web Software Requirements on page 769
- Installing the J-Web Software on page 769

J-Web Software Requirements

To access the J-Web interface for all platforms, your management device requires the following software:

- Supported browsers— Microsoft Internet Explorer version 7.0 or Mozilla Firefox version 3.0
- Language support— English-version browsers
- Supported OS— Microsoft Windows XP Service Pack 3

Other browser versions might not provide access to the J-Web interface.

Installing the J-Web Software

Your Juniper Networks device comes with the Junos OS installed on it. When you power on the Juniper device, all software starts automatically.

If your device is not shipped with the J-Web software on it, you must download the J-Web software package from the Juniper Networks webpage and install it on your device. After the installation, you must enable Web management of the device with the CLI.

To install and enable the J-Web software:

1. Using a Web browser, navigate to the Juniper Networks Customer Support Center at <https://www.juniper.net/customers/csc/software/>.
2. Log in to the Juniper Networks authentication system with the username (generally your e-mail address) and password supplied by Juniper Networks representatives.
3. Download the J-Web software to your local host. Select the version that is the same as the Junos OS version running on the device.
4. Copy the software package to the device. We recommend that you copy it to the `/var/tmp` directory.

5. If you have previously installed the J-Web software on the device, you must delete it before installing the new version. To do so, from operational mode in the CLI, enter the following command:

```
user@host> request system software delete jweb
```

6. Install the new package on the device. From operational mode in the CLI, enter the following command:

```
user@host> request system software add path/filename
```

Replace *path* with the full pathname to the J-Web software package. Replace *filename* with the filename of the J-Web software package.

7. Enable Web management of the device. From configuration mode in the CLI, enter the following command:

```
user@host# system services web-management http
```

CHAPTER 35

Configuring Secure Web Access to a Device

- [Secure Web Access Overview on page 771](#)
- [Generating SSL Certificates on page 771](#)
- [Configuring Secure Web Access on page 772](#)
- [Establishing J-Web Sessions on page 772](#)

Secure Web Access Overview

A Juniper Networks device uses the Secure Sockets Layer (SSL) protocol to provide secure management of devices through the Web interface. SSL uses public-private key technology that requires a paired private key and an authentication certificate for the SSL service. SSL encrypts communication between your device and the Web browser with a session key negotiated by the SSL server certificate.

An SSL certificate includes identifying information such as a public key and a signature made by a certificate authority (CA). When you access the device through HTTPS, an SSL handshake authenticates the server and the client and begins a secure session. If the information does not match or the certificate has expired, you are not able to access the device through HTTPS.

Without SSL encryption, communication between your device and the browser is sent in the open and can be intercepted. We recommend that you enable HTTPS access on your WAN interfaces.

Generating SSL Certificates

To enable secure Web access, you must first generate a digital SSL certificate, and then enable HTTPS access on the Juniper Networks device.

To generate an SSL certificate:

1. Enter the following **openssl** command in your Secure Shell command-line interface. The **openssl** command generates a self-signed SSL certificate in the Privacy-Enhanced Mail (PEM) format. It writes the certificate and an unencrypted 1024-bit RSA private key to the specified file.

```
% openssl req -x509 -nodes -newkey rsa:1024 -keyout filename.pem -out filename.pem
```

Replace **filename** with the name of a file in which you want the SSL certificate to be written—for example, **new.pem**.

2. When prompted, type the appropriate information in the identification form. For example, type **US** for the country name.
3. Display the contents of the **new.pem** file.

```
cat new.pem
```

Copy the contents of this file for installing the SSL certificate.

Go on to “[Configuring Secure Web Access](#)” on page 772 to install the SSL certificate and enable HTTPS.

Configuring Secure Web Access

Navigate to the Management Access Configuration page by selecting **Configure>System Properties>Management Access**. Click **Edit** from the main pane to open the Edit Management Access page. On this page, you can enable HTTP and HTTPS access on interfaces for managing Services Routers through the Web interface. You can also install SSL certificates and enable JUNOScript over SSL with the Secure Access page.

For more information, see *Help Contents* of this J-Web page.

Establishing J-Web Sessions

You establish a J-Web session through an HTTP-enabled or HTTPS-enabled Web browser. The HTTPS protocol, which uses 128-bit encryption, is available only in domestic versions of the Junos OS. To use HTTPS, you must have installed the certificate provided by the device.

When you attempt to log in through the J-Web interface, the system authenticates your username with the same methods used for Telnet and SSH.

The device can support multiple J-Web sessions for a single user who logs in to each session. However, if a single user attempts to launch multiple J-Web *windows*—for example, by right-clicking a link to launch another instance of a Web browser—the session can have unpredictable results.

If the device does not detect any activity through the J-Web user interface for 15 minutes, the session times out and is terminated. You must log in again to begin a new session.

To explicitly terminate a J-Web session at any time, click **Logout** in the top pane.

[Table 70](#) shows the maximum number of concurrent J-Web sessions on SRX Series devices.

Table 70: Concurrent Web Sessions on SRX Series Devices

Device Type	Maximum Number of Users
SRX300, SRX320, SRX340, SRX345, SRX1500	7
SRX5400, SRX5600, SRX5800	1024

CHAPTER 36

Configuring a Device Using J-Web

- [Configuring Basic Settings on page 776](#)
- [J-Web Configuration Pages Overview on page 778](#)
- [Editing a Configuration on page 779](#)
- [J-Web Commit Options Guidelines on page 782](#)
- [Committing a Configuration on page 783](#)

Configuring Basic Settings

Before you begin initial configuration, complete the following tasks:

- Install the Juniper Networks device in its permanent location, as described in the hardware installation guide or the Getting Started Guide for your device.
- Gather the following information:
 - Hostname for the router on the network
 - Domain that the router belongs to on the network
 - Password for the root user
 - Time zone where the router is located
 - IP address of a Network Time Protocol (NTP) server (if NTP is used to set the time on the router)
 - IP address of a Domain Name System (DNS) server
 - List of domains that can be appended to hostnames for DNS resolution
 - IP address of the default gateway
 - IP address to be used for the loopback interface
 - IP address of the built-in Ethernet interface that you will use for management purposes
- Collect the following equipment:
 - A management device, such as a laptop, with an Ethernet port
 - An Ethernet cable

To configure basic settings with J-Web Initial Configuration:

1. Enter information into the Initial Configuration Set Up page (see [Figure 28](#)), as described in [Table 71](#).
2. Click **Apply** to apply the configuration.

Figure 28: J-Web Set Up Initial Configuration Page

Management Access

The following access methods are considered insecure as any information sent over them will be sent without encryption and could possibly be intercepted during transmission.

Allow Telnet Access: ☒

Allow JUNOScript over Clear-Text Access: ☐

The following access method is considered secure as any information sent over it will be encrypted before transmission.

Allow SSH Access: ☒

In order to enable HTTPS or JUNOScript over SSL, you will need to visit the SSL configuration page to configure certificates and associations.

Table 71: Initial Configuration Set Up Summary

Field	Function	Your Action
Identification		
Host Name (required)	Defines the hostname of the router.	Type the hostname.
Domain Name	Defines the network or subnetwork that the machine belongs to.	Type the domain name.
Root Password (required)	Sets the root password that the user “root” can use to log in to the router.	Type a plain-text password that the system encrypts. NOTE: After a root password has been defined, it is required when you log in to the J-Web user interface or the CLI.
Verify Root Password (required)	Verifies that the root password has been typed correctly.	Retype the password.
Time		
Time Zone	Identifies the time zone that the router is located in.	From the list, select the appropriate time zone.
NTP Servers	Specify an NTP server that the router can reach to synchronize the system time.	To add an IP address, type it in the box to the left of the Add button, then click Add . To delete an IP address, click it in the box above the Add button, then click Delete .

Table 71: Initial Configuration Set Up Summary (*continued*)

Field	Function	Your Action
Current System Time	Synchronizes the system time with the NTP server, or manually sets the system time and date.	<ul style="list-style-type: none"> To immediately set the time using the NTP server, click Set Time via NTP. The router sends a request to the NTP server and synchronizes the system time. NOTE: If you are configuring other settings on this page, the router also synchronizes the system time using the NTP server when you click Apply. To set the time manually, click Set Time Manually. A pop-up window allows you to select the current date and time from lists.
Network		
DNS Name Servers	Specify a DNS server that the router can use to resolve hostnames into addresses.	<p>To add an IP address, type it in the box to the left of the Add button, then click Add.</p> <p>To delete an IP address, click it in the box above the Add button, then click Delete.</p>
Domain Search	Adds each domain name that the router is included in to the configuration so that they are included in a DNS search.	<p>To add a domain name, type it in the box to the left of the Add button, then click Add.</p> <p>To delete a domain name, click it in the box above the Add button, then click Delete.</p>
Default Gateway	Defines a default gateway through which to direct packets addressed to networks not explicitly listed in the routing table.	Type a 32-bit IP address, in dotted decimal notation.
Loopback Address	Defines a reserved IP address that is always available on the router. If no address is entered, this address is set to 127.0.0.1/32 .	Type a 32-bit IP address and prefix length, in dotted decimal notation.
Management Access		
Allow Telnet Access	Allows remote access to the router by using Telnet.	To enable Telnet access, select the check box.
Allow JUNOScript protocol over Clear-Text Access	Allows JUNOScript to access the router by using a protocol for sending unencrypted text over a TCP connection.	To enable JUNOScript access over clear text, select the check box.
Allow SSH Access	Allows remote access to the router by using SSH.	To enable SSH access, select the check box.

J-Web Configuration Pages Overview

J-Web configuration pages offer you several different ways to configure your Juniper Networks device. Configuration pages provide access to all the configuration statements

supported by the device, so you can fully configure it without using the CLI. You can also manage the configuration, monitor user access, and set a rescue configuration.

Table 72 provides a summary of the J-Web configuration pages.

Table 72: J-Web Configuration Pages Summary

J-Web Configuration Task	Description	More Information
Edit the configuration using a clickable interface	Expand the entire configuration hierarchy in the side pane and click a configuration statement to view or edit. The main pane displays all the options for the statement, with a text box for each option.	For more information, go to Configure>CLI Tools>Point and Click CLI in the J-Web user interface.
Edit the configuration in text format	Paste a complete configuration hierarchy into a scrollable text box, or edit individual lines in the configuration text.	For more information, go to Configure>CLI Tools>CLI Editor in the J-Web user interface.
Upload a configuration file	Upload a complete configuration.	For more information, go to Maintain>Config Management>Upload in the J-Web user interface.
View the configuration in text format	View the entire configuration on the device in text format.	For more information, go to Configure>CLI Tools>CLI Viewer in the J-Web user interface.

Editing a Configuration

To edit the configuration on a series of pages of clickable options that step you through the hierarchy, select **Configure>CLI Tools>Point and Click**. The side pane displays the top level of the configuration hierarchy, and the main pane displays configured hierarchy options and the Icon Legend (see Figure 29).

Figure 29: Edit Configuration Page

The screenshot displays the J-Web configuration editor interface. On the left, a sidebar shows a configuration hierarchy with 'Expand all' and 'Hide all' buttons. The main area is titled 'Configuration' and contains a list of configuration options, each with a 'Configure' link. The 'System' option is selected, showing fields for 'Access profile name' and 'Jsrc partition name'. Below these are advanced options for 'Apply groups' and an 'Icon Legend' section.

See the video for an example of how to use the J-Web configuration editor to configure and manage stateless firewall filters.

Video: Managing Firewall Filters with J-Web

To expand or hide the hierarchy of all the statements in the side pane, click **Expand all** or **Hide all**. To expand or hide an individual statement in the hierarchy, click the expand (+) or collapse (–) icon to the left of the statement.

NOTE: Only those statements included in the committed configuration are displayed in the side pane hierarchy.

The configuration information in the main pane consists of configuration options that correspond to configuration statements. Configuration options that contain subordinate statements are identified by the term *nested configuration*.

To include, edit, or delete statements in the candidate configuration, click one of the links described in [Table 73](#) in the main pane. Then specify configuration information by typing into a field, selecting a value from a list, or clicking a check box (toggle).

Table 73: J-Web Edit Configuration Links

Link	Function
Add new entry	Displays fields and lists for a statement identifier, allowing you to add a new identifier to a statement.
Configure	Displays information for a configuration option that has not been configured, allowing you to include a statement.
Delete	Deletes the corresponding statement or identifier from the configuration. All subordinate statements and identifiers contained within a deleted statement are also discarded.
Edit	Displays information for a configuration option that has already been configured, allowing you to edit a statement.
<i>identifier</i>	Displays fields and lists for an existing statement identifier, allowing you to edit the identifier.

As you navigate through the configuration, the hierarchy level is displayed at the upper right of the main pane. You can click a statement or identifier in the hierarchy to return to the corresponding configuration options in the main pane.

The main pane includes icons that display information about statements and identifiers when you place your cursor over them. [Table 74](#) describes the meaning of these icons.

Table 74: J-Web Edit Configuration Icons

Icon	Meaning
C	Displays a comment about a statement.
I	Indicates that a statement is inactive.
M	Indicates that a statement has been added or modified, but has not been committed.
*	Indicates that the statement or identifier is required in the configuration.
?	Provides Help information.

J-Web Commit Options Guidelines

Using the J-Web Commit Preference, you can configure the commit options either to commit all global configurations together or to commit each configuration change immediately. Do one of the following to commit a configuration:

- Set Commit Preference to **Validate and commit configuration changes**, and then click **OK**.
- Set Commit Preference to **Validate configuration changes**, click **OK** to check your configuration and save it as a candidate configuration, and then click **Commit Options>Commit**.

For example, suppose you want to delete a firewall and add a new one.

- If Commit Preference is set to **Validate and commit configuration changes**, then you would need to commit your changes twice for each action.
- If Commit Preference is set to **Validate configuration changes**, then you work in a copy of the current configuration to create a candidate configuration. The changes you make to the candidate configuration are visible through the user interface immediately, allowing other users to edit those configurations, but the changes do not take effect on the device platform until you commit them. When you commit the configuration, the candidate file is checked for proper syntax, activated, and marked as the current, operational software configuration file. If multiple users are editing the configuration when you commit the candidate configuration, changes made by all the users take effect.

You use the single commit feature to commit all your configurations in J-Web simultaneously. This helps to reduce the time J-Web takes to commit configurations because when changes are committed at every step, rollback configurations pile up quickly.

.....

NOTE: If you end a session with a particular Commit Preference, the subsequent sessions for that particular browser will automatically come up with the preference you previously selected. If you start the subsequent session on a different browser, the session will come up with the default commit preference.

.....

.....

NOTE: There are some pages whose configurations would need to be committed immediately. For such pages, even if you configure the commit options to perform a single global commit for them, the system displays appropriate information notification windows to remind you to commit your changes immediately. Examples of such pages are Switching, Interfaces, and Class of Service.

.....

Committing a Configuration

When you finish making changes to a candidate configuration with the J-Web configuration editor, you must commit the changes to use them in the current operational software running on the Juniper Networks device.

If another user is editing an exclusive candidate configuration with the CLI, you cannot commit a configuration until the user has committed the configuration. For more information about editing an exclusive candidate configuration, see the *Junos OS CLI User Guide*.

To commit a candidate configuration:

1. In the J-Web configuration editor, click **Commit**.

The main pane displays a summary of your changes in statement form.

2. To confirm the commit operation, click **OK**.

If multiple users are editing the configuration when you commit the candidate configuration, all changes made by all users take effect.

3. To display all the edits applied to the running configuration, click **Refresh**.

Managing J-Web Sessions and Users

- [Setting J-Web Session Limits on page 785](#)
- [Terminating J-Web Sessions on page 785](#)

Setting J-Web Session Limits

By default, an unlimited number of users can log in to the J-Web interface on a Juniper Networks device, and each session remains open for 24 hours (1440 minutes). Using CLI commands, you can limit the maximum number of simultaneous J-Web user sessions and set a default session timeout for all users.

- To limit the number of simultaneous J-Web user sessions, enter the following commands:

```
user@host# edit system services web-management session
user@host# set session-limit session-limit
```

Range: 1 through 1024. Default: Unlimited

- To change the J-Web session idle time limit, enter the following commands:

```
user@host# edit system services web-management session
user@host# set idle-timeout minutes
```

Range: 1 through 1440. Default: 1440

You can also configure the maximum number of simultaneous subordinate HTTP processes that the device creates in response to user requests.

To configure the maximum number of subordinate httpd processes, enter the following commands:

```
user@host# edit system services web-management limits
```

```
user@host# active-child-process process-limit
```

The default is 5, and the range is 0 through 32.

Terminating J-Web Sessions

To explicitly terminate a J-Web session at any time, click **Logout** in the top pane. You must log in again to begin a new session.

By default, if the Juniper Networks device does not detect any activity through the J-Web interface for 24 hours, the session times out and is terminated. For information about changing the idle time limit, see [“Setting J-Web Session Limits” on page 785](#).

PART 8

Troubleshooting

- [Troubleshooting the J-Web User Interface on page 789](#)

CHAPTER 38

Troubleshooting the J-Web User Interface

- [Lost Router Connectivity on page 789](#)
- [Unpredictable J-Web Behavior on page 789](#)
- [No J-Web Access on page 789](#)

Lost Router Connectivity

- Problem** **Description:** After completing initial configuration, I lost connectivity to the Juniper device through J-Web.
- Cause** If you change the IP address of the management interface and have the management device configured to use DHCP, you lose your DHCP lease and your connection to the Juniper Networks device through the J-Web interface.
- Solution** To reestablish a connection, either set the IP address on the management device manually, or connect the management interface to the management network and access the Juniper device another way—for example, through the console port.

Unpredictable J-Web Behavior

- Problem** **Description:** I have multiple J-Web windows open and am experiencing unpredictable results.
- Solution** Close the extra windows. The Juniper Networks device can support multiple J-Web sessions for a single user who logs in to each session. However, if a single user attempts to launch multiple J-Web windows—for example, by right-clicking a link to launch another instance of a Web browser—the session can have unpredictable results.

No J-Web Access

- Problem** **Description:** I cannot access J-Web from my browser.
- Solution** **Solution 1**—On the Juniper Networks device, verify that you have successfully installed the J-Web software package and enabled Web management on the platform, as described in [“Installing the J-Web Software” on page 769](#).

Solution 2—If the device is running the worldwide version of the Junos OS and you are using the Microsoft Internet Explorer Web browser, you must disable the **Use SSL 3.0** option in the Web browser to access J-Web on the device.

Administration Guide for Security Devices

PART 9

User Access and Authentication

- [User Access and Authentication Overview on page 795](#)
- [Configuring Junos OS User Accounts on page 807](#)
- [Configuring User Access Privileges on page 829](#)
- [Permissions Flags for User Access Privileges on page 839](#)
- [Configuring Authentication Methods on page 1011](#)

User Access and Authentication Overview

- [Understanding Login Classes on page 795](#)
- [Understanding User Accounts on page 798](#)
- [Understanding Junos OS Access Privilege Levels on page 799](#)
- [Understanding User Authentication Methods on page 804](#)
- [Hardening Shared Secrets in Junos OS on page 804](#)

Understanding Login Classes

All users who log in to the device must be in a login class. You can define any number of login classes. You then apply one login class to an individual user account. With login classes, you define the following:

- Access privileges users have when they are logged in to the device.
- Commands and statements that users can and cannot specify.
- How long a login session can be idle before it times out and the user is logged off.

You can define any number of login classes and then apply one login class to an individual user account.

[Table 75](#) contains a few predefined login classes. The predefined login classes cannot be modified.

Table 75: Predefined Login Classes

Login Class	Permission Bits Set
operator	clear, network, reset, trace, view
read-only	view
super-user and superuser	all
unauthorized	None

**NOTE:**

- You cannot modify a predefined login class name. If you issue the **set** command on a predefined class name, the Junos OS appends **-local** to the login class name. The following message also appears:

warning: '<class-name>' is a predefined class name; changing to '<class-name>-local'

- You cannot issue the **rename** or **copy** command on a predefined login class. Doing so results in the following error message:

error: target '<class-name>' is a predefined class

This section contains the following topics:

- [Permission Bits on page 796](#)
- [Denying or Allowing Individual Commands on page 798](#)

Permission Bits

Each top-level command-line interface (CLI) command and each configuration statement has an access privilege level associated with it. Users can execute only those commands and configure and view only those statements for which they have access privileges. The access privileges for each login class are defined by one or more permission bits (see [Table 76](#)).

Two forms for the permissions control the individual parts of the configuration:

- "Plain" form—Provides read-only capability for that permission type. An example is **interface**.
- Form that ends in **-control**—Provides read and write capability for that permission type. An example is **interface-control**.

Table 76: Permission Bits for Login Classes

Permission Bit	Access
admin	Can view user account information in configuration mode and with the show configuration command.
admin-control	Can view user accounts and configure them (at the [edit system login] hierarchy level).
access	Can view the access configuration in configuration mode and with the show configuration operational mode command.
access-control	Can view and configure access information (at the [edit access] hierarchy level).
all	Has all permissions.
clear	Can clear (delete) information learned from the network that is stored in various network databases (using the clear commands).

Table 76: Permission Bits for Login Classes (*continued*)

Permission Bit	Access
configure	Can enter configuration mode (using the configure command) and commit configurations (using the commit command).
control	Can perform all control-level operations (all operations configured with the -control permission bits).
field	Reserved for field (debugging) support.
firewall	Can view the firewall filter configuration in configuration mode.
firewall-control	Can view and configure firewall filter information (at the [edit firewall] hierarchy level).
floppy	Can read from and write to the removable media.
interface	Can view the interface configuration in configuration mode and with the show configuration operational mode command.
interface-control	Can view chassis, class of service, groups, forwarding options, and interfaces configuration information. Can configure chassis, class of service, groups, forwarding options, and interfaces (at the [edit] hierarchy).
maintenance	Can perform system maintenance, including starting a local shell on the device and becoming the superuser in the shell (by issuing the su root command), and can halt and reboot the device (using the request system commands).
network	Can access the network by entering the ping , ssh , telnet , and traceroute commands.
reset	Can restart software processes using the restart command and can configure whether software processes are enabled or disabled (at the [edit system processes] hierarchy level).
rollback	Can use the rollback command to return to a previously committed configuration other than the most recently committed one.
routing	Can view general routing, routing protocol, and routing policy configuration information in configuration and operational modes.
routing-control	Can view general routing, routing protocol, and routing policy configuration information and configure general routing (at the [edit routing-options] hierarchy level), routing protocols (at the [edit protocols] hierarchy level), and routing policy (at the [edit policy-options] hierarchy level).
secret	Can view passwords and other authentication keys in the configuration.
secret-control	Can view passwords and other authentication keys in the configuration and can modify them in configuration mode.
security	Can view security configuration in configuration mode and with the show configuration operational mode command.

Table 76: Permission Bits for Login Classes (*continued*)

Permission Bit	Access
security-control	Can view and configure security information (at the [edit security] hierarchy level).
shell	Can start a local shell on the device by entering the start shell command.
snmp	Can view SNMP configuration information in configuration and operational modes.
snmp-control	Can view SNMP configuration information and configure SNMP (at the [edit snmp] hierarchy level).
system	Can view system-level information in configuration and operational modes.
system-control	Can view system-level configuration information and configure it (at the [edit system] hierarchy level).
trace	Can view trace file settings in configuration and operational modes.
trace-control	Can view trace file settings and configure trace file properties.
view	Can use various commands to display current system-wide, routing table, and protocol-specific values and statistics.

Denying or Allowing Individual Commands

By default, all top-level CLI commands have associated access privilege levels. Users can execute only those commands and view only those statements for which they have access privileges. For each login class, you can explicitly deny or allow the use of operational and configuration mode commands that are otherwise permitted or not allowed by a permission bit.

Related Documentation

- [Understanding User Authentication Methods on page 804](#)
- [Understanding User Accounts on page 798](#)
- [Understanding Template Accounts on page 810](#)
- [Example: Configuring New Users on page 807](#)

Understanding User Accounts

User accounts provide one way for users to access the device. Users can access the device without accounts if you configured RADIUS or TACACS+ servers. After you have created an account, the device creates a home directory for the user. An account for the user **root** is always present in the configuration. For each user account, you can define the following:

- Username—Name that identifies the user. It must be unique within the device. Do not include spaces, colons, or commas in the username.
- User's full name—If the full name contains spaces, enclose it in quotation marks (" "). Do not include colons or commas.
- User identifier (UID)—Numeric identifier that is associated with the user account name. The identifier range from 100 through 64,000 and must be unique within the device. If you do not assign a UID to a username, the software assigns one when you commit the configuration, preferring the lowest available number.
- User's access privilege—You can create login classes with specific permission bits or use one of the predefined classes.
- Authentication method or methods and passwords that the user can use to access the device—You can use SSH or an MD5 password, or you can enter a plain-text password that Junos OS encrypts using MD5-style encryption before entering it in the password database. If you configure the plain-text-password option, you are prompted to enter and confirm the password.

Understanding Junos OS Access Privilege Levels

Each top-level command-line interface (CLI) command and each configuration statement have an access privilege level associated with them. Users can execute only those commands and configure and view only those statements for which they have access privileges. The access privileges for each login class are defined by one or more *permission flags*.

For each login class, you can explicitly deny or allow the use of operational and configuration mode commands that would otherwise be permitted or not allowed by a privilege level specified in the **permissions** statement.

The following sections provide additional information about permissions:

- [Junos OS Login Class Permission Flags on page 799](#)
- [Allowing or Denying Individual Commands for Junos OS Login Classes on page 803](#)

Junos OS Login Class Permission Flags

The **permissions** statement specifies one or more of the permission flags listed in [Table 77](#). Permission flags are not cumulative, so for each class you must list all the permission flags needed, including **view** to display information and **configure** to enter configuration mode. Two forms of permissions control for individual parts of the configuration are:

- "Plain" form—Provides read-only capability for that permission type. An example is **interface**.
- Form that ends in **-control**—Provides read and write capability for that permission type. An example is **interface-control**.

Table 77 lists the Junos OS login class permission flags that you can configure by including the **permissions** statement at the **[edit system login class *class-name*]** hierarchy level.

Table 77: Login Class Permission Flags

Permission Flag	Description
access	Can view the access configuration in configuration mode and with the show configuration operational mode command.
access-control	Can view and configure access information at the [edit access] hierarchy level.
admin	Can view user account information in configuration mode and with the show configuration operational mode command.
admin-control	Can view user accounts and configure them at the [edit system login] hierarchy level.
all-control	Can access all operational mode commands and configuration mode commands. Can modify configuration in all the configuration hierarchy levels.
clear	Can clear (delete) information learned from the network that is stored in various network databases by using the clear commands.
configure	Can enter configuration mode by using the configure command.
control	Can perform all control-level operations—all operations configured with the -control permission flags.
field	Can view field debug commands. Reserved for debugging support.
firewall	Can view the firewall filter configuration in configuration mode.
firewall-control	Can view and configure firewall filter information at the [edit firewall] hierarchy level.
floppy	Can read from and write to the removable media.
flow-tap	Can view the flow-tap configuration in configuration mode.
flow-tap-control	Can view the flow-tap configuration in configuration mode and can configure flow-tap configuration information at the [edit services flow-tap] hierarchy level.

Table 77: Login Class Permission Flags (*continued*)

Permission Flag	Description
flow-tap-operation	<p>Can make flow-tap requests to the router or switch. For example, a Dynamic Tasking Control Protocol (DTCP) client must authenticate itself to the Junos OS as an administrative user. That account must have flow-tap-operation permission.</p> <p>NOTE: The flow-tap-operation option is not included in the all-control permissions flag.</p>
idp-profiler-operation	Can view profiler data.
interface	Can view the interface configuration in configuration mode and with the show configuration operational mode command.
interface-control	<p>Can view chassis, class of service (CoS), groups, forwarding options, and interfaces configuration information. Can edit configuration at the following hierarchy levels:</p> <ul style="list-style-type: none"> • [edit chassis] • [edit class-of-service] • [edit groups] • [edit forwarding-options] • [edit interfaces]
maintenance	Can perform system maintenance, including starting a local shell on the router or switch and becoming the superuser in the shell by using the su root command, and can halt and reboot the router or switch by using the request system commands.
network	Can access the network by using the ping , ssh , telnet , and traceroute commands.
pgcp-session-mirroring	Can view the pgcp session mirroring configuration.
pgcp-session-mirroring-control	Can modify the pgcp session mirroring configuration.
reset	Can restart software processes by using the restart command and can configure whether software processes are enabled or disabled at the [edit system processes] hierarchy level.
rollback	Can use the rollback command to return to a previously committed configuration other than the most recently committed one.
routing	Can view general routing, routing protocol, and routing policy configuration information in configuration and operational modes.

Table 77: Login Class Permission Flags (*continued*)

Permission Flag	Description
routing-control	Can view general routing, routing protocol, and routing policy configuration information and can configure general routing at the [edit routing-options] hierarchy level, routing protocols at the [edit protocols] hierarchy level, and routing policy at the [edit policy-options] hierarchy level.
secret	Can view passwords and other authentication keys in the configuration.
secret-control	Can view passwords and other authentication keys in the configuration and can modify them in configuration mode.
security	Can view security configuration in configuration mode and with the show configuration operational mode command.
security-control	Can view and configure security information at the [edit security] hierarchy level.
shell	Can start a local shell on the router or switch by using the start shell command.
snmp	Can view Simple Network Management Protocol (SNMP) configuration information in configuration and operational modes.
snmp-control	Can view SNMP configuration information and can modify SNMP configuration at the [edit snmp] hierarchy level.
system	Can view system-level information in configuration and operational modes.
system-control	Can view system-level configuration information and configure it at the [edit system] hierarchy level.
trace	Can view trace file settings and configure trace file properties.
trace-control	Can modify trace file settings and configure trace file properties.
view	Can use various commands to display current system-wide, routing table, and protocol-specific values and statistics. Cannot view the secret configuration.
view-configuration	<p>Can view all of the configuration excluding secrets, system scripts, and event options.</p> <p>NOTE: Only users with the maintenance permission can view commit script, op script, or event script configuration.</p>

Allowing or Denying Individual Commands for Junos OS Login Classes

By default, all top-level CLI commands have associated access privilege levels. Users can execute only those commands and view only those statements for which they have access privileges. For each login class, you can explicitly deny or allow the use of operational and configuration mode commands that would otherwise be permitted or not allowed by a privilege level specified in the **permissions** statement.

Permission flags are used to grant a user access to operational mode commands and configuration hierarchy levels and statements. By specifying a specific permission flag on the user's login class at the **[edit system login class]** hierarchy level, you grant the user access to the corresponding commands and configuration hierarchy levels and statements. To grant access to all commands and configuration statements, use the **all** permissions flag. For permission flags that grant access to configuration hierarchy levels and statements, the flags grant read-only privilege to that configuration. For example, the **interface** permissions flag grants read-only access to the **[edit interfaces]** hierarchy level. The **-control** form of the flag grants read-write access to that configuration. Using the preceding example, **interface-control** grants read-write access to the **[edit interfaces]** hierarchy level.

- The **all** login class permission bits take precedence over extended regular expressions when a user with **rollback** permission issues the **rollback** command.
- Expressions used to allow and deny commands for users on RADIUS and TACACS+ servers have been simplified. Instead of a single, long expression with multiple commands (**allow-commands=cmd1 cmd2 ... cmdn**), you can specify each command as a separate expression. This new syntax is valid for **allow-configuration-regexps** and **deny-configuration-regexps**, **allow-commands** and **deny-commands**, and all user permission bits.
- Users cannot issue the **load override** command when specifying an extended regular expression. Users can only issue the **merge**, **replace**, and **patch** configuration commands.
- If you allow and deny the same commands, the **allow-commands** permissions take precedence over the permissions specified by the **deny-commands**. For example, if you include **allow-commands "request system software add"** and **deny-commands "request system software add"**, the login class user is allowed to install software using the **request system software add** command.
- Regular expressions for **allow-commands** and **deny-commands** can also include the **commit**, **load**, **rollback**, **save**, **status**, and **update** commands.
- If you specify a regular expression for **allow-commands** and **deny-commands** with two different variants of a command, the longest match is always executed.

For example, if you specify a regular expression for **allow-commands** with the **commit-synchronize** command and a regular expression for **deny-commands** with the **commit** command, users assigned to such a login class would be able to issue the **commit synchronize** command, but not the **commit** command. This is because **commit-synchronize** is the longest match between **commit** and **commit-synchronize** and it is specified for **allow-commands**.

Likewise, if you specify a regular expression for **allow-commands** with the **commit** command and a regular expression for **deny-commands** with the **commit-synchronize** command, users assigned to such a login class would be able to issue the **commit** command, but not the **commit-synchronize** command. This is because **commit-synchronize** is the longest match between **commit** and **commit-synchronize** and it is specified for **deny-commands**.

Understanding User Authentication Methods

Junos OS supports three methods of user authentication: local password authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+).

With local password authentication, you configure a password for each user allowed to log in to the device.

RADIUS and TACACS+ are authentication methods for validating users who attempt to access the device using Telnet. Both are distributed client/server systems—the RADIUS and TACACS+ clients run on the device, and the server runs on a remote network system.

You can configure the device to use RADIUS or TACACS+ authentication, or both, to validate users who attempt to access the device. If you set up both authentication methods, you also can configure which method the device will try first.

Hardening Shared Secrets in Junos OS

- [Understanding Hardening Shared Secrets on page 804](#)

Understanding Hardening Shared Secrets

Existing shared secrets (\$9\$ format) in Junos OS currently use an obfuscation algorithm, which is not a very strong encryption for configuration secrets. If you want a strong encryption for your configuration secrets, you can configure a master password. The master password is used to derive an encryption key that is used with AES256-GCM to

encrypt configuration secrets. This new encryption method uses the `8` formatted strings.

Starting with Junos OS Release 15.1X49-D50, new CLI commands are introduced to configure a system master password. The master password encrypts secrets like the RADIUS password, IKE preshared keys, and other shared secrets in the Junos OS management process (mgd) configuration. The master password itself is not saved as part of the configuration. The password quality is evaluated for strength, and the device gives feedback if weak passwords are used.

The master password is used as input to the password based key derivation function (PBKDF2) to generate an encryption key. the key is used as input to the Advanced Encryption Standard in Galois/Counter Mode (AES256-GCM). The plain text that the user enters is processed by the encryption algorithm (with key) to produce the encrypted text (cipher text). See [Figure 30](#)

Figure 30: Master Password Encryption

The `8` configuration secrets can only be shared between devices using the same master password.

The `8`-encrypted passwords have the following format:

`8crypt-algo$hash-algo$iterations$salt$ivtagencrypted`. See [Table 78](#) for the master password format details.

Table 78: `8`-encrypted Password Format

Format	Description
crypt-algo	Encryption/decryption algorithm to be used. Currently only AES256-GCM is supported.
hash-algo	Hash (prf) algorithm to be used for the PBKDF2 key derivation.
iterations	The number of iterations to use for the PBKDF2 hash function. Current iteration-count default is 100. The iteration count slows the hashing count, thus slowing attacker guesses.
salt	Sequence of ASCII64-encoded pseudorandom bytes generated during encryption that are to be used to <i>salt</i> (a random, but known string) the password and input to the PBKDF2 key derivation.
iv	A sequence of ASCII64-encoded pseudorandom bytes generated during encryption that are to be used as initialization vector for the AES256-GCM encryption function.
tag	ASCII64-encoded representation of the tag.

Table 78: \$8\$-encrypted Password Format (*continued*)

encrypted	ASCII64-encoded representation of the encrypted password.
-----------	---

The ASCII64 encoding is Base64 (RFC 4648) compatible, except no padding (character “=”) is used to keep the strings short. For example:
\$8\$aes256-gcm\$hmhac-sha2-256\$100\$y/4YMC4YDLU\$FzYDI4jjiN6YCyQsYLsaf8A\$llu4jLcZarD9YnyD
/Hejww\$okhBlc0cGakSqYxKww

Chassis Cluster Considerations

When defining a chassis cluster on SRX Series devices, be aware of the following restrictions:

- For SRX Series devices, first configure the master password on each node, and then build the cluster. The same master password should be configured on each node.
- In chassis cluster mode, the master password cannot be deleted.

NOTE: A change in the master password would mean disruption in chassis clustering; therefore you must change the password on both nodes independently.

- [Example: Configuring System Retry Options on page 823](#)

Example: Configuring New Users

This example shows how to configure new users.

- [Requirements on page 807](#)
- [Overview on page 807](#)
- [Configuration on page 808](#)
- [Verification on page 810](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

You can add new users to the device's local database. For each account, you define a login name and password for the user and specify a login class for access privileges. The login password must meet the following criteria:

- The password must be at least six characters long.
- You can include most character classes in a password (alphabetic, numeric, and special characters), but not control characters.
- The password must contain at least one change of case or character class.

In this example, you create a login class named `operator-and-boot` and allow it to reboot the device. You can define any number of login classes. You then allow the

operator-and-boot login class to use commands defined in the clear, network, reset, trace, and view permission bits.

Then you create user accounts. User accounts provide enable you to access the device. (You can access the device without accounts if you configured RADIUS or TACACS+ servers.) You set the username as cmartin and the login class as superuser. Finally, you define the encrypted password for the user.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system login class operator-and-boot allow-commands "request system reboot"
set class system login operator-and-boot permissions [clear network reset trace view]
set system login user cmartin class superuser authentication encrypted-password
$1$ABC123
```

GUI Step-by-Step Procedure

To configure new users:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The Edit User Management dialog box appears.
3. Select the **Users** tab.
4. Click **Add** to add a new user. The Add User dialog box appears.
5. In the User name box, type a unique name for the user.

Do not include spaces, colons, or commas in the username.

6. In the User ID box, type a unique ID for the user.
7. In the Full Name box, type the user's full name.

If the full name contains spaces, enclose it in quotation marks. Do not include colons or commas.

8. In the Password and Confirm Password boxes, enter a login password for the user and verify your entry.
9. From the Login Class list, select the user's access privilege:

- **operator**
- **read-only**
- **unauthorized**

This list also includes any user-defined login classes.

10. Click **OK** in the Add User dialog box and Edit User Management dialog box.
11. Click **OK** to check your configuration and save it as a candidate configuration.
12. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure new users:

1. Set the name of the login class and allow the use of the reboot command.

```
[edit system login]
user@host# set class operator-and-boot allow-commands "request system reboot"
```

2. Set the permission bits for the login class.

```
[edit system login]
user@host# set class operator-and-boot permissions [clear network reset trace
view]
```

3. Set the username, login class, and encrypted password for the user.

```
[edit system login]
user@host# set user cmartin class superuser authentication encrypted-password
$1$ABC123
```

Results From configuration mode, confirm your configuration by entering the **show system login** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
class operator-and-boot {
permissions [ clear network reset trace view ];
allow-commands "request system reboot";
}
user cmartin {
class superuser;
authentication {
encrypted-password "$1$ABC123";
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: To completely set up RADIUS or TACACS+ authentication, you must configure at least one RADIUS or TACACS+ server and specify a user template account. Do one of the following tasks:

- Configure a RADIUS server. See [“Example: Configuring a RADIUS Server for System Authentication” on page 1014](#).
- Configure a TACACS+ server. See [“Example: Configuring a TACACS+ Server for System Authentication” on page 1019](#).
- Configure a user. See [“Example: Configuring New Users” on page 807](#).
- Configure template accounts. See [“Example: Creating Template Accounts” on page 810](#).

Verification

Confirm that the configuration is working properly.

Verifying the New Users Configuration

Purpose Verify that the new users have been configured.

Action From operational mode, enter the **show system login** command.

Related Documentation

- [Understanding Login Classes on page 795](#)

Understanding Template Accounts

You use local user template accounts when you need different types of templates. Each template can define a different set of permissions appropriate for the group of users who use that template. These templates are defined locally on the device and referenced by the TACACS+ and RADIUS authentication servers.

When you configure local user templates and a user logs in, Junos OS issues a request to the authentication server to authenticate the user's login name. If a user is authenticated, the server returns the local username to the device, which then determines whether a local username is specified for that login name (**local-username** for TACACS+, **Juniper-Local-User** for RADIUS). If so, the device selects the appropriate local user template locally configured on the device. If a local user template does not exist for the authenticated user, the device defaults to the **remote** template.

Example: Creating Template Accounts

This example shows how to create template accounts.

- [Requirements on page 811](#)
- [Overview on page 811](#)
- [Configuration on page 811](#)
- [Verification on page 813](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

You can create template accounts that are shared by a set of users when you are using RADIUS or TACACS+ authentication. When a user is authenticated by a template account, the CLI username is the login name, and the privileges, file ownership, and effective user ID are inherited from the template account.

By default, Junos OS uses the **remote** template account when:

- The authenticated user does not exist locally on the device.
- The authenticated user's record in the RADIUS or TACACS+ server specifies local user, or the specified local user does not exist locally on the device.

In this example, you create a remote template account and set the username to remote and the login class for the user as operator. You create a remote template that is applied to users authenticated by RADIUS or TACACS+ that do not belong to a local template account.

You then create a local template account and set the username as admin and the login class as superuser. You use local template accounts when you need different types of templates. Each template can define a different set of permissions appropriate for the group of users who use that template.

Configuration

- [Creating a Remote Template Account on page 811](#)
- [Creating a Local Template Account on page 812](#)

Creating a Remote Template Account

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system login user remote class operator
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To create a remote template account:

- Set the username and the login class for the user.

```
[edit system login]
user@host# set user remote class operator
```

Results From configuration mode, confirm your configuration by entering the **show system login** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
user remote {
class operator;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Creating a Local Template Account

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system login user admin class superuser
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To create a local template account:

1. Set the username and the login class for the user.

```
[edit system login]
user@host# set user admin class superuser
```

Results From configuration mode, confirm your configuration by entering the **show system login** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login
user admin {
class super-user;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: To completely set up RADIUS or TACACS+ authentication, you must configure at least one RADIUS or TACACS+ server and specify a system authentication order. Do one of the following tasks:

- Configure a RADIUS server. See [“Example: Configuring a RADIUS Server for System Authentication” on page 1014.](#)
- Configure a TACACS+ server. See [“Example: Configuring a TACACS+ Server for System Authentication” on page 1019.](#)
- Configure system authentication order. See [“Example: Configuring Authentication Order” on page 1022.](#)

Verification

Confirm that the configuration is working properly.

Verifying the Template Accounts Creation

Purpose Verify that the template accounts have been created.

Action From operational mode, enter the **show system login** command.

Related Documentation

- [Understanding Login Classes on page 795](#)
- [Understanding Template Accounts on page 810](#)

Understanding Administrative Roles

A system user can be a member of a class that allows the user to act as a particular kind of administrator for the system. Requiring a specific role to view or modify an item restricts the extent of information a user can obtain from the system. It also limits how much of the system is open to intentional or unintentional modification or observation by a user. We recommend that you use the following guidelines when you are designing administrative roles:

- Do not allow any user to log in to the system as **root**.
- Restrict each user to the smallest set of privileges needed to perform the user's duties.
- Do not allow any user to belong to a login class containing the **shell** permission flag. The **shell** permission flag allows users to run the **start shell** command from the CLI.
- Allow users to have rollback permissions. Rollback permissions allow users to undo an action performed by an administrator but does not allow them to commit the changes.

You can assign an administrative role to a user by configuring a login class to have the privileges required for that role. You can configure each class to allow or deny access to configuration statements and commands by name. These specific restrictions override and take precedence over any permission flags also configured in the class. You can assign one of the following role attributes to an administrative user.

- **Crypto-administrator**—Allows the user to configure and monitor cryptographic data.
- **Security-administrator**—Allows the user to configure and monitor security data.
- **Audit-administrator**—Allows the user to configure and monitor audit data.
- **IDS-administrator**—Allows the user to monitor and clear the intrusion detection service (IDS) security logs.

Each role can perform the following specific management functions:

- **Cryptographic Administrator**
 - Configures the cryptographic self-test.
 - Modifies the cryptographic security data parameters.
- **Audit Administrator**
 - Configures and deletes the audit review search and sort feature.
 - Searches and sorts audit records.
 - Configures search and sort parameters.
 - Manually deletes audit logs.
- **Security Administrator**
 - Invokes, determines, and modifies the cryptographic self-test behavior.
 - Enables, disables, determines, and modifies the audit analysis and audit selection functions and configures the device to automatically delete audit logs.
 - Enables or disables security alarms.
 - Specifies limits for quotas on Transport Layer connections.
 - Specifies the limits, network identifiers, and time periods for quotas on controlled connection-oriented resources.
 - Specifies the network addresses permitted to use Internet Control Message Protocol (ICMP) or Address Resolution Protocol (ARP).
 - Configures the time and date used in time stamps.
 - Queries, modifies, deletes, and creates the information flow or access control rules and attributes for the unauthenticated information flow security function policy (SFP), the authenticated information flow SFP, the unauthenticated device services, and the discretionary access control policy.
 - Specifies initial values that override default values when object information is created under unauthenticated information flow SFP, the authenticated information flow

SFP, the unauthenticated target of evaluation (TOE) services, and the discretionary access control policy.

- Creates, deletes, or modifies the rules that control the address from which management sessions can be established.
- Specifies and revokes security attributes associated with the users, subjects, and objects.
- Specifies the percentage of audit storage capacity at which the device alerts administrators.
- Handles authentication failures and modifies the number of failed authentication attempts through SSH or from the CLI that can occur before progressive throttling is enforced for further authentication attempts and before the connection is dropped.
- Manages basic network configuration of the device.
- **IDS Administrator**—Specifies IDS security alarms, intrusion alarms, audit selections, and audit data.

You need to set the security-role attribute in the classes created for these administrative roles. This attribute restricts which users can show and clear the security logs, actions that cannot be performed through configuration alone.

For example, you need to set the security-role attribute in the **ids-admin** class created for the IDS administrator role if you want to restrict clearing and showing IDS logs to the IDS administrator role. Likewise, you need to set the security-role to one of the other admin values to restrict that class from being able to clear and show non-IDS logs only.

NOTE: When a user deletes an existing configuration, the configuration statements under the hierarchy level of the deleted configuration (that is, the child objects that the user does not have permission to modify), now remain in the device.

Related Documentation

- [Example: Configuring Administrative Roles on page 815](#)

Example: Configuring Administrative Roles

This example shows how to configure individual administrative roles for a distinct, unique set of privileges apart from all other administrative roles.

- [Requirements on page 816](#)
- [Overview on page 816](#)
- [Configuration on page 816](#)
- [Verification on page 821](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

This example configures four users:

- **audit-officer** of the class **audit-admin**
- **crypto-officer** of the class **crypto-admin**
- **security-officer** of the class **security-admin**
- **ids-officer** of the class **ids-admin**

When a **security-admin** class is configured, the privileges for creating administrators are revoked from the user who created the **security-admin** class. Creation of new users and logins is at the discretion of the **security-officer**.

In this example, you create audit admin, crypto admin, security admin, and ids admin with permission flags pertaining to this role. Then you allow or deny access to configuration statements and commands by name for each administrative role. These specific restrictions take precedence over the permission flags also configured in the class. For example, only the **crypto-admin** can run the **request system set-encryption-key** command, which requires having the **security** permission flag to access it. Only the **security-admin** can include the **system time-zone** statement in the configuration, which requires having the **system-control** permission flag.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system login class audit-admin permissions security
set system login class audit-admin permissions trace
set system login class audit-admin permissions maintenance
set system login class audit-admin allow-commands "^clear (log|security log)"
set system login class audit-admin deny-commands "^clear (security alarms|system
login lockout)|^file (copy|delete|rename)|^request (security|system
set-encryption-key)|^rollback|^set date|^show security
(alarms|dynamic-policies|match-policies|policies)|^start shell";

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To configure users in administrative roles:

1. Create the **audit-admin** login class.

```

[edit]
user@host# set system login class audit-admin
[edit system login class audit-admin]

```

```

user@host# set permissions security
user@host# set permissions trace
user@host# set permissions maintenance

```

2. Configure the **audit-admin** login class restrictions.

```

[edit system login class audit-admin]
user@host# set allow-commands "^clear (log|security log)"
user@host# set deny-commands "^clear (security alarms|system login logout)|^file
(copy|delete|rename)|^request (security|system
set-encryption-key)|^rollback|^set date|^show security
(alarms|dynamic-policies|match-policies|policies)|^start shell"
user@host# set security-role audit-administrator

```

3. Create the **crypto-admin** login class.

```

[edit]
user@host# set system login class crypto-admin

```

```

[edit system login class crypto-admin]
user@host# set permissions admin-control
user@host# set permissions configure
user@host# set permissions maintenance
user@host# set permissions security-control
user@host# set permissions system-control
user@host# set permissions trace

```

4. Configure the **crypto-admin** login class restrictions.

```

[edit system login class crypto-admin]
user@host# set allow-commands "^request system set-encryption-key"
user@host# set deny-commands "^clear (log|security alarms|security log|system
login logout)|^file (copy|delete|rename)|^rollback|^set date|^show security
(alarms|dynamic-policies|match-policies|policies)|^start shell"
user@host# set allow-configuration-regexps "security (ike|ipsec) (policy|proposal)"
"security ipsec ^vpn$.* manual (authentication|encryption|protocol|spi)" "system
fips self-test after-key-generation"
user@host# set security-role crypto-administrator

```

5. Create the **security-admin** login class.

```

[edit]
user@host# set system login class security-admin

```

```

[edit system login class security-admin]
user@host# set permissions all

```

6. Configure the **security-admin** login class restrictions.

```

[edit system login class security-admin]
user@host# set deny-commands "^clear (log|security log)|^(clear|show) security
alarms alarm-type idp|^request (security|system
set-encryption-key)|^rollback|^start shell"
user@host# set deny-configuration-regexps "security alarms potential-violation
idp" "security (ike|ipsec) (policy|proposal)" "security ipsec ^vpn$.* manual
(authentication| encryption|protocol|spi)" "security log cache" "security log
exclude.* event-id IDP_.*" "system fips self-test after-key- generation"
user@host# set security-role security-administrator

```

7. Create the **ids-admin** login class.

```
[edit]
user@host# set system login class ids-admin
```

```
[edit system login class ids-admin]
user@host# set permissions configure
user@host# set permissions maintenance
user@host# set permissions security-control
user@host# set permissions trace
```

8. Configure the **ids-admin** login class restrictions.

```
[edit system login class ids-admin]
user@host# set allow-configuration-regexps "security alarms potential-violation
idp" "security log exclude .* event-id IDP_.*"
set system login class ids-admin deny-commands "^clear log|^ (clear|show) security
alarms (alarm-id|all|newer-than|older- than|process|severity)|^ (clear|show)
security alarms alarm-type
(authentication|cryptographic-self-test|decryption-failures|encryption-failures|
ike-phase1-failures|ike-phase2-failures|key-generation-self-test|
non-cryptographic-self-test|policy|replay-attacks)|^ file
(copy|delete|rename)|^ request (security|system set-encryption-key)|
^rollback|^set date|^show security (dynamic-policies|match-policies|policies)|^start
shell"
set system login class ids-admin deny-configuration-regexps "security alarms
potential-violation (authentication|cryptographic-self-test|decryption-
failures|encryption-failures|ike-phase1-failures|ike-phase2-failures|
key-generation-self-test|non-cryptographic-self-test|policy|replay-attacks)"
user@host# set security-role ids-administrator
```

9. Assign users to the roles.

```
[edit]
user@host# set system login

[edit system login]
user@host# set user audit-officer class audit-admin
user@host# set user crypto-officer class crypto-admin
user@host# set user security-officer class security-admin
user@host# set user ids-officer class ids-admin
```

10. Configure passwords for the users.

```
[edit system login]
user@host# set user audit-officer authentication plain-text-password
user@host# set user crypto-officer authentication plain-text-password
user@host# set user security-officer authentication plain-text-password
user@host# set user ids-officer authentication plain-text-password
```

Results

From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@host# show system
system {
  login {
    class audit-admin {
      permissions [ maintenance security trace ];

        exclude.* event-id IDP_.*";
      deny-configuration-regexps "security alarms potential-violation
        (authentication|cryptographic-self-test|decryption-
        failures|encryption-failures|ike-phase1-failures|ike-phase2-failures|
        key-generation-self-test|non-cryptographic-self-test|policy|replay-attacks)"
      security-role ids-administrator;
    }
  }
  user audit-officer {
    class audit-admin;
    authentication {

```

```

        encrypted-password "$1$ABC123"; ## SECRET-DATA
    }
}
user crypto-officer {
    class crypto-admin;
    authentication {
        encrypted-password "$1$ABC123."; ## SECRET-DATA
    }
}
user security-officer {
    class security-admin;
    authentication {
        encrypted-password "$1$ABC123."; ##SECRET-DATA
    }
}
user ids-officer {
    class ids-admin;
    authentication {
        encrypted-password "$1$ABC123/"; ## SECRET-DATA
    }
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Login Permissions

Purpose Verify the login permissions for the current user.

Action From operational mode, enter the **show cli authorization** command.

```

user@host>show cli authorization
Current user: 'example' class 'super-user'
Permissions:
  admin      -- Can view user accounts
  admin-control-- Can modify user accounts
  clear      -- Can clear learned network info
  configure  -- Can enter configuration mode
  control    -- Can modify any config
  edit       -- Can edit full files
  field      -- Can use field debug commands
  floppy     -- Can read and write the floppy
  interface  -- Can view interface configuration
  interface-control-- Can modify interface configuration
  network    -- Can access the network
  reset      -- Can reset/restart interfaces and daemons
  routing    -- Can view routing configuration
  routing-control-- Can modify routing configuration
  shell      -- Can start a local shell
  snmp       -- Can view SNMP configuration
  snmp-control-- Can modify SNMP configuration
  system     -- Can view system configuration

```

```

system-control-- Can modify system configuration
trace          -- Can view trace file settings
trace-control-- Can modify trace file settings
view           -- Can view current values and statistics
maintenance   -- Can become the super-user
firewall       -- Can view firewall configuration
firewall-control-- Can modify firewall configuration
secret         -- Can view secret statements
secret-control-- Can modify secret statements
rollback       -- Can rollback to previous configurations
security       -- Can view security configuration
security-control-- Can modify security configuration
access         -- Can view access configuration
access-control-- Can modify access configuration
view-configuration-- Can view all configuration (not including secrets)
flow-tap       -- Can view flow-tap configuration
flow-tap-control-- Can modify flow-tap configuration
idp-profiler-operation-- Can Profiler data
pgcp-session-mirroring-- Can view pgcp session mirroring configuration
pgcp-session-mirroring-control-- Can modify pgcp session mirroring configuration
storage        -- Can view fibre channel storage protocol configuration
storage-control-- Can modify fibre channel storage protocol configuration
all-control    -- Can modify any configuration
Individual command authorization:
Allow regular expression: none
Deny regular expression: none
Allow configuration regular expression: none
Deny configuration regular expression: none

```

This output summarizes the login permissions.

Handling Authorization Failure

The security administrator can configure the number of times a user can try to log in to the device with invalid login credentials. The device can be locked after the specified number of unsuccessful authentication attempts. This helps to protect the device from malicious users attempting to access the system by guessing an account's password. The security administrator can unlock the user account or define a time period for the user account to remain locked.

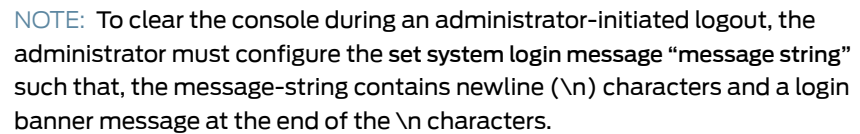

The system **lockout-period** defines the amount of time the device can be locked for a user account after a specified number of unsuccessful login attempts.

The security administrator can configure a period of time after which an inactive session will be locked and require re-authentication to be unlocked. This helps to protect the device from being idle for a long period before the session times out.

The system **idle-timeout** defines length of time the CLI operational mode prompt remains active before the session times out.

The security administrator can configure a banner with an advisory notice to be displayed before the identification and authentication screen.

The number of reattempts the device allows is defined by the **tries-before-disconnect** option. The device allows 3 unsuccessful attempts by default or as configured by the administrator. The device prevents the locked users to perform activities that require authentication, until a security administrator manually clears the lock or the defined time period for the device to remain locked has elapsed. However, the existing locks are ignored when the user attempts to log in from the local console.

[illegible]

Overview

823

Device lockout allows you to configure the number of failed attempts before the user account is locked out of the device and configure the amount of time before the user can attempt to log in to the device again. You can configure the amount of time in-between failed login attempts of a user account and can manually lock and unlock user accounts.

**NOTE:**

This example includes the following settings:

- **backoff-factor** — Sets the length of delay in seconds after each failed login attempt. When a user incorrectly logs in to the device, the user must wait the configured amount of time before attempting to log in to the device again. The length of delay increases by this value for each subsequent login attempt after the value specified in the **backoff-threshold** statement. The default value for this statement is five seconds, with a range of five to ten seconds.
- **backoff-threshold** — Sets the threshold for the number of failed login attempts on the device before the user experiences a delay when attempting to reenter a password. When a user incorrectly logs in to the device and hits the threshold of failed login attempts, the user experiences a delay that is set in the **backoff-factor** statement before attempting to log in to the device again. The default value for this statement is two, with a range of one through three.
- **lockout-period** — Sets the amount of time in minutes before the user can attempt to log in to the device after being locked out due to the number of failed login attempts specified in the **tries-before-disconnect** statement. When a user fails to correctly login after the number of allowed attempts specified by the **tries-before-disconnect** statement, the user must wait the configured amount of minutes before attempting to log in to the device again. The lockout-period must be greater than zero. The range at which you can configure the lockout-period is one through 43,200 minutes.
- **tries-before-disconnect** — Sets the maximum number of times the user is allowed to enter a password to attempt to log in to the device through SSH or Telnet. When the user reaches the maximum number of failed login attempts, the user is locked out of the device. The user must wait the configured amount of minutes in the **lockout-period** statement before attempting to log back in to the device. The **tries-before-disconnect** statement must be set when the **lockout-period** statement is set; otherwise, the **lockout-period** statement is meaningless. The default number of attempts is ten, with a range of one through ten attempts.

Once a user is locked out of the device, if you are the security administrator, you can manually remove the user from this state using the `clear system login lockout <username>` command. You can also use the `show system login lockout` command to view which users are currently locked out, when the lockout period began for each user, and when the lockout period ends for each user.

If the security administrator is locked out of the device, he can log in to the device from the console port, which ignores any user locks. This provides a way for the administrator to remove the user lock on their own user account.

In this example the user waits for the **backoff-threshold** multiplied by the **backoff-factor** interval, in seconds, to get the login prompt. In this example, the user must wait 5 seconds after the first failed login attempt and 10 seconds after the second failed login attempt to get the login prompt. The user gets disconnected after 15 seconds after the third failed attempt because the **tries-before-disconnect** option is configured as 3.

The user cannot attempt another login until 120 minutes has elapsed, unless a security administrator manually clears the lock sooner.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system login retry-options backoff-factor 5
set system login retry-options backoff-threshold 1
set system login retry-options lockout-period 120
set system login retry-options tries-before-disconnect 3
```

Step-by-Step Procedure To configure system retry-options:

1. Configure the backoff factor.

```
[edit]
user@host# set system login retry-options backoff-factor 5
```
2. Configure the backoff threshold.

```
[edit]
user@host# set system login retry-options backoff-threshold 1
```
3. Configure the amount of time the device gets locked after failed attempts.

```
[edit]
user@host# set system login retry-options lockout-period 5
```
4. Configure the number of unsuccessful attempts during which, the device can remain unlocked.

```
[edit]
user@host# set system login retry-options tries-before-disconnect 3
```

Results From configuration mode, confirm your configuration by entering the **show system login retry-options** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system login retry-options
backoff-factor 5;
backoff-threshold 1;
lockout-period 5;
tries-before-disconnect 3;
```

Confirm that the configuration is working properly.

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Displaying the Locked User Logins

Purpose Verify that the login lockout configuration is enabled.

Action Attempt three unsuccessful logins for a particular username. The device will be locked for that username; then log in to the device with a different username. From operational mode, enter the **show system login lockout** command.

Meaning When you perform three unsuccessful login attempts with a particular username, the device is locked for that user for five minutes, as configured in the example. You can verify that the device is locked for that user by logging in to the device with a different username and entering the **show system login lockout** command.

- [Example: Specifying Access Privileges Using allow/deny-configuration-regexps Statements on page 835](#)

Configuring Access Privilege Levels

Each top-level command-line interface (CLI) command and each configuration statement have an access privilege level associated with it. Users can execute only those commands and configure and view only those statements for which they have access privileges.

To configure access privilege levels, include the **permissions** statement at the **[edit system login class *class-name*]** hierarchy level:

```
[edit system login class class-name]  
permissions [ permissions ];
```

Related Documentation

- [Example: Configuring User Permissions with Access Privilege Levels on page 830](#)
- [Understanding Junos OS Access Privilege Levels on page 799](#)
- [Specifying Access Privileges for Junos OS Operational Mode Commands on page 830](#)
- *permissions*

Example: Configuring User Permissions with Access Privilege Levels

Create two access privilege classes on the router or switch, one for configuring and viewing user accounts only and the second for configuring and viewing SNMP parameters only:

In this example, you create two custom login classes on the router or switch and assign access privileges to each class through permission flags. The first custom login class is called **user-accounts** and it only includes access privileges for configuring and viewing user accounts. The second custom login class is called **network-mgmt** and only includes access privileges for configuring SNMP parameters.

```
[edit]
system {
  login {
    class user-accounts {
      permissions [ configure admin admin-control ];
    }
    class network-mgmt {
      permissions [ configure snmp snmp-control ];
    }
  }
}
```

1. Create the **user-accounts** custom login class and give it control over user accounts with the **configure admin admin-control** permission flag.

```
[edit system login]
user@router# set class user-accounts permissions configure admin admin-control
```

2. Create the **network-mgmt** custom login class and use the **configure snmp snmp-control** permission flag to assign it SNMP configuration privileges.

```
[edit system login]
user@router# set class network-mgmt permissions configure snmp snmp-control
```

3. Check your configuration by using the **show system login** command.

```
user@router# show system login
class user-accounts {
  permissions [ configure admin admin-control ];
}
class network-mgmt {
  permissions [ configure snmp snmp-control ];
}
```

Specifying Access Privileges for Junos OS Operational Mode Commands

You can specify extended regular expressions by using the **allow-commands** and **deny-commands** statements to define a user's access privileges to individual operational mode commands. Doing so takes precedence over a login class permissions bit set for a user. You can include one **deny-commands** and one **allow-commands** statement in each login class.

To explicitly provide use of an individual operational mode command that would otherwise be denied, include the **allow-commands** statement at the **[edit system login class *class-name*]** hierarchy level:

```
[edit system login class class-name]
  allow-commands "regular-expression";
```

To explicitly deny access to an individual operational mode command that would otherwise be supported, include the **deny-commands** statement at the **[edit system login class *class-name*]** hierarchy level:

```
[edit system login class class-name]
  deny-commands "regular-expression";
```

NOTE: The regular expression to allow/deny commands for any login class is supported at the command level but not at the argument level. For example, you can completely block ping but not ping *argument1*.

If the regular expression contains any spaces, operators, or wildcard characters, enclose the expression in quotation marks. Regular expressions are not case-sensitive.

```
allow-commands "show interfaces";
```

NOTE: Modifiers are not supported within the regular expression string to be matched. If a modifier is used, then nothing is matched.

For example, the deny command **set protocols** does not match anything, whereas **protocols** matches *protocols*.

Explicitly providing access to operational mode commands using the **allow-commands** statement adds to the regular permissions set using the **permissions** statement. Likewise, explicitly denying access to operational mode commands using the **deny-commands** statement removes permissions for the specified commands from the default permissions provided by the **permissions** statement.

For example, if a login class has the permission **view** and the **allow-commands** statement includes the **request system software add** command, the specified login class user can install software, in addition to the permissions specified by the **view** permissions flag. Likewise, if a login class has the permission **all** and the **deny-commands** statement includes the **request system software add** command, the specified login class user can perform all operations allowed by the **all** permissions flag, except installing software using the **request system software add** command.

If you allow and deny the same commands, the **allow-commands** permissions take precedence over the permissions specified by **deny-commands**. For example, if you include **allow-commands "request system software add"** and **deny-commands "request system software add"**, the login class user is allowed to install software using the **request system software add** command.

If you specify a regular expression for **allow-commands** and **deny-commands** with two different variants of a command, the longest match is always executed.

For example, if you specify a regular expression for **allow-commands** with the **commit-synchronize** command and a regular expression for **deny-commands** with the **commit** command, users assigned to such a login class would be able to issue the **commit synchronize** command, but not the **commit** command. This is because **commit-synchronize** is the longest match between **commit** and **commit-synchronize**, and it is specified for **allow-commands**.

Likewise, if you specify a regular expression for **allow-commands** with the **commit** command and a regular expression for **deny-commands** with the **commit-synchronize** command, users assigned to such a login class would be able to issue the **commit** command, but not the **commit-synchronize** command. This is because **commit-synchronize** is the longest match between **commit** and **commit-synchronize**, and it is specified for **deny-commands**.

Anchors are required when specifying complex regular expressions with **allow-commands** or **deny-commands** statements. For example, when specifying multiple commands using the pipe (|) symbol for **allow-commands**, the following syntax is incorrect:

allow-commands = "(monitor.*)"|(ping.*)"|(show.*)"|(exit)" . Instead, you must specify the expression using the following syntax: **allow-commands = "(^monitor) | (^ping) | (^show) | (^exit)"** OR **allow-commands = "^ (monitor | ping | show | exit)"**

Example: Configuring User Permissions with Access Privileges for Operational Mode Commands

Each operational mode command has an access privilege level associated with it. Access privileges control the commands that each custom login class can execute, configure, and view. Custom login classes are groups of users who are assigned with customized levels of access to different commands and statements. This ensures that each group of users can only use commands appropriate to their function, preventing unauthorized users from executing sensitive commands that could potentially cause damage to the network.

In this example, you create three custom login classes on the router or switch and assign access privileges for operational mode commands through the **allow-commands** and **deny-commands** settings. Each custom login class uses the same set of permission flags as the default login class **operator**, but **the login class is** allowed or denied certain operational mode commands. The first custom login class is called **operator-and-boot** and it has access to the **request system reboot** operational mode command. The second custom login class is called **operator-no-set** and it is denied access to any **set** commands. The third login class is called **operator-and-install-but-no-bgp** and it has access to the **request system software add** and **show route** operational mode commands, but it is denied access to the **show bgp** command.

```
[edit]
system {
  login {
    class operator-and-boot {
      permissions [ clear network reset trace view ];
      allow-commands "request system reboot";
    }
    class operator-no-set {
      permissions [ clear network reset trace view ];
      deny-commands "set";
    }
    class operator-and-install-but-no-bgp {
      permissions [ clear network reset trace view ];
      allow-commands "(request system software add)|(show route$)";
      deny-commands "show bgp";
    }
  }
}
```

1. Create the **operator-and-boot** custom login class, give it **operator** level permission flags, and authorize it to use the **request system reboot** command.

```
[edit system login]
user@router# set class operator-and-boot permissions clear network reset trace view
user@router# set class operator-and-boot allow-commands request system reboot
```

2. Create the **operator-no-set** custom login class, give it **operator** level permission flags, and deny it access to the **set** command.

```
[edit system login]
user@router# set class operator-no-set clear network reset trace view
user@router# set class operator-no-set deny-commands set
```

3. Create the **operator-and-install-but-no-bgp** custom login class, give it **operator** level permission flags, authorize it to use the **request system software add** and **show route** commands, and deny it access to the **show bgp** command.

```
[edit system login]
user@router# set class operator-and-install-but-no-bgp clear network reset trace
view
user@router# set class operator-and-install-but-no-bgp request system software
add show route
user@router# set class operator-and-install-but-no-bgp show bgp
```

4. Check your configuration by using the **show system login** command.

```
user@router# show system login
class operator-and-boot {
  permissions [ clear network reset trace view ];
  allow-commands "request system reboot";
}
class operator-no-set {
  permissions [ clear network reset trace view ];
  deny-commands "set";
}
class operator-and-install-but-no-bgp {
  permissions [ clear network reset trace view ];
  allow-commands "(request system software add)|(show route$)";
  deny-commands "show bgp";
}
```

Specifying Access Privileges for Junos OS Configuration Mode Hierarchies

The **allow/deny-configuration** and **allow/deny-configuration-regexps** statements let you explicitly allow or deny users access privileges to portions of the configuration hierarchy. Each of these statements is added to named login classes and configured with one or more regular expressions to be allowed or denied. Each login class is assigned to specific users or user IDs.

The search and match methods differ in the two forms of these statements. You must select which form to use within a login class—you cannot configure **allow-configuration** and **allow-configuration-regexps** together in the same login class. You must select just one. If you have existing configurations using the **allow/deny-configuration** form of the statements, using the same configuration options with the **allow/deny-configuration-regexps** form of the statements might not produce the same results.

- **Allow/deny-configuration** statements perform slower matching, with more flexibility, especially in wildcard matching. However, it can take a very long time to evaluate all of the possible statements if a great number of full path regular expressions or wildcard expressions are configured, possibly impacting performance. These statements were introduced before Junos OS Release 7.4.

- **Allow/deny-configuration-regexps** statements perform faster matching, with less flexibility. You configure a set of strings in which each string is a regular expression, with spaces between the terms of the string. This provides very fast matching. However, it is more tedious to use wildcard expressions in this form of the statement, because you must set up wildcards for each token (term) of the space-delimited string you want to match. These statements were introduced in Junos OS Release 11.2.

Example: Specifying Access Privileges Using allow/deny-configuration-regexps Statements

This example shows how to set up configuration access privileges using the **allow-configuration-regexps** and **deny-configuration-regexps** statements.

- [Requirements on page 835](#)
- [Overview on page 835](#)
- [Configuration on page 836](#)
- [Examples Using Allow or Deny Configurations with Regular Expressions on page 836](#)

Requirements

This example uses the following hardware and software components:

- One Juniper Networks M Series, MX Series, or T Series device
- Junos OS Release 11.2 or later
 - There must be at least one user assigned to a login class.
 - There can be more than one login class, each with varying permission configurations, and more than one user on the device.

Overview

The **allow-configuration-regexps** and **deny-configuration-regexps** statements let you explicitly allow or deny users assigned to named user classes access privileges to portions of the configuration hierarchy, giving the system administrator precision control over who can change specific configurations in the system.

NOTE: The statements **allow-configuration-regexps** and **deny-configuration-regexps** perform similar functions as the statements **allow-configuration** and **deny-configuration**, except you can configure sets of strings in which the strings include spaces when using the first set of statements. You cannot use the two kinds of statements together.

Configuration

To set up configuration access privileges:

1. To explicitly allow one or more individual configuration mode hierarchies that would otherwise be denied, include the **allow-configuration-regexps** statement at the **[edit system login class class-name]** hierarchy level, configured with the regular expressions to be allowed.

```
[edit system login class class-name]
user@host# set allow-configuration-regexps "regular expression 1" "regular expression
2" "regular expression 3" "regular expression 4" ...
```

2. To explicitly deny one or more individual configuration hierarchies that would otherwise be allowed, include the **deny-configuration-regexps** statement at the **[edit system login class class-name]** hierarchy level, configured with the regular expressions to be denied.

```
[edit system login class class-name]
user@host# set deny-configuration-regexps "regular expression 1" "regular-expression
2" "regular expression 3" "regular expression 4"...
```

3. Assign the login class to one or more users.

```
[edit system login]
user@host# set user username class class-name
```

4. Commit your changes.

Users assigned this login class have the permissions you have set for the class.

Examples Using Allow or Deny Configurations with Regular Expressions

Purpose This section provides examples of access privilege configurations to give you ideas for creating configurations appropriate for your system. You can use combinations of privilege statements for configuration access and for operational mode commands to give precise control over classes of access privileges.

Allow Configuration Changes The following example login class lets the user make changes at the **[edit system services]** hierarchy level and issue configuration mode commands (such as **commit**), in addition to the permissions specified by the **configure** permissions flag, which allows the user to enter configuration mode using the **configure** command.

```
[edit system login class class-name]
user@host# set permissions configure view view-configuration
user@host# set allow-configuration-regexps "system services"
```

Deny Configuration Changes The following example login class lets the user perform all operations allowed by the **all** permissions flag. However, it denies modifying the configuration at the **[edit system services]** hierarchy level.

```
[edit system login class class-name]
user@host# set permissions all configure view view-configuration
user@host# set deny-configuration-regexps "system services"
```

If the following statement is included in the configuration and the user's login class permission bit is set to **all**, the user cannot configure telnet parameters:

```
[edit system login class class-name]
user@host# set deny-configuration "system services telnet"
```

If the following statement is included in the configuration and the user's login class permission bit is set to **all**, the user cannot issue login class commands within any login class whose name begins with "m":

```
[edit system login class class-name]
user@host# set deny-configuration "system login class m ."
```

If the following statement is included in the configuration and the user's login class permission bit is set to **all**, the user cannot edit the configuration or issue commands (such as **commit**) at the **[edit system login class]** or the **[edit system services]** hierarchy levels:

```
[edit system login class class-name]
user@host# set deny-configuration "system login class" "system services"
```

Allow and Deny Configuration Changes

The following example login class lets the user perform all operations allowed by the **all** permissions flag, and explicitly grants configuration access to **[system "interfaces .*" unit .*" family inet address .*" protocols]**. However, the user is denied configuration access to the SNMP hierarchy level.

NOTE: You can use the * wildcard character when denoting regular expressions. However, it must be used as a portion of a regular expression. You cannot use [*] or [.*] alone.

```
[edit system login class class-name]
user@host# set permissions all configure view view-configuration
user@host# set allow-configuration-regexps system "interfaces .* unit .* family inet
address ." protocols
user@host# set deny-configuration-regexps snmp
```

Allow and Deny Multiple Configuration Changes

The following example login class lets the user perform all operations allowed by the **all** permissions flag, and explicitly grants configuration access to multiple hierarchy levels for interfaces. It denies configuration access to the **[edit system]** and **[edit protocols]** hierarchy levels.

NOTE: You can configure as many regular expressions as needed to be allowed or denied. Regular expressions to be denied take precedence over configurations to be allowed.

```
[edit system login class class-name]
user@host# set permissions all configure view view-configuration
user@host# set allow-configuration-regexps "interfaces .* description ." "interfaces .*
unit .* description ." "interfaces .* unit .* family inet address ." "interfaces .* disable"
user@host# set deny-configuration-regexps "system" "protocols"
```

Allow Configuration Changes and Deny Operations Commands

You can combine allow and deny configuration statements with allow and deny operational commands statements to fine-tune access privileges. The following example login class uses a combination of the **deny-commands** operational permissions statement and the **allow-configuration-regexps** configuration permissions statement to let the user configure and commit changes to the OSPF and BGP protocols. However, this class of user cannot issue the **show system statistics** or the **show bgp summary** commands.

```
[edit system login class class-name]
user@host# set permissions all configure view view-configuration
user@host# set deny-commands "(show system statistics)|(show bgp summary)"
user@host# set allow-configuration-regexps "protocols ospf|bgp"
```

The following shows permissions set for individual configuration mode hierarchies:

```
[edit]
system {
  login { # This login class has operator privileges and the additional ability to edit
    # configuration at the system services hierarchy level.
    class only-system-services {
      permissions [ configure ];
      allow-configuration "system services";
    }
    # services commands.
    class all-except-system-services { # This login class has operator privileges but
      # cannot edit any system services configuration.
      permissions [ all ];
      deny-configuration "system services";
    }
  }
}
```

Verification To verify that you have set the access privileges correctly:

1. Configure a login class and commit the changes.
2. Assign the login class to a *username*.
3. Log in as the *username* assigned with the new login class.
4. Attempt to perform the configurations that have been allowed or denied.
 - You should be able to perform configuration changes to hierarchy levels and regular expressions that have been allowed.
 - You should not be able to perform configuration changes to hierarchy levels and regular expressions that have been denied.
 - Denied expressions should take precedence over allowed expressions.
 - Any allowed or denied expressions should take precedence over any permissions granted with the **permissions** statement.

Access Privilege User Permission Flags Overview

Permission flags are used to grant a user access to operational mode commands and configuration hierarchy levels and statements. By specifying a specific permission flag on the user's login class at the **[edit system login class]** hierarchy level, you grant the user access to the corresponding commands and configuration hierarchy levels and statements. To grant access to all commands and configuration statements, use the **all** permissions flag.

For permission flags that grant access to configuration hierarchy levels and statements, the flags grant read-only privilege to that configuration. For example, the **interface** permissions flag grants read-only access to the **[edit interfaces]** hierarchy level. The **-control** form of the flag grants read-write access to that configuration. Using the preceding example, **interface-control** grants read-write access to the **[edit interfaces]** hierarchy level.

The permission flags listed in "Related Documentation" grant a specific set of access privileges. Each permission flag is listed with the operational mode commands and configuration hierarchy levels and statements for which that flag grants access.

NOTE: Each command listed represents that command and all subcommands with that command as a prefix. Each configuration statement listed represents the top of the configuration hierarchy to which that flag grants access.

Configuring RADIUS Server Authentication

RADIUS authentication is a method of authenticating users who attempt to access the router or switch.

The Junos OS supports two protocols for central authentication of users on multiple routers: RADIUS and TACACS+. We recommend RADIUS because it is a multivendor IETF standard, and its features are more widely accepted than those of TACACS+ or other proprietary systems. In addition, we recommend using a one-time-password system for increased security, and that all vendors of these systems support RADIUS.

You should use RADIUS when your priorities are interoperability and performance:

- Interoperability—RADIUS is more interoperable than TACACS+, primarily because of the proprietary nature of TACACS+. While TACACS+ supports more protocols, RADIUS is universally supported.
- Performance—RADIUS is much lighter on your routers and switches and for this reason, network engineers generally prefer RADIUS over TACACS+.

To use RADIUS authentication on the device, configure information about one or more RADIUS servers on the network by including one **radius-server** statement at the **[edit system]** hierarchy level for each RADIUS server.

Because remote authentication is configured on multiple devices, it is commonly configured inside of a configuration group. As such, the steps shown here are in a configuration group called **global**. Using a configuration group is optional.

To configure authentication by a RADIUS server:

1. Add an IPv4 or IPv6 server address.

- Configure an IPv4 source address and server address:

```
[edit groups global]
user@host# set system radius-server server-address source-address source-address
```

For example:

```
[edit groups global]
user@host# set system radius-server 192.168.17.28 source-address 192.168.17.1
```

- Configure an IPv6 source address and server address:

```
[edit groups global system radius-server server-address]
user@host# set server-address secret "secretkey" source-address source-address
```

For example:

```
[edit groups global system radius-server ::17.22.22.162]
user@host# set secret $9$ABC123 source-address ::17.22.22.1
```

The source address is a valid IPv4 or IPv6 address configured on one of the router or switch interfaces. This configuration sets a fixed address as the source address for locally generated IP packets.

Server address is a unique IPv4 or IPv6 address that is assigned to a particular server and used to route information to the server. If the Junos OS device has several interfaces that can reach the RADIUS server, assign an IP address that Junos OS can use for all its communication with the RADIUS server.

2. Include a shared secret password.

You must specify a password in the **secret *password*** statement. If the password contains spaces, enclose it in quotation marks. The secret password used by the local router or switch must match that used by the server. The secret password configures the password that the Junos OS device uses to access the RADIUS server.

```
[edit groups global system radius-server server-address]
user@host# set secret password
```

For example:

```
[edit groups global system radius-server 192.168.69.162]
user@host# set secret $9$ABC123ABC123
```

3. If necessary, specify a port on which to contact the RADIUS server.

By default, port number 1812 is used (as specified in RFC 2865).

NOTE: You can also specify an accounting port to send accounting packets with the **accounting-port** statement. The default is 1813 (as specified in RFC 2866).

```
[edit groups global system radius-server server-address]
user@host# set port port-number
```

For example:

```
[edit groups global system radius-server 192.168.69.162]
user@host# set port 1845
```

4. Specify the order in which Junos OS attempts authentication.

You must include the **authentication-order** statement in your remote authentication configuration.

The example assumes your network includes both RADIUS and TACACS+ servers. In this example, whenever a user attempts to log in, Junos OS begins by querying the RADIUS server for authentication. If it fails, it next attempts authentication with locally configured user accounts. Finally the TACACS+ server is tried.

```
[edit groups global system]
user@host# set authentication-order [ authentication-methods ]
```

For example:

```
[edit groups global system]
user@host# set authentication-order [ radius password tacplus ]
```

5. Assign a login class to RADIUS-authenticated users.

You can assign different user templates and login classes to RADIUS-authenticated users. This allows RADIUS-authenticated users to be granted different administrative permissions on the Junos OS device. By default, RADIUS-authenticated users use the **remote** user template and are assigned to the associated class, which is specified in the **remote** user template, if the **remote** user template is configured. The username **remote** is a special case in Junos OS. It acts as a template for users who are authenticated by a remote server, but do not have a locally-configured user account on the device. In this method, Junos OS applies the permissions of the remote template to those authenticated users without a locally defined account. All users mapped to the remote template are of the same login class.

In the Junos OS configuration, a user template is configured in the same way as a regular local user account, except that no local authentication password is configured because the authentication is remotely performed on the RADIUS server.

- To use the same permissions for all RADIUS-authenticated users:

```
[edit groups global system login]
user@host# set user remote class class
```

For example:

```
[edit groups global system login]
user@host# set user remote class super-user
```

- To have different login classes be used for different RADIUS-authenticated users, granting them different permissions:
 - a. Create multiple user templates in the Junos OS configuration.

Every user template can be assigned a different login class.

For example:

```
[edit groups global system login]
```

```
set user RO class read-only
set user OP class operator
set user SU class super-user
set user remote full-name "default remote access user template"
set user remote class read-only
```

- b. Have the RADIUS server specify the name of the user template to be applied to the authenticated user.

For a RADIUS server to indicate which user template is to be applied, it needs to include the `Juniper-Local-User-Name` attribute (Vendor 2636, type 1, string) `Juniper VSA` (vendor-specific attribute) in the RADIUS Access-Accept message. The string value in the `Juniper-Local-User-Name` must correspond to the name of a configured user template on the device. For a list of relevant Juniper RADIUS VSAs, see [Juniper Networks Vendor-Specific RADIUS Attributes](#).

If the `Juniper-Local-User-Name` is not included in the Access-Accept message or the string contains a user template name that does not exist on the device, the user is assigned to the **remote** user template, if configured. If it is not configured, authentication fails for the user.

After logging in, the remotely authenticated user retains the same username that was used to log in. However, the user inherits the user class from the assigned user template.

In a RADIUS server, users can be assigned a `Juniper-Local-User-Name` string, which indicates the user template to be used in the Junos OS device. From the previous example, the string would be `RO`, `OP`, or `SU`.

Configuration of the RADIUS server depends on the server being used. For instructions for the Juniper Steel-Belted Radius server, see [Steel-Belted Radius \(SBR\) Enterprise](#). For information on using FreeRADIUS, see <http://kb.juniper.net/InfoCenter/index?page=content&id=KB19446>.

Example: Configuring a RADIUS Server for System Authentication

This example shows how to configure a RADIUS server for system authentication.

- [Requirements on page 1014](#)
- [Overview on page 1015](#)
- [Configuration on page 1015](#)
- [Verification on page 1016](#)

Requirements

Before you begin:

- Perform the initial device configuration. See the Getting Started Guide for your device.
- Configure at least one RADIUS server. For more details, see [RADIUS Authentication and Accounting Servers Configuration Overview](#).

Overview

In this example, you add a new RADIUS server with an IP address of 172.16.98.1 and specify the shared secret password of the RADIUS server as Radiussecret1. The secret is stored as an encrypted value in the configuration database. Finally, you specify the source address to be included in the RADIUS server requests by the device. In most cases you can use the loopback address of the device, which in this example is 10.0.0.1.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system radius-server address 172.16.98.1
set system radius-server 172.16.98.1 secret Radiussecret1
set system radius-server 172.16.98.1 source-address 10.0.0.1
```

GUI Step-by-Step Procedure

To configure a RADIUS server for system authentication:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The Edit User Management dialog box appears.
3. Select the **Authentication Method and Order** tab.
4. In the RADIUS section, click **Add**. The Add Radius Server dialog box appears.
5. In the IP Address box, type the server's 32-bit IP address.
6. In the Password and Confirm Password boxes, type the secret password for the server and verify your entry.
7. In the Server Port box, type the appropriate port.
8. In the Source Address box, type the source IP address of the server.
9. In the Retry Attempts box, specify the number of times that the server should try to verify the user's credentials.
10. In the Time Out box, specify the amount of time (in seconds) the device should wait for a response from the server.
11. Click **OK** to check your configuration and save it as a candidate configuration.
12. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see ["Using the CLI Editor in Configuration Mode" on page 434](#) in the *CLI User Guide*.

To configure a RADIUS server for system authentication:

1. Add a new RADIUS server and set its IP address.
[edit system]

```
user@host# set radius-server address 172.16.98.1
```

2. Specify the shared secret (password) of the RADIUS server.

```
[edit system]
user@host# set radius-server 172.16.98.1 secret Radiussecret1
```

3. Specify the device's loopback address source address.

```
[edit system]
user@host# set radius-server 172.16.98.1 source-address 10.0.0.1
```

Results From configuration mode, confirm your configuration by entering the **show system radius-server** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system radius-server
radius-server 172.16.98.1 {
  secret Radiussecret1;
  source-address 10.0.0.1;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: To completely set up RADIUS authentication, you must create user template accounts and specify a system authentication order. Do one of the following tasks:

- Configure a system authentication order. See [“Example: Configuring Authentication Order” on page 1022](#).
- Configure a user. See [“Example: Configuring New Users” on page 807](#).
- Configure local user template accounts. See [“Example: Creating Template Accounts” on page 810](#).

Verification

Confirm that the configuration is working properly.

Verifying the RADIUS Server System Authentication Configuration

Purpose Verify that the RADIUS server has been configured for system authentication.

Action From operational mode, enter the **show system radius-server** command.

Related Documentation

- [Understanding User Authentication Methods on page 804](#)
- [Understanding User Accounts on page 798](#)
- [Example: Configuring a TACACS+ Server for System Authentication on page 1019](#)

- [Understanding Login Classes on page 795](#)

Configuring TACACS+ Authentication

TACACS+ authentication is a method of authenticating users who attempt to access the router or switch. Tasks to configure TACACS+ configuration are:

- [Configuring TACACS+ Server Details on page 1017](#)
- [Specifying a Source Address for the Junos OS to Access External TACACS+ Servers on page 1018](#)
- [Configuring the Same Authentication Service for Multiple TACACS+ Servers on page 1018](#)
- [Configuring Juniper Networks Vendor-Specific TACACS+ Attributes on page 1019](#)

Configuring TACACS+ Server Details

To use TACACS+ authentication on the router or switch, configure information about one or more TACACS+ servers on the network by including the **tacplus-server** statement at the **[edit system]** hierarchy level:

```
[edit system]
tacplus-server server-address {
  port port-number;
  secret password;
  single-connection;
  timeout seconds;
}
```

server-address is the address of the TACACS+ server.

port-number is the TACACS+ server port number.

You must specify a secret (password) that the local router or switch passes to the TACACS+ client by including the **secret** statement. If the password included spaces, enclose the password in quotation marks. The secret used by the local router or switch must match that used by the server.

Optionally, you can specify the length of time that the local router or switch waits to receive a response from a TACACS+ server by including the **timeout** statement. By default, the router or switch waits 3 seconds. You can configure this to be a value in the range from 1 through 90 seconds.

Optionally, you can have the software maintain one open Transmission Control Protocol (TCP) connection to the server for multiple requests, rather than opening a connection for each connection attempt by including the **single-connection** statement.

NOTE: Early versions of the TACACS+ server do not support the **single-connection** option. If you specify this option and the server does not support it, the Junos OS will be unable to communicate with that TACACS+ server.

To configure multiple TACACS+ servers, include multiple **tacplus-server** statements.

To configure a set of users that share a single account for authorization purposes, you create a template user. To do this, include the **user** statement at the **[edit system login]** hierarchy level, as described in *Overview of Template Accounts for RADIUS and TACACS+ Authentication*.

Specifying a Source Address for the Junos OS to Access External TACACS+ Servers

You can specify which source address the Junos OS uses when accessing your network to contact an external TACACS+ server for authentication. You can also specify which source address the Junos OS uses when contacting a TACACS+ server for sending accounting information.

To specify a source address for a TACACS+ server for authentication, include the **source-address** statement at the **[edit system tacplus-server server-address]** hierarchy level:

```
[edit system tacplus-server server-address]
source-address source-address;
```

source-address is a valid IP address configured on one of the router or switch interfaces.

To specify a source address for a TACACS+ server for system accounting, include the **source-address** statement at the **[edit system accounting destination tacplus server server-address]** hierarchy level:

```
[edit system accounting destination tacplus server server-address]
source-address source-address;
```

source-address is a valid IP address configured on one of the router or switch interfaces.

Configuring the Same Authentication Service for Multiple TACACS+ Servers

To configure the same authentication service for multiple TACACS+ servers, include statements at the **[edit system tacplus-server]** and **[edit system tacplus-options]** hierarchy levels. For information about how to configure a TACACS+ server at the **[edit system tacplus-server]** hierarchy level, see [“Configuring TACACS+ Authentication” on page 1017](#).

To assign the same authentication service to multiple TACACS+ servers, include the **service-name** statement at the **[edit system tacplus-options]** hierarchy level:

```
[edit system tacplus-options]
service-name service-name;
```

service-name is the name of the authentication service. By default, the service name is set to **junos-exec**.

The following example shows how to configure the same authentication service for multiple TACACS+ servers:

```
[edit system]
tacplus-server {
  10.2.2.2 secret "$ABC123"; ## SECRET-DATA
  10.3.3.3 secret "$ABC123"; ## SECRET-DATA
}
```

```

}
tacplus-options {
  service-name bob;
}

```

Configuring Juniper Networks Vendor-Specific TACACS+ Attributes

The Juniper Networks Vendor-Specific TACACS+ Attributes enable you to configure access privileges for users on a TACACS+ server. They are specified in the TACACS+ server configuration file on a per-user basis. The Junos OS retrieves these attributes through an authorization request of the TACACS+ server after authenticating a user. You do not need to configure these attributes to run the Junos OS with TACACS+.

To specify these attributes, include a **service** statement of the following form in the TACACS+ server configuration file:

```

service = junos-exec {
  local-user-name = <username-local-to-router>
  allow-commands = "<allow-commands-regex>"
  allow-configuration-regexps = "<allow-configuration-regex>"
  deny-commands = "<deny-commands-regex>"
  deny-configuration-regexps = "<deny-configuration-regex>"
}

```

This **service** statement can appear in a **user** or **group** statement.

Related Documentation

- [Example: Configuring a TACACS+ Server for System Authentication on page 1019](#)

Example: Configuring a TACACS+ Server for System Authentication

This example shows how to configure a TACACS+ server for system authentication.

- [Requirements on page 1019](#)
- [Overview on page 1019](#)
- [Configuration on page 1020](#)
- [Verification on page 1021](#)

Requirements

Before you begin:

- Perform the initial device configuration. See the Getting Started Guide for your device.
- Configure at least one TACACS+ server.

Overview

In this example, you set the IP address to 172.16.98.24 and the shared secret password of the TACACS+ server to Tacacssecret1. The secret password is stored as an encrypted value in the configuration database. You then set the loopback source address as 10.0.0.1

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system tacplus-server address 172.16.98.24
set system tacplus-server 172.16.98.24 secret Tacacssecret1
set system tacplus-server 172.16.98.24 source-address 10.0.0.1
```

GUI Step-by-Step Procedure To configure a TACACS+ server for system authentication:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The Edit User Management dialog box appears.
3. Select the **Authentication Method and Order** tab.
4. In the TACACS section, click **Add**. The Add TACACS Server dialog box appears.
5. In the IP Address box, type the server's 32-bit IP address.
6. In the Password and Confirm Password boxes, type the secret password for the server and verify your entry.
7. In the Server Port box, type the appropriate port.
8. In the Source Address box, type the locally configured interface address, which is used as the source address for TACACS+ packets.

NOTE: The Source Address box can accept either a hostname or an IP address.

9. In the Retry Attempts box, specify the number of times that the server should try to verify the user's credentials.
10. In the Time Out box, specify the amount of time (in seconds) the device should wait for a response from the server.
11. Click **OK** to check your configuration and save it as a candidate configuration.
12. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see ["Using the CLI Editor in Configuration Mode" on page 434](#) in the *CLI User Guide*.

To configure a TACACS+ server for system authentication:

1. Add a new TACACS+ server and set its IP address.

```
[edit system]
user@host# set tacplus-server address 172.16.98.24
```

2. Specify the shared secret (password) of the TACACS+ server.

```
[edit system]
user@host# set tacplus-server 172.16.98.24 secret Tacacssecret1
```
3. Specify the device's loopback address as the source address.

```
[edit system]
user@host# set tacplus-server 172.16.98.24 source-address 10.0.0.1
```

Results From configuration mode, confirm your configuration by entering the **show system tacplus-server** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system tacplus-server
tacplus-server 172.16.98.24 {
  secret Tacacssecret1;
  source-address 10.0.0.1;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: To completely set up TACACS+ authentication, you must create user template accounts and specify a system authentication order. Do one of the following tasks:

- Configure a system authentication order. See [“Example: Configuring Authentication Order” on page 1022](#).
- Configure a user. See [“Example: Configuring New Users” on page 807](#).
- Configure local user template accounts. See [“Example: Creating Template Accounts” on page 810](#).

Verification

Confirm that the configuration is working properly.

Verifying the TACACS+ Server System Authentication Configuration

Purpose Verify that the TACACS+ server has been configured for system authentication.

Action From operational mode, enter the **show system tacplus-server** command.

Related Documentation

- [Understanding User Authentication Methods on page 804](#)
- [Understanding User Accounts on page 798](#)
- [Example: Configuring a RADIUS Server for System Authentication on page 1014](#)
- [Understanding Login Classes on page 795](#)

Example: Configuring Authentication Order

This example shows how to configure authentication order.

- [Requirements on page 1022](#)
- [Overview on page 1022](#)
- [Configuration on page 1022](#)
- [Verification on page 1023](#)

Requirements

Before you begin, perform the initial device configuration. See the Getting Started Guide for your device.

Overview

You can configure the authentication methods that the device uses to verify that a user can gain access. For each login attempt, the device tries the authentication methods in order, starting with the first one, until the password matches. If you do not configure system authentication, users are verified based on their configured local passwords.

This example configures the device to attempt user authentication with the local password first, then with the RADIUS server, and finally with the TACACS+ server.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
insert system authentication-order radius after password
insert system authentication-order tacplus after radius
```

GUI Step-by-Step Procedure

To configure authentication order:

1. In the J-Web user interface, select **Configure>System Properties>User Management**.
2. Click **Edit**. The Edit User Management dialog box appears.
3. Select the **Authentication Method and Order** tab.
4. Under Available Methods, select the authentication method the device should use to authenticate users, and use the arrow button to move the item to the Selected Methods list. Available methods include:
 - RADIUS
 - TACACS+
 - Local Password

If you want to use multiple methods to authenticate users, repeat this step to add the additional methods to the Selected Methods list.

5. Under Selected Methods, use the Up Arrow and Down Arrow to specify the order in which the device should execute the authentication methods.
6. Click **OK** to check your configuration and save it as a candidate configuration.
7. If you are done configuring the device, click **Commit Options>Commit**.

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure authentication order:

1. Add RADIUS authentication to the authentication order.

```
[edit]
user@host# insert system authentication-order radius after password
```
2. Add TACACS+ authentication to the authentication order.

```
[edit]
user@host# insert system authentication-order tacplus after radius
```

Results From configuration mode, confirm your configuration by entering the **show system authentication-order** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show system authentication-order
authentication-order [password, radius, tacplus];
```

If you are done configuring the device, enter **commit** from configuration mode.

NOTE: To completely set up RADIUS or TACACS+ authentication, you must configure at least one RADIUS or TACACS+ server and create user template accounts. Do one of the following tasks:

- Configure a RADIUS server. See [“Example: Configuring a RADIUS Server for System Authentication” on page 1014](#).
- Configure a TACACS+ server. See [“Example: Configuring a TACACS+ Server for System Authentication” on page 1019](#).
- Configure a user. See [“Example: Configuring New Users” on page 807](#).
- Configure template accounts. See [“Example: Creating Template Accounts” on page 810](#).

Verification

Confirm that the configuration is working properly.

Verifying the Authentication Order Configuration

Purpose Verify that the authentication order has been configured.

Action From operational mode, enter the **show system authentication-order** command.

Secure Web Access Overview

You can manage a Juniper Networks device remotely through the J-Web interface. To communicate with the device, the J-Web interface uses the Hypertext Transfer Protocol (HTTP). HTTP allows easy Web access but no encryption. The data that is transmitted between the Web browser and the device by means of HTTP is vulnerable to interception and attack. To enable secure Web access, the Juniper Networks devices support HTTP over Secure Sockets Layer (HTTPS). You can enable HTTP or HTTPS access on specific interfaces and ports as needed.

The Juniper Networks device uses the Secure Sockets Layer (SSL) protocol to provide secure device management through the Web interface. SSL uses public-private key technology that requires a paired private key and an authentication certificate for providing the SSL service. SSL encrypts communication between your device and the Web browser with a session key negotiated by the SSL server certificate.

An SSL certificate includes identifying information such as a public key and a signature made by a certificate authority (CA). When you access the device through HTTPS, an SSL handshake authenticates the server and the client and begins a secure session. If the information does not match or the certificate has expired, you cannot access the device through HTTPS.

Without SSL encryption, communication between your device and the browser is sent in the open and can be intercepted. We recommend that you enable HTTPS access on your WAN interfaces.

HTTP access is enabled by default on the built-in management interfaces. By default, HTTPS access is supported on any interface with an SSL server certificate.

- [Generating a Self-Signed SSL Certificate on page 1028](#)
- [Configuring Device Addresses on page 1029](#)
- [Example: Configuring Secure Web Access on page 1031](#)

Generating an SSL Certificate Using the openssl Command

To generate an SSL certificate using the **openssl** command:

1. Enter **openssl** in the CLI. The **openssl** command generates a self-signed SSL certificate in privacy-enhanced mail (PEM) format. It writes the certificate and an unencrypted 1024-bit RSA private key to the specified file.

NOTE: Run this command on a LINUX or UNIX device because Juniper Networks Services Gateways do not support the **openssl** command.

```
% openssl req -x509 -nodes -newkey rsa:1024 -keyout filename.pem -out  
filename.pem
```

Replace **filename** with the name of a file in which you want the SSL certificate to be written—for example, **new.pem**.

2. When prompted, type the appropriate information in the identification form. For example, type **US** for the country name.
3. Display the contents of the file **new.pem**.

```
cat new.pem
```

Copy the contents of this file for installing the SSL certificate.

**Related
Documentation**

- [Secure Web Access Overview on page 1027](#)

Generating a Self-Signed SSL Certificate

To generate a self-signed SSL certificate on Juniper Networks devices:

1. Establish basic connectivity.
2. Reboot the system. The self-signed certificate is automatically generated at bootup time.

```
user@host> request system reboot  
Reboot the system ? [yes,no] yes
```

3. Specify **system-generated-certificate** under HTTPS Web management.

```
[edit]
user@host# show system services web-management https
system-generated-certificate
```

Related Documentation • [Generating an SSL Certificate Using the openssl Command on page 1028](#)

Manually Generating Self-Signed SSL Certificates

To manually generate a self-signed SSL certificate on Juniper Networks devices:

1. Establish basic connectivity.
2. If you have root login access, you can manually generate the self-signed certificate by using the following commands:

```
root@host> request security pki generate-size 512 certificate-id certname
```

Generated key pair *sslcert*, key size 512 bits

```
root@host> request security pki local-certificate generate-self-signed certificate-id
cert-name email email domain-name domain-name ip-address ip-address subject
"DC= Domain name, CN= Common-Name, OU= Organizational-Unit-name, O=
Organization-Name, ST= state, C= Country"
```

Self-signed certificate generated and loaded successfully

NOTE: When generating the certificate, you must specify the subject, e-mail address, and either domain-name or ip-address.

3. Specify **local-certificate** under HTTPS Web management.

```
[edit]
root@host# show system services web-management https local-certificate certname
```

Related Documentation • [Generating a Self-Signed SSL Certificate on page 1028](#)

Configuring Device Addresses

You can use the Management tab to configure IPv4 and loopback addresses on the device.

To configure IPv4 and loopback addresses:

1. In the J-Web user interface, select **Configure > System Properties > Management Access**.
2. Click **Edit**. The Edit Management Access dialog box appears.
3. Select the **Management** tab.
4. If you want to enable a loopback address for the device, enter an address and corresponding subnet mask in the **Loopback address** section.

5. If you want to enable an IPv4 address for the device, select **IPv4 address** and enter a corresponding management port, subnet mask, and default gateway.
6. Click **OK** to save the configuration or **Cancel** to clear it.

Related Documentation

- [Enabling Access Services on page 1030](#)

Enabling Access Services

You can use the Services tab to specify the type of connections that users can make to the device. For instance, you can enable secure HTTPS sessions to the device or enable access to the Junos XML protocol XML scripting API.

To enable access services:

1. In the J-Web user interface, select **Configure>System Properties>Management Access**.
2. Click **Edit**. The Edit Management Access dialog box appears.
3. Select the **Services** tab.
4. If you want to enable users to create secure Telnet or secure SSH connections to the device, select **Enable Telnet** or **Enable SSH**.
5. If you want to enable access to the Junos XML protocol XML scripting API, select **Enable Junos XML protocol over clear text** or **Enable Junos XML protocol over SSL**. If you enable Junos XML protocol over SSL, select the certificate you want to use for encryption from the **Junos XML protocol certificate** drop-down list.
6. Select **Enable HTTP** if you want users to connect to device interfaces over an HTTP connection. Then specify the interfaces that should use the HTTP connection:
 - **Enable on all interfaces**—Select this option if you want to enable HTTP on all device interfaces.
 - **Selected interfaces**—Use the arrow buttons to populate this list with individual interfaces if you want to enable HTTP on only some of the device interfaces.
7. If you want users to connect to device interfaces over a secure HTTPS connection, select **Enable HTTPS**. Then select which certificate you want to use to secure the connection from the **HTTPS certificates** list and specify the interfaces that should use the HTTPS connection:
 - **Enable on all interfaces**—Select this option if you want to enable HTTPS on all device interfaces.
 - **Selected interfaces**—Use the arrow buttons to populate this list with individual interfaces if you want to enable HTTPS on only some of the device interfaces.
8. Click **OK** to save the configuration or **Cancel** to clear it.

To verify that Web access is enabled correctly, connect to the device using one of the following methods:

- For HTTP access—In your Web browser, type **http://URL** or **http://IP address**.

- For HTTPS access—In your Web browser, type **https://URL** or **https://IP address**.
- For SSL Junos XML protocol access—A Junos XML protocol client such as Junos Scope is required.

Example: Configuring Secure Web Access

This example shows how to configure secure Web access on your device.

- [Requirements on page 1031](#)
- [Overview on page 1031](#)
- [Configuration on page 1031](#)
- [Verification on page 1032](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

NOTE: You can enable HTTPS access on specified interfaces. If you enable HTTPS without specifying an interface, HTTPS is enabled on all interfaces.

Overview

In this example, you import the SSL certificate that you have generated as a new and private key in PEM format. You then enable HTTPS access and specify the SSL certificate to be used for authentication. Finally, you specify the port as 8443 on which HTTPS access is to be enabled.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set security certificates local new load-key-file /var/tmp/new.pem
set system services web-management https local-certificate new port 8443
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure secure Web access on your device:

1. Import the SSL certificate and private key.

```
[edit security]
user@host# set certificates local new load-key-file /var/tmp/new.pem
```

2. Enable HTTPS access and specify the SSL certificate and port.

```
[edit system]
user@host# set services web-management https local-certificate new port 8443
```

Results From configuration mode, confirm your configuration by entering the **show security** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show security
certificates {
  local {
    new {
      "-----BEGIN RSA PRIVATE KEY-----\nMIICXQIBAAKBgQC/C5UI4frNqbi

      fLUYAnBYmsYWOH\n -----END CERTIFICATE-----\n"; ## SECRET-DATA
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying an SSL Certificate Configuration on page 1032](#)
- [Verifying a Secure Access Configuration on page 1032](#)

Verifying an SSL Certificate Configuration

Purpose Verify the SSL certificate configuration.

Action From operational mode, enter the **show security** command.

Verifying a Secure Access Configuration

Purpose Verify the secure access configuration.

Action From operational mode, enter the **show system services** command. The following sample output displays the sample values for secure Web access:

```
[edit]
```

```

user@host# show system services
web-management {
  http;
  https {
    port 8443;
    local-certificate new;
  }
}

```

Adding, Editing, and Deleting Certificates on the Device

You can use the Certificates tab to upload SSL certificates to the device, edit existing certificates on the device, or delete certificates from the device. You can use the certificates to secure HTTPS and Junos XML protocol sessions.

To add, edit, or delete a certificate:

1. In the J-Web user interface, select **Configure>System Properties>Management Access**.
2. Click **Edit**. The Edit Management Access dialog box appears.
3. Select the **Certificates** tab.
4. Choose one of the following options:
 - If you want to add a new certificate, click **Add**. The Add Certificate section is expanded.
 - If you want to edit the information for an existing certificate, select it and click **Edit**. The Edit Certificate section is expanded.
 - If you want to delete an existing certificate, select it and click **Delete**. (You can skip the remaining steps in this section.)
5. In the **Certificate Name** box, type a name—for example, **new**.
6. In the **Certificate content** box, paste the generated certificate and RSA private key.
7. Click **Save**.
8. Click **OK** to save the configuration or **Cancel** to clear it.

USB Modem Interface Overview

Juniper Networks devices support the use of USB modems for remote management. You can use Telnet or SSH to connect to the device from a remote location through two modems over a telephone network. The USB modem is connected to the USB port on the device, and a second modem is connected to a remote management device such as a PC or laptop computer.

You can configure your device to fail over to a USB modem connection when the primary Internet connection experiences interruption.

A USB modem connects to a device through modem interfaces that you configure. The device applies its own modem AT commands to initialize the attached modem. Modem setup requires that you connect and configure the USB modem at the device and the modem at the user end of the network.

You use either the J-Web configuration editor or CLI configuration editor to configure the USB modem and its supporting dialer interfaces.

NOTE: Low-latency traffic such as VoIP traffic is not supported over USB modem connections.

NOTE: We recommend using a US Robotics USB 56k V.92 Modem, model number USR Model 5637.

USB Modem Interfaces

You configure two types of interfaces for USB modem connectivity:

- A physical interface which uses the naming convention **umdn0**. The device creates this interface when a USB modem is connected to the USB port.
- A logical interface called the dialer interface. You use the dialer interface, **dln**, to configure dialing properties for USB modem connections. The dialer interface can be configured using Point-to-Point Protocol (PPP) encapsulation. You can also configure the dialer interface to support authentication protocols—PPP Challenge Handshake (CHAP) or Password Authentication Protocol (PAP). You can configure multiple dialer interfaces for different functions on the device. After configuring the dialer interface, you must configure a backup method such as a dialer backup, a dialer filter, or a dialer watch.

The USB modem provides a dial-in remote management interface, and supports dialer interface features by sharing the same dial pool as a dialer interface. The dial pool allows the logical dialer interface and the physical interface to be bound together dynamically on a per-call basis. You can configure the USB modem to operate either as a dial-in console for management or as a dial-in WAN backup interface. Dialer pool priority has a range from 1 to 255, with 1 designating the lowest priority interfaces and 255 designating the highest priority interfaces.

Dialer Interface Rules

The following rules apply when you configure dialer interfaces for USB modem connections:

- The dialer interface must be configured to use PPP encapsulation. You cannot configure Cisco High-Level Data Link Control (HDLC) or Multilink PPP (MLPPP) encapsulation on dialer interfaces.
- The dialer interface cannot be configured as a constituent link in a multilink bundle.
- The dialer interface can perform backup, dialer filter, and dialer watch functions, but these operations are mutually exclusive. You can configure a single dialer interface to operate in only one of the following ways:
 - As a backup interface—for one primary interface
 - As a dialer filter
 - As a dialer watch interface

The backup dialer interfaces are activated only when the primary interface fails. USB modem backup connectivity is supported on all interfaces except `lsq-0/0/0`.

The dial-on-demand routing backup method allows a USB modem connection to be activated only when network traffic configured as an “interesting packet” arrives on the network. Once the network traffic is sent, an inactivity timer is triggered and the connection is closed. You define an interesting packet using the dialer filter feature of the device. To configure dial-on-demand routing backup using a dialer filter, you first configure the dialer filter and then apply the filter to the dialer interface.

Dialer watch is a backup method that integrates backup dialing with routing capabilities and provides reliable connectivity without relying on a dialer filter to trigger outgoing USB modem connections. With dialer watch, the device monitors the existence of a specified route. If the route disappears, the dialer interface initiates the USB modem connection as a backup connection.

How the Device Initializes USB Modems

When you connect the USB modem to the USB port on the device, the device applies the modem AT commands configured in the **init-command-string** command to the initialization commands on the modem.

If you do not configure modem AT commands for the **init-command-string** command, the device applies the following default sequence of initialization commands to the modem: **AT S7=45 S0=0 V1 X4 &C1 E0 Q0 &Q8 %C0**. [Table 79](#) describes the commands. For more information about these commands, see the documentation for your modem.

Table 79: Default Modem Initialization Commands

Modem Command	Description
AT	Attention. Informs the modem that a command follows.
S7=45	Instructs the modem to wait 45 seconds for a telecommunications service provider (carrier) signal before terminating the call.
S0=0	Disables the auto answer feature, whereby the modem automatically answers calls.
V1	Displays result codes as words.
&C1	Disables reset of the modem when it loses the carrier signal.
E0	Disables the display on the local terminal of commands issued to the modem from the local terminal.
Q0	Enables the display of result codes.
&Q8	Enables Microcom Networking Protocol (MNP) error control mode.
%C0	Disables data compression.

When the device applies the modem AT commands in the **init-command-string** command or the default sequence of initialization commands to the modem, it compares them to

the initialization commands already configured on the modem and makes the following changes:

- If the commands are the same, the device overrides existing modem values that do not match. For example, if the initialization commands on the modem include **S0=0** and the device's **init-command-string** command includes **S0=2**, the device applies **S0=2**.
- If the initialization commands on the modem do not include a command in the device's **init-command-string** command, the device adds it. For example, if the **init-command-string** command includes the command **L2**, but the modem commands do not include it, the device adds **L2** to the initialization commands configured on the modem.

**Related
Documentation**

- [USB Modem Configuration Overview on page 1038](#)
- [Example: Configuring a USB Modem Interface on page 1040](#)
- [Example: Configuring a Dialer Interface for USB Modem Dial-In on page 1046](#)

USB Modem Configuration Overview

Before you begin:

1. Install device hardware. For more information, see the Getting Started Guide for your device.
2. Establish basic connectivity. For more information, see the Getting Started Guide for your device.
3. Order a US Robotics USB 56k V.92 Modem, model number USR Model 5637 (<http://www.usr.com/>).
4. Order a public switched telephone network (PSTN) line from your telecommunications service provider. Contact your service provider for more information.
5. Connect the USB modem to the device's USB port.

NOTE: When you connect the USB modem to the USB port on the device, the USB modem is initialized with the modem initialization string configured for the USB modem interface on the device.

- a. Plug the modem into the USB port.
- b. Connect the modem to your telephone network.

Suppose you have a branch office router and a head office router each with a USB modem interface and a dialer interface. This example shows you how to establish a backup connection between the branch office and head office routers. See [Table 80](#) for a summarized description of the procedure.

Table 80: Configuring Branch Office and Head Office Routers for USB Modem Backup Connectivity

Router Location	Configuration Requirement	Procedure
Branch Office	Configure the logical dialer interface on the branch office router for USB modem dial backup.	To configure the logical dialer interface, see "Example: Configuring a USB Modem Interface" on page 1040.
	Configure the dialer interface dl0 on the branch office router using one of the following backup methods: <ul style="list-style-type: none"> Configure the dialer interface dl0 as the backup interface on the branch office router's primary T1 interface t1-1/0/0. Configure a dialer filter on the branch office router's dialer interface. Configure a dialer watch on the branch office router's dialer interface. 	Configure the dialer interface using one of the following backup methods: <ul style="list-style-type: none"> To configure dl0 as a backup for t1-1/0/0 see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>. To configure a dialer filter on dl0, see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>. To configure a dialer watch on dl0, see <i>Example: Configuring Dialer Interfaces and Backup Methods for USB Modem Dial Backup</i>.
Head Office	Configure dial-in on the dialer interface dl0 on the head office router.	To configure dial-in on the head office router, see "Example: Configuring a Dialer Interface for USB Modem Dial-In" on page 1046.

If the dialer interface is configured to accept only calls from a specific caller ID, the device matches the incoming call's caller ID against the caller IDs configured on its dialer interfaces. If an exact match is not found and the incoming call's caller ID has more digits than the configured caller IDs, the device performs a right-to-left match of the incoming call's caller ID with the configured caller IDs and accepts the incoming call if a match is found. For example, if the incoming call's caller ID is 4085321091 and the caller ID configured on a dialer interface is 5321091, the incoming call is accepted. Each dialer interface accepts calls from only callers whose caller IDs are configured on it.

See [Table 81](#) for a list of available incoming map options.

Table 81: Incoming Map Options

Option	Description
accept-all	Dialer interface accepts all incoming calls. You can configure the accept-all option for only one of the dialer interfaces associated with a USB modem physical interface. The dialer interface with the accept-all option configured is used only if the incoming call's caller ID does not match the caller IDs configured on other dialer interfaces.

Table 81: Incoming Map Options (*continued*)

Option	Description
caller	<p>Dialer interface accepts calls from a specific caller ID. You can configure a maximum of 15 caller IDs per dialer interface.</p> <p>The same caller ID must not be configured on different dialer interfaces. However, you can configure caller IDs with more or fewer digits on different dialer interfaces. For example, you can configure the caller IDs 14085551515, 4085551515, and 5551515 on different dialer interfaces.</p>

You configure dialer interfaces to support PAP. PAP allows a simple method for a peer to establish its identity using a two-way handshake during initial link establishment. After the link is established, an ID and password pair are repeatedly sent by the peer to the authenticator until authentication is acknowledged or the connection is terminated.

**Related
Documentation**

- [USB Modem Interface Overview on page 1035](#)
- [Example: Configuring a USB Modem Interface on page 1040](#)

Example: Configuring a USB Modem Interface

This example shows how to configure a USB modem interface for dial backup.

- [Requirements on page 1040](#)
- [Overview on page 1040](#)
- [Configuration on page 1040](#)
- [Verification on page 1041](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

In this example, you create an interface called as umd0 for USB modem connectivity and set the dialer pool priority to 25. You also configure a modem initialization string to autoanswer after a specified number of rings. The default modem initialization string is **AT S7=45 S0=0 V1 X4 &C1 E0 Q0 &Q8 %C0**. The modem command **S0=0** disables the modem from autoanswering the calls. Finally, you set the modem to act as a dial-in WAN backup interface.

Configuration

**CLI Quick
Configuration**

To quickly configure this example, copy the following command, paste it into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the command into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces umd0 dialer-options pool usb-modem-dialer-pool priority 25
```

```
set modem-options init-command-string "ATSO=2 \n" dialin routable
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure a USB modem interface for dial backup:

1. Create an interface.

```
[edit]
user@host# edit interfaces umd0
```
2. Set the dialer options and priority.

```
[edit interfaces umd0]
user@host# set dialer-options pool usb-modem-dialer-pool priority 25
```
3. Specify the modem options.

```
[edit interfaces umd0]
user@host# set modem-options init-command-string "ATSO=2 \n"
```
4. Set the modem to act as a dial-in WAN backup interface.

```
[edit interfaces umd0]
user@host# set modem-options dialin routable
```

Results From configuration mode, confirm your configuration by entering the **show interface umd0** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interface umd0
modem-options {
  init-command-string "ATSO=2 \n";
  dialin routable;
}
dialer-options {
  pool usb-modem-dialer-pool priority 25;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the Configuration

Purpose Verify a USB modem interface for dial backup.

Action From configuration mode, enter the **show interfaces umd0 extensive** command. The output shows a summary of interface information and displays the modem status.

Example: Configuring a Dialer Interface

This example shows how to configure a logical dialer interface for the device.

- [Requirements on page 1042](#)
- [Overview on page 1043](#)
- [Configuration on page 1043](#)
- [Verification on page 1045](#)

Requirements

Before you begin:

- Install device hardware and establish basic connectivity. See the Getting Started Guide for your device.
- Order a US Robotics USB 56k V.92 Modem, model number USR Model 5637, from US Robotics (<http://www.usr.com/>).
- Order a dial-up modem for the PC or laptop computer at the remote location from where you want to connect to the device.
- Order a PSTN line from your telecommunications service provider. Contact your service provider.

Overview

In this example, you configure a logical dialer interface called `dl0` to establish USB connectivity. You can configure multiple dialer interfaces for different functions on the device. You add a description to differentiate among different dialer interfaces. For example, this modem is called `USB-modem-remote-management`. Configure PPP encapsulation and set the logical unit as 0. You then specify the name of the dialer pool as `usb-modem-dialer-pool` and set the source and destination IP addresses as 172.20.10.2, and 172.20.10.1, respectively.

NOTE: You cannot configure Cisco High-Level Data Link Control (HDLC) or Multilink PPP (MLPPP) encapsulation on dialer interfaces used in USB modem connections.

NOTE: If you configure multiple dialer interfaces, ensure that the same IP subnet address is not configured on different dialer interfaces. Configuring the same IP subnet address on multiple dialer interfaces can result in inconsistency in the route and packet loss. The device might route packets through another dialer interface with the IP subnet address instead of through the dialer interface to which the USB modem call is mapped.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the `[edit]` hierarchy level, and then enter `commit` from configuration mode.

```
set interfaces dl0 description USB-modem-remote-management encapsulation ppp
set interfaces dl0 unit 0 dialer-options pool usb-modem-dialer-pool
set interfaces dl0 unit 0 family inet address 172.20.10.2 destination 172.20.10.1
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

To configure a logical dialer interface for the device:

1. Create an interface.

```
[edit]
user@host# set interfaces dl0
```

2. Add a description and configure PPP encapsulation.

```
[edit interfaces dl0]
user@host# set description USB-modem-remote-management
user@host# set encapsulation ppp
```

3. Create the logical unit.

NOTE: The logical unit number must be 0.

```
[edit interfaces dl0]
user@host# set unit 0
```

4. Configure the name of the dialer pool to use for USB modem connectivity.

```
[edit interfaces dl0 unit 0]
user@host# set dialer-options pool usb-modem-dialer-pool
```

5. Configure source and destination IP addresses for the dialer interface.

```
[edit interfaces dl0 unit 0]
user@host# set family inet address 172.20.10.2 destination 172.20.10.1
```

Results From configuration mode, confirm your configuration by entering the **show interfaces dl0** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces dl0
description USB-modem-remote-management;
encapsulation ppp;
unit 0 {
  family inet {
    address 172.20.10.2/32 {
      destination 172.20.10.1;
    }
  }
  dialer-options {
    pool usb-modem-dialer-pool;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying a Dialer Interface

Purpose Verify that the dialer interface has been configured.

Action From configuration mode, enter the **show interfaces d10 extensive** command. The output shows a summary of dialer interface information.

Example: Configuring a Dialer Interface for USB Modem Dial-In

This example shows how to configure a dialer interface for USB modem dial-in.

- [Requirements on page 1046](#)
- [Overview on page 1046](#)
- [Configuration on page 1047](#)
- [Verification on page 1047](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

To enable connections to the USB modem from a remote location, you must configure the dialer interfaces set up for USB modem use to accept incoming calls. You can configure a dialer interface to accept all incoming calls or accept only calls from one or more caller IDs.

If the dialer interface is configured to accept only calls from a specific caller ID, the system matches the incoming call's caller ID against the caller IDs configured on its dialer interfaces. If an exact match is not found and the incoming call's caller ID has more digits than the configured caller IDs, the system performs a right-to-left match of the incoming call's caller ID with the configured caller IDs and accepts the incoming call if a match is found. For example, if the incoming call's caller ID is 4085550115 and the caller ID

configured on a dialer interface is 5550115, the incoming call is accepted. Each dialer interface accepts calls from only callers whose caller IDs are configured on it.

You can configure the following incoming map options for the dialer interface:

- **accept-all**—Dialer interface accepts all incoming calls.

You can configure the **accept-all** option for only one of the dialer interfaces associated with a USB modem physical interface. The device uses the dialer interface with the **accept-all** option configured only if the incoming call's caller ID does not match the caller IDs configured on other dialer interfaces.

- **caller**—Dialer interface accepts calls from a specific caller ID—for example, **4085550115**. You can configure a maximum of 15 caller IDs per dialer interface.

The same caller ID must not be configured on different dialer interfaces. However, you can configure caller IDs with more or fewer digits on different dialer interfaces. For example, you can configure the caller IDs 14085550115, 4085550115, and 5550115 on different dialer interfaces.

In this example, you configure the incoming map option as caller 4085550115 for dialer interface d10.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following command, paste it into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the command into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces d10 unit 0 dialer-options incoming-map caller 4085550115
```

Step-by-Step Procedure

To configure a dialer interface for USB modem dial-in:

1. Select a dialer interface.

```
[edit]
user@host# edit interfaces d10
```
2. Configure the incoming map options.

```
[edit]
user@host# edit unit 0 dialer-options incoming-map caller 4085551515
```
3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show interface d10** command.

Configuring a Dial-Up Modem Connection Remotely

To remotely connect to the USB modem connected to the USB port on the device, you must configure a dial-up modem connection on the PC or laptop computer at your remote location. Configure the dial-up modem connection properties to disable IP header compression.

To configure a dial-up modem connection remotely:

1. At your remote location, connect a modem to a management device such as a PC or laptop computer.
2. Connect the modem to your telephone network.
3. On the PC or laptop computer, select **Start>Settings>Control Panel>Network Connections**. The Network Connections page appears.
4. Click **Create a new connection**. The New Connection Wizard appears.
5. Click **Next**. The New Connection Wizard: Network Connection Type page appears.
6. Select **Connect to the network at my workplace**, and then click **Next**.
The New Connection Wizard: Network Connection page appears.
7. Select **Dial-up connection**, and then click **Next**. The New Connection Wizard: Connection Name page appears.
8. In the Company Name box, type the dial-up connection name, for example **USB-modem-connect**. Then, click **Next**. The New Connection Wizard: Phone Number to Dial page appears.
9. In the Phone number box, type the telephone number of the PSTN line connected to the USB modem at the device end.
10. Click **Next** twice, and then click **Finish**. The Connect USB-modem-connect page appears.
11. If CHAP is configured on the dialer interface used for the USB modem interface at the device end, type the username and password configured in the CHAP configuration in the User name and Password boxes.
12. Click **Properties**. The USB-modem-connect Properties page appears.
13. In the Networking tab, select **Internet Protocol (TCP/IP)**, and then click **Properties**. The Internet Protocol (TCP/IP) Properties page appears.
14. Click **Advanced**. The Advanced TCP/IP Settings page appears.
15. Clear the **Use IP header compression** check box.

Connecting to the Device Remotely

To remotely connect to the device through a USB modem connected to the USB port on the device:

1. On the PC or laptop computer at your remote location, select **Start>Settings>Control Panel>Network Connections**. The Network Connections page appears.
2. Double-click the **USB-modem-connect** dial-up connection. The Connect USB-modem-connect page appears.
3. Click **Dial** to connect to the Juniper Networks device.

When the connection is complete, you can use Telnet or SSH to connect to the device.

Modifying USB Modem Initialization Commands

NOTE: These instructions use Hayes-compatible modem commands to configure the modem. If your modem is not Hayes-compatible, see the documentation for your modem and enter equivalent modem commands.

You can use the CLI configuration editor to override the value of an initialization command configured on the USB modem or configure additional commands for initializing USB modems.

NOTE: If you modify modem initialization commands when a call is in progress, the new initialization sequence is applied on the modem only when the call ends.

You can configure the following modem AT commands to initialize the USB modem:

- The command **S0=2** configures the modem to automatically answer calls on the second ring.
- The command **L2** configures medium speaker volume on the modem.

You can insert spaces between commands.

When you configure modem commands in the CLI configuration editor, you must follow these conventions:

- Use the newline character `\n` to indicate the end of a command sequence.

- Enclose the command string in double quotation marks.

You can override the value of the **S0=0** command in the initialization sequence configured on the modem and add the **L2** command.

To modify the initialization commands on a USB modem:

1. Configure the modem AT commands to initialize the USB modem.

```
[edit interfaces umd0]
```

```
user@host# set modem-options init-command-string "AT S0=2 L2 \n"
```

2. If you are done configuring the device, enter **commit** from configuration mode.

Resetting USB Modems

If the USB modem does not respond, you can reset the modem.

CAUTION: If you reset the modem when a call is in progress, the call is terminated.

To reset the USB modem, in operational mode, enter the following command:

```
user@host> request interface modem reset umd0
```

Securing the Console Port Configuration Overview

You can use the console port on the device to connect to the device through an RJ-45 serial cable. From the console port, you can use the CLI to configure the device. By default, the console port is enabled. To secure the console port, you can configure the device to take the following actions:

- Log out of the console session when you unplug the serial cable connected to the console port.
- Disable root login connections to the console. This action prevents a non-root user from performing password recovery operation using the console.
- Disable the console port. We recommend disabling the console port to prevent unauthorized access to the device, especially when the device is used as customer premises equipment (CPE) and is forwarding sensitive traffic.

NOTE: It is not always possible to disable the console port, because console access is important during operations such as software upgrades.

To secure the console port:

1. Do one of the following:

- Disable the console port. Enter

```
[edit system ports console]  
user@host# set disable
```

- Disable root login connections to the console. Enter

```
[edit system ports console]  
user@host# set insecure
```

NOTE: After configuring the console port as insecure, if a user tries to perform password recovery operation by booting in single-user mode, the device will prompt for the root password. This way, the user will be unable to log in to single-user mode for password recovery unless the root password is known.

- Log out the console session when the serial cable connected to the console port is unplugged. Enter

```
[edit system ports console]  
user@host# set log-out-on-disconnect
```

2. If you are done configuring the device, enter **commit** from configuration mode.

Related Documentation

- [The ssh Command on page 1063](#)
- [Configuring Password Retry Limits for Telnet and SSH Access on page 1052](#)
- [Configuring Reverse Telnet and Reverse SSH on page 1053](#)

Configuring Password Retry Limits for Telnet and SSH Access

To prevent brute force and dictionary attacks, the device performs the following actions for Telnet or SSH sessions by default:

- Disconnects a session after a maximum of 10 consecutive password retries.
- After the second password retry, introduces a delay in multiples of 5 seconds between subsequent password retries.

For example, the device introduces a delay of 5 seconds between the third and fourth password retry, a delay of 10 seconds between the fourth and fifth password retry, and so on.

- Enforces a minimum session time of 20 seconds during which a session cannot be disconnected. Configuring the minimum session time prevents malicious users from disconnecting sessions before the password retry delay goes into effect, and attempting brute force and dictionary attacks with multiple logins.

You can configure the password retry limits for Telnet and SSH access. In this example, you configure the device to take the following actions for Telnet and SSH sessions:

- Allow a maximum of four consecutive password retries before disconnecting a session.
- Introduce a delay in multiples of 5 seconds between password retries that occur after the second password retry.
- Enforce a minimum session time of 40 seconds during which a session cannot be disconnected.

To configure password retry limits for Telnet and SSH access:

1. Set the maximum number of consecutive password retries before a Telnet or SSH or telnet session is disconnected. The default number is **10**, but you can set a number from 1 through 10.

```
[edit system login retry-options]  
user@host# set tries-before-disconnect 4
```

2. Set the threshold number of password retries after which a delay is introduced between two consecutive password retries. The default number is **2**, but you can specify a value from 1 through 3.

```
[edit system login retry-options]  
user@host# set backoff-threshold 2
```

3. Set the delay (in seconds) between consecutive password retries after the threshold number of password retries. The default delay is in multiples of **5** seconds, but you can specify a value from 5 through 10 seconds.

```
[edit system login retry-options]  
user@host# set backoff-factor 5
```

4. Set the minimum length of time (in seconds) during which a Telnet or SSH session cannot be disconnected. The default is **20** seconds, but you can specify an interval from 20 through 60 seconds.

```
[edit system login retry-options]  
user@host# set minimum-time 40
```

5. If you are done configuring the device, enter **commit** from configuration mode.

- [The ssh Command on page 1063](#)
- [Configuring Reverse Telnet and Reverse SSH on page 1053](#)

Configuring Reverse Telnet and Reverse SSH

To configure reverse telnet and reverse ssh:

1. Enable reverse telnet.

```
[edit]  
user@host# set system services reverse telnet
```

2. Specify the port to be used for reverse telnet. If you do not specify a port, 2900 is the default port that is used.

[edit]

user@host# **set system services reverse telnet port 5000**

3. Enable reverse ssh to encrypt the connection between the device and the client.

[edit]

user@host# **set system services reverse ssh**

4. Specify the port for reverse ssh. If you do not specify a port, 2901 is the default port that is used.

[edit]

user@host# **set system services reverse ssh port 6000**

5. If you are done configuring the device, enter **commit** from configuration mode.

Example: Controlling Management Access on SRX Series Devices

This example shows how to control management access on SRX Series devices.

- [Requirements on page 1054](#)
- [Overview on page 1054](#)
- [Configuration on page 1054](#)
- [Verification on page 1057](#)

Requirements

No special configuration beyond device initialization is required before configuring this feature.

Overview

By default, any host on the trusted interface can manage a security device. To limit the IP addresses that can manage a device, you can configure a firewall filter to deny all, with the exception of the IP address or addresses to which you want to grant management access. This example shows how to limit management access to a specific IP addresses to allow it to manage SRX Series devices.

Configuration

- [Configuring an IP Address List to Restrict Management Access to a Device on page 1054](#)

Configuring an IP Address List to Restrict Management Access to a Device

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set policy-options prefix-list manager-ip 192.168.4.254/32
set policy-options prefix-list manager-ip 10.0.0.0/8
set firewall filter manager-ip term block_non_manager from source-address 0.0.0.0/0
set firewall filter manager-ip term block_non_manager from source-prefix-list manager-ip
except
set firewall filter manager-ip term block_non_manager from protocol tcp
set firewall filter manager-ip term block_non_manager from destination-port ssh
set firewall filter manager-ip term block_non_manager from destination-port https
set firewall filter manager-ip term block_non_manager from destination-port telnet
set firewall filter manager-ip term block_non_manager from destination-port http
set firewall filter manager-ip term block_non_manager then discard
set firewall filter manager-ip term accept_everything_else then accept
set interfaces lo0 unit 0 family inet filter input manager-ip

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [“Using the CLI Editor in Configuration Mode” on page 434](#) in the *CLI User Guide*.

1. Define a set of host addresses, called "manager-ip", that are allowed to manage the device.

```

[edit policy-options]
user@host# set prefix-list manager-ip 192.168.4.254/32
user@host# set prefix-list manager-ip 10.0.0.0/8

```

NOTE: The configured list is referenced in the actual filter, where you can change your defined set of addresses.

2. Configure a firewall filter to deny traffic from all IP addresses except the IP addresses defined in the "manager-ip" list. Management traffic that uses any of the listed destination ports is rejected when the traffic comes from an address in the list.

```

[edit firewall filter]
user@host# set manager-ip term block_non_manager from source-address 0.0.0.0/0
user@host# set manager-ip term block_non_manager from source-prefix-list
manager-ip except
user@host# set manager-ip term block_non_manager from protocol tcp
user@host# set manager-ip term block_non_manager from destination-port ssh
user@host# set manager-ip term block_non_manager from destination-port https
user@host# set manager-ip term block_non_manager from destination-port telnet
user@host# set manager-ip term block_non_manager from destination-port http
user@host# set manager-ip term block_non_manager then discard
user@host# set manager-ip term accept_everything_else then accept

```

3. Apply stateless firewall filters to the loopback interface to filter the packets originating from the hosts to which you are granting management access.

```

[edit interfaces lo0 unit 0 ]
user@host# set family inet filter input manager-ip

```

NOTE: This configuration applies to traffic that terminates at the device. For traffic that terminates at the device interface (such as IPsec, OSPF, RIP, or BGP), you must also include the management IP addresses in the `manager-ip` prefix-list.

Results From configuration mode, confirm your configuration by entering **show configuration** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@host# show configuration policy-options
  prefix-list manager-ip {
    10.0.0.0/8;
    192.168.4.254/32;
  }

user@host# show configuration firewall
  filter manager-ip {
    term block_non_manager {
      from {
        source-address {
          0.0.0.0/0;
        }
        source-prefix-list {
          manager-ip except;
        }
      }
      protocol tcp;
      destination-port [ ssh https telnet http ];
    }
    then {
      discard;
    }
  }
  term accept_everything_else {
    then accept;
  }
}

user@host# show configuration interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
        input manager-ip;
      }
    }
  }
}

user@host# show configuration interfaces lo0
unit 0 {
  family inet {
    filter {

```

```
        input manager-ip;
    }
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying Interfaces

Purpose Verify if the interfaces are configured correctly.

Action From operational mode, enter the following commands:

- show policy-options
- show firewall
- show interfaces

Related Documentation

- [Securing the Console Port Configuration Overview on page 1051](#)

Example: Configuring a Filter to Block Telnet and SSH Access

- [Requirements on page 1057](#)
- [Overview on page 1057](#)
- [Configuration on page 1058](#)
- [Verification on page 1060](#)

Requirements

You must have access to a remote host that has network connectivity with this device.

Overview

In this example, you create an IPv4 stateless firewall filter that logs and rejects Telnet or SSH access packets unless the packet is destined for or originates from the 192.168.1.0/24 subnet.

- To match packets destined for or originating from the **address 192.168.1.0/24** subnet, you use the **address 192.168.1.0/24** IPv4 match condition.
- To match packets destined for or originating from a TCP port, Telnet port, or SSH port, you use the **protocol tcp**, **port telnet**, and **telnet ssh** IPv4 match conditions.

Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see [“Using the CLI Editor in Configuration Mode” on page 434](#).

To configure this example, perform the following tasks:

- [Configure the Stateless Firewall Filter on page 1058](#)
- [Apply the Firewall Filter to the Loopback Interface on page 1059](#)
- [Confirm and Commit Your Candidate Configuration on page 1059](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set firewall family inet filter local_acl term terminal_access from address 192.168.1.0/24
set firewall family inet filter local_acl term terminal_access from protocol tcp
set firewall family inet filter local_acl term terminal_access from port ssh
set firewall family inet filter local_acl term terminal_access from port telnet
set firewall family inet filter local_acl term terminal_access then accept
set firewall family inet filter local_acl term terminal_access_denied from protocol tcp
set firewall family inet filter local_acl term terminal_access_denied from port ssh
set firewall family inet filter local_acl term terminal_access_denied from port telnet
set firewall family inet filter local_acl term terminal_access_denied then log
set firewall family inet filter local_acl term terminal_access_denied then reject
set firewall family inet filter local_acl term default-term then accept
set interfaces lo0 unit 0 family inet filter input local_acl
set interfaces lo0 unit 0 family inet address 127.0.0.1/32
```

Configure the Stateless Firewall Filter

Step-by-Step Procedure

To configure the stateless firewall filter that selectively blocks Telnet and SSH access:

1. Create the stateless firewall filter **local_acl**.

```
[edit]
user@myhost# edit firewall family inet filter local_acl
```

2. Define the filter term **terminal_access**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access from address 192.168.1.0/24
user@myhost# set term terminal_access from protocol tcp
user@myhost# set term terminal_access from port ssh
user@myhost# set term terminal_access from port telnet
user@myhost# set term terminal_access then accept
```

3. Define the filter term **terminal_access_denied**.

```
[edit firewall family inet filter local_acl]
user@myhost# set term terminal_access_denied from protocol tcp
user@myhost# set term terminal_access_denied from port ssh
user@myhost# set term terminal_access_denied from port telnet
```

```

user@myhost# set term terminal_access_denied then log
user@myhost# set term terminal_access_denied then reject
user@myhost# set term default-term then accept

```

Apply the Firewall Filter to the Loopback Interface

Step-by-Step Procedure

- To apply the firewall filter to the loopback interface:

```

[edit]
user@myhost# set interfaces lo0 unit 0 family inet filter input local_acl
user@myhost# set interfaces lo0 unit 0 family inet address 127.0.0.1/32

```

Confirm and Commit Your Candidate Configuration

Step-by-Step Procedure

To confirm and then commit your candidate configuration:

1. Confirm the configuration of the stateless firewall filter by entering the **show firewall** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]
user@myhost# show firewall
family inet {
  filter local_acl {
    term terminal_access {
      from {
        address {
          192.168.1.0/24;
        }
        protocol tcp;
        port [ssh telnet];
      }
      then accept;
    }
    term terminal_access_denied {
      from {
        protocol tcp;
        port [ssh telnet];
      }
      then {
        log;
        reject;
      }
    }
    term default-term {
      then accept;
    }
  }
}

```

2. Confirm the configuration of the interface by entering the **show interfaces** configuration mode command. If the command output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

[edit]

```

```
user@myhost# show interfaces
lo0 {
  unit 0 {
    family inet {
      filter {
        input local_acl;
      }
      address 127.0.0.1/32;
    }
  }
}
```

3. If you are done configuring the device, commit your candidate configuration.

```
[edit]
user@myhost# commit
```

Verification

Confirm that the configuration is working properly.

- [Verifying Accepted Packets on page 1060](#)
- [Verifying Logged and Rejected Packets on page 1061](#)

Verifying Accepted Packets

Purpose Verify that the actions of the firewall filter terms are taken.

- Action**
1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **ssh *hostname*** command to verify that you can log in to the device using only SSH. This packet should be accepted, and the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> ssh myhost
user@myhosts's password:
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC

% cli
user@myhost>
```

3. From a host at an IP address *within* the 192.168.1.0/24 subnet, use the **telnet *hostname*** command to verify that you can log in to your router or switch using only Telnet. This packet should be accepted, and the packet header information for this packet should not be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-A> telnet myhost
Trying 192.168.249.71...
Connected to myhost-fxp0.acme.net.
Escape character is '^['.
```

```
host (ttyp0)
```

```
login: user
```

Password:

```
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
```

```
% cli
user@myhost>
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

Verifying Logged and Rejected Packets

Purpose Verify that the actions of the firewall filter terms are taken.

- Action** 1. Clear the firewall log on your router or switch.

```
user@myhost> clear firewall log
```

2. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **ssh hostname** command to verify that you cannot log in to the device using only SSH. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the Packet Forwarding Engine.

```
user@host-B ssh myhost
ssh: connect to host sugar port 22: Connection refused
--- JUNOS 11.1-20101102.0 built 2010-11-02 04:48:46 UTC
%
```

3. From a host at an IP address *outside of* the 192.168.1.0/24 subnet, use the **telnet hostname** command to verify that you can log in to the device using only Telnet. This packet should be rejected, and the packet header information for this packet should be logged in the firewall filter log buffer in the PFE.

```
user@host-B> telnet myhost
Trying 192.168.249.71...
telnet: connect to address 192.168.187.3: Connection refused
telnet: Unable to connect to remote host
%
```

4. Use the **show firewall log** command to verify that the routing table on the device does not contain any entries with a source address in the 192.168.1.0/24 subnet.

```
user@myhost> show firewall log
```

Time	Filter	Action	Interface	Protocol	Src Addr	Dest Addr
18:41:25	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
18:41:25	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
18:41:25	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
...						
18:43:06	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
18:43:06	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
18:43:06	local_acl	R	fxp0.0	TCP	192.168.187.5	192.168.187.1
...						

Related Documentation • [Example: Controlling Management Access on SRX Series Devices on page 1054](#)

The telnet Command

You can use the CLI **telnet** command to open a Telnet session to a remote device:

```
user@host> telnet host <8bit> <bypass-routing> <inet> <interface interface-name>
<no-resolve> <port port> <routing-instance routing-instance-name> <source address>
```

NOTE: On SRX300, SRX320, SRX340, SRX345, and SRX1500 devices, the maximum number of concurrent Telnet sessions is as follows:

SRX300	SRX320	SRX340	SRX345	SRX1500
3	3	3	5	5

To exit the Telnet session and return to the Telnet command prompt, press Ctrl-].

To exit the Telnet session and return to the CLI command prompt, enter **quit**.

Table 82 describes the **telnet** command options.

Table 82: CLI telnet Command Options

Option	Description
8bit	Use an 8-bit data path.
bypass-routing	Bypass the routing tables and open a Telnet session only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.
host	Open a Telnet session to the specified hostname or IP address.
inet	Force the Telnet session to an IPv4 destination.
interface source-interface	Open a Telnet session to a host on the specified interface. If you do not include this option, all interfaces are used.
no-resolve	Suppress the display of symbolic names.
port port	Specify the port number or service name on the host.
routing-instance routing-instance-name	Use the specified routing instance for the Telnet session.
source address	Use the specified source address for the Telnet session.

- Related Documentation**

 - [Configuring Password Retry Limits for Telnet and SSH Access on page 1052](#)
 - [Configuring Reverse Telnet and Reverse SSH on page 1053](#)

The ssh Command

You can use the CLI **ssh** command to use the secure shell (SSH) program to open a connection to a remote device:

```
user@host> ssh host <bypass-routing> <inet> <interface interface-name>  
<routing-instance routing-instance-name> <source address> <v1> <v2>
```

NOTE: On SRX300, SRX320, SRX340, SRX345, and SRX1500 devices, the maximum number of concurrent SSH sessions is as follows:

SRX300	SRX320	SRX340	SRX345	SRX1500
3	3	3	5	5

Table 83 describes the **ssh** command options.

Table 83: CLI ssh Command Options

Option	Description
bypass-routing	Bypass the routing tables and open an SSH connection only to hosts on directly attached interfaces. If the host is not on a directly attached interface, an error message is returned.
host	Open an SSH connection to the specified hostname or IP address.
inet	Force the SSH connection to an IPv4 destination.
interface source-interface	Open an SSH connection to a host on the specified interface. If you do not include this option, all interfaces are used.
routing-instance routing-instance-name	Use the specified routing instance for the SSH connection.
source address	Use the specified source address for the SSH connection.
v1	Force SSH to use version 1 for the connection.
v2	Force SSH to use version 2 for the connection.

Configuring Outbound SSH Service

You can configure a device running the Junos OS to initiate a TCP/IP connection with a client management application that would be blocked if the client attempted to initiate the connection (for example, if the device is behind a firewall). The **outbound-ssh** command instructs the device to create a TCP/IP connection with the client management application and to forward the identity of the device. Once the connection is established, the management application acts as the client and initiates the SSH sequence, and the device acts as the server and authenticates the client.

NOTE: There is no initiation command with outbound SSH. Once outbound SSH is configured and committed, the device begins to initiate an outbound SSH connection based on the committed configuration. The device repeatedly attempts to create this connection until successful. If the connection between the device and the client management application is dropped, the device again attempts to create a new outbound SSH connection until successful. This connection is maintained until the outbound SSH stanza is removed from the configuration.

To configure the device for outbound SSH connections, include the **outbound-ssh** statement at the **[edit system services]** hierarchy level:

[edit system services outbound-ssh]

The following topics describe the tasks for configuring the outbound SSH service:

- [Configuring the Device Identifier for Outbound SSH Connections on page 1064](#)
- [Sending the Public SSH Host Key to the Outbound SSH Client on page 1065](#)
- [Configuring Keepalive Messages for Outbound SSH Connections on page 1066](#)
- [Configuring a New Outbound SSH Connection on page 1066](#)
- [Configuring the Outbound SSH Client to Accept NETCONF as an Available Service on page 1066](#)
- [Configuring Outbound SSH Clients on page 1067](#)

Configuring the Device Identifier for Outbound SSH Connections

Each time the device establishes an outbound SSH connection, it first sends an initiation sequence to the management client. This sequence identifies the device to the management client. Within this transmission is the value of **device-id**.

To configure the device identifier of the device, include the **device-id** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]  
device-id device-id;
```

The initiation sequence when **secret** is not configured:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
```

Sending the Public SSH Host Key to the Outbound SSH Client

Each time the router or switch establishes an outbound SSH connection, it first sends an initiation sequence to the management client. This sequence identifies the router or switch to the management client. Within this transmission is the value of *device-id*.

To configure the device identifier of the router or switch, include the **device-id** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]
device-id device-id;
```

The initiation sequence when **secret** is not configured:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
```

During the initialization of an SSH connection, the client authenticates the identity of the device using the public SSH host key of the device. Therefore, before the client can initiate the SSH sequence, it needs the public SSH key of the device. When you configure the **secret** statement, the device passes its public SSH key as part of the outbound SSH connection initiation sequence.

When the **secret** statement is set and the device establishes an outbound SSH connection, the device communicates its device ID, its public SSH key, and an SHA1 hash derived in part from the **secret** statement. The value of the **secret** statement is shared between the device and the management client. The client uses the shared secret to authenticate the public SSH host key it is receiving to determine whether the public key is from the device identified by the **device-id** statement.

Using the **secret** statement to transport the public SSH host key is optional. You can manually transport and install the public key onto the client system.

NOTE: Including the **secret** statement means that the device sends its public SSH host key every time it establishes a connection to the client. It is then up to the client to decide what to do with the SSH host key if it already has one for that device. We recommend that you replace the client's copy with the new key. Host keys can change for various reasons and by replacing the key each time a connection is established, you ensure that the client has the latest key.

To send the router's or switch's public SSH host key when the device connects to the client, include the **secret** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]
secret password;
```

The following message is sent by the device when the **secret** attribute is configured:

```
MSG-ID: DEVICE-CONN-INFO\r\n
MSG-VER: V1\r\n
DEVICE-ID: <device-id>\r\n
HOST-KEY: <public-hot-key>\r\n
HMAC:<HMAC(pub-SSH-host-key, <secret>>)>\r\n
```

Configuring Keepalive Messages for Outbound SSH Connections

Once the client application has the router's or switch's public SSH host key, it can then initiate the SSH sequence as if it had created the TCP/IP connection and can authenticate the device using its copy of the router's or switch's public host SSH key as part of that sequence. The device authenticates the client user through the mechanisms supported in the Junos OS (RSA/DSA public string or password authentication).

To enable the device to send SSH protocol keepalive messages to the client application, configure the **keep-alive** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]
keep-alive {
  retry number;
  timeout seconds;
}
```

Configuring a New Outbound SSH Connection

When disconnected, the device begins to initiate a new outbound SSH connection. To specify how the device reconnects to the server after a connection is dropped, include the **reconnect-strategy** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client-id]
reconnect-strategy (sticky | in-order);
```

You can also specify the number of retry attempts and set the amount of time before the reconnection attempts stop. See [“Configuring Keepalive Messages for Outbound SSH Connections”](#) on page 1066.

Configuring the Outbound SSH Client to Accept NETCONF as an Available Service

To configure the application to accept NETCONF as an available service, include the **services netconf** statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]
services {
  netconf;
}
```

Configuring Outbound SSH Clients

To configure the clients available for this outbound SSH connection, list each client with a separate address statement at the **[edit system services outbound-ssh client *client-id*]** hierarchy level:

```
[edit system services outbound-ssh client client-id]  
  address address {  
    retry number;  
    timeout seconds;  
    port port-number;  
  }
```

NOTE: Outbound SSH connections support IPv4 and IPv6 address formats.

PART 11

Configuring DNS

- [Example: Configuring Secure Domains and Trusted Keys for DNSSEC on page 1074](#)
- [DNS Proxy Overview on page 1076](#)
- [Configuring the Device as a DNS Proxy on page 1080](#)

DNS Overview

A Domain Name System (DNS) is a distributed hierarchical system that converts hostnames to IP addresses. The DNS is divided into sections called zones. Each zone has name servers that respond to the queries belonging to their zones.

This topic includes the following sections:

- [DNS Components on page 1071](#)
- [DNS Server Caching on page 1072](#)

DNS Components

DNS includes three main components:

- **DNS resolver** — Resides on the client side of the DNS. When a user sends a hostname request, the resolver sends a DNS query request to the name servers to request the hostname's IP address.
- **Name servers** — Processes the DNS query requests received from the DNS resolver and returns the IP address to the resolver.
- **Resource records** — Data elements that define the basic structure and content of the DNS.

DNS Server Caching

DNS name servers are responsible for providing the hostname IP address to users. The TTL field in the resource record defines the period for which DNS query results are cached. When the TTL value expires, the name server sends a fresh DNS query and updates the cache.

- Related Documentation**
- [Example: Configuring the TTL Value for DNS Server Caching on page 1072](#)
 - [DNSSEC Overview on page 1073](#)

Example: Configuring the TTL Value for DNS Server Caching

This example shows how to configure the TTL value for a DNS server cache to define the period for which DNS query results are cached.

- [Requirements on page 1072](#)
- [Overview on page 1072](#)
- [Configuration on page 1072](#)
- [Verification on page 1073](#)

Requirements

No special configuration beyond device initialization is required before performing this task.

Overview

The DNS name server stores DNS query responses in its cache for the TTL period specified in the TTL field of the resource record. When the TTL value expires, the name server sends a fresh DNS query and updates the cache. You can configure the TTL value from 0 to 604,800 seconds. You can also configure the TTL value for cached negative responses. Negative caching is the storing of the record that a value does not exist. In this example, you set the maximum TTL value for cached (and negative cached) responses to 86,400 seconds.

Configuration

Step-by-Step Procedure

To configure the TTL value for a DNS server cache:

1. Specify the maximum TTL value for cached responses, in seconds.

[edit]
user@host# **set system services dns max-cache-ttl 86400**
2. Specify the maximum TTL value for negative cached responses, in seconds.

[edit]
user@host# **set system services dns max-ncache-ttl 86400**
3. If you are done configuring the device, commit the configuration.

[edit]

```
user@host# commit
```

Verification

To verify the configuration is working properly, enter the **show system services** command.

Related Documentation

- [DNS Overview on page 1071](#)

DNSSEC Overview

Junos OS devices support the domain name service security extensions (DNSSEC) standard. DNSSEC is an extension of DNS that provides authentication and integrity verification of data by using public-key based signatures.

In DNSSEC, all the resource records in a DNS are signed with the private key of the zone owner. The DNS resolver uses the public key of the owner to validate the signature. The zone owner generates a private key to encrypt the hash of a set of resource records. The private key is stored in RRSIG record. The corresponding public key is stored in the DNSKEY record. The resolver uses the public key to decrypt the RRSIG and compares the result with the hash of the resource record to verify that it has not been altered.

Similarly, the hash of the public DNSKEY is stored in a DS record in a parent zone. The zone owner generates a private key to encrypt the hash of the public key. The private key is stored in the RRSIG record. The resolver retrieves the DS record and its corresponding RRSIG record and public key. Using the public key, the resolver decrypts the RRSIG record and compares the result with the hash of the public DNSKEY to verify that it has not been altered. This establishes a chain of trust between the resolver and the name servers.

Related Documentation

- [DNS Overview on page 1071](#)
- [Example: Configuring Keys for DNSSEC on page 1074](#)
- [Example: Configuring Secure Domains and Trusted Keys for DNSSEC on page 1074](#)

Example: Configuring DNSSEC

DNS-enabled devices run a DNS resolver (proxy) that listens on loopback address 127.0.0.1 or ::1. The DNS resolver performs a hostname resolution for DNSSEC. Users need to set name server IP address to 127.0.0.1 or ::1 so the DNS resolver forwards all DNS queries to DNSSEC instead of to DNS. If the name server IP address is not set, DNS will handle all queries instead of to DNSSEC.

The following example shows how to set the server IP address to 127.0.0.1:

```
[edit]
```

```
user@host# set system name-server 127.0.0.1
```

The DNSSEC feature is enabled by default. You can disable DNSSEC in the server by using the following CLI command:

```
[edit]
```

```
set system services dns dnssec disable
```

**Related
Documentation**

- [DNSSEC Overview on page 1073](#)

Example: Configuring Keys for DNSSEC

You can load a public key from a file or you can copy and paste the key file from a terminal. In both cases, you must save the keys to the configuration instead of to a file. The following example shows how to load a key from a file:

```
[edit system services dns dnssec trusted-keys]
#load-key filename
```

The following example explains how to load the key from a terminal:

```
[edit system services dns dnssec trusted-keys]
# set key "...pasted-text..."
```

If you are done loading the keys from the file or terminal, click **commit** in the CLI editor.

**Related
Documentation**

- [DNSSEC Overview on page 1073](#)
- [Example: Configuring Secure Domains and Trusted Keys for DNSSEC on page 1074](#)

Example: Configuring Secure Domains and Trusted Keys for DNSSEC

This example shows how to configure secure domains and trusted keys for DNSSEC.

- [Requirements on page 1074](#)
- [Overview on page 1074](#)
- [Configuration on page 1075](#)

Requirements

Set the name server IP address so the DNS resolver forwards all DNS queries to DNSSEC instead of DNS. See [“Example: Configuring DNSSEC” on page 1073](#) for more information.

Overview

You can configure secure domains and assign trusted keys to the domains. Both signed and unsigned responses can be validated when DNSSEC is enabled.

When you configure a domain as a secure domain and if DNSSEC is enabled, all unsigned responses to that domain are ignored and the server returns a SERVFAIL error code to the client for the unsigned responses. If the domain is not configured as a secure domain, unsigned responses will be accepted.

When the server receives a signed response, it checks if the DNSKEY in the response matches any of the trusted keys that are configured. If it finds a match, the server accepts the signed response.

You can also attach a DNS root zone as a trusted anchor to a secure domain to validate the signed responses. When the server receives a signed response, it queries the DNS root zone for a DS record. When it receives the DS record, it checks if the DNSKEY in the DS record matches the DNSKEY in the signed response. If it finds a match, the server accepts the signed response.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set system services dns dnssec secure-domains domain1.net
set system services dns dnssec secure-domains domain2.net
set system services dns dnssec trusted-keys key domain1.net.ABC123ABCh
set system services dns dnssec dlv domain domain2.net trusted-anchor dlv.isc.org
```

Step-by-Step Procedure To configure secure domains and trusted keys for DNSSEC:

1. Configure domain1.net and domain2.net as secure domains.

```
[edit]
user@host# set system services dns dnssec secure-domains domain1.net
user@host# set system services dns dnssec secure-domains domain2.net
```

2. Configure trusted keys to domain1.net.

```
[edit]
user@host# set system services dns dnssec trusted-keys key
"domain1.net.ABC123ABCh"
```

3. Attach a root zone div.isc.org as a trusted anchor to a secure domain.

```
[edit]
user@host# set system services dns dnssec dlv domain domain2.net trusted-anchor
dlv.isc.org
```

Results From configuration mode, confirm your configuration by entering the **show system services** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
dns {
  dnssec {
    trusted-keys {
      key domain1.net.ABC123ABCh; ## SECRET-DATA
    }
    dlv {
      domain domain2.net trusted-anchor dlv.isc.org;
    }
    secure-domains {
      domain1.net;
      domain2.net;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

DNS Proxy Overview

A dynamic name system (DNS) proxy allows clients to use a device as a DNS proxy server. A DNS proxy improves domain lookup performance by caching previous lookups. A typical DNS proxy processes DNS queries by issuing a new DNS resolution query to each name server that it has detected until the hostname is resolved.

- [DNS Proxy Cache on page 1076](#)
- [DNS Proxy with Split DNS on page 1076](#)
- [Dynamic Domain Name System Client on page 1078](#)

DNS Proxy Cache

When a DNS query is resolved by a DNS proxy, the result is stored in the device's DNS cache. This stored cache helps the device to resolve subsequent queries from the same domain and avoid network latency delay.

NOTE: If the proxy cache is not available, the device sends the query to the configured DNS server, which results in network latency delays.

DNS proxy maintains a cache entry for each resolved DNS query. These entries have a time-to-live (TTL) timer so the device purges each entry from the cache as it reaches its TTL and expires. You can clear a cache by using the **clear cache** command, or the cache will automatically expire along with TTL when it goes to zero.

DNS Proxy with Split DNS

The split DNS proxy feature allows you to configure your proxy server to split the DNS query based on both the interface and the domain name. You can also configure a set of name servers and associate them with a given domain name. When you query that domain name, the device sends the DNS queries to only those name servers that are configured for that domain name to ensure localization of DNS queries.

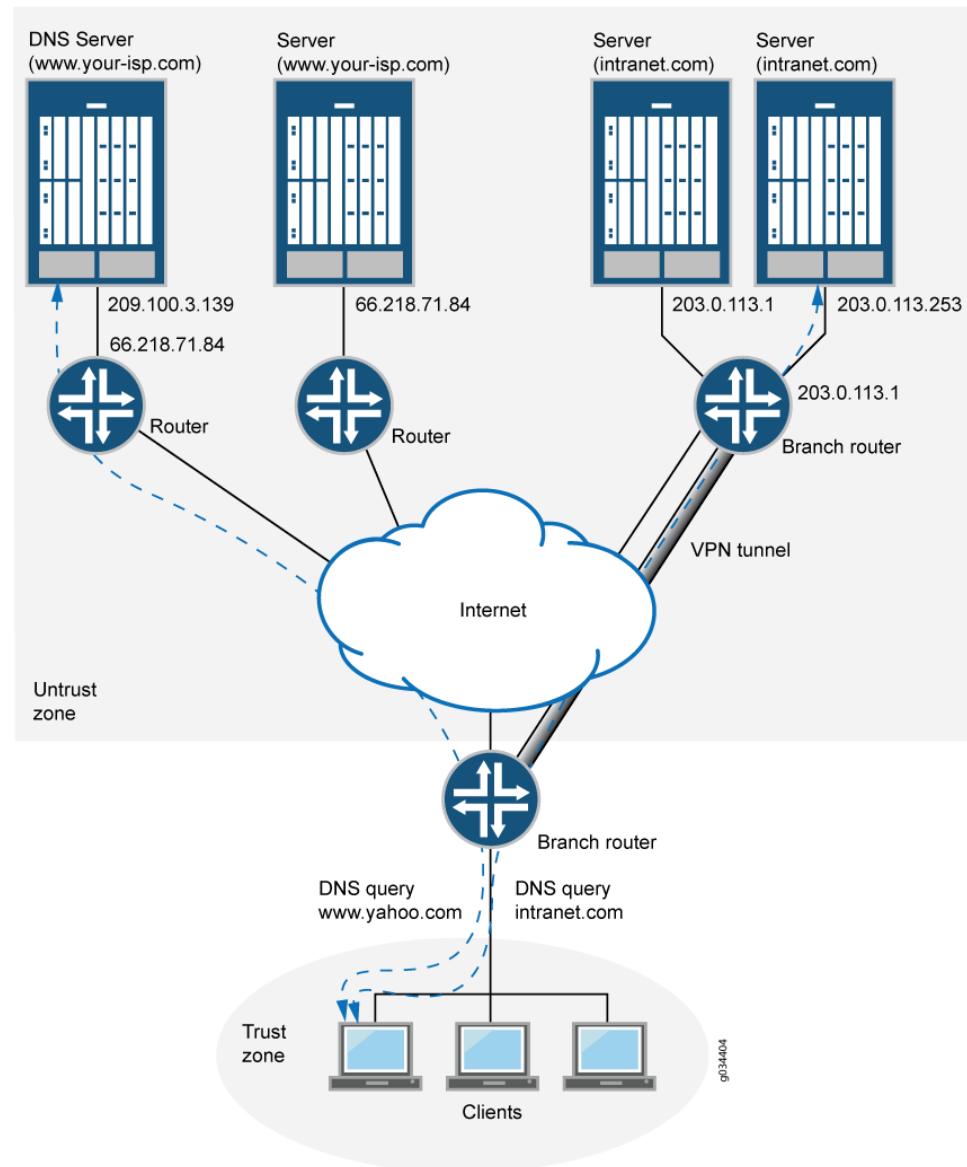

You can configure the transport method used to resolve a given domain name—for example, when the device connects to the corporate network through an IPsec VPN or any other secure tunnel. When you configure a secure VPN tunnel to transport the domain names belonging to the corporate network, the DNS resolution queries are not leaked to the ISP DNS server and are contained within the corporate network.

You can also configure a set of default domain (*) and name servers under the default domain to resolve the DNS queries for a domain for which a name server is not configured.

Each DNS proxy must be associated with an interface. If an interface has no DNS proxy configuration, all the DNS queries received on that interface are dropped.

Figure 31 shows how the split DNS proxy works in a corporate network.

Figure 31: DNS Proxy with Split DNS

In the corporate network shown in Figure 31, a PC client that points to the SRX Series device as its DNS server makes two queries—to `www.your-isp.com` and to `www.intranet.com`. The DNS proxy redirects the `www.intranet.com` query to the `www.intranet.com` DNS server (203.0.113.253), while the `www.your-isp.com` query is redirected to the ISP DNS server (209.100.3.130). Although the query for `www.your-isp.com` is sent to the ISP DNS server as a regular DNS query using clear text

protocols (TCP/UDP), the query for the `www.intranet.com` domain goes to the intranet's DNS servers over a secure VPN tunnel.

A split DNS proxy has the following advantages:

- Domain lookups are usually more efficient. For example, DNS queries meant for a corporate domain (such as `acme.com`) can go to the corporate DNS server exclusively, while all others go to the ISP DNS server. Splitting DNS lookups reduces the load on the corporate server and can also prevent corporate domain information from leaking onto the Internet.
- A DNS proxy allows you to transmit selected DNS queries through a tunnel interface, which prevents malicious users from learning about the internal configuration of a network. For example, DNS queries bound for the corporate server can pass through a tunnel interface to use security features such as authentication and encryption.

Dynamic Domain Name System Client

Dynamic DNS (DDNS) allows clients to dynamically update IP addresses for registered domain names. This feature is useful when an ISP uses Point-to-Point Protocol (PPP), Dynamic Host Configuration Protocol (DHCP), or external authentication (XAuth) to dynamically change the IP address for a customer premises equipment (CPE) router (such as a security device) that protects a Web server. Internet clients can reach the Web server by using a domain name even if the IP address of the security device has previously changed dynamically.

A DDNS server maintains a list of the dynamically changed addresses and their associated domain names. The device updates these DDNS servers with this information periodically or in response to IP address changes. The Junos OS DDNS client supports popular DDNS servers such as `dyndns.org` and `ddo.jp`.

[Figure 32](#) illustrates how the DDNS client works.

Figure 32: Dynamic DNS

The IP address of the internal Web server is translated by Network Address Translation (NAT) to the IP address of the untrust zone interface on the device. The hostname

abc-host.com is registered with the DDNS server and is associated with the IP address of the device's untrust zone interface, which is monitored by the DDNS client on the device. When the IP address of abc-host.com is changed, the DDNS server is informed of the new address.

If a client in the network shown in [Figure 32](#) needs to access abc-host.com, the client queries the DNS servers on the Internet. When the query reaches the DDNS server, it resolves the request and provides the client with the latest IP address of abc-host.com.

Configuring the Device as a DNS Proxy

The Junos operating system (Junos OS) incorporates domain name system (DNS) support, which allows you to use domain names as well as IP addresses for identifying locations. A DNS server keeps a table of the IP addresses associated with domain names. Using DNS enables a device to reference locations by domain name (such as www.example.net) in addition to using the routable IP address.

DNS features include:

- **DNS proxy**—The device proxies hostname resolution requests on behalf of the clients behind the SRX Series device. DNS proxy improves domain lookup performance by using caching.
- **Split DNS**—The device redirects DNS queries over a secure connection to a specified DNS server in the private network. Split DNS prevents malicious users from learning the network configuration, and thus also prevents domain information leaks. Once configured, split DNS operates transparently.
- **Dynamic DNS (DDNS) client**—Servers protected by the device remain accessible despite dynamic IP address changes. For example, a protected Web server continues to be accessible with the same hostname, even after the dynamic IP address is changed because of address reassignment by the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol (PPP) by Internet service provider (ISP).

To configure the device as a DNS proxy, you enable DNS on a logical interface and configure DNS proxy servers. Configuring a static cache enables branch office and corporate devices to use hostnames to communicate. Configuring dynamic DNS (DDNS) clients allows IP address changes.

Perform the following procedure to configure the device as a DNS proxy server by enabling DNS proxy on a logical interface—for example, ge-0/0/1.0—and configuring a set of name servers that are to be used for resolving the specified domain names. You can specify a default domain name by using an asterisk (*) and then configure a set of name servers for resolution. Use this approach when you need global name servers to resolve domain name entries that do not have a specific name server configured.

1. **DNS proxy configuration**
 - Enable DNS proxy on a logical interface.

```
[edit system services]
user@host# set dns dns-proxy interface ge-0/0/1.0
```

- Set a default domain name, and specify global name servers according to their IP addresses.

```
[edit system services]
user@host# set dns dns-proxy default-domain * forwarders 172.17.28.100
```

- If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

To verify if the configuration is working properly, execute the show command.

```
user@host# show system services dns dns-proxy
```

2. Dynamic DNS proxy configuration

- Enable client.

```
[edit system services]
user@host# set dynamic-dns client abc.com agent juniper interface ge-0/0/1.0
username test password test123
```

- If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

To verify if the configuration is working properly

```
user@host# show system services dynamic-dns
```

DHCP Overview

The Dynamic Host Configuration Protocol (DHCP) can serve as a DHCP local server, a DHCP client, or a DHCP relay agent.

DHCP Local Server

You can enable an SRX Series device to function as a DHCP local server, and then configure its options on the device. The DHCP local server provides an IP address and other configuration information in response to a client request.

To configure the DHCP local server on the device, include the **dhcp-local-server** statement at the **[edit system services]** hierarchy level.

NOTE: You cannot configure the DHCP local server and the DHCP relay agent on the same interface.

DHCP Client, DHCP Local Server, and Address-Assignment Pool Interaction

In a typical branch network configuration, the DHCP client is on the subscriber's computer, and the DHCP local server is configured on the device. The following steps provide a high-level description of the interaction among the DHCP client, DHCP local server, and address-assignment pools.

1. The DHCP client sends a discover packet to one or more DHCP local servers in the network to obtain configuration parameters and an IP address for the subscriber.
2. Each DHCP local server that receives the discover packet then searches its address-assignment pool for the client address and configuration options. Each local server creates an entry in its internal client table to keep track of the client state, then sends a DHCP offer packet to the client.

3. On receipt of the offer packet, the DHCP client selects the DHCP local server from which to obtain configuration information and sends a request packet indicating the DHCP local server selected to grant the address and configuration information.
