YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Table of Contents

	About the Documentation	lvii
	Documentation and Release Notes	lvii
	Supported Platforms	lvii
	Using the Examples in This Manual	lvii
	Merging a Full Example	lviii
	Merging a Snippet	lviii
	Documentation Conventions	lix
	Documentation Feedback	lxi
	Requesting Technical Support	lxi
	Self-Help Online Tools and Resources	lxi
	Opening a Case with JTAC	lxii
Part 1	Services Interfaces Overview	
Chapter 1	Overview	3
	Understanding Services PICs	3
	Adaptive services and Multiservices PICs	3
	Encryption Services (ES) PIC	4
	Multilink Services and Link Services PICs	4
	Monitoring Services PICs	4
	Tunnel Services PIC	5
	Multiservices MIC and Multiservices MPC	5
	Multiservices MIC and Multiservices MPC (MS-MIC and MS-MPC) Overview	5
	Supported Platforms	7
Chapter 2	Configuration Overview	9
	Services Interface Naming Overview	9
	Enabling Service Packages	11
	Layer 2 Service Package Capabilities and Interfaces	14
	Services Configuration Procedure	15
	Example: Service Interfaces Configuration	16
	Configuring Default Timeout Settings for Services Interfaces	19
	Configuring System Logging for Services Interfaces	20
Part 2	Adaptive Services Overview	
Chapter 3	Adaptive Services Overview	25
	Adaptive Services Overview	25
	Packet Flow Through the Adaptive Services or Multiservices PIC	27

Chapter 4	Adaptive Services Configuration Overview	29
	Understanding Service Sets	29
	Configuring Service Sets to be Applied to Services Interfaces	31
	Configuring Interface Service Sets	31
	Configuring Next-Hop Service Sets	33
	Determining Traffic Direction	34
	Interface Style Service Sets	34
	Next-Hop Style Service Sets	35
	Configuring Service Rules	36
	Configuring Service Set Limitations	37
	Enabling Services PICs to Accept Multicast Traffic	38
	Applying Filters and Services to Interfaces	38
	Configuring Service Filters	39
	Example: Configuring Service Sets	41
	Configuring AS or Multiservices PIC Redundancy	41
	Examples: Configuring Services Interfaces	44
	Configuring the Address and Domain for Services Interfaces	45
	Configuring System Logging for Service Sets	47
	Tracing Services PIC Operations	48
	Configuring the Adaptive Services Log Filename	49
	Configuring the Number and Size of Adaptive Services Log Files	49
	Configuring Access to the Log File	50
	Configuring a Regular Expression for Lines to Be Logged	50
	Configuring the Trace Operations	50
 Part 3	 Translating IP Addresses Using NAT	
Chapter 5	NAT Overview	55
	Junos Address Aware Network Addressing Overview	55
	NAT Concept and Facilities Overview	56
	IPv4-to-IPv4 Basic NAT	57
	Basic NAT	57
	NAPT	57
	Static Destination NAT	57
	Twice NAT	57
	IPv6 NAT	58
	Application-Level Gateway (ALG) Support	58
	NAT-PT with DNS ALG	58
	Dynamic NAT	59
	Stateful NAT64	59
	Dual-Stack Lite	59
	Junos Address Aware Network Addressing Line Card Support	60
	Junos OS Carrier-Grade NAT Implementation Overview	60
	Carrier-Grade NAT Feature Comparison for Junos Address Aware by Type of Interface Card	61

Chapter 6	NAT Configuration Overview	65
	Network Address Translation Configuration Overview	65
	Configuring Source and Destination Addresses Network Address Translation	
	Overview	66
	Configuring Pools of Addresses and Ports for Network Address Translation	
	Overview	67
	Configuring NAT Pools	67
	Preserve Range and Preserve Parity	68
	Specifying Destination and Source Prefixes without Configuring a Pool	68
	Network Address Translation Rules Overview	69
	Configuring Match Direction for NAT Rules	70
	Configuring Match Conditions in NAT Rules	70
	Configuring Actions in NAT Rules	71
	Configuring Translation Types	73
	Configuring Service Sets for Network Address Translation	75
	Carrier-Grade NAT Implementation: Best Practices	76
	Use APP and Round-Robin Address-Allocation	77
	Do Not Use EIM with SIP	77
	Do Not Use EIM with HTTP, DNS, or When Not Needed	78
	Define PBA Blocks Based on User Profiles	79
	Do Not Change the PBA Configuration on Running Systems	79
	Do Not Allocate Excessively Large NAT Pools	80
	Configure the System Log for PBA Only When Needed	81
	Use Redundant Service PIC (RSP) Interfaces for Failover	83
	Contain the Effects of Missing IP Fragments	84
	Do Not Use Configurations Prone to Routing Loops	84
Chapter 7	Avoiding IPv4 Exhaustion Using Junos Address Aware Network Addressing and Stateful NAT64	87
	Sample IPv6 Transition Scenarios	87
	Example 1: IPv4 Depletion with a Non-IPv6 Access Network	87
	Example 2: IPv4 Depletion with an IPv6 Access Network	88
	Example 3: IPv4 Depletion for Mobile Networks	89
	Configuring Stateful NAT64	89
Chapter 8	Hiding Private Networks Using Static Source NAT	93
	Configuring Static Source Translation in IPv4 Networks	93
	Configuring the NAT Pool and Rule	93
	Configuring the Service Set for NAT	95
	Configuring Trace Options	97
	Sample Configuration - Static Source NAT Using a Static Pool With An Address Prefix And An Address Range	98
	Sample Configuration - Static Source Nat for One-To-One Mapping Between a Private Subnet and a Public Subnet	98
	Configuring Static Source Translation in IPv6 Networks	99
	Configuring the NAT Pool and Rule	100
	Configuring the Service Set for NAT	101

	Configuring Trace Options	102
	Example: Configuring Basic NAT44	103
	Example: Configuring NAT for Multicast Traffic	105
	Rendezvous Point Configuration	105
	Router 1 Configuration	108
Chapter 9	Making Private Servers Available Using Static Destination NAT	111
	Configuring Static Destination Address Translation in IPv4 Networks	111
Chapter 10	Allowing Components of a Private Network to Share a Single Address Using NAPT	117
	Configuring Address Pools for Network Address Port Translation (NAPT)	
	Overview	117
	Round-Robin Allocation for NAPT	118
	Sequential Allocation for NAPT	118
	Preserve Parity and Preserve Range for NAPT	119
	Address Pooling and Endpoint Independent Mapping for NAPT	119
	Address Pooling	119
	Endpoint Independent Mapping and Endpoint Independent Filtering	120
	Port Block Allocation for NAPT	121
	Secured Port Block Allocation for NAPT	121
	Interim Logging for Port Block Allocation	122
	Deterministic Port Block Allocation for NAPT	122
	Understanding Deterministic Port Block Allocation Algorithms	122
	Deterministic Port Block Allocation Algorithm Usage	123
	Deterministic Port Block Allocation Restrictions	125
	Comparison of NAPT Implementation Methods	126
	Configuring Dynamic Source Address and Port Translation in IPv4 Networks	127
	Configuring Dynamic Source Address and Port Translation for IPv6 Networks	131
	Example: Configuring NAT with Port Translation	133
	Example: NAPT Configuration for the MS-MPC	134
	Example: Dynamic Source NAT as a Next-Hop Service	138
Chapter 11	Securing Traffic Using NAT-PT and ALGs	141
	ALGs Available by Default for Junos OS Address Aware NAT	141
	Configuring Protocol Translation Between IPv6 and IPv4 Networks -	
	NAT-PT	143
	Configuring the DNS ALG Application	144
	Configuring the NAT Pool and NAT Rule	144
	Configuring the Service Set for NAT	147
	Configuring Trace Options	148
	Example: Configuring NAT-PT	150
Chapter 12	Reducing Traffic and Bandwidth Requirements Using Port Control Protocol	165
	Port Control Protocol Overview	165
	Configuring Port Control Protocol	167
	Configuring PCP Server Options	167
	Configuring a PCP Rule	168
	Configuring a Service Set to Apply PCP	169

	SYSLOG Message Configuration	169
	Example: Configuring Port Control Protocol with NAPT44	170
Chapter 13	Automatically Assigning Ports Using Port Block Allocation	177
	Secured Port Block Allocation for NAPT	177
	Interim Logging for Port Block Allocation	177
	Configuring Secured Port Block Allocation	178
	Configuring Deterministic Port Block Allocation	180
Chapter 14	Connecting Specific Ports and Addresses Using Port Forwarding	183
	Configuring Port Forwarding for Static Destination Address Translation	183
	Configuring Port Forwarding Without Destination Address Translation	186
	Example: Configuring Port Forwarding with Twice NAT	187
Chapter 15	Allocating a Few Public Addresses to Many Private Hosts Using Dynamic NAT	191
	Configuring Dynamic Address-Only Source Translation in IPv4 Networks	191
	Example: Dynamic Source NAT as a Next-Hop Service	195
	Example: Assigning Addresses from a Dynamic Pool for Static Use	197
Chapter 16	Achieving Line-Rate, Low-Latency Translations Using Inline NAT	199
	Inline Network Address Translation Overview for MPC Types 1, 2, and 3	199
	Example: Configuring Inline Network Address Translation - Interface-Service Service Set	201
Chapter 17	Monitoring NAT	209
	Configuring NAT Session Logs	209
	Monitoring NAT Pool Usage	210
Part 4	Transitioning to IPv6 Using Softwires	
Chapter 18	Softwires Overview	213
	Tunneling Services for IPv4-to-IPv6 Transition Overview	213
	6to4 Overview	213
	Basic 6to4	214
	6to4 Anycast	214
	6to4 Provider-Managed Tunnels	215
	DS-Lite Softwires—IPv4 over IPv6	215
	6rd Softwires—IPv6 over IPv4	216
Chapter 19	Softwires Configuration Overview	219
	Configuring Softwire Rules	219
	Configuring Service Sets for Softwire	220
Chapter 20	Transitioning to IPv6 Using 6to4 Softwires	223
	Configuring a 6to4 Provider-Managed Tunnel	223

Chapter 21	Transitioning to IPv6 Using DS-Lite Softwires	227
	Configuring a DS-Lite Softwire Concentrator	227
	Example: Basic DS-Lite Configuration	228
	Example: Configuring DS-Lite and 6rd in the Same Service Set	234
	Protecting CGN Devices Against Denial of Service (DOS) Attacks	241
	Mapping Refresh Behavior	241
	EIF Inbound Flow Limit	242
	DS-Lite Subnet Limitation	242
	DS-Lite Per Subnet Limitation Overview	242
	Configuring DS-Lite Per Subnet Session Limitation to Prevent Denial of Service Attacks	243
Chapter 22	Transitioning to IPv6 Using 6rd Softwires	245
	Configuring a 6rd Softwire Concentrator	245
	Configuring Stateful Firewall Rules for 6rd Softwire	246
	Example: Basic 6rd Configuration	247
	Inter-Chassis High Availability for MS-MIC and MS-MPC	252
	Inter-Chassis High Availability for Stateful Firewall and NAPT44 Overview (MS-MIC, MS-MPC)	252
	Configuring Inter-Chassis High Availability for Stateful Firewall and NAPT44 (MS-MPC, MS-MIC)	253
	Example: Inter-Chassis Stateful High Availability for NAT and Stateful Firewall (MS-MIC, MS-MPC)	254
	High Availability and Load Balancing for 6rd Softwires	264
	Load Balancing a 6rd Domain Across Multiple Services PICs	264
	Example: Load Balancing a 6rd Domain Across Multiple Services PICs	264
	Configuring High Availability for 6rd Using 6rd Anycast	269
Chapter 23	Monitoring and Troubleshooting Softwires	271
	Ping and Traceroute for DS-Lite	271
	Monitoring Softwire Statistics	271
	Monitoring CGN, Stateful Firewall, and Softwire Flows	273
Part 5	Enabling Traffic to Pass Securely Using ALGs	
Chapter 24	ALG Overview	277
	ALG Descriptions	277
	Supported ALGs	277
	ALG Support Details	278
	Basic TCP ALG	279
	Basic UDP ALG	279
	BOOTP	280
	DCE RPC Services	280
	DNS	280
	FTP	280
	H323	281
	ICMP	282
	IIOP	282
	IP	282
	NetBIOS	282

	NetShow	283
	ONC RPC Services	283
	PPTP	283
	RealAudio	283
	Sun RPC and RPC Portmap Services	284
	RTSP	285
	SIP	286
	SNMP	286
	SQLNet	286
	TFTP	287
	Traceroute	287
	UNIX Remote-Shell Services	287
	Winframe	288
	Juniper Networks Defaults	288
	Examples: Referencing the Preset Statement from the Junos Default Group	298
	ALGs Available by Default for Junos OS Address Aware NAT	300
Chapter 25	ALGs Configuration Overview	303
	Configuring Application Sets	303
	Configuring Application Protocol Properties	303
	Configuring an Application Protocol	304
	Configuring the Network Protocol	306
	Configuring the ICMP Code and Type	307
	Configuring Source and Destination Ports	309
	Configuring the Inactivity Timeout Period	312
	Configuring SIP	312
	SIP ALG Interaction with Network Address Translation	313
	Junos OS SIP ALG Limitations	319
	Configuring an SNMP Command for Packet Matching	320
	Configuring an RPC Program Number	320
	Configuring the TTL Threshold	320
	Configuring a Universal Unique Identifier	320
	Examples: Configuring Application Protocols	321
	ICMP, Ping, and Traceroute ALGs for MS-MICs and MS-MPCs	322
	Monitoring Port Control Protocol Operations	323
Part 6	Securing Content Using Junos Network Secure and IDS	
Chapter 26	Junos Network Secure Overview	327
	Junos Network Secure Overview	327
	Stateful Firewall Support for Application Protocols	328
	Stateful Firewall Anomaly Checking	328
Chapter 27	Junos Network Secure Configuration Overview	331
	Configuring Stateful Firewall Rules	331
	Configuring Match Direction for Stateful Firewall Rules	332
	Configuring Match Conditions in Stateful Firewall Rules	332

	Configuring Actions in Stateful Firewall Rules	334
	Configuring IP Option Handling	334
	Configuring Stateful Firewall Rule Sets	335
	Examples: Configuring Stateful Firewall Rules	335
	Example: BOOTP and Broadcast Addresses	338
	Example: Configuring Layer 3 Services and the Services SDK on Two PICs	339
	Example: Virtual Routing and Forwarding (VRF) and Service Configuration . . .	351
Chapter 28	IDS Configuration Overview	355
	Configuring IDS Rules	355
	Configuring Match Direction for IDS Rules	356
	Configuring Match Conditions in IDS Rules	357
	Configuring Actions in IDS Rules	358
	Configuring IDS Rule Sets	363
	Examples: Configuring IDS Rules	364
Chapter 29	Monitoring Junos Network Secure	367
	Monitoring Stateful Firewall Conversations	367
	Monitoring CGN, Stateful Firewall, and Software Flows	367
	Monitoring Global Stateful Firewall Statistics	368
Part 7	Creating Secure Tunnels Using Junos VPN Site Secure	
Chapter 30	Junos VPN Site Secure Overview	371
	Understanding Junos VPN Site Secure	371
	IPsec	371
	Security Associations	372
	IKE	372
	Comparison of IPsec on ES PICs and Junos VPN Site Secure on Multiservices Line Cards	372
	Authentication Algorithms	374
	Encryption Algorithms	374
	IPsec Protocols	376
	Supported IPsec and IKE Standards	378
	IPsec Terms and Acronyms	379
Chapter 31	Junos VPN Site Secure Configuration Overview	383
	Minimum Security Association Configurations	383
	Minimum Manual SA Configuration	383
	Minimum Dynamic SA Configuration	384
	Configuring Security Associations	385
	Configuring Manual Security Associations	385
	Configuring the Direction for IPsec Processing	386
	Configuring the Protocol for a Manual IPsec SA	387
	Configuring the Security Parameter Index	387
	Configuring the Auxiliary Security Parameter Index	388
	Configuring Authentication for a Manual IPsec SA	388

Configuring Encryption for a Manual IPsec SA	389
Configuring Dynamic Security Associations	390
Clearing Security Associations	390
Example: Configuring Manual SAs	391
Configuring IKE Proposals	405
Configuring the Authentication Algorithm for an IKE Proposal	406
Configuring the Authentication Method for an IKE Proposal	406
Configuring the Diffie-Hellman Group for an IKE Proposal	407
Configuring the Encryption Algorithm for an IKE Proposal	408
Configuring the Lifetime for an IKE SA	408
Example: Configuring an IKE Proposal	409
Configuring IKE Policies	409
Configuring the IKE Phase	411
Configuring the Mode for an IKE Policy	411
Configuring the Proposals in an IKE Policy	411
Configuring the Preshared Key for an IKE Policy	411
Configuring the Local Certificate for an IKE Policy	412
Configuring a Certificate Revocation List	413
Configuring the Description for an IKE Policy	413
Configuring Local and Remote IDs for IKE Phase 1 Negotiation	413
Enabling Invalid SPI Recovery	414
Example: Configuring an IKE Policy	414
Configuring IPsec Proposals	415
Configuring the Authentication Algorithm for an IPsec Proposal	416
Configuring the Description for an IPsec Proposal	418
Configuring the Encryption Algorithm for an IPsec Proposal	418
Configuring the Lifetime for an IPsec SA	418
Configuring the Protocol for a Dynamic SA	419
Configuring IPsec Policies	420
Configuring the Description for an IPsec Policy	420
Configuring Perfect Forward Secrecy	421
Configuring the Proposals in an IPsec Policy	421
IPsec Policy for Dynamic Endpoints	421
Example: Configuring an IPsec Policy	422
Configuring IPsec Rules	422
Configuring Match Direction for IPsec Rules	424
Configuring Match Conditions in IPsec Rules	424
Configuring Actions in IPsec Rules	426
Enabling IPsec Packet Fragmentation	427
Configuring Destination Addresses for Dead Peer Detection	427
Configuring or Disabling IPsec Anti-Replay	428
Enabling System Log Messages	429
Specifying the MTU for IPsec Tunnels	429
Configuring IPsec Rule Sets	429
Service Sets for IPsec Tunnels	430
Configuring IPsec Service Sets	430
Configuring the Local Gateway Address for IPsec Service Sets	431
IKE Addresses in VRF Instances	432
Configuring IKE Access Profiles for IPsec Service Sets	432

	Configuring Certification Authorities for IPsec Service Sets	433
	Configuring or Disabling Antireplay Service	433
	Clearing the Don't-Fragment Bit	434
	Configuring Passive-Mode Tunneling	435
	Configuring the Tunnel MTU Value	436
	Tracing Junos VPN Site Secure Operations	436
	Disabling IPsec Tunnel Endpoint in Traceroute	437
	Tracing IPsec PKI Operations	438
	Multitask Example: Configuring IPsec Services	438
	Configuring the IKE Proposal	439
	Configuring the IKE Policy (and Referencing the IKE Proposal)	439
	Configuring the IPsec Proposal	440
	Configuring the IPsec Policy (and Referencing the IPsec Proposal)	441
	Configuring the IPsec Rule (and Referencing the IKE and IPsec Policies)	441
	Configuring IPsec Trace Options	442
	Configuring the Access Profile (and Referencing the IKE and IPsec Policies)	443
	Configuring the Service Set (and Referencing the IKE Profile and the IPsec Rule)	444
Chapter 32	Enhancing Security with Static IPsec over VRF	447
	Example: Configuring Statically Assigned IPsec Tunnels over a VRF Instance	447
Chapter 33	Dynamically Assigning Tunnels Using Junos VPN Site Secure	455
	Configuring Dynamic Endpoints for IPsec Tunnels	455
	Authentication Process	456
	Implicit Dynamic Rules	456
	Reverse Route Insertion	457
	Configuring an IKE Access Profile	457
	Referencing the IKE Access Profile in a Service Set	459
	Configuring the Interface Identifier	459
	Default IKE and IPsec Proposals	460
	Example: Configuring Dynamically Assigned Policy Based Tunnels	461
	Example: Configuring IKE Dynamic SAs	466
	Example: IKE Dynamic SA Configuration with Digital Certificates	483
Chapter 34	Enabling IPsec for the Services SDK	507
	Configuring Junos VPN Site Secure or IPsec VPN	507
Part 8	Alleviating Congestion and Controlling Service Using CoS	
Chapter 35	Class of Service Overview	511
	Class of Service Overview	511
Chapter 36	Class of Service Configuration Overview	513
	Restrictions and Cautions for CoS Configuration on Services Interfaces	513
	Configuring CoS Rules	514
	Configuring Match Direction for CoS Rules	515
	Configuring Match Conditions In CoS Rules	515

	Configuring Actions in CoS Rules	516
	Configuring Application Profiles for Use as CoS Rule Actions	517
	Configuring Reflexive and Reverse CoS Rule Actions	518
	Example: Configuring CoS Rules	518
	Configuring CoS Rule Sets	519
	Examples: Configuring CoS on Services Interfaces	519
Chapter 37	Configuring Class of Service on LSQ Interfaces	523
	Configuring CoS Scheduling Queues on Logical LSQ Interfaces	523
	Configuring Scheduler Buffer Size	524
	Configuring Scheduler Priority	525
	Configuring Scheduler Shaping Rate	525
	Configuring Drop Profiles	525
	Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces	527
	Configuring Link Services and CoS on Services PICs	529
	Oversubscribing Interface Bandwidth on LSQ Interfaces	532
	Examples: Oversubscribing an LSQ Interface	535
	Configuring Guaranteed Minimum Rate on LSQ Interfaces	537
	Example: Configuring Guaranteed Minimum Rate	539
Part 9	Configuring Interface Redundancy and Bundling on LSQ Interfaces	
Chapter 38	Overview	543
	Layer 2 Service Package Capabilities and Interfaces	543
Chapter 39	Configuring Interface Redundancy with SONET APS and Virtual Interfaces	545
	Configuring LSQ Interface Redundancy Across Multiple Routers Using SONET APS	545
	Configuring the Association between LSQ and SONET Interfaces	546
	Configuring SONET APS Interoperability with Cisco Systems FRF.16	547
	Restrictions on APS Redundancy for LSQ Interfaces	547
	Configuring LSQ Interface Redundancy in a Single Router Using SONET APS	548
	Configuring LSQ Interface Redundancy in a Single Router Using Virtual Interfaces	548
	Configuring Redundant Paired LSQ Interfaces	549
	Restrictions on Redundant LSQ Interfaces	550
	Configuring Link State Replication for Redundant Link PICs	551
	Examples: Configuring Redundant LSQ Interfaces for Failure Recovery	553
Chapter 40	Enabling Bundling on LSQ Interfaces	559
	Inline MLPPP for WAN Interfaces Overview	559
	Reserving Bundle Bandwidth for Link-Layer Overhead on LSQ Interfaces	561
	Configuring Multiclass MLPPP on LSQ Interfaces	562
	Enabling Inline LSQ Services	563
	Configuring LSQ Interfaces as NxT1 or NxEl Bundles Using MLPPP	565
	Example: Configuring an LSQ Interface as an NxT1 Bundle Using MLPPP	568
	Configuring LSQ Interfaces as NxT1 or NxEl Bundles Using FRF.16	571
	Example: Configuring an LSQ Interface as an NxT1 Bundle Using FRF.16	574

	Configuring LSQ Interfaces as NxT1 or NxE1 Bundles Using FRF.15	576
	Configuring LSQ Interfaces for Single Fractional T1 or E1 Interfaces Using MLPPP and LFI	577
	Example: Configuring an LSQ Interface for a Fractional T1 Interface Using MLPPP and LFI	580
	Configuring LSQ Interfaces for Single Fractional T1 or E1 Interfaces Using FRF.12	582
	Examples: Configuring an LSQ Interface for a Fractional T1 Interface Using FRF.12	585
	Configuring LSQ Interfaces for T3 Links Configured for Compressed RTP over MLPPP	589
	Configuring LSQ Interfaces as T3 or OC3 Bundles Using FRF.12	591
	Configuring LSQ Interfaces for ATM2 IQ Interfaces Using MLPPP	593
Part 10	Enabling Load Balancing and High Availability Using Multiservices Interfaces	
Chapter 41	Enabling Load Balancing and High Availability Using Multiservices Interfaces	599
	Understanding Aggregated Multiservices Interfaces	599
	Aggregated Multiservices Interface	599
	IPv6 Traffic on AMS Interfaces Overview	603
	Member Failure Options and High Availability Settings	604
	Configuring Load Balancing on AMS Infrastructure	605
	Configuring AMS Infrastructure	606
	Configuring High Availability	607
	Load Balancing Network Address Translation Flows	607
	Example: Configuring an Aggregated Multiservices Interface (AMS)	608
	Example: Configuring Next-Hop Style Services on an Aggregated Multiservices Interface	613
	Example: Configuring Static Source Translation on AMS Infrastructure	616
Part 11	Handling VoIP, HTTP, and Layer 2 Traffic	
Chapter 42	Handling VoIP Traffic Using Voice Services	621
	Voice Services Overview	621
	Configuring Services Interfaces for Voice Services	622
	Configuring the Logical Interface Address for the MLPPP Bundle	622
	Configuring Compression of Voice Traffic	623
	Configuring Delay-Sensitive Packet Interleaving	624
	Example: Configuring Compression of Voice Traffic	624
	Configuring Encapsulation for Voice Services	625
	Configuring Network Interfaces for Voice Services	626
	Configuring Voice Services Bundles with MLPPP Encapsulation	626
	Configuring the Compression Interface with PPP Encapsulation	626
	Examples: Configuring Voice Services	627

Chapter 43	Handling HTTP Traffic Using HTTP Content Manager (HCM)	631
	HTTP Content Manager (HCM)	631
	Configuring the HTTP-Manager Package on the Router	631
	HTTP URL Tracking and Policy Control for Client Requests	634
	Guidelines for Configuring HTTP URL Monitoring for Client Requests	635
	Configuring HTTP URL Tracking and Policy Control	635
Chapter 44	Tunneling PPP Packets Across a Network Using Layer 2 Tunneling	637
	Layer 2 Tunneling Protocol Overview	637
	L2TP Services Configuration Overview	638
	L2TP Minimum Configuration	639
	Configuring L2TP Tunnel Groups	641
	Configuring Access Profiles for L2TP Tunnel Groups	642
	Configuring the Local Gateway Address and PIC	642
	Configuring Window Size for L2TP Tunnels	643
	Configuring Timers for L2TP Tunnels	643
	Hiding Attribute-Value Pairs for L2TP Tunnels	644
	Configuring System Logging of L2TP Tunnel Activity	644
	Configuring the Identifier for Logical Interfaces that Provide L2TP Services	646
	Example: Configuring Multilink PPP on a Shared Logical Interface	646
	AS PIC Redundancy for L2TP Services	648
	Examples: Configuring L2TP Services	648
	Tracing L2TP Operations	652
Part 12	Configuring Application Aware Services Interfaces	
Chapter 45	Configuring Stateless, Rule-Based Services Using Application-Aware Access Lists	657
	AACL Overview	657
	Best-Effort Application Identification of DPI-Serviced Flows	658
	Features that Support Application-Level Filtering	659
	Best-Effort Application Determination	659
	APPID, AACL, and L-PDF Processing in Preconvergence Scenarios	659
	Prior to a Final or Best-Effort Application Identification	659
	Upon Best-Effort Application Identification	660
	While Application Identification Is on a Best-Effort Basis	660
	If a Flow Ends Before an Application Identification Is Made	660
	If a Flow Ends While Application Identification on a Best-Effort Basis	660
	Configuring AACL Rules	661
	Configuring Match Direction for AACL Rules	662
	Configuring Match Conditions in AACL Rules	662
	Configuring Actions in AACL Rules	664
	Logging AACL Flows Based on Application	665
	Example: Configuring AACL Rules	666
	Configuring AACL Rule Sets	666
	Configuring Logging of AACL Flows	667

Chapter 46	Grouping Applications Together Using APPID	669
	APPID Overview	669
	Best-Effort Application Identification of DPI-Serviced Flows	671
	Features that Support Application-Level Filtering	672
	Best-Effort Application Determination	672
	APPID, ACL, and L-PDF Processing in Preconvergence Scenarios	672
	Prior to a Final or Best-Effort Application Identification	672
	Upon Best-Effort Application Identification	673
	While Application Identification Is on a Best-Effort Basis	673
	If a Flow Ends Before an Application Identification Is Made	673
	If a Flow Ends While Application Identification on a Best-Effort Basis	673
	Defining an Application Identification	674
	Configuring APPID Rules	676
	Using Stateful Firewall Rules to Identify Data Sessions	677
	Configuring Application Profiles	679
	Configuring Application Groups	680
	Application Identification for Nested Applications	681
	Disabling Application Identification for Nested Applications	682
	Configuring Global APPID Properties	683
	Configuring APPID Support for Heuristics	684
	Configuring APPID Support for Unidirectional Traffic	685
	Configuring Automatic Download of Application Package Updates	686
	Tracing APPID Operations	686
	Configuring the APPID Log Filename	687
	Configuring the Number and Size of APPID Log Files	687
	Configuring Access to the Log File	687
	Configuring a Regular Expression for Lines to Be Logged	688
	Configuring the Tracing Flags	688
	Examples: Configuring Application Identification Properties	688
Chapter 47	Detecting Suspicious and Anomalous Network Traffic Using IDP	691
	IDP Overview	691
	Best-Effort Application Identification of DPI-Serviced Flows	693
	Features that Support Application-Level Filtering	693
	Best-Effort Application Determination	694
	APPID, ACL, and L-PDF Processing in Preconvergence Scenarios	694
	Prior to a Final or Best-Effort Application Identification	694
	Upon Best-Effort Application Identification	695
	While Application Identification Is on a Best-Effort Basis	695
	If a Flow Ends Before an Application Identification Is Made	695
	If a Flow Ends While Application Identification on a Best-Effort Basis	695
Chapter 48	Collecting Statistics and Tracking Data Using L-PDF	697
	L-PDF Overview	697
	Best-Effort Application Identification of DPI-Serviced Flows	699
	Features that Support Application-Level Filtering	699
	Best-Effort Application Determination	700

	APPID, ACL, and L-PDF Processing in Preconvergence Scenarios	700
	Prior to a Final or Best-Effort Application Identification	700
	Upon Best-Effort Application Identification	701
	While Application Identification Is on a Best-Effort Basis	701
	If a Flow Ends Before an Application Identification Is Made	701
	If a Flow Ends While Application Identification on a Best-Effort Basis	701
	Configuring Statistics Profiles	702
	Configuring an L-PDF Statistics Profile	703
	Configuring an ACL Statistics Profile	704
	Applying L-PDF Profiles to Service Sets	705
	Tracing L-PDF Operations	707
Part 13	Configuring Link and Multilink Services Interfaces	
Chapter 49	Overview	711
	Link and Multilink Services Overview	711
	Multilink and Link Services PICs Overview	714
	Multilink Interfaces on Channelized MICs Overview	715
	Multilink and Link Services Logical Interface Configuration Overview	717
	Default Settings for Multilink and Link Services Logical Interfaces	717
Chapter 50	Achieving Greater Bandwidth, Load Balancing, and Redundancy with Multilink Bundles	719
	Understanding MLPPP Bundles and Link Fragmentation and Interleaving (LFI) on Serial Links	719
	Configuring the Number of Bundles on Link Services PICs	720
	Configuring the Links in a Multilink or Link Services Bundle	721
	Example: Configuring a Link Services Interface with Two Links	722
Chapter 51	Configuring the Physical and Logical Interfaces in a Multilink Configuration	725
	Configuring Link Services Physical Interfaces	725
	Default Settings for Link Services Interfaces	726
	Configuring Encapsulation for Link Services Physical Interfaces	726
	Configuring Acknowledgment Timers on Link Services Physical Interfaces	727
	Configuring Differential Delay Alarms on Link Services Physical Interfaces with MLFR FRF.16	727
	Configuring Keepalives on Link Services Physical Interfaces	728
	Configuring Encapsulation for Multilink and Link Services Logical Interfaces	729
	Configuring the Drop Timeout Period on Multilink and Link Services Logical Interfaces	730
	Limiting Packet Payload Size on Multilink and Link Services Logical Interfaces	732
	Configuring the Minimum Number of Active Links on Multilink and Link Services Logical Interfaces	733
	Configuring MRRU on Multilink and Link Services Logical Interfaces	734

	Configuring the Sequence Header Format on Multilink and Link Services Logical Interfaces	735
	Example: Configuring Link Interfaces on Channelized MICs	735
Chapter 52	Bundling Multiple PPP Links on a Single Link Using MLPPP	747
	Example: Configuring a Multilink Interface with MLPPP	747
	Example: Configuring a Multilink Interface with MLPPP over ATM 2 Interfaces	748
	Example: Configuring an MLPPP Bundle	750
	Example: Configuring a Link Services Interface with MLPPP	753
	Example: Configuring Inline MLPPP and Multilink Frame Relay End-to-End (FRF.15) for WAN Interfaces	754
	Enabling MLPPP Link Fragmentation and Interleaving	769
	Configuring Delay-Sensitive Packet Interleaving on Link Services Logical Interfaces	773
	Configuring LFI with DLCI Scheduling	774
	Example: Configuring LFI with DLCI Scheduling	775
Chapter 53	Bundling Multiple Frame Relay DLCIs into a Single Link Using MLFR	777
	Configuring DLCIs on Link Services Logical Interfaces	777
	Configuring Point-to-Point DLCIs for MLFR FRF.16 and MLPPP Bundles	777
	Configuring Multicast-Capable DLCIs for MLFR FRF.16 Bundles	778
	Example: Configuring a Multilink Interface with MLFR FRF.15	778
	Example: Configuring Multilink Frame Relay FRF.16	779
	Example: Configuring Multilink Frame Relay FRF.15	783
	Example: Configuring a Link Services Interface with MLFR FRF.15	786
	Example: Configuring a Link Services PIC with MLFR FRF.16	787
	Example: Configuring Inline Multilink Frame Relay (FRF.16) for WAN Interfaces	788
Chapter 54	Configuring Additional Services on Link Services Interfaces	801
	Configuring CoS on Link Services Interfaces	801
	CoS for Link Services Interfaces on M Series and T Series Routers	801
	Example: Configuring CoS on Link Services Interfaces	803
	Example: Configuring Link and Voice Services Interfaces with a Combination of Bundle Types	806
Part 14	Flow Monitoring and Flow Collection Services	
Chapter 55	Monitoring Traffic Using Active Flow Monitoring	815
	Active Flow Monitoring Overview	815
	Configuring Flow Monitoring	818
	Configuring Flow-Monitoring Interfaces	818
	Configuring Flow-Monitoring Properties	820
	Directing Traffic to Flow-Monitoring Interfaces	820
	Exporting Flows	821
	Configuring Time Periods when Flow Monitoring is Active and Inactive	821

	Example: Configuring Flow Monitoring	822
	Example: Configuring Active Monitoring on Logical Systems	823
	Configuring Services Interface Redundancy with Flow Monitoring	826
	Flow Offloading	827
Chapter 56	Monitoring Traffic Using Passive Flow Monitoring	829
	Passive Flow Monitoring Overview	829
	Enabling Passive Flow Monitoring	830
	Passive Flow Monitoring for MPLS Encapsulated Packets	832
	Removing MPLS Labels from Incoming Packets	833
	Example: Enabling IPv4 Passive Flow Monitoring	834
	Example: Enabling IPv6 Passive Flow Monitoring	836
Chapter 57	Processing and Exporting Multiple Records Using Flow Collection	839
	Flow Collection Overview	839
	Configuring Flow Collection	840
	Configuring Destination FTP Servers for Flow Records	840
	Configuring a Packet Analyzer	841
	Configuring File Formats	841
	Configuring Interface Mappings	842
	Configuring Transfer Logs	842
	Configuring Retry Attempts	843
	Sending cflowd Records to Flow Collector Interfaces	843
	Configuring Flow Collection Mode and Interfaces on Services PICs	844
Part 15	Flow Capture Services	
Chapter 58	Dynamically Capturing Packet Flows Using Junos Capture Vision	847
	Understanding Junos Capture Vision	847
	Junos Capture Vision Architecture	847
	Liberal Sequence Windowing	848
	Intercepting IPv6 Flows	849
	Configuring Junos Capture Vision	849
	Configuring the Capture Group	849
	Configuring the Content Destination	850
	Configuring the Control Source	851
	Configuring the DFC PIC Interface	852
	Configuring the Firewall Filter	853
	Configuring System Logging	853
	Configuring Tracing Options for Junos Capture Vision Events	854
	Configuring Thresholds	854
	Limiting the Number of Duplicates of a Packet	855
	Example: Configuring Junos Capture Vision	855
Chapter 59	Detecting Threats and Intercepting Flows Using Junos Packet Vision	859
	Understanding Junos Packet Vision	859
	Junos Packet Vision Architecture	860
	Configuring Junos Packet Vision	861
	Configuring the Junos Packet Vision Interface	861
	Strengthening Junos Packet Vision Security	862

	Restrictions on Junos Packet Vision Services	863
	Configuring FlowTapLite	864
	Examples: Configuring Junos Packet Vision	865
Part 16	Sampling, Discard Accounting, and Port Mirroring Services	
Chapter 60	Sampling Data Using Traffic Sampling and Discard Accounting	871
	Configuring Traffic Sampling	871
	Configuring Firewall Filter for Traffic Sampling	871
	Configuring Traffic Sampling on a Logical Interface	873
	Disabling Traffic Sampling	874
	Sampling Once	874
	Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets	875
	Configuring Traffic Sampling Output	876
	Traffic Sampling Output Format	877
	Tracing Traffic Sampling Operations	878
	Traffic Sampling Examples	878
	Example: Sampling a Single SONET/SDH Interface	878
	Example: Sampling All Traffic from a Single IP Address	879
	Example: Sampling All FTP Traffic	880
	Sampling Instance Configuration	881
	Configuring Discard Accounting	883
Chapter 61	Sampling Data Using Inline Sampling	885
	Understanding Inline Active Flow Monitoring	885
	Inline Active Flow Monitoring	885
	Inline Active Flow Monitoring Limitations and Restrictions	886
	IPFIX and Version 9 Templates	887
	Fields Included in the IPFIX IPv4 Template	888
	Fields Included in the IPFIX IPv6 Template	888
	Fields Included in the Version 9 IPv4 Template	889
	Configuring Inline Active flow Monitoring	890
	Configuring Inline Active Flow Monitoring on MX80 Routers	894
Chapter 62	Sampling Data Using Flow Aggregation	897
	Understanding Flow Aggregation	897
	Enabling Flow Aggregation	898
	Configuring Flow Aggregation to Use Version 5 or Version 8 cflowd	898
	Configuring Flow Aggregation to Use Version 9 Flow Templates	902
	Configuring the Traffic to Be Sampled	903
	Configuring the Version 9 Template Properties	904
	Customizing Template ID, Observation Domain ID, and Source ID for Version 9 flow Templates	905
	Restrictions	906
	Fields Included in Each Template Type	906
	MPLS Sampling Behavior	908
	Verification	908
	Examples: Configuring Version 9 Flow Templates	909

	Configuring Flow Aggregation to Use IPFIX Flow Templates	912
	Configuring the IPFIX Template Properties	913
	Restrictions	914
	Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates	914
	Fields Included in the IPv4 Template	915
	Fields Included in the IPv6 Template	916
	Verification	916
	Example: Configuring an IPFIX Flow Templates and Flow Sampling	917
	Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows	918
	Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows	921
	Directing Replicated Flows to Multiple Flow Servers	926
	Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers	926
	Directing Replicated Version 9 Flow Aggregates to Multiple Servers	927
	Logging cflowd Flows Before Export	928
Chapter 63	Sending Packets for Analysis Using Port Mirroring	931
	Understanding Port Mirroring	931
	Configuring Port Mirroring	931
	Configuring Tunnels	934
	Port Mirroring with Next-Hop Groups	936
	Configuring Inline Port Mirroring	937
	Filter-Based Forwarding with Multiple Monitoring Interfaces	938
	Restrictions	938
	Configuring Port Mirroring on Services Interfaces	939
	Examples: Configuring Port Mirroring	940
	Defining a Next-Hop Group for Port Mirroring	948
	Example: Multiple Port Mirroring with Next-Hop Groups Configuration	949
Part 17	Real-Time Performance Monitoring and Video Monitoring Services	
Chapter 64	Monitoring Traffic Using Real-Time Performance Monitoring	957
	Real-Time Performance Monitoring Services Overview	957
	Configuring RPM Probes	959
	Configuring RPM Receiver Servers	963
	Limiting the Number of Concurrent RPM Probes	964
	Configuring RPM Timestamping	964
	Configuring TWAMP	968
	Configuring TWAMP Interfaces	969
	Configuring TWAMP Servers	969
	Configuring BGP Neighbor Discovery Through RPM	971
	Examples: Configuring BGP Neighbor Discovery Through RPM	973
	Tracing RPM Operations	975
	Configuring the RPM Log File Name	975
	Configuring the Number and Size of RPM Log Files	975
	Configuring Access to the Log File	976

	Configuring a Regular Expression for Lines to Be Logged	976
	Configuring the Trace Operations	976
	Examples: Configuring Real-Time Performance Monitoring	977
	Enabling RPM for the Junos OS extension-provider package	981
Chapter 65	Testing the Performance of Network Devices Using RFC 2544-Based Benchmarking	983
	RFC2544-Based Benchmarking Tests Overview	983
	Layer 2 RFC2544-Based Benchmarking Tests Overview	986
	Supported RFC2544-Based Benchmarking Statements on MX104 Routers	988
	Configuring an RFC 2544-Based Benchmarking Test	989
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a IPv4 Network	989
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for an Ethernet Pseudowire	991
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a Layer 2 E-LAN Service in Bridge Domain	992
	Example: Configuring an RFC 2544-Based Benchmarking Test for Layer 3 IPv4 Services	993
	Example: Configuring an RFC 2544-Based Benchmarking Test for UNI Direction of Ethernet Pseudowires	1001
	Example: Configuring an RFC 2544-Based Benchmarking Test for NNI Direction of Ethernet Pseudowires	1008
	Example: Configuring RFC2544-Based Benchmarking Tests for Layer 2 E-LAN Services in Bridge Domains	1016
Chapter 66	Tracking Streaming Media Traffic Using Inline Video Monitoring	1043
	Inline Video Monitoring Overview	1043
	Configuring Inline Video Monitoring	1045
	Configuring Media Delivery Indexing Criteria	1045
	Configuring Interface Flow Criteria	1047
	Inline Video Monitoring Syslog Messages	1047
Part 18	Sampling, Discard Accounting, and Port Mirroring Services	
Chapter 67	Sampling Data Using Traffic Sampling and Discard Accounting	1051
	Configuring Traffic Sampling	1051
	Configuring Firewall Filter for Traffic Sampling	1051
	Configuring Traffic Sampling on a Logical Interface	1053
	Disabling Traffic Sampling	1054
	Sampling Once	1054
	Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets	1055
	Configuring Traffic Sampling Output	1056
	Traffic Sampling Output Format	1057
	Tracing Traffic Sampling Operations	1058
	Traffic Sampling Examples	1058
	Example: Sampling a Single SONET/SDH Interface	1058
	Example: Sampling All Traffic from a Single IP Address	1059

	Example: Sampling All FTP Traffic	1060
	Sampling Instance Configuration	1061
	Configuring Discard Accounting	1063
Chapter 68	Sampling Data Using Inline Sampling	1065
	Understanding Inline Active Flow Monitoring	1065
	Inline Active Flow Monitoring	1065
	Inline Active Flow Monitoring Limitations and Restrictions	1066
	IPFIX and Version 9 Templates	1067
	Fields Included in the IPFIX IPv4 Template	1068
	Fields Included in the IPFIX IPv6 Template	1068
	Fields Included in the Version 9 IPv4 Template	1069
	Configuring Inline Active flow Monitoring	1070
	Configuring Inline Active Flow Monitoring on MX80 Routers	1074
Chapter 69	Sampling Data Using Flow Aggregation	1077
	Understanding Flow Aggregation	1077
	Enabling Flow Aggregation	1078
	Configuring Flow Aggregation to Use Version 5 or Version 8 cflowd	1078
	Configuring Flow Aggregation to Use Version 9 Flow Templates	1082
	Configuring the Traffic to Be Sampled	1083
	Configuring the Version 9 Template Properties	1084
	Customizing Template ID, Observation Domain ID, and Source ID for Version 9 flow Templates	1085
	Restrictions	1086
	Fields Included in Each Template Type	1086
	MPLS Sampling Behavior	1088
	Verification	1088
	Examples: Configuring Version 9 Flow Templates	1089
	Configuring Flow Aggregation to Use IPFIX Flow Templates	1092
	Configuring the IPFIX Template Properties	1093
	Restrictions	1094
	Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates	1094
	Fields Included in the IPv4 Template	1095
	Fields Included in the IPv6 Template	1096
	Verification	1096
	Example: Configuring an IPFIX Flow Templates and Flow Sampling	1097
	Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows	1098
	Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows	1101
	Directing Replicated Flows to Multiple Flow Servers	1106
	Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers	1106
	Directing Replicated Version 9 Flow Aggregates to Multiple Servers	1107
	Logging cflowd Flows Before Export	1108

Chapter 70	Sending Packets for Analysis Using Port Mirroring	1111
	Understanding Port Mirroring	1111
	Configuring Port Mirroring	1111
	Configuring Tunnels	1114
	Port Mirroring with Next-Hop Groups	1116
	Configuring Inline Port Mirroring	1117
	Filter-Based Forwarding with Multiple Monitoring Interfaces	1118
	Restrictions	1118
	Configuring Port Mirroring on Services Interfaces	1119
	Examples: Configuring Port Mirroring	1120
	Example: Multiple Port Mirroring with Next-Hop Groups Configuration	1128
 Part 19	 Real-Time Performance Monitoring and Video Monitoring Services	
 Chapter 71	 Monitoring Traffic Using Real-Time Performance Monitoring	 1135
	Real-Time Performance Monitoring Services Overview	1135
	Configuring RPM Probes	1137
	Configuring RPM Receiver Servers	1141
	Limiting the Number of Concurrent RPM Probes	1142
	Configuring RPM Timestamping	1142
	Configuring TWAMP	1146
	Configuring TWAMP Interfaces	1147
	Configuring TWAMP Servers	1147
	Configuring BGP Neighbor Discovery Through RPM	1149
	Examples: Configuring BGP Neighbor Discovery Through RPM	1151
	Tracing RPM Operations	1153
	Configuring the RPM Log File Name	1153
	Configuring the Number and Size of RPM Log Files	1153
	Configuring Access to the Log File	1154
	Configuring a Regular Expression for Lines to Be Logged	1154
	Configuring the Trace Operations	1154
	Examples: Configuring Real-Time Performance Monitoring	1155
	Enabling RPM for the Junos OS extension-provider package	1159
 Chapter 72	 Testing the Performance of Network Devices Using RFC 2544-Based Benchmarking	 1161
	RFC2544-Based Benchmarking Tests Overview	1161
	Configuring an RFC 2544-Based Benchmarking Test	1163
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a IPv4 Network	1164
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for an Ethernet Pseudowire	1165
	Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a Layer 2 E-LAN Service in Bridge Domain	1167
	Example: Configuring an RFC 2544-Based Benchmarking Test for Layer 3 IPv4 Services	1168
	Example: Configuring an RFC 2544-Based Benchmarking Test for UNI Direction of Ethernet Pseudowires	1175

	Example: Configuring an RFC 2544-Based Benchmarking Test for NNI Direction of Ethernet Pseudowires	1183
Chapter 73	Tracking Streaming Media Traffic Using Inline Video Monitoring	1191
	Inline Video Monitoring Overview	1191
	Configuring Inline Video Monitoring	1193
	Configuring Media Delivery Indexing Criteria	1193
	Configuring Interface Flow Criteria	1195
	Inline Video Monitoring Syslog Messages	1195
Part 20	Tunnel Services	
Chapter 74	Overview	1199
	Tunnel Services Overview	1199
	Configuring Tunnel Interfaces on MX Series Routers	1202
	Configuring Tunnel Interfaces on T4000 Routers	1203
Chapter 75	Encapsulating One Protocol Over Another Using GRE Interfaces	1205
	GRE Keepalive Time Overview	1205
	Configuring GRE Keepalive Time	1205
	Configuring Keepalive Time and Hold time for a GRE Tunnel Interface	1206
	Display GRE Keepalive Time Configuration	1206
	Display Keepalive Time Information on a GRE Tunnel Interface	1207
	Enabling Fragmentation on GRE Tunnels	1208
Chapter 76	Encapsulating One IP Packet Over Another Using IP-IP Interfaces	1211
	Configuring IPv6-over-IPv4 Tunnels	1211
	Example: Configuring an IPv6-over-IPv4 Tunnel	1211
Chapter 77	Filtering Unicast Packets Through Multicast Tunnel Interfaces	1213
	Configuring Unicast Tunnels	1213
	Configuring a Key Number on GRE Tunnels	1215
	Enabling Fragmentation on GRE Tunnels	1216
	Specifying an MTU Setting for the Tunnel	1216
	Configuring a GRE Tunnel to Copy ToS Bits to the Outer IP Header	1217
	Configuring Packet Reassembly	1217
	Examples: Configuring Unicast Tunnels	1218
	Restricting Tunnels to Multicast Traffic	1219
Chapter 78	Connecting Logical Systems Using Logical Tunnel Interfaces	1221
	Configuring Logical Tunnel Interfaces	1221
	Connecting Logical Systems	1221
	Example: Configuring Logical Tunnels	1222
	Redundant Logical Tunnels Overview	1224
	Redundant Logical Tunnel Configuration	1224
	Redundant Logical Tunnel Failure Detection and Failover	1225
	Configuring Redundant Logical Tunnels	1226
	Example: Configuring Redundant Logical Tunnels	1227
Chapter 79	Understanding Default PIM Tunnel Configurations	1237
	Configuring PIM Tunnels	1237

Chapter 80	Facilitating VRF Table Lookup Using Virtual Loopback Tunnel Interfaces	1239
	Configuring Virtual Loopback Tunnels for VRF Table Lookup	1239
	Configuring Tunnel Interfaces for Routing Table Lookup	1241
	Example: Configuring a Virtual Loopback Tunnel for VRF Table Lookup	1241
	Example: Virtual Routing and Forwarding (VRF) and Service Configuration . . .	1242
Chapter 81	Enabling a VPN to Travel Through a Non-MPLS Network Using Dynamic Tunnels	1245
	Configuring Dynamic Tunnels	1245
Part 21	Encryption Services	
Chapter 82	Overview	1249
	Encryption Overview	1249
	Configuring an ES Tunnel Interface for a Layer 3 VPN	1249
Chapter 83	Sending Encrypted Traffic Through Tunnels	1251
	Configuring Encryption Interfaces	1251
	Specifying the Security Association Name for Encryption Interfaces	1252
	Configuring the MTU for Encryption Interfaces	1252
	Example: Configuring an Encryption Interface	1252
	Configuring Filters for Traffic Transiting the ES PIC	1253
	Traffic Overview	1253
	Configuring the Security Association	1254
	Configuring an Outbound Traffic Filter	1255
	Example: Configuring an Outbound Traffic Filter	1255
	Applying the Outbound Traffic Filter	1256
	Example: Applying the Outbound Traffic Filter	1256
	Configuring an Inbound Traffic Filter	1256
	Example: Configuring an Inbound Traffic Filter	1257
	Applying the Inbound Traffic Filter to the Encryption Interface	1257
	Example: Applying the Inbound Traffic Filter to the Encryption Interface	1257
Chapter 84	Configuring Redundancy in Case of Service Failure	1259
	Configuring ES PIC Redundancy	1259
	Example: Configuring ES PIC Redundancy	1259
	Configuring IPsec Tunnel Redundancy	1260
Part 22	Configuration Statements and Operational Commands	
Chapter 85	Configuration Statements	1265
	General Services Interfaces Configuration Statements	1265
	address (Interfaces)	1266
	applications (Services ALGs)	1267
	applications (Services CoS)	1267
	applications (Services IDS)	1268
	applications (Services NAT)	1268
	applications (Services Stateful Firewall)	1269

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

Supported Platforms

For the features described in this document, the following platforms are supported:

- M Series
- MX Series
- T Series

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see the *CLI User Guide*.

Documentation Conventions

Table 1 on page [lix](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page [lx](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> Introduces or emphasizes important new terms. Identifies guide names. Identifies RFC and Internet draft titles. 	<ul style="list-style-type: none"> A policy <i>term</i> is a named structure that defines match conditions and actions. <i>Junos OS CLI User Guide</i> RFC 1997, <i>BGP Communities Attribute</i>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level. The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric metric>;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (string1 string2 string3)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [community-ids]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

GUI Conventions

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> In the Logical Interfaces box, select All Interfaces. To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page at the Juniper Networks Technical Documentation site at <http://www.juniper.net/techpubs/index.html>, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at <https://www.juniper.net/cgi-bin/docbugreport/>.
- E-mail—Send your comments to techpubs-comments@juniper.net. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or JNASC support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes:
<http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications:
<http://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum:
<http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

PART 1

Services Interfaces Overview

- [Overview on page 3](#)
- [Configuration Overview on page 9](#)

CHAPTER 1

Overview

- [Understanding Services PICs on page 3](#)
- [Multiservices MIC and Multiservices MPC \(MS-MIC and MS-MPC\) Overview on page 5](#)
- [Supported Platforms on page 7](#)

Understanding Services PICs

Interfaces used in router networks can be broadly classified into two:

- Networking interfaces, such as Ethernet and SONET interfaces, that primarily provide traffic connectivity. For more information on these interfaces, see the Junos[®] OS Network Interfaces.
- Services interfaces, such as Adaptive Services interfaces and Multiservices interfaces, that provide specific capabilities for manipulating traffic before it is delivered to its destination.

Services interfaces enable you to add services to your network incrementally. Junos OS supports the following services interfaces:

- [Adaptive services and Multiservices PICs on page 3](#)
- [Encryption Services \(ES\) PIC on page 4](#)
- [Multilink Services and Link Services PICs on page 4](#)
- [Monitoring Services PICs on page 4](#)
- [Tunnel Services PIC on page 5](#)
- [Multiservices MIC and Multiservices MPC on page 5](#)

Adaptive services and Multiservices PICs

Adaptive Services [AS] PICs and Multiservices PICs enable you to perform multiple services on the same PIC by configuring a set of services and applications. The AS and Multiservices PICs offer a range of services that you can configure in one or more service sets. The following are some of the services you can configure on Adaptive services or multiservices interfaces:

- Class-of-service
- Intrusion detection service (IDS)

- IP Security (IPsec)
- Layer 2 tunneling protocols
- Monitoring services
- Network Address Translation (NAT)
- Stateful firewalls
- Voice services

For more information about these services, see [“Adaptive Services Overview” on page 25](#).

NOTE: On Juniper Networks MX Series 3D Universal Edge Routers, the Multiservices DPC provides essentially the same capabilities as the Multiservices PIC. The interfaces on both platforms are configured in the same way.

Encryption Services (ES) PIC

ES PIC provides a security suite for the IP version 4 (IPv4) and IP version 6 (IPv6) network layers. The suite provides functionality such as authentication of origin, data integrity, confidentiality, replay protection, and nonrepudiation of source. It also defines mechanisms for key generation and exchange, management of security associations, and support for digital certificates. For more information about encryption interfaces, see [“Configuring Encryption Interfaces” on page 1251](#).

Multilink Services and Link Services PICs

Multilink Services and Link Services PICs enable you to split, recombine, and sequence datagrams across multiple logical data links. The goal of multilink operation is to coordinate multiple independent links between a fixed pair of systems, providing a virtual link with greater bandwidth than any of the members. The Junos OS supports two services PICs based on the Multilink Protocol: the Multilink Services PIC and the Link Services PIC.

For more information about multilink and link services interfaces, see *Link and Multilink Services Interfaces Feature Guide for Routing Devices*.

Monitoring Services PICs

Monitoring Services PICs enable you to monitor traffic flow and export the monitored traffic. Monitoring traffic allows you to perform the following tasks:

- Gather and export detailed information about IPv4 traffic flows between source and destination nodes in your network.
- Sample all incoming IPv4 traffic on the monitoring interface and present the data in cflowd record format.
- Perform discard accounting on an incoming traffic flow.

- Encrypt or tunnel outgoing cflowd records, intercepted IPv4 traffic, or both.
- Direct filtered traffic to different packet analyzers and present the data in its original format.

For more information about flow monitoring interfaces, see *Monitoring, Sampling, and Collection Services Interfaces Feature Guide for Routing Devices*.

Tunnel Services PIC

Tunnel Services PIC provides a private, secure path through an otherwise public network by encapsulating arbitrary packets inside a transport protocol. Tunnels connect discontinuous subnetworks and enable encryption interfaces, virtual private networks (VPNs), and MPLS.

For more information about tunnel interfaces, see *Tunnel Properties*.

Multiservices MIC and Multiservices MPC

The Multiservices Modular Interfaces Card (MS-MIC) and the Multiservices Modular PIC Concentrator (MS-MPC), introduced in Junos OS Release 13.2, provide improved scaling and high performance. The MS-MIC and MS-MPC have enhanced memory (16 GB for MS-MIC, 32 GB per NPU of MS-MPC) and processing capabilities.

The services interfaces on MS-MPC and MS-MIC are identified in the configuration with an **ms-** prefix (for example, **ms-1/2/1**).

The following services packages come preinstalled and preconfigured on MS-MICs and MS-MPCs in Junos OS Release 13.2:

- Junos Traffic Vision (formerly referred to as Jflow/Flow Monitoring)
- Junos Address Aware (formerly referred to as NAT features)
- Junos VPN Site Secure (formerly referred to as IPsec features)
- Junos Network Secure (formerly referred to as the Stateful Firewall feature)

For information about MS-MIC and MS-MPC, see “[Multiservices MIC and Multiservices MPC \(MS-MIC and MS-MPC\) Overview](#)” on page 5.

Related Documentation

- [Packet Flow Through the Adaptive Services or Multiservices PIC on page 27](#)
- [Enabling Service Packages on page 11](#)
- [Services Configuration Procedure on page 15](#)
- [Services Interface Naming Overview on page 9](#)

Multiservices MIC and Multiservices MPC (MS-MIC and MS-MPC) Overview

Juniper Networks supports the Multiservices Modular Interfaces Card (MS-MIC) and the Multiservices Modular PIC Concentrator (MS-MPC) that provide improved scaling and

high performance. The MS-MIC and MS-MPC have enhanced memory (16 GB for MS-MIC, 32 GB per NPU of MS-MPC) and processing capabilities.

The services interfaces on MS-MPC and MS-MIC are identified in the configuration with an **ms-** prefix (for example, **ms-1/2/1**). The following services packages come preinstalled and preconfigured on MS-MICs and MS-MPCs:

- Junos Traffic Vision (formerly referred to as Jflow)
- Junos Address Aware (formerly referred to as NAT features)
- Junos VPN Site Secure (formerly referred to as IPsec features)
- Junos Network Secure (formerly referred to as the Stateful Firewall feature)
- Junos Services Crypto Base PIC Package
- Junos Services Application Level Gateways

NOTE: You can check the default packages on an MS-MIC or MS-MPC by executing the **show extension-provider system packages interface ms-interace** operational mode command.

The MS-MIC and MS-MPC also support the captive portal content delivery (HTTP redirect) service package when configured for installation using the **set chassis** operational mode command.

Table 3 on page 6 lists the platforms on which the MS-MIC and MS-MPC are supported.

Table 3: MX Series Routers that Support MS-MIC and MS-MPC

	MX5	MX10	MX40	MX80	MX240	MX480	MX960	MX2010	MX2020
MS-MIC	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
NOTE: Only Junos Traffic Vision is supported.									
MS-MPC	No	No	No	No	Yes	Yes	Yes	No	No

You can install an MS-MIC on one of the following line cards:

- MPC-Type1
- MPC-Type2

Services Interface Naming Overview

Each interface has an interface name, which specifies the media type, the slot the FPC is located in, the location on the FPC that the PIC is installed in, and the PIC port. The interface name uniquely identifies an individual network connector in the system. You use the interface name when configuring interfaces and when enabling various functions and properties, such as routing protocols, on individual interfaces. The system uses the interface name when displaying information about the interface, for example, in the **show interfaces** command.

The interface name is represented by a physical part, a logical part, and a channel part in the following format:

physical<:channel>.logical

The channel part of the name is optional for all interfaces except channelized DS3, E1, OC12, and STM1 interfaces.

The physical part of an interface name identifies the physical device, which corresponds to a single physical network connector. This part of the interface name has the following format:

type-fpc/pic/port

type is the media type, which identifies the network device. For service interfaces, it can be one of the following:

- **ams**—Aggregated multiservices (AMS) interface. An AMS interface is a bundle of services interfaces that can function as a single interface. An AMS interface is denoted as **amsN** in the configuration, where **N** is a unique number that identifies an AMS interface (for example, **ams0**). The member interfaces in an AMS interface are identified in the configuration with an **mams-** prefix (for example, **mams-1/2/0**).
- **cp**—Flow collector interface.
- **es**—Encryption interface.
- **gr**—Generic routing encapsulation tunnel interface.
- **gre**—This interface is internally generated and not configurable.
- **ip**—IP-over-IP encapsulation tunnel interface.
- **ipip**—This interface is internally generated and not configurable.
- **ls**—Link services interface.
- **lsq**—Link services intelligent queuing (IQ) interface; also used for voice services.
- **mams**—Member interface in an AMS interface.
- **ml**—Multilink interface.
- **mo**—Monitoring services interface. The logical interface **mo-fpc/pic/port.16383** is an internally generated, nonconfigurable interface for router control traffic.
- **ms**—Multiservices interfaces on multiservices modular interfaces card (MS-MIC) and multiservices modular port concentrators (MS-MPC).
- **mt**—Multicast tunnel interface. This interface is automatically generated, but you can configure properties on it if needed.
- **mtun**—This interface is internally generated and not configurable.
- **rlsq**—Redundancy LSQ interface.
- **rsp**—Redundancy adaptive services interface.
- **si**—Services inline interface, configured on MX3D Series routers only.
- **sp**—Adaptive services interface. The logical interface **sp-fpc/pic/port.16383** is an internally generated, nonconfigurable interface for router control traffic.
- **tap**—This interface is internally generated and not configurable.
- **vt**—Virtual loopback tunnel interface.

Enabling Service Packages

For AS PICs, Multiservices PICs, Multiservices DPCs, and the internal Adaptive Services Module (ASM) in the M7i router, there are two service packages: Layer 2 and Layer 3. Both service packages are supported on all adaptive services interfaces, but you can enable only one service package per PIC, with the exception of a combined package supported on the ASM. On a single router, you can enable both service packages by installing two or more PICs on the platform.

NOTE: Graceful Routing Engine switchover (GRES) is automatically enabled on all services PICs and DPCs except the ES PIC. It is supported on all M Series, MX Series, and T Series routers except for TX Matrix routers. Layer 3 services should retain state after switchover, but Layer 2 services will restart. For IPsec services, Internet Key Exchange (IKE) negotiations are not stored and must be restarted after switchover. For more information about GRES, see the *Junos OS High Availability Library for Routing Devices*.

You enable service packages per PIC, not per port. For example, if you configure the Layer 2 service package, the entire PIC uses the configured package. To enable a service package, include the service-package statement at the `[edit chassis fpc slot-number pic pic-number adaptive-services]` hierarchy level, and specify `layer-2` or `layer-3`:

```
[edit chassis fpc slot-number pic pic-number adaptive-services]
service-package (layer-2 | layer-3);
```

To determine which package an AS PIC supports, issue the `show chassis hardware` command: if the PIC supports the Layer 2 package, it is listed as **Link Services II**, and if it supports the Layer 3 package, it is listed as **Adaptive Services II**. To determine which package a Multiservices PIC supports, issue the `show chassis pic fpc-slot slot-number pic-slot slot-number` command. The **Package** field displays the value **Layer-2** or **Layer-3**.

NOTE: The ASM has a default option (`layer-2-3`) that combines the features available in the Layer 2 and Layer 3 service packages.

After you commit a change in the service package, the PIC is taken offline and then brought back online immediately. You do not need to manually take the PIC offline and online.

NOTE: Changing the service package causes all state information associated with the previous service package to be lost. You should change the service package only when there is no active traffic going to the PIC.

The services supported in each package differ by PIC and platform type. [Table 4 on page 12](#) lists the services supported within each service package for each PIC and platform.

On the AS and Multiservices PICs, *link services* support includes Junos OS CoS components, LFI (FRF.12), MLFR end-to-end (FRF.15), MLFR UNI NNI (FRF.16), MLPPP (RFC 1990), and multiclass MLPPP. For more information, see “[Layer 2 Service Package Capabilities and Interfaces](#)” on page 14 and “[Layer 2 Service Package Capabilities and Interfaces](#)” on page 543.

NOTE: The AS PIC II for Layer 2 Service is dedicated to supporting the Layer 2 service package only.

For additional information about Layer 3 services, see the *Junos OS, Release 14.2*.

Table 4: AS and Multiservices PIC Services by Service Package, PIC, and Platform

Services	ASM	AS/AS2 PICs and Multiservices PICs	AS/AS2 and Multiservices PICs	AS2 and Multiservices PICs	AS2 and Multiservices PICs

• Logical tunnels (<i>lt-fpc/pic/port</i>)	No	No	No	No	No
• Multicast tunnels (<i>mt-fpc/pic/port</i>)	Yes	Yes	Yes	Yes	Yes
• PIM de-encapsulation (<i>pd-fpc/pic/port</i>)	Yes	Yes	Yes	Yes	Yes

Table 4: AS and Multiservices PIC Services by Service Package, PIC, and Platform (*continued*)

Services	ASM	AS/AS2 PICs and Multiservices PICs	AS/AS2 and Multiservices PICs	AS2 and Multiservices PICs	AS2 and Multiservices PICs
• PIM encapsulation (pe-fpc/pic/port)	Yes	Yes	Yes	Yes	Yes
• Virtual tunnels (vt-fpc/pic/port)	Yes	Yes	Yes	Yes	Yes

Layer 2 Service Package Capabilities and Interfaces

When you enable the Layer 2 service package, you can configure link services. On the AS and Multiservices PICs and the ASM, link services include support for the following:

- Junos CoS components—“[Layer 2 Service Package Capabilities and Interfaces](#)” on [page 543](#) describes how the Junos CoS components work on link services IQ (**lsq**) interfaces. For detailed information about Junos CoS components, see the *Class of Service Feature Guide for Routing Devices*.
- LFI on Frame Relay links using FRF.12 end-to-end fragmentation—The standard for FRF.12 is defined in the specification FRF.12, *Frame Relay Fragmentation Implementation Agreement*.
- LFI on MLPPP links.
- MLFR UNI NNI (FRF.16)—The standard for FRF.16 is defined in the specification FRF.16.1, *Multilink Frame Relay UNI/NNI Implementation Agreement*.
- MLPPP (RFC 1990)
- MLFR end-to-end (FRF.15)

For the LSQ interface on the AS and Multiservices PICs, the configuration syntax is almost the same as for Multilink and Link Services PICs. The primary difference is the use of the interface-type descriptor **lsq** instead of **ml** or **ls**. When you enable the Layer 2 service package, the following interfaces are automatically created:

```
gr-fpc/pic/port
ip-fpc/pic/port
lsq-fpc/pic/port
lsq-fpc/pic/port:0
...
lsq-fpc/pic/port:N
mt-fpc/pic/port
pd-fpc/pic/port
pe-fpc/pic/port
sp-fpc/pic/port
vt-fpc/pic/port
```

Interface types **gr**, **ip**, **mt**, **pd**, **pe**, and **vt** are standard tunnel interfaces that are available on the AS and Multiservices PICs whether you enable the Layer 2 or the Layer 3 service package. These tunnel interfaces function the same way for both service packages,

except that the Layer 2 service package does not support some tunnel functions, as shown in [Table 4 on page 12](#).

Interface type `lsq-fpc/pic/port` is the physical link services IQ (`lsq`) interface. Interface types `lsq-fpc/pic/port:0` through `lsq-fpc/pic/port:N` represent FRF.16 bundles. These interface types are created when you include the `mlfr-uni-nni-bundles` statement at the `[edit chassis fpc slot-number pic pic-number]` option. For more information, see “[Layer 2 Service Package Capabilities and Interfaces](#)” on page 543 and *Link and Multilink Services Interfaces Feature Guide for Routing Devices*.

NOTE: Interface type `sp` is created because it is needed by the Junos OS. For the Layer 2 service package, the `sp` interface is not configurable, but you should not disable it.

Services Configuration Procedure

You follow these general steps to configure services:

1. Define application objects by configuring statements at the `[edit applications]` hierarchy level.
2. Define service rules by configuring statements at the `[edit services (ids | ipsec-vpn | nat | stateful-firewall) rule]` hierarchy level.
3. Group the service rules by configuring the `rule-set` statement at the `[edit services (ids | ipsec-vpn | nat | stateful-firewall)]` hierarchy level.
4. Group service rule sets under a service-set definition by configuring the `service-set` statement at the `[edit services]` hierarchy level.
5. Apply the service set on an interface by including the `service-set` statement at the `[edit interfaces interface-name unit logical-unit-number family inet service (input | output)]` hierarchy level. Alternatively, you can configure logical interfaces as a next-hop destination by including the `next-hop-service` statement at the `[edit services service-set service-set-name]` hierarchy level.

NOTE: You can configure IDS, NAT, and stateful firewall service rules within the same service set. You must configure IPsec services in a separate service set, although you can apply both service sets to the same PIC.

Example: Service Interfaces Configuration

The following configuration includes all the items necessary to configure services on an interface.

```
[edit]
interfaces {
  fe-0/1/0 {
    unit 0 {
      family inet {
        service {
          input {
            service-set Firewall-Set;
          }
          output {
            service-set Firewall-Set;
          }
        }
        address 10.1.3.2/24;
      }
    }
  }
  fe-0/1/1 {
    unit 0 {
      family inet {
        filter {
          input Sample;
        }
        address 172.16.1.2/24;
      }
    }
  }
  sp-1/0/0 {
    unit 0 {
      family inet {
        address 172.16.1.3/24 {
        }
      }
    }
  }
}
forwarding-options {
  sampling {
    input {
      family inet {
        rate 1;
      }
    }
  }
}
```

```
output {
  cflowd 10.1.3.1 {
    port 2055;
    version 5;
  }
  flow-inactive-timeout 15;
  flow-active-timeout 60;
  interface sp-1/0/0 {
    engine-id 1;
    engine-type 136;
    source-address 10.1.3.2;
  }
}
}
}
firewall {
  filter Sample {
    term Sample {
      then {
        count Sample;
        sample;
        accept;
      }
    }
  }
}
}
services {
  stateful-firewall {
    rule Rule1 {
      match-direction input;
      term 1 {
        from {
          application-sets Applications;
        }
        then {
          accept;
        }
      }
    }
    term accept {
      then {
        accept;
      }
    }
  }
  rule Rule2 {
    match-direction output;
    term Local {
      from {
        source-address {
          10.1.3.2/32;
        }
      }
      then {
        accept;
      }
    }
  }
}
```

```
    }
  }
  ids {
    rule Attacks {
      match-direction output;
      term Match {
        from {
          application-sets Applications;
        }
        then {
          logging {
            syslog;
          }
        }
      }
    }
  }
}
nat {
  pool public {
    address-range low 172.16.2.1 high 172.16.2.32;
    port automatic;
  }
  rule Private-Public {
    match-direction input;
    term Translate {
      then {
        translated {
          source-pool public;
          translation-type source napt-44;
        }
      }
    }
  }
}
service-set Firewall-Set {
  stateful-firewall-rules Rule1;
  stateful-firewall-rules Rule2;
  nat-rules Private-Public;
  ids-rules Attacks;
  interface-service {
    service-interface sp-1/0/0;
  }
}
applications {
  application ICMP {
    application-protocol icmp;
  }
  application FTP {
    application-protocol ftp;
    destination-port ftp;
  }
  application-set Applications {
    application ICMP;
    application FTP;
  }
}
```

```
}
```

Configuring Default Timeout Settings for Services Interfaces

You can specify global default settings for certain timers that apply for the entire interface. There are three statements of this type:

- **inactivity-timeout**—Sets the inactivity timeout period for established flows, after which they are no longer valid.
- **open-timeout**—Sets the timeout period for Transmission Control Protocol (TCP) session establishment, for use with SYN-cookie defenses against network intrusion.
- **close-timeout**—Sets the timeout period for Transmission Control Protocol (TCP) session tear-down.

To configure a setting for the inactivity timeout period, include the **inactivity-timeout** statement at the **[edit interfaces *interface-name* services-options]** hierarchy level:

```
[edit interfaces interface-name services-options]
  inactivity-timeout seconds;
```

The default value is 30 seconds. The range of possible values is from 4 through 86,400 seconds. Any value you configure in the application protocol definition overrides the value specified here; for more information, see [“Configuring Application Protocol Properties” on page 303](#).

To configure a setting for the TCP session establishment timeout period, include the **open-timeout** statement at the **[edit interfaces *interface-name* services-options]** hierarchy level:

```
[edit interfaces interface-name services-options]
  open-timeout seconds;
```

The default value is 5 seconds. The range of possible values is from 4 through 224 seconds. Any value you configure in the intrusion detection service (IDS) definition overrides the value specified here; for more information, see [Intrusion Detection Properties](#).

To configure a setting for the TCP session teardown timeout period, include the **close-timeout** statement at the **[edit interfaces *interface-name* services-options]** hierarchy level:

```
[edit interfaces interface-name services-options]
  close-timeout seconds;
```

The default value is 1 second. The range of possible values is from 2 through 300 seconds.

Use of Keep-Alive Messages for Greater Control of TCP Inactivity Timeouts

Keep-alive messages are generated automatically to prevent TCP inactivity timeouts. The default number of keep-alive messages is 4. However, you can configure the number of keep-alive messages by entering the **tcp-tickles** statement at the **[edit interfaces *interface-name* service-options]** hierarchy level.

When timeout is generated for a bidirectional TCP flow, keep-alive packets are sent to reset the timer. If number of consecutive keep-alive packets sent in a flow reaches the default or configured limit, the conversation is deleted. There are several possible scenarios, depending on the setting of the **inactivity-timer** and the default or configured maximum number of keep-alive messages.

- If the configured value of keep-alive messages is zero and **inactivity-timeout** is NOT configured (in which case the default timeout value of 30 is used), no keep-alive packets are sent. The conversation is deleted when any flow in the conversation is idle for more than 30 seconds.
- If the configured value of keep-alive messages is zero and the **inactivity-timeout** is configured, no keep-alive packets are sent, and the conversation is deleted when any flow in the conversation is idle for more than the configured timeout value.
- If the default or configured maximum number of keep-alive messages is some positive integer, and any of the flows in a conversation is idle for more than the default or configured value for **inactivity-timeout** keep-alive packets are sent. If hosts do not respond to the configured number of consecutive keep-alive packets, the conversation is deleted. The interval between keep-alive packets will be 1 second. However, if the host sends back an ACK packet, the corresponding flow becomes active, and keep-alive packets are not sent until the flow becomes idle again.

- [Configuring System Logging for Services Interfaces on page 20](#)
- [Applying Filters and Services to Interfaces on page 38](#)
- [Examples: Configuring Services Interfaces on page 44](#)

Configuring System Logging for Services Interfaces

You specify properties that control how system log messages are generated for the interface as a whole. If you configure different values for the same properties at the **[edit services service-set service-set-name]** hierarchy level, the service-set values override the values configured for the interface. For more information on configuring service-set properties, see [“Configuring System Logging for Service Sets” on page 47](#).

To configure interface-wide default system logging values, include the **syslog** statement at the **[edit interfaces interface-name services-options]** hierarchy level:

```
[edit interfaces interface-name services-options]
syslog {
  host hostname {
    services severity-level;
    facility-override facility-name;
    log-prefix prefix-value;
    port port-number;
  }
}
```

Configure the **host** statement with a hostname or an IP address that specifies the system log target server. The hostname **local** directs system log messages to the Routing Engine. For external system log servers, the hostname must be reachable from the same routing instance to which the initial data packet (that triggered session establishment) is delivered. You can specify only one system logging hostname.

Table 5 on page 21 lists the severity levels that you can specify in configuration statements at the **[edit interfaces *interface-name* services-options syslog host *hostname*]** hierarchy level. The levels from **emergency** through **info** are in order from highest severity (greatest effect on functioning) to lowest.

Table 5: System Log Message Severity Levels

Severity Level	Description
any	Includes all severity levels
emergency	System panic or other condition that causes the router to stop functioning
alert	Conditions that require immediate correction, such as a corrupted system database
critical	Critical conditions, such as hard drive errors
error	Error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels
warning	Conditions that warrant monitoring
notice	Conditions that are not errors but might warrant special handling
info	Events or nonerror conditions of interest

We recommend setting the system logging severity level to **error** during normal operation. To monitor PIC resource usage, set the level to **warning**. To gather information about an intrusion attack when an intrusion detection system error is detected, set the level to **notice** for a specific interface. To debug a configuration or log Network Address Translation (NAT) functionality, set the level to **info**.

For more information about system log messages, see the *Junos OS System Log Messages Reference*.

To use one particular facility code for all logging to the specified system log host, include the **facility-override** statement at the **[edit interfaces *interface-name* services-options syslog host *hostname*]** hierarchy level:

```
[edit interfaces interface-name services-options]
  facility-override facility-name;
```

The supported facilities include **authorization**, **daemon**, **ftp**, **kernel**, **user**, and **local0** through **local7**.

To specify a text prefix for all logging to this system log host, include the **log-prefix** statement at the **[edit interfaces *interface-name* services-options syslog host *hostname*]** hierarchy level:

```
[edit interfaces interface-name services-options]  
log-prefix prefix-value;
```

Adaptive Services Overview

MultiServices PICs and MultiServices Dense Port Concentrators (MS-DPCs) provide *adaptive services interfaces*, which allow you to coordinate multiple services on a single PIC by configuring a set of services and applications. MultiServices PICs and MS-DPCs offer a special range of services you configure in one or more service sets.

The MultiServices PIC is available in three versions, the MultiServices 100, the MultiServices 400, and the MultiServices 500, which differ in memory size and performance. All versions offer enhanced performance in comparison with AS PICs. MultiServices PICs are supported on M Series and T Series routers except M20 routers.

The MultiServices DPC is available for MX Series routers; it includes a subset of the functionality supported on the MultiServices PIC. Currently the MultiServices DPC supports the following Layer 3 services: stateful firewall, NAT, IDS, IPsec, active flow monitoring, RPM, and generic routing encapsulation (GRE) tunnels (including GRE key and fragmentation); it also supports graceful Routing Engine switchover (GRES) and Dynamic Application Awareness for Junos OS. For more information about supported packages, see [“Enabling Service Packages” on page 11](#).

It is also possible to group several Multiservices PICs into an aggregated Multiservices (AMS) system. An AMS configuration eliminates the need for separate routers within a system. The primary benefit of having an AMS configuration is the ability to support load balancing of traffic across multiple services PICs. Starting with Junos OS 11.4, all MX Series routers will support high availability (HA) and Network Address Translation (NAT) on AMS infrastructure. See [“Configuring Load Balancing on AMS Infrastructure” on page 605](#) for more information.

NOTE: The MultiServices PICs are polling based and not interrupt based; as a result, a high value in the `show chassis pic` “Interrupt load average” field may not mean that the PIC has reached its maximum limit of processing.

The following services are configured within a service set and are available only on adaptive services interfaces:

- Stateful firewall—A type of firewall filter that considers state information derived from previous communications and other applications when evaluating traffic.
- Network Address Translation (NAT)—A security procedure for concealing host addresses on a private network behind a pool of public addresses.
- Intrusion detection service (IDS)—A set of tools for detecting, redirecting, and preventing certain kinds of network attack and intrusion.
- IP Security (IPsec)—A set of tools for configuring manual or dynamic security associations (SAs) for encryption of data traffic.
- Class of service (CoS)—A subset of CoS functionality for services interfaces, limited to DiffServ code point (DSCP) marking and forwarding-class assignment. CoS BA classification is not supported on services interfaces.

The configuration for these services comprises a series of rules that you can arrange in order of precedence as a *rule set*. Each rule follows the structure of a firewall filter, with a **from** statement containing input or match conditions and a **then** statement containing actions to be taken if the match conditions are met.

The following services are also configured on the MultiServices PICs and MS-DPCs, but do not use the rule set definition:

- Layer 2 Tunneling Protocol (L2TP)—A tool for setting up secure tunnels using Point-to-Point Protocol (PPP) encapsulation across Layer 2 networks.
- Link Services Intelligent Queuing (LSQ)—Interfaces that support Junos OS class-of-service (CoS) components, link fragmentation and interleaving (LFI) (FRF.12), Multilink Frame Relay (MLFR) user-to-network interface (UNI) network-to-network interface (NNI) (FRF.16), and Multilink PPP (MLPPP).
- Voice services—A feature that uses the Compressed Real-Time Transport Protocol (CRTP) to enable voice over IP traffic to use low-speed links more effectively.

In addition, Junos OS includes the following tools for configuring services:

- Application protocols definition—Allows you to configure properties of application protocols that are subject to processing by router services, and group the application definitions into application sets.
- Service-set definition—Allows you to configure combinations of directional rules and default settings that control the behavior of each service in the service set.

NOTE: Logging of adaptive services interfaces messages to an external server by means of the `fxp0` port is not supported on M Series routers. The architecture does not support system logging traffic out of a management interface. Instead, access to an external server is supported on a Packet Forwarding Engine interface.

Packet Flow Through the Adaptive Services or Multiservices PIC

You can optionally configure service sets to be applied at one of the following three points while the packets transit the router:

- An interface service set applied at the inbound interface.
- A next-hop service set applied at the forwarding table.
- An interface service set applied at the outbound interface.

The packet flow is as follows, graphically displayed in [Figure 1 on page 28](#). (You can configure a service set as either an interface service set or a next-hop service set.)

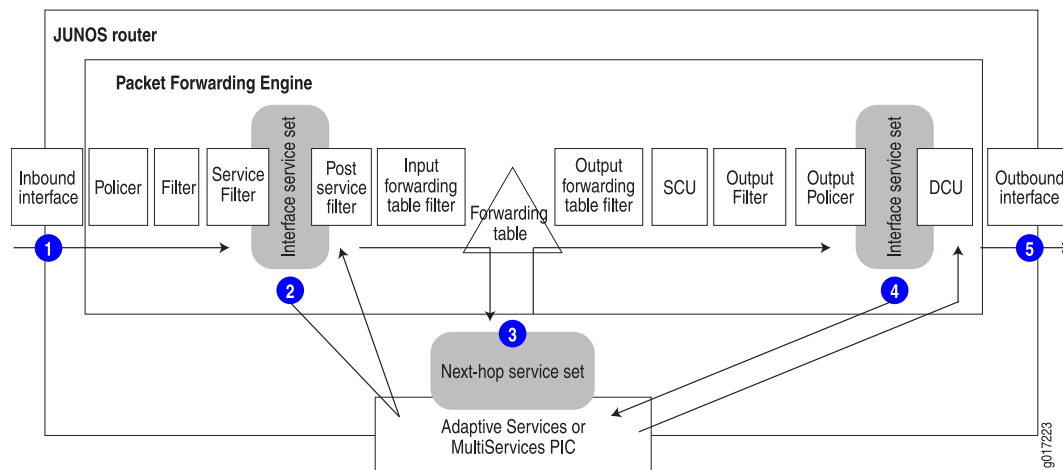

1. Packets enter the router on the inbound interface.
2. A policer, filter, service filter, service set, postservice filter, and input forwarding-table filter are applied sequentially to the traffic; these are all optional items in the configuration. If an interface service set is applied, the packets are forwarded to the AS or MultiServices PIC for services processing and then sent back to the Packet Forwarding Engine; if a service filter is also applied, only packets matching the service filter are sent to the PIC. The optional postservice filter is applied and postprocessing takes place.
3. A next-hop service set can be applied to the VPN routing and forwarding (VRF) table or to **inet.0**. If it is applied, packets are sent to the PIC for services processing and sent back to the Packet Forwarding Engine.

NOTE: For NAT, the next-hop service set can only be applied to the VRF table. For all other services, the next-hop service set can be applied to either the VRF table or to **inet.0**.

4. On the output interface, an output filter, output policer, and interface service set can be applied sequentially to the traffic if you have configured any of these items. If an interface service set is applied, the traffic is forwarded to the PIC for processing and sent back to the Packet Forwarding Engine, which then forwards the traffic.
5. Packets exit the router.

Figure 1: Packet Flow Through the Adaptive Services or MultiServices PIC

NOTE: When an AS PIC experiences persistent back pressure as a result of high traffic volume for 3 seconds, the condition triggers an automatic core dump and reboot of the PIC to help clear the blockage. A system log message at level LOG_ERR is generated. This mechanism applies to both Layer 2 and Layer 3 service packages.

Understanding Service Sets

Junos OS enables you to create service sets that define a collection of services to be performed by an Adaptive Services interface (AS) or Multiservices line cards (MS-DPC, MS-MIC, and MS-MPC). You can configure the service set either as an interface style service set or as a next-hop style service set.

An interface service set is used as an action modifier across an entire interface. You can use an interface style service set when you want to apply services to packets passing through an interface.

A next-hop service set is a route-based method of applying a particular service. Only packets destined for a specific next hop are serviced by the creation of explicit static routes. This configuration is useful when services need to be applied to an entire virtual private network (VPN) routing and forwarding (VRF) table, or when routing decisions determine that services need to be performed. When a next-hop service is configured, the service interface is considered to be a two-legged module with one leg configured to be the inside interface (inside the network) and the other configured as the outside interface (outside the network).

To configure service sets, include the following statements at the **[edit services]** hierarchy level:

```
[edit services]
service-set service-set-name {
  (ids-rules rule-names | ids-rule-sets rule-set-name);
  (ipsec-vpn-rules rule-names | ipsec-vpn-rule-sets rule-set-name);
  (nat-rules rule-names | nat-rule-sets rule-set-name);
  (pgcp-rules rule-names | pgcp-rule-sets rule-set-name);

  allow-multicast;
  extension-service service-name {
    provider-specific rules;
  }
  interface-service {
    service-interface interface-name;
  }
  ipsec-vpn-options {
    anti-replay-window-size bits;
    clear-dont-fragment-bit;
    ike-access-profile profile-name;
    local-gateway address;
    no-anti-replay;
    passive-mode-tunneling;
    trusted-ca [ ca-profile-names ];
    tunnel-mtu bytes;
  }
  max-flows number;
  next-hop-service {
    inside-service-interface interface-name.unit-number;
    outside-service-interface interface-name.unit-number;
    service-interface-pool name;
  }
  syslog {
    host hostname {
      services severity-level;
      facility-override facility-name;
      log-prefix prefix-value;
    }
  }
}
adaptive-services-pics {
  traceoptions {
    file filename <files number> <match regex> <size size> <(world-readable |
      no-world-readable)>;
    flag flag;
  }
}
logging {
  traceoptions {
    file filename <files number> <match regex> <size size> <(world-readable |
      no-world-readable)>;
    flag flag;
  }
}
```

}

Configuring Service Sets to be Applied to Services Interfaces

You configure a services interface to specify the adaptive services interface on which the service is to be performed. Services interfaces are used with either of the service set types described in the following sections.

- [Configuring Interface Service Sets on page 31](#)
- [Configuring Next-Hop Service Sets on page 33](#)
- [Determining Traffic Direction on page 34](#)

Configuring Interface Service Sets

An interface service set is used as an action modifier across an entire interface. To configure the services interface, include the **interface-service** statement at the **[edit services service-set service-set-name]** hierarchy level:

```
[edit services service-set service-set-name]
interface-service {
  service-interface interface-name;
}
```

Only the device name is needed, because the router software manages logical unit numbers automatically. The services interface must be an adaptive services interface for which you have configured **unit 0 family inet** at the **[edit interfaces interface-name]** hierarchy level.

When you have defined and grouped the service rules by configuring the service-set definition, you can apply services to one or more interfaces installed on the router. When you apply the service set to an interface, it automatically ensures that packets are directed to the PIC.

To associate a defined service set with an interface, include a **service-set** statement with the **input** or **output** statement at the **[edit interfaces interface-name unit logical-unit-number family inet service]** hierarchy level:

```
[edit interfaces interface-name unit logical-unit-number family inet service]
input {
```

```
service-set service-set-name <service-filter filter-name>;
post-service-filter filter-name;
}
output {
  service-set service-set-name <service-filter filter-name>;
}
```

If a packet is entering the interface, the match direction is **input**. If a packet is leaving the interface, the match direction is **output**. The service set retains the input interface information even after services are applied, so that functions such as filter-class forwarding and destination class usage (DCU) that depend on input interface information continue to work.

You configure the same service set on the input and output sides of the interface. You can optionally include filters associated with each service set to refine the target and additionally process the traffic. If you include the **service-set** statement without a **service-filter** definition, the router software assumes the match condition is true and selects the service set for processing automatically.

NOTE: If you configure service sets with filters, they must be configured on the input and output sides of the interface.

You can include more than one service set definition on each side of the interface. If you include multiple service sets, the router software evaluates them in the order in which they appear in the configuration. The system executes the first service set for which it finds a match in the service filter and ignores the subsequent definitions. A maximum of six service sets can be applied to an interface. When you apply multiple service sets to an interface, you must also configure and apply a service filter to the interface.

An additional statement allows you to specify a filter for processing the traffic after the input service set is executed. To configure this type of filter, include the **post-service-filter** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet service input]** hierarchy level:

```
post-service-filter filter-name;
```

The **post-service-filter** statement is not supported when the service interface is on an MS-MIC or MS-MPC.

For an example, see [“Example: Configuring Service Sets” on page 41](#).

NOTE: With interface-style service sets that are configured with Junos OS extension-provide packages, the traffic fails to get serviced when the ingress interface is part of a VRF instance and the service interface is not part of the same VRF instance.

NOTE: When the MultiServices PIC configured for a service set is either administratively taken offline or undergoes a failure, all the traffic entering the configured interface with an IDP service set would be dropped without notification. To avoid this traffic loss, include the `bypass-traffic-on-pic-failure` statement at the `[edit services service-set service-set-name service-set-options]` hierarchy level. When this statement is configured, the affected packets are forwarded in the event of a MultiServices PIC failure or offlining, as though interface-style services were not configured. This issue applies only to Junos Application Aware (previously known as Dynamic Application Awareness) configurations using IDP service sets. This forwarding feature worked only with the Packet Forwarding Engine (PFE) initially. Starting with Junos OS Release 11.3, the packet-forwarding feature is extended to packets generated by the Routing Engine for bypass service sets as well.

Configuring Next-Hop Service Sets

A next-hop service set is a route-based method of applying a particular service. Only packets destined for a specific next hop are serviced by the creation of explicit static routes. This configuration is useful when services need to be applied to an entire virtual private network (VPN) routing and forwarding (VRF) table, or when routing decisions determine that services need to be performed.

When a next-hop service is configured, the AS or Multiservices PIC is considered to be a two-legged module with one leg configured to be the inside interface (inside the network) and the other configured as the outside interface (outside the network).

NOTE: You can create IFL indexes greater than 8000 only if the interface service set is not configured.

To configure the domain, include the `service-domain` statement at the `[edit interfaces interface-name unit logical-unit-number]` hierarchy level:

```
service-domain (inside | outside);
```

The `service-domain` setting must match the configuration for the next-hop service inside and outside interfaces. To configure the inside and outside interfaces, include the `next-hop-service` statement at the `[edit services service-set service-set-name]` hierarchy level. The interfaces you specify must be logical interfaces on the same AS PIC. You cannot configure `unit 0` for this purpose, and the logical interface you choose must not be used by another service set.

```
next-hop-service {
  inside-service-interface interface-name.unit-number;
  outside-service-interface interface-name.unit-number;
}
```

Traffic on which the service is applied is forced to the inside interface using a static route. For example:

```
routing-options {  
  static {  
    route 10.1.2.3 next-hop sp-1/1/0.1;  
  }  
}
```

After the service is applied, traffic exits by way of the outside interface. A lookup is then performed in the Packet Forwarding Engine (PFE) to send the packet out of the AS or Multiservices PIC.

The reverse traffic enters the outside interface, is serviced, and sent to the inside interface. The inside interface forwards the traffic out of the AS or Multiservices PIC.

Determining Traffic Direction

When you configure next-hop service sets, the AS PIC functions as a two-part interface, in which one part is the *inside* interface and the other part is the *outside* interface. The following sequence of actions takes place:

1. To associate the two parts with logical interfaces, you configure two logical interfaces with the **service-domain** statement, one with the **inside** value and one with the **outside** value, to mark them as either an inside or outside service interface.
2. The router forwards the traffic to be serviced to the inside interface, using the next-hop lookup table.
3. After the service is applied, the traffic exits from the outside interface. A route lookup is then performed on the packets to be sent out of the router.
4. When the reverse traffic returns on the outside interface, the applied service is undone; for example, IPsec traffic is decrypted or NAT addresses are unmasked. The serviced packets then emerge on the inside interface, the router performs a route lookup, and the traffic exits the router.

A service rule's match direction, whether input, output, or input/output, is applied with respect to the traffic flow through the AS PIC, not through a specific inside or outside interface.

When a packet is sent to an AS PIC, packet direction information is carried along with it. This is true for both interface style and next-hop style service sets.

Interface Style Service Sets

Packet direction is determined by whether a packet is entering or leaving any Packet Forwarding Engine interface (with respect to the forwarding plane) on which the **interface-service** statement is applied. This is similar to the input and output direction for stateless firewall filters.

The match direction can also depend on the network topology. For example, you might route all the external traffic through one interface that is used to protect the other interfaces on the router, and configure various services on this interface specifically.

Alternatively, you might use one interface for priority traffic and configure special services on it, but not care about protecting traffic on the other interfaces.

Next-Hop Style Service Sets

Packet direction is determined by the AS PIC interface used to route packets to the AS PIC. If you use the **inside-interface** statement to route traffic, then the packet direction is **input**. If you use the **outside-interface** statement to direct packets to the AS PIC, then the packet direction is **output**.

The interface to which you apply the service sets affects the match direction. For example, apply the following configuration:

```
sp-1/1/0 unit 1 service-domain inside;
sp-1/1/0 unit 2 service-domain outside;
```

If you configure **match-direction input**, you include the following statements:

```
[edit]
services service-set test1 next-hop-service inside-service-interface sp-1/0/0.1;
services service-set test1 next-hop-service outside-service-interface sp-1/0/0.2;
services ipsec-vpn rule test-ipsec-rule match-direction input;
routing-options static route 10.0.0.0/24 next-hop sp-1/1/0.1;
```

If you configure **match-direction output**, you include the following statements:

```
[edit]
services service-set test2 next-hop-service inside-service-interface sp-1/0/0.1;
services service-set test2 next-hop-service outside-service-interface sp-1/0/0.2;
services ipsec-vpn rule test-ipsec-rule match-direction output;
routing-options static route 10.0.0.0/24 next-hop sp-1/1/0.2;
```

The essential difference between the two configurations is the change in the match direction and the static routes' next hop, pointing to either the AS PIC's inside or outside interface.

- [Configuring Service Rules on page 36](#)
- [Configuring IPsec Service Sets on page 430](#)
- [Configuring Service Set Limitations on page 37](#)
- [Configuring System Logging for Service Sets on page 47](#)
- [Example: Configuring Service Sets on page 41](#)

Configuring Service Rules

You specify the collection of rules and rule sets that constitute the service set. The router performs rule sets in the order in which they appear in the configuration. You can include only one rule set for each service type. You configure the rule names and content for each service type at the **[edit services name]** hierarchy level for each type:

- You configure intrusion detection service (IDS) rules at the **[edit services ids]** hierarchy level; for more information, see [“Configuring IDS Rules” on page 355](#).
- You configure IP Security (IPsec) rules at the **[edit services ipsec-vpn]** hierarchy level; for more information, see *Junos VPN Site Secure*.
- You configure Network Address Translation (NAT) rules at the **[edit services nat]** hierarchy level; for more information, see *Junos Address Aware Carrier Grade NAT and IPv6 Feature Guide*.
- You configure packet-triggered subscribers and policy control (PTSP) rules at the **[edit services ptsp]** hierarchy level; for more information, see *Packet-Triggered Subscribers and Policy Control Feature Guide*.
- You configure softwire rules for DS-Lite or 6rd softwires at the **[edit services softwire]** hierarchy level; for more information, see *Softwire Services*.
- You configure stateful firewall rules at the **[edit services stateful-firewall]** hierarchy level; for more information, see *Junos Network Secure*.

To configure the rules and rule sets that constitute a service set, include the following statements at the **[edit services service-set service-set-name]** hierarchy level:

```
([ ids-rules rule-names ] | ids-rule-sets rule-set-name);
([ ipsec-vpn-rules rule-names ] | ipsec-vpn-rule-sets rule-set-name);
([ nat-rules rule-names ] | nat-rule-sets rule-set-name);
([ pgcp-rules rule-names ] | pgcp-rule-sets rule-set-name);
([ softwire-rules rule-names ] | softwire-rule-sets rule-set-name);
([ stateful-firewall-rules rule-names ] | stateful-firewall-rule-sets rule-set-name);
```

For each service type, you can include one or more individual rules, or one rule set.

If you configure a service set with IPsec rules, it must not contain rules for any other services. You can, however, configure another service set containing rules for the other services and apply both service sets to the same interface.

NOTE: You can also include Junos Application Aware (previously known as Dynamic Application Awareness) functionality within service sets. To do this, you must include an **idp-profile** statement at the **[edit services service-set]** hierarchy level, along with application identification (APPID) rules, and, as appropriate, application-aware access list (AACL) rules and a **policy-decision-statistics-profile**. Only one service sets can be applied to a single interface when Junos Application Aware functionality is used. For more information, see *Intrusion Detection and Prevention, Application Identification, and Application Aware Services Interfaces Feature Guide for Routing Devices*.

- [Understanding Service Sets on page 29](#)
- [Configuring Service Sets to be Applied to Services Interfaces on page 31](#)
- [Configuring Service Set Limitations on page 37](#)
- [Configuring System Logging for Service Sets on page 47](#)

Configuring Service Set Limitations

You can set the following limitations on service set capacity:

- You can limit the maximum number of flows allowed per service set. To configure the maximum value, include the **max-flows** statement at the **[edit services service-set service-set-name]** hierarchy level:

max-flows *number*;

The **max-flows** statement permits you to assign a single flow limit value. For IDS service sets only, you can specify various types of flow limits with a finer degree of control. For more information, see the description of the **session-limit** statement in “[Configuring IDS Rule Sets](#)” on page 363.

NOTE: When an aggregated multiservices (AMS) interface is configured as the service interface for a service set, the **max-flow** value configured for the service set is applied to each of the member interfaces in the AMS interface. That is, if you have configured 1000 as the **max-flow** value for a service set that uses an AMS interface with four active member interfaces, each of the member interfaces can handle 1000 flows each, resulting in an effective **max-flow** value of 4000.

- You can limit the maximum segment size (MSS) allowed by the Transmission Control Protocol (TCP). To configure the maximum value, include the **tcp-mss** statement at the **[edit services service-set service-set-name]** hierarchy level:

tcp-mss *number*;

The TCP protocol negotiates an MSS value during session connection establishment between two peers. The MSS value negotiated is primarily based on the MTU of the interfaces to which the communicating peers are directly connected to. However in the network, due to variation in link MTU on the path taken by the TCP packets, some packets which are still well within the MSS value may be fragmented when the concerned packet's size exceeds the link's MTU.

If the router receives a TCP packet with the SYN bit and MSS option set and the MSS option specified in the packet is larger than the MSS value specified by the **tcp-mss** statement, the router replaces the MSS value in the packet with the lower value specified by the **tcp-mss** statement. The range for the **tcp-mss mss-value** parameter is from **536** through **65535**.

To view statistics of SYN packets received and SYN packets whose MSS value, is modified, issue the **show services service-sets statistics tcp-mss** operational mode

command. For more information on this topic, see the *Junos OS Administration Library for Routing Devices*.

Enabling Services PICs to Accept Multicast Traffic

To allow multicast traffic to be sent to the Adaptive Services or Multiservices PIC, include the **allow-multicast** statement at the **[edit services service-set service-set-name]** hierarchy level. If this statement is not included, multicast traffic is dropped by default. This statement applies only to multicast traffic using a next-hop service set; interface service set configuration is not supported. Only unidirectional flows are created for multicast packets.

Applying Filters and Services to Interfaces

When you have defined and grouped the service rules by configuring the service-set definition, you can apply services to one or more interfaces on the router. To associate a defined service set with an interface, include the **service-set** statement with the **input** or **output** statement at the **[edit interfaces interface-name unit logical-unit-number family inet service]** hierarchy level:

```
[edit interfaces interface-name unit logical-unit-number family inet service]
input {
  service-set service-set-name <service-filter filter-name>;
  post-service-filter filter-name;
}
output {
  service-set service-set-name <service-filter filter-name>;
}
```

NOTE: When you enable services on an interface, reverse-path forwarding is not supported. You cannot configure services on the management interface (fxp0) or the loopback interface (lo0).

You can configure different service sets on the input and output sides of the interface. However, for service sets with bidirectional service rules, you must include the same service set definition in both the **input** and **output** statements. Any service set you include in the **service** statement must be configured with the **interface-service** statement at the **[edit services service-set *service-set-name*]** hierarchy level; for more information, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).

NOTE: If you configure an interface with an input firewall filter that includes a reject action and with a service set that includes stateful firewall rules, the router executes the input firewall filter before the stateful firewall rules are run on the packet. As a result, when the Packet Forwarding Engine sends an Internet Control Message Protocol (ICMP) error message out through the interface, the stateful firewall rules might drop the packet because it was not seen in the input direction.

Possible workarounds are to include a forwarding-table filter to perform the reject action, because this type of filter is executed after the stateful firewall in the input direction, or to include an output service filter to prevent the locally generated ICMP packets from going to the stateful firewall service.

Configuring Service Filters

You can optionally include filters associated with each service set to refine the target and additionally process the traffic. If you include the **service-set** statement without a **service-filter** definition, the router software assumes that the match condition is true and selects the service set for processing automatically.

To configure service filters, include the **firewall** statement at the **[edit]** hierarchy level:

```
firewall {
  family inet {
    service-filter filter-name {
      term term-name {
        from {
          match-conditions;
        }
        then {
          action;
          action-modifiers;
        }
      }
    }
  }
}
```

NOTE: You must specify **inet** as the address family to configure a service filter.

You configure service filters in a similar way to firewall filters. Service filters have the same match conditions as firewall filters, but the following specific actions:

- **count**—Add the packet to a counter total.
- **log**—Log the packet.
- **port-mirror**—Port-mirror the packet.
- **sample**—Sample the packet.
- **service**—Forward the packet for service processing.
- **skip**—Omit the packet from service processing.

For more information about configuring firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

You can also include more than one service set definition on each side of the interface. If you include multiple service sets, the router software evaluates them in the order specified in the configuration. It executes the first service set for which it finds a match in the service filter and ignores the subsequent definitions.

An additional statement allows you to specify a filter for processing the traffic after the input service set is executed. To configure this type of filter, include the **post-service-filter** statement at the `[edit interfaces interface-name unit logical-unit-number family inet service input]` hierarchy level:

post-service-filter *filter-name*;

NOTE: The software performs postservice filtering only when it has selected and executed a service set. If the traffic does not meet the match criteria for any of the configured service sets, the postservice filter is ignored. The **post-service-filter** statement is not supported when the service interface is on an MS-MIC or MS-MPC.

For an example of applying a service set to an interface, see [“Examples: Configuring Services Interfaces” on page 44](#).

For more information on applying filters to interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*. For general information on filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

NOTE: After NAT processing is applied to packets, they are not subject to output service filters. The service filters affect only untranslated traffic.

Configuring AS or Multiservices PIC Redundancy

You can configure AS or Multiservices PIC redundancy on M Series and T Series routers, except TX Matrix routers, that have multiple AS or Multiservices PICs. To configure redundancy, you specify a redundancy services PIC (**rsp**) interface in which the primary PIC is active and a secondary PIC is on standby. If the primary PIC fails, the secondary PIC becomes active, and all service processing is transferred to it. If the primary AS or Multiservices PIC is restored, it remains on standby and does not preempt the secondary PIC; you need to manually restore the services to the primary PIC. To determine which PIC is currently active, issue the **show interfaces redundancy** command.

Failover to the secondary PIC occurs under the following conditions:

- The primary PIC, FPC, or Packet Forwarding Engine goes down, resets, or is physically removed from the router.
- The PIC or FPC is taken offline using the **request chassis pic fpc-slot slot-number pic-slot slot-number offline** or **request chassis fpc slot slot-number offline** command. For more information, see the [CLI Explorer](#).
- The driver watchdog timer expires.
- The **request interface switchover** command is issued. For more information, see the [CLI Explorer](#).

NOTE: Adaptive Services and Multiservices PICs in Layer-2 mode (running Layer 2 services) are not rebooted when a MAC flow-control situation is detected.

NOTE: When you perform a switchover from a primary PIC to a secondary or standby PIC or a revert operation by issuing request interfaces (`revert | switchover`) command for redundancy services PICs (`rsp`), the PIC that was previously the active PIC before the switchover or reversion is automatically rebooted. The reboot of the PIC that was previously active and functioning as the primary PIC does not disrupt traffic forwarding.

The physical interface type `rsp` specifies the pairings between primary and secondary `sp` interfaces to enable redundancy. To configure an AS or Multiservices PIC as the backup, include the `redundancy-options` statement at the `[edit interfaces rspnumber]` hierarchy level:

```
[edit interfaces rspnumber]
redundancy-options {
  primary sp-fpc/pic/port;
  secondary sp-fpc/pic/port;
  hot-standby;
}
```

For the `rsp` interface, *number* can be from 0 through 15.

NOTE: You can include a similar redundancy configuration for Link Services IQ (LSQ) PICs at the `[edit interfaces rlsqnumber]` hierarchy level. For more information, see “[Configuring LSQ Interface Redundancy in a Single Router Using Virtual Interfaces](#)” on page 548.

The following constraints apply to redundant AS or Multiservices PIC configurations:

- The services supported in redundancy configurations include stateful firewall, NAT, IDS, and IPsec. Services mounted on the AS or Multiservices PIC that use interface types other than **sp**- interfaces, such as tunneling and voice services, are not supported. For information on flow monitoring redundancy, see [“Configuring Services Interface Redundancy with Flow Monitoring” on page 826](#).

NOTE: For IPsec functionality, the router no longer needs to renegotiate security associations (SAs) during warm standby PIC switchover. Instead, the warm standby feature has been made stateful by periodically setting a checkpoint between the working state of the PIC and the Routing Engine, which should lessen the downtime during switchover. If you prefer to retain the earlier behavior, you can include the `clear-ipsec-sas-on-pic-restart` statement at the `[edit services ipsec-vpn]` hierarchy level. If you enable this capability, the router renegotiates the IPsec SAs on warm standby PIC switchover. For more information, see *Clearing Security Associations*.

- We recommend that you pair the same model type in RSP configurations, such as two ASMs or two AS2 PICs. If you pair unlike models, the two PICs may perform differently.
- You can specify an AS or Multiservices PIC (**sp** interface) as the primary for only one **rsp** interface.
- An **sp** interface can be a secondary for multiple **rsp** interfaces. However, the same **sp** interface cannot be configured as a primary interface in one **rsp** configuration and as a secondary in another configuration.
- When the secondary PIC is active, if another primary PIC that is paired with it in an **rsp** configuration fails, no failover takes place.
- When you configure an AS or Multiservices PIC within a redundant configuration, the **sp** interface cannot have any configured services. Apply the configurations at the `[edit interfaces rspnumber]` hierarchy level, using, for example, the **unit** and **services-options** statements. Exceptions include the **multiservice-options** statement used in flow monitoring configurations, which can be configured separately for the primary and secondary **sp** interfaces, and the **traceoptions** statement.
- All the operational mode commands that apply to **sp** interfaces also apply to **rsp** interfaces. You can issue **show** commands for the **rsp** interface or the primary and secondary **sp** interfaces.
- If a secondary PIC fails while it is in use, the **rsp** interface returns to the “not present” state. If the primary PIC comes up later, service is restored to it.
- For redundant Multiservices (**rms**-) interfaces, similar to the configuration of other bundle interfaces, the properties of the Multiservices (**ms**-) member interfaces, such as the logical unit and the address family, are inherited from the underlying **rms**- interface. If you previously configured the member **ms**- interface properties separately, and attempt to configure the **rms**- interface properties by using the relevant statements at the `[edit interfaces rmsnumber]` hierarchy level, an error occurs when you perform a commit check operation. You must configure the properties of interfaces that are part

of the `rms-` interface only by using the statements at the `[edit interfaces rmsnumber]` hierarchy level.

Examples: Configuring Services Interfaces

Apply the `my-service-set` service set on an interface-wide basis. All traffic that is accepted by `my_input_filter` has `my-input-service-set` applied to it. After the service set is applied, additional filtering is done using the `my_post_service_input_filter` filter.

```
[edit interfaces fe-0/1/0]
unit 0 {
  family inet {
    filter {
      input my_input_filter;
      output my_output_filter;
    }
    service {
      input {
        service-set my-input-service-set;
        post-service-filter my_post_service_input_filter;
      }
      output {
        service-set my-output-service-set;
      }
    }
  }
}
```

Configure two redundancy interfaces, `rsp0` and `rsp1`, and associated services.

```
[edit interfaces]
rsp0 {
  redundancy-options {
    primary sp-0/0/0;
    secondary sp-1/3/0;
  }
  unit 0 {
    family inet;
  }
  unit 30 {
    family inet;
    service-domain inside;
  }
  unit 31 {
    family inet;
    service-domain outside;
  }
}
rsp1 {
```

```

    redundancy-options {
        primary sp-0/1/0;
        secondary sp-1/3/0;
    }
    unit 0 {
        family inet;
    }
    unit 20 {
        family inet;
        service-domain inside;
    }
    unit 21 {
        family inet;
        service-domain outside;
    }
}
[edit services]
service-set null-sfw-with-nat {
    stateful-firewall-rules allow-all;
    nat-rules rule1;
    next-hop-service {
        inside-service-interface rsp0.30;
        outside-service-interface rsp0.31;
    }
}
[edit routing-instances]
vpna {
    interface rsp0.0;
}

```

Related Documentation

- [Example: Configuring an Aggregated Multiservices Interface \(AMS\) on page 608](#)

Configuring the Address and Domain for Services Interfaces

On the AS or Multiservices PIC, you configure a source address for system log messages by including the **address** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet]** hierarchy level:

```

address address {
    ...
}

```

Assign an IP address to the interface by configuring the **address** value. The AS or Multiservices PIC generally supports only IP version 4 (IPv4) addresses configured using the **family inet** statement, but IPsec services support IP version 6 (IPv6) addresses as well, configured using the **family inet6** statement.

NOTE: If you configure the same address on multiple interfaces in the same routing instance, Junos OS uses only the first configuration, the remaining address configurations are ignored and can leave interfaces without an address. Interfaces that do not have an assigned address cannot be used as a donor interface for an unnumbered Ethernet interface.

For example, in the following configuration the address configuration of interface xe-0/0/1.0 is ignored:

```
interfaces {
  xe-0/0/0 {
    unit 0 {
      family inet {
        address 192.168.1.1/24;
      }
    }
  }
  xe-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.1.1/24;
      }
    }
  }
}
```

For more information on configuring the same address on multiple interfaces, see *Configuring the Interface Address*.

For information on other addressing properties you can configure that are not specific to service interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

The **service-domain** statement specifies whether the interface is used within the network or to communicate with remote devices. The software uses this setting to determine which default stateful firewall rules to apply, and to determine the default direction for service rules. To configure the domain, include the **service-domain** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level:

service-domain (inside | outside);

If you are configuring the interface in a next-hop service-set definition, the **service-domain** setting must match the configuration for the **inside-service-interface** and **outside-service-interface** statements; for more information, see “[Configuring Service Sets to be Applied to Services Interfaces](#)” on page 31.

Related Documentation

- [Example: Configuring an Aggregated Multiservices Interface \(AMS\) on page 608](#)

Configuring System Logging for Service Sets

You specify properties that control how system log messages are generated for the service set. These values override the values configured at the **[edit interfaces interface-name services-options]** hierarchy level.

To configure service-set-specific system logging values, include the **syslog** statement at the **[edit services service-set service-set-name]** hierarchy level:

```
syslog {
  host hostname {
    class class-name
    facility-override facility-name;
    log-prefix prefix-value;
    port port-number
    services severity-level;
    source-address source-address
  }
}
```

Configure the **host** statement with a hostname or an IP address that specifies the system log target server. The hostname **local** directs system log messages to the Routing Engine. For external system log servers, the hostname must be reachable from the same routing instance to which the initial data packet (that triggered session establishment) is delivered. You can specify only one system logging hostname. The **source-address** parameter is supported on the ms, rms, and mams interfaces.

Table 6 on page 47 lists the severity levels that you can specify in configuration statements at the **[edit services service-set service-set-name syslog host hostname]** hierarchy level. The levels from **emergency** through **info** are in order from highest severity (greatest effect on functioning) to lowest.

Table 6: System Log Message Severity Levels

Severity Level	Description
any	Includes all severity levels
emergency	System panic or other condition that causes the router to stop functioning
alert	Conditions that require immediate correction, such as a corrupted system database
critical	Critical conditions, such as hard drive errors
error	Error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels
warning	Conditions that warrant monitoring
notice	Conditions that are not errors but might warrant special handling

Table 6: System Log Message Severity Levels (*continued*)

Severity Level	Description
info	Events or non-error conditions of interest

We recommend setting the system logging severity level to **error** during normal operation. To monitor PIC resource usage, set the level to **warning**. To gather information about an intrusion attack when an intrusion detection system error is detected, set the level to **notice** for a specific service set. To debug a configuration or log NAT functionality, set the level to **info**.

For more information about system log messages, see the *Junos OS System Log Messages Reference*.

To select the class of messages to be logged to the specified system log host, include the **class** statement at the `[edit services service-set service-set-name syslog host hostname]` hierarchy level:

```
class class-name;
```

To use one particular facility code for all logging to the specified system log host, include the **facility-override** statement at the `[edit services service-set service-set-name syslog host hostname]` hierarchy level:

```
facility-override facility-name;
```

The supported facilities are: **authorization**, **daemon**, **ftp**, **kernel**, **user**, and **local0** through **local7**.

To specify a text prefix for all logging to this system log host, include the **log-prefix** statement at the `[edit services service-set service-set-name syslog host hostname]` hierarchy level:

```
log-prefix prefix-value;
```

- [Configuring Service Sets to be Applied to Services Interfaces on page 31](#)
- [Tracing Services PIC Operations on page 48](#)

Tracing Services PIC Operations

Tracing operations track all adaptive services operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

By default, no events are traced. If you include the **traceoptions** statement at the `[edit services adaptive-services-pics]` or `[edit services logging]` hierarchy level, the default tracing behavior is the following:

- Important events are logged in a file called **serviced** located in the `/var/log` directory.

- When the file **serviced** reaches 128 kilobytes (KB), it is renamed **serviced.0**, then **serviced.1**, and so on, until there are three trace files. Then the oldest trace file (**serviced.2**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)
- Log files can be accessed only by the user who configures the tracing operation.

You cannot change the directory (**/var/log**) in which trace files are located. However, you can customize the other trace file settings by including the following statements:

```
file filename <files number> <match regular-expression> <size size> <world-readable |
no-world-readable>;
flag {
  all;
  command-queued;
  config;
  handshake;
  init;
  interfaces;
  mib;
  removed-client;
  show;
}
```

You include these statements at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level.

These statements are described in the following sections:

- [Configuring the Adaptive Services Log Filename on page 49](#)
- [Configuring the Number and Size of Adaptive Services Log Files on page 49](#)
- [Configuring Access to the Log File on page 50](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 50](#)
- [Configuring the Trace Operations on page 50](#)

Configuring the Adaptive Services Log Filename

By default, the name of the file that records trace output is **serviced**. You can specify a different name by including the **file** statement at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level:

```
file filename;
```

Configuring the Number and Size of Adaptive Services Log Files

By default, when the trace file reaches 128 kilobytes (KB) in size, it is renamed **filename.0**, then **filename.1**, and so on, until there are three trace files. Then the oldest trace file (**filename.2**) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level:

```
file <filename> files number size size;
```

For example, set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation (*filename*) reaches 2 MB, *filename* is renamed *filename.0*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0* is renamed *filename.1* and *filename* is renamed *filename.0*. This process repeats until there are 20 trace files. Then the oldest file (*filename.19*) is overwritten by the newest file (*filename.0*).

The number of files can be from 2 through 1000 files. The file size of each file can be from 10 KB through 1 gigabyte (GB).

Configuring Access to the Log File

By default, log files can be accessed only by the user who configures the tracing operation.

To specify that any user can read all log files, include the **file world-readable** statement at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level:

```
file <filename> world-readable;
```

To explicitly set the default behavior, include the **file no-world-readable** statement at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level:

```
file <filename> no-world-readable;
```

Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including the **match** statement at the **[edit services adaptive-services-pics traceoptions file filename]** or **[edit services logging traceoptions]** hierarchy level and specifying a regular expression (regex) to be matched:

```
file <filename> match regular-expression;
```

Configuring the Trace Operations

By default, if the **traceoptions** configuration is present, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit services adaptive-services-pics traceoptions]** or **[edit services logging traceoptions]** hierarchy level:

```
flag {  
  all;  
  configuration;  
  routing-protocol;  
  routing-socket;  
  snmp;  
}
```

[Table 7 on page 51](#) describes the meaning of the adaptive services tracing flags.

Table 7: Adaptive Services Tracing Flags

Flag	Description	Default Setting
all	Trace all operations.	Off
command-queued	Trace command enqueue events.	Off
config	Log reading of the configuration at the [edit services] hierarchy level.	Off
handshake	Trace handshake events.	Off
init	Trace initialization events.	Off
interfaces	Trace interface events.	Off
mib	Trace GGSN SNMP MIB events.	Off
removed-client	Trace client cleanup events.	Off
show	Trace CLI command servicing.	Off

To display the end of the log, issue the **show log serviced | last** operational mode command:

```
[edit]
user@host# run show log serviced | last
```

Junos Address Aware Network Addressing Overview

Junos Address Aware Network Addressing provides Network Address Translation (NAT) functionality for translating IP addresses. It supports a wide range of networking goals, including concealing a set of host addresses on a private network behind a pool of public addresses and providing a security measure to protect the host addresses from direct targeting in network attacks.

Junos Address Aware Network Addressing also provides a tool set to deal with IPv4 exhaustion avoidance, IPv4-IPv6 coexistence, and IPv6 transition technologies. This is particularly important because the Internet Assigned Numbers Authority (IANA) allocated the last large block of IPv4 addresses in early 2011. Service providers, large enterprises, cloud providers, e-tailers, and federal agencies can use Junos Address Aware Network Addressing to pragmatically transition to IPv6 based on business requirements and ensure uninterrupted subscriber and service growth.

NAT Concept and Facilities Overview

Junos Address Aware Network Addressing provides carrier-grade NAT (CGN) for IPv4 and IPv6 networks, and facilitates the transit of traffic between different types of networks.

Junos Address Aware Network Addressing supports a diverse set of NAT translation options:

- Static-source translation—Allows you to hide a private network. It features a one-to-one mapping between the original address and the translated address; the mapping is configured statically. For more information, see [“Basic NAT” on page 57](#).
- Dynamic-source translation—Includes two options: dynamic address-only source translation and Network Address Port Translation (NAPT):
 - Dynamic address-only source translation—A NAT address is picked up dynamically from a source NAT pool and the mapping from the original source address to the translated address is maintained as long as there is at least one active flow that uses this mapping. For more information, see [“Dynamic NAT” on page 59](#).
 - NAPT—Both the original source address and the source port are translated. The translated address and port are picked up from the corresponding NAT pool. For more information, see [“NAPT” on page 57](#).
- Static destination translation—Allows you to make selected private servers accessible. It features a one-to-one mapping between the translated address and the destination address; the mapping is configured statically. For more information, see [“Static Destination NAT” on page 57](#).
- Protocol translation—Allows you to assign addresses from a pool on a static or dynamic basis as sessions are initiated across IPv4 or IPv6 boundaries. For more information, see [“Configuring Protocol Translation Between IPv6 and IPv4 Networks - NAT-PT” on page 143](#), [“NAT-PT with DNS ALG” on page 58](#), and [“Stateful NAT64” on page 59](#).
- Encapsulation of IPv4 packets into IPv6 packets using softwires—Enables packets to travel over softwires to a carrier-grade NAT endpoint where they undergo source-NAT processing to hide the original source address. For more information, see [“Tunneling Services for IPv4-to-IPv6 Transition Overview” on page 213](#).

Junos Address Aware Network Addressing supports NAT functionality described in IETF RFCs and Internet drafts, as shown in *“Supported NAT and SIP Standards”* in *Standards Reference*.

NOTE: Not all types of NAT are supported on all interface types. See [“Carrier-Grade NAT Feature Comparison for Junos Address Aware by Type of Interface Card” on page 61](#), which lists features available on supported interfaces.

IPv4-to-IPv4 Basic NAT

Basic Network Address Translation or Basic NAT is a method by which IP addresses are mapped from one group to another, transparent to end users. Network Address Port Translation or NAPT is a method by which many network addresses and their TCP/UDP ports are translated into a single network address and its TCP/UDP ports. Together, these two operations, referred to as traditional NAT, provide a mechanism to connect a realm with private addresses to an external realm with globally unique registered addresses.

Traditional NAT, specified in RFC 3022, *Traditional IP Network Address Translator*, is fully supported by Junos Address Aware Network Addressing. In addition, NAPT is supported for source addresses.

Basic NAT

With Basic NAT, a block of external addresses is set aside for translating addresses of hosts in a private domain as they originate sessions to the external domain. For packets outbound from the private network, Basic NAT translates source IP addresses and related fields such as IP, TCP, UDP, and ICMP header checksums. For inbound packets, Basic NAT translates the destination IP address and the checksums listed above.

NAPT

Use NAPT to enable the components of the private network to share a single external address. NAPT translates the transport identifier (for example, TCP port number, UDP port number, or ICMP query ID) of the private network into a single external address. NAPT can be combined with Basic NAT to use a pool of external addresses in conjunction with port translation.

For packets outbound from the private network, NAPT translates the source IP address, source transport identifier (TCP/UDP port or ICMP query ID), and related fields, such as IP, TCP, UDP, and ICMP header checksums. For inbound packets, NAPT translates the destination IP address, the destination transport identifier, and the IP and transport header checksums.

Static Destination NAT

Use static destination NAT to translate the destination address for external traffic to an address specified in a destination pool. The destination pool contains one address and no port configuration.

For more information about static destination NAT, see RFC 2663, *IP Network Address Translator (NAT) Terminology and Considerations*.

Twice NAT

In Twice NAT, both the source and destination addresses are subject to translation as packets traverse the NAT router. The source information to be translated can be either address only or address and port. For example, you would use Twice NAT when you are connecting two networks in which all or some addresses in one network overlap with

addresses in another network (whether the network is private or public). In traditional NAT, only one of the addresses is translated.

To configure Twice NAT, you must specify both a destination address and a source address for the match direction, pool or prefix, and translation type.

You can configure application-level gateways (ALGs) for ICMP and traceroute under stateful firewall, NAT, or class-of-service (CoS) rules when Twice NAT is configured in the same service set. These ALGs cannot be applied to flows created by the Packet Gateway Control Protocol (PGCP). Twice NAT does not support other ALGs. By default, the Twice NAT feature can affect IP, TCP, and UDP headers embedded in the payload of ICMP error messages.

Twice NAT, specified in RFC 2663, *IP Network Address Translator (NAT) Terminology and Considerations*, is fully supported by Junos Address Aware Network Addressing.

IPv6 NAT

IPv6-to-IPv6 NAT (NAT66), defined in Internet draft draft-mrw-behave-nat66-01, *IPv6-to-IPv6 Network Address Translation (NAT66)*, is fully supported by Junos Address Aware Network Addressing.

Application-Level Gateway (ALG) Support

Junos Address Aware Network Addressing supports a number of ALGs. You can use NAT rules to filter incoming traffic based on ALGS. For more information, see [“Network Address Translation Rules Overview” on page 69](#)

NAT-PT with DNS ALG

NAT-PT and Domain Name System (DNS) ALG are used to facilitate communication between IPv6 hosts and IPv4 hosts. Using a pool of IPv4 addresses, NAT-PT assigns addresses from that pool to IPv6 nodes on a dynamic basis as sessions are initiated across IPv4 or IPv6 boundaries. Inbound and outbound sessions must traverse the same NAT-PT router so that it can track those sessions. RFC 2766, *Network Address Translation - Protocol Translation (NAT-PT)*, recommends the use of NAT-PT for translation between IPv6-only nodes and IPv4-only nodes, and *not* for IPv6-to-IPv6 translation between IPv6 nodes or IPv4-to-IPv4 translation between IPv4 nodes.

DNS is a distributed hierarchical naming system for computers, services, or any resource connected to the Internet or a private network. The DNS ALG is an application-specific agent that allows an IPv6 node to communicate with an IPv4 node and vice versa.

When DNS ALG is employed with NAT-PT, the DNS ALG translates IPv6 addresses in DNS queries and responses to the corresponding IPv4 addresses and vice versa. IPv4 name-to-address mappings are held in the DNS with “A” queries. IPv6 name-to-address mappings are held in the DNS with “AAAA” queries.

NOTE: For IPv6 DNS queries, use the `do-not-translate-AAAA-query-to-A-query` statement at the `[edit applications application application-name]` hierarchy level.

Dynamic NAT

Dynamic NAT flow is shown in [Figure 2 on page 59](#).

Figure 2: Dynamic NAT Flow

With dynamic NAT, you can map a private IP address (source) to a public IP address drawing from a pool of registered (public) IP addresses. NAT addresses from the pool are assigned dynamically. Assigning addresses dynamically also allows a few public IP addresses to be used by several private hosts, in contrast with an equal-sized pool required by source static NAT.

For more information about dynamic address translation, see RFC 2663, *IP Network Address Translator (NAT) Terminology and Considerations*.

Stateful NAT64

Stateful NAT64 flow is shown in [Figure 3 on page 59](#).

Figure 3: Stateful NAT64 Flow

Stateful NAT64 is a mechanism to move to an IPv6 network and at the same time deal with IPv4 address depletion. By allowing IPv6-only clients to contact IPv4 servers using unicast UDP, TCP, or ICMP, several IPv6-only clients can share the same public IPv4 server address. To allow sharing of the IPv4 server address, NAT64 translates incoming IPv6 packets into IPv4 (and vice versa).

When stateful NAT64 is used in conjunction with DNS64, no changes are usually required in the IPv6 client or the IPv4 server. DNS64 is out of scope of this document because it is normally implemented as an enhancement to currently deployed DNS servers.

Stateful NAT64, specified in RFC 6146, *Stateful NAT64: Network Address and Protocol Translation from IPv6 Clients to IPv4 Servers*, is fully supported by Junos Address Aware Network Addressing.

Dual-Stack Lite

Dual-stack lite (DS-Lite) flow is shown in [Figure 4 on page 60](#).

Figure 4: DS-Lite Flow

DS-Lite employs IPv4-over-IPv6 tunnels to cross an IPv6 access network to reach a carrier-grade IPv4-IPv4 NAT. This facilitates the phased introduction of IPv6 on the Internet by providing backward compatibility with IPv4.

Junos Address Aware Network Addressing Line Card Support

Junos Address Aware Network Addressing technologies are available on the following line cards:

- MultiServices Dense Port Concentrator (MS-DPC)
- MS-100, MS-400, and MS-500 MultiServices PICS
- MultiServices Modular Port Concentrator (MS-MPC) and MultiServices Modular Interface Card (MS-MIC)
- Modular Port Concentrator Types 1, 2, and 3 (inline NAT).

Related Documentation

- [ALGs Available by Default for Junos OS Address Aware NAT on page 141](#)

Junos OS Carrier-Grade NAT Implementation Overview

Junos OS enables you to implement and scale a Carrier-Grade Network Address Translation (CGNAT) solution based on the type of services interfaces used for your implementation:

- MultiServices Denser Port Concentrator (MS-DPC)—The layer 3 services package is used to configure NAT for MS-DPC adaptive services PICs. You must configure the layer-3 services package before implementing NAT on the MS-DPC. This solution provides the NAT functionality described in *Network Address Translation Overview for MS-DPC, MS-MPC, and MS-MIC Line Cards*.
- MultiServices Modular Port Concentrator (MS-MPC) and MultiServices Modular Interface Card (MS-MIC)—MS-MPCs and MS-MICs are pre-configured to enable configuration of carrier-grade NAT. This solution provides the NAT functionality described in *Network Address Translation Overview for MS-DPC, MS-MPC, and MS-MIC Line Cards*.

- Inline NAT for Type 1, 2, and 3 Modular Port Concentrator (MPC Line Cards)—Inline NAT leverages the services capabilities of TRIO-based MPC line cards, allowing a cost-effective implementation of NAT functionality on the data plane, as described in [“Inline Network Address Translation Overview for MPC Types 1, 2, and 3” on page 199](#).

Network Address Translation Configuration Overview

To configure network address translation (NAT), complete the following high-level steps:

1. Configure the source and destination addresses. For more information, see [“Configuring Source and Destination Addresses Network Address Translation Overview” on page 66](#).
2. Define the addresses or prefixes, address ranges, and ports used for NAT. For more information, see [“Configuring Pools of Addresses and Ports for Network Address Translation Overview” on page 67](#)
3. If applicable, configure the address pools for network address port translation (NAPT). For more information, see [“Configuring Address Pools for Network Address Port Translation \(NAPT\) Overview” on page 117](#).
4. Configure the NAT rules. Within the rules, include match directions, match conditions, actions, and translation types. For more information, see [“Network Address Translation Rules Overview” on page 69](#).
5. Configure service sets for NAT processing. Within each service set, define the interfaces for handling inbound and outbound traffic and a NAT rule or ruleset. For more information, see [“Configuring Service Sets for Network Address Translation” on page 75](#).

Related Documentation

- [Network Address Translation Overview for MS-DPC, MS-MPC, and MS-MIC Line Cards](#)
- [Carrier-Grade NAT Feature Comparison for Junos Address Aware by Type of Interface Card on page 61](#)

Configuring Source and Destination Addresses Network Address Translation Overview

You must configure a specific address, a prefix, or the address-range boundaries:

- The following addresses, while valid in **inet.0**, cannot be used for NAT translation:
 - **0.0.0.0/32**
 - **127.0.0.0/8** (loopback)
 - **128.0.0.0/16** (martian)
 - **191.255.0.0/16** (martian)
 - **192.0.0.0/24** (martian)
 - **223.255.255.0/24** (martian)
 - **224.0.0.0/4** (multicast)
 - **240.0.0.0/4** (reserved)
 - **255.255.255.255** (broadcast)

The addresses that are specified as valid in the **inet.0** routing table and not supported for NAT translation are **orlonger** match filter types. You cannot specify any regions within such address prefixes in a NAT pool.

- On MX Series routers with MS-MPCs and MS-MICs, if you configure a NAT address pool with a prefix length that is equal to or greater than /16, the PIC does not contain sufficient memory to provision the configured pool. Also, memory utilization problems might occur if you attempt to configure many pools whose combined total IP addresses exceed /16. In such circumstances, a system logging message is generated stating that the NAT pool name is failed to be created and that the service set is not activated. On MS-MPCs and MS-MICs, you must not configure NAT pools with prefix lengths greater than or equal to /16.
- You can specify one or more IPv4 address prefixes in the **pool** statement and in the **from** clause of the NAT rule term. This enables you to configure source translation from a private subnet to a public subnet without defining a rule term for each address in the subnet. Destination translation cannot be configured by this method. For more information, see *Examples: Configuring NAT Rules*.
- When you configure static source NAT, the **address** prefix size you configure at the **[edit services nat pool *pool-name*]** hierarchy level must be larger than the **source-address** prefix range configured at the **[edit services nat rule *rule-name* term *term-name* from]** hierarchy level. The **source-address** prefix range must also map to a single subnet or range of IPv4 or IPv6 addresses in the **pool** statement. Any pool addresses that are not used by the **source-address** prefix range are left unused. Pools cannot be shared.

NOTE: When you include a NAT configuration that changes IP addresses, it might affect forwarding path features elsewhere in your router configuration, such as source class usage (SCU), destination class usage (DCU), filter-based forwarding, or other features that target specific IP addresses or prefixes.

NAT configuration might also affect routing protocol operation, because the protocol peering, neighbor, and interface addresses can be altered when routing protocols packets transit the Adaptive Services (AS) or Multiservices PIC.

Configuring Pools of Addresses and Ports for Network Address Translation Overview

- [Configuring NAT Pools on page 67](#)
- [Preserve Range and Preserve Parity on page 68](#)
- [Specifying Destination and Source Prefixes without Configuring a Pool on page 68](#)

Configuring NAT Pools

You can use the **pool** statement to define the addresses (or prefixes), address ranges, and ports used for Network Address Translation (NAT). To configure the information, include the **pool** statement at the **[edit services nat]** hierarchy level:

```
[edit services nat]
pool nat-pool-name {
  address ip-prefix</prefix-length>;
  address-range low minimum-value high maximum-value;
  port {
    automatic (sequential | random-allocation);
    range low minimum-value high maximum-value random-allocation;
    preserve-parity;
    preserve-range {
    }
  }
}
```

To configure pools for traditional NAT, specify either a destination pool or a source pool.

With static source NAT and dynamic source NAT, you can specify multiple IPv4 addresses (or prefixes) and IPv4 address ranges. Up to 32 prefixes or address ranges (or a combination) can be supported within a single pool.

With static destination NAT, you can also specify multiple address prefixes and address ranges in a single term. Multiple destination NAT terms can share a destination NAT pool. However, the netmask or range for the **from** address must be smaller than or equal to the netmask or range for the destination pool address. If you define the pool to be larger than required, some addresses will not be used. For example, if you define the pool size as 100 addresses and the rule specifies only 80 addresses, the last 20 addresses in the pool are not used.

For constraints on specific translation types, see [“Network Address Translation Rules Overview” on page 69](#).

With source static NAT, the prefixes and address ranges cannot overlap between separate pools.

In an address range, the **low** value must be a lower number than the **high** value. When multiple address ranges and prefixes are configured, the prefixes are depleted first, followed by the address ranges.

When you specify a port for dynamic source NAT, address ranges are limited to a maximum of 65,000 addresses, for a total of (65,000 x 65,535) or 4,259,775,000 flows. A dynamic NAT pool with no address port translation supports up to 65,535 addresses. There is no limit on the pool size for static source NAT.

Preserve Range and Preserve Parity

You can configure your carrier-grade NAT (CGN) to preserve the range or parity of the packet source port when it allocates a source port for an outbound connection. You can configure the preserve parity and preserve range options under the NAT pool definition by including the **preserve-range** and **preserve-parity** configuration statements at the **[edit services nat pool poolname port]** hierarchy level.

- Preserve range—RFC 4787, *Network Address Translation (NAT) Behavioral Requirements for Unicast UDP*, defines two ranges: 0 through 1023, and 1024 through 65,535. When the **preserve-range** knob is configured and the incoming port falls into one of these ranges, CGN allocates a port from that range only. However, if there is no available port in the range, the port allocation request fails and that session is not created. The failure is reflected on counters and system logging, but no Internet Control Message Protocol (ICMP) message is generated. If this knob is not configured, allocation is based on the configured port range without regard to the port range that contains the incoming port. The exception is some application-level gateways (ALGs), such as hello, that have special zones.
- Preserve parity—When the **preserve-parity** knob is configured, CGN allocates a port with the same even or odd parity as the incoming port. If the incoming port number is odd or even, the outgoing port number should correspondingly be odd or even. If a port number of the desired parity is not available, the port allocation request fails, the session is not created, and the packet is dropped.

Specifying Destination and Source Prefixes without Configuring a Pool

You can directly specify the destination or source prefix used in NAT without configuring a pool.

To configure the information, include the **rule** statement at the **[edit services nat]** hierarchy level:

```
[edit services nat]
rule rule-name {
  term term-name {
    then {
      translated {
```

```

        destination-prefix prefix;
    }
}
}
}

```

Network Address Translation Rules Overview

To configure a NAT rule, include the **rule** *rule-name* statement at the **[edit services nat]** hierarchy level:

```

[edit services nat]
rule rule-name {
  match-direction (input | output);
  term term-name {
    from {
      application-sets set-name;
      applications [ application-names ];
      destination-address (address | any-unicast) <except>;
      destination-address-range low minimum-value high maximum-value <except>;
      destination-prefix-list list-name <except>;
      source-address (address | any-unicast) <except>;
      source-address-range low minimum-value high maximum-value <except>;
      source-prefix-list list-name <except>;
    }
    then {
      no-translation;
      translated {
        address-pooling paired;
        destination-pool nat-pool-name;
        destination-prefix destination-prefix;
        dns-alg-pool dns-alg-pool;
        dns-alg-prefix dns-alg-prefix;
        filtering-type endpoint-independent;
        mapping-type endpoint-independent;
        overload-pool overload-pool-name;
        overload-prefix overload-prefix;
        source-pool nat-pool-name;
        source-prefix source-prefix;
        translation-type {
          (basic-nat-pt | basic-nat44 | basic-nat66 | dnat-44 | dynamic-nat44 | napt-44 |
           napt-66 | napt-pt | stateful-nat64 | twice-basic-nat-44 | twice-dynamic-nat-44
           | twice-napt-44);
        }
      }
    }
    syslog;
  }
}
}

```

Each rule must include a **match-direction** statement that specifies the direction in which the match is applied.

In addition, each NAT rule consists of a set of terms, similar to a firewall filter. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

The following sections explain how the components of NAT rules:

- [Configuring Match Direction for NAT Rules on page 70](#)
- [Configuring Match Conditions in NAT Rules on page 70](#)
- [Configuring Actions in NAT Rules on page 71](#)
- [Configuring Translation Types on page 73](#)

Configuring Match Direction for NAT Rules

Each rule must include a **match-direction** statement that specifies the direction in which the match is applied. To configure where the match is applied, include the **match-direction** statement at the **[edit services nat rule *rule-name*]** hierarchy level:

```
[edit services nat rule rule-name]  
match-direction (input | output);
```

The match direction is used with respect to the traffic flow through the Multiservices DPC and Multiservices PICs. When a packet is sent to the PIC, direction information is carried along with it. The packet direction is determined based on the following criteria:

- With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.
- With a next-hop service set, packet direction is determined by the interface used to route the packet to the Multiservices DPC or Multiservices PIC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the PIC or DPC, the packet direction is output. For more information about inside and outside interfaces, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).
- On the Multiservices DPC and Multiservices PIC, a flow lookup is performed. If no flow is found, rule processing is performed. All rules in the service set are considered. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that matches the packet direction are considered.

Configuring Match Conditions in NAT Rules

To configure NAT match conditions, include the **from** statement at the **[edit services nat rule *rule-name* term *term-name*]** hierarchy level:

```
[edit services nat rule rule-name term term-name]  
from {  
  application-sets set-name;  
  applications [ application-names ];  
  destination-address (address | any-unicast) <except>;  
  destination-address-range low minimum-value high maximum-value <except>;  
  destination-prefix-list list-name <except>;  
  source-address (address | any-unicast) <except>;
```

```

source-address-range low minimum-value high maximum-value <except>;
source-prefix-list list-name <except>;
}

```

To configure traditional NAT, you can use the destination address, a range of destination addresses, the source address, or a range of source addresses as a match condition, in the same way that you would configure a firewall filter; for more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Alternatively, you can specify a list of source or destination prefixes by including the **prefix-list** statement at the **[edit policy-options]** hierarchy level and then including either the **destination-prefix-list** or **source-prefix-list** statement in the NAT rule. For an example, see “[Examples: Configuring Stateful Firewall Rules](#)” on page 335.

If the **translation-type** statement in the **then** statement of the nat rule is set to **stateful-nat-64**, the range specified by the **destination-address-range** or the **destination-prefix-list** in the **from** statement must be within the range specified by the **destination-prefix** statement in the **then** statement.

If at least one NAT term within a NAT rule has the address pooling paired (APP) functionality enabled (by including the **address-pooling** statement at the **[edit services nat rule rule-name term term-name then translated]** hierarchy level, all the other terms in the NAT rule that use the same NAT address pool as the address pool for the term with APP enabled must have APP enabled. Otherwise, if you add a NAT rule term without enabling APP to a rule that contains other terms with APP enabled, all the terms with APP enabled in a NAT rule drop traffic flows that match the specified criteria in the NAT rule.

For MX Series routers with MS-MICs and MS-MPCs, although the address pooling paired (APP) functionality is enabled within a NAT rule (by including the **address-pooling** statement at the **[edit services nat rule rule-name term term-name then translated]** hierarchy level), it is a characteristic of a NAT pool. Such a NAT pool for which APP is enabled cannot be shared with NAT rules that do not have APP configured.

Configuring Actions in NAT Rules

To configure NAT actions, include the **then** statement at the **[edit services nat rule rule-name term term-name]** hierarchy level:

```

[edit services nat]
rule rule-name {
  term term-name {
    from {
      destination-address-range low minimum-value high maximum-value <except>;
      destination-prefix-list list-name <except>;
    }
    then {
      destination-prefix destination-prefix;
    }
  }
}

[edit services nat rule rule-name term term-name]
then {
  no-translation;
  syslog;
}

```

```
translated {  
  destination-pool nat-pool-name;  
  destination-prefix destination-prefix;  
  source-pool nat-pool-name;  
  source-prefix source-prefix;  
  translation-type (basic-nat-pt | basic-nat44 | basic-nat66 | dnat-44 | dynamic-nat44  
    | napt-44 | napt-66 | napt-pt | stateful-nat64 | twice-basic-nat-44 |  
    twice-dynamic-nat-44 | twice-napt-44);  
}  
}
```

- The **no-translation** statement allows you to specify addresses that you want excluded from NAT.
- The **system log** statement enables you to record an alert in the system logging facility.
- The **destination-pool**, **destination-prefix**, **source-pool**, and **source-prefix** statements specify addressing information that you define by including the **pool** statement at the **[edit services nat]** hierarchy level; for more information, see [“Configuring Pools of Addresses and Ports for Network Address Translation Overview” on page 67](#).
- The **translation-type** statement specifies the type of NAT used for source or destination traffic. The options are **basic-nat-pt**, **basic-nat44**, **basic-nat66**, **dnat-44**, **dynamic-nat44**, **napt-44**, **napt-66**, **napt-pt**, **stateful-nat64**, **twice-basic-nat-44**, **twice-dynamic-nat-44**, and **twice-napt-44**.

NOTE: In Junos OS Release 13.2 and earlier, the following restriction was not enforced by the CLI: if the **translation-type** statement in the then statement of a NAT rule was set to **stateful-nat-64**, the range specified by the **destination-address-range** or the **destination-prefix-list** in the from statement needed to be within the range specified by the **destination-prefix** statement in the then statement. Starting in Junos OS Release 13.3R1, this restriction is enforced.

Configuring Translation Types

The implementation details of the nine options of the **translation-type** statement are as follows:

- **basic-nat44**—This option implements the static translation of source IP addresses without port mapping. You must configure the **from source-address** statement in the match condition for the rule. The size of the address range specified in the statement must be the same as or smaller than the source pool. You must specify either a source pool or a destination prefix. The referenced pool can contain multiple addresses but you cannot specify ports for translation.

NOTE: In an interface service set, all packets destined for the source address specified in the match condition are automatically routed to the services PIC, even if no service set is associated with the interface.

NOTE: Prior to Junos OS Release 11.4R3, you could only use a source NAT pool in a single service set. As of Junos OS Release 11.4R3 and subsequent releases, you can reuse a source NAT pool in multiple service sets.

- **basic-nat66**—This option implements the static translation of source IP addresses without port mapping in IPv6 networks. The configuration is similar to the **basic-nat44** implementation, but with IPv6 addresses.
- **basic-nat-pt**—This option implements translation of addresses of IPv6 hosts, as they originate sessions to the IPv4 hosts in an external domain and vice versa. This option is always implemented with DNS ALG. You must define the source and destination pools of IPv4 addresses. You must configure one rule and define two terms. Configure the IPv6 addresses in the **from** statement in both **term** statements. In the **then** statement of the first term within the rule, reference both the source and destination pools and configure **dns-alg-prefix**. Configure the source prefix in the **then** statement of the second term within the same rule.
- **dnat-44**—This option implements static translation of destination IP addresses without port mapping. The size of the pool address space must be greater than or equal to the destination address space. You must specify a name for the **destination pool** statement. The referenced pool can contain multiple addresses, ranges, or prefixes, as long as the number of NAT addresses in the pool is larger than the number of destination addresses in the **from** statement. You must include exactly one **destination-address** value at the **[edit services nat rule rule-name term term-name from]** hierarchy level; if it is a prefix, the size must be less than or equal to the pool prefix size. Any addresses in the pool that are not matched in the yvalue remain unused, because a pool cannot be shared among multiple terms or rules.
- **dynamic-nat44**—This option implements dynamic translation of source IP addresses without port mapping. You must specify a **source-pool**. The referenced pool must include an **address** configuration (for address-only translation).

The **dynamic-nat44** address-only option supports translating up to 16,777,216 addresses to a smaller size pool. The requests from the source address range are assigned to the addresses in the pool until the pool is used up, and any additional requests are rejected. A NAT address assigned to a host is used for all concurrent sessions from that host. The address is released to the pool only after all the sessions for that host expire. This feature enables the router to share a few public IP addresses between several private hosts. Because all the private hosts might not simultaneously create sessions, they can share a few public IP addresses.

- **napt-44**—This option implements dynamic translation of source IP addresses with port mapping. You must specify a name for the **source-pool** statement. The referenced pool must include a **port** configuration. If the port is configured as automatic or a port range is specified, then it implies that Network Address Port Translation (NAPT) is used.
- **napt-66**—This option implements dynamic address translation of source IP addresses with port mapping for IPv6 addresses. The configuration is similar to the **napt-44** implementation, but with IPv6 addresses.
- **napt-pt**—This option implements dynamic address and port translation for source and static translation of destination IP address. You must specify a name for the **source-pool** statement. The referenced pool must include a port configuration (for NAPT). Additionally, you must configure two rules, one for the DNS traffic and the other for the rest of the traffic. The rule meant for the DNS traffic should be DNS ALG enabled and the **dns-alg-prefix** statement should be configured. Moreover, the prefix configured in the **dns-alg-prefix** statement must be used in the second rule to translate the destination IPv6 addresses to IPv4 addresses.
- **stateful-nat64**—This option implements dynamic address and port translation for source IP addresses and prefix removal translation for destination IP addresses. You must specify the IPv4 addresses used for translation at the **[edit services nat pool]** hierarchy level. This pool must be referenced in the rule that translates the IPv6 addresses to IPv4.
- **twice-basic-nat-44**—This option implements static source and static destination translation for IPv4 addresses, thus combining **basic-nat44** for source and **dnat-44** for destination addresses.
- **twice-dynamic-nat-44**—This option implements source dynamic and destination static translation for IPv4 addresses, combining **dynamic-nat44** for source and **dnat-44** for destination addresses.
- **twice-napt-44**—This option implements source NAPT and destination static translation for IPv4 addresses, combining **napt-44** for source and **dnat-44** for destination addresses.

NOTE: When configuring NAT, if any traffic is destined for the following addresses and does not match a NAT flow or NAT rule, the traffic is dropped:

- Addresses specified in the `from destination-address` statement when you are using destination translation
- Addresses specified in the source NAT pool when you are using source translation

For more information on NAT methods, see RFC 2663, *IP Network Address Translator (NAT) Terminology and Considerations*.

Configuring Service Sets for Network Address Translation

When configuring a service set for NAT processing, make sure you have defined:

- Service interface(s) for handling inbound and outbound traffic

NOTE: Prior to Junos OS Release 11.4R3, you could only use a source NAT pool in a single service set. As of Junos OS Release 11.4R3 and subsequent releases, you can reuse a source or destination NAT pool in multiple service sets, provided that the service interfaces associated with the service sets are in different virtual routing and forwarding (VRF) instances.

- For interface style service sets, when a NAT pool is reused in multiple service sets, the service interfaces used in the `interface-service service-interface` option of each service set must be in different VRFs.
- For next-hop style service sets, when a NAT pool is reused in multiple service sets, the service interfaces used in the `outside-interface` option of each service set must be in different VRFs.

Not adhering to these service interface restrictions will cause multiple routes to be installed in the same VRF for the same NAT addresses, causing reverse traffic to be processed incorrectly.

To enable sharing of source NAT pools, include the `allow-overlapping-nat-pools` statement at the `[edit services nat]` hierarchy level.

- A NAT rule or ruleset

NOTE: To configure an MX-DPC interface to be used exclusively for carrier-grade NAT (CGN) or related services (intrusion detection, stateful firewall, and software), include the `cg-pic` statement at the `[edit interfaces interface-name services-options]` hierarchy level.

To configure a NAT service set:

1. At the **[edit services]** hierarchy level, define the service set.

```
[edit services]
user@host# edit service-set service-set-name
```

2. Configure either an interface service, which requires a single service interface, or a next-hop service, which requires an inside and outside service interface.

```
[edit services service-set service-set-name]
user@host# set interface-service service-interface interface-name
```

Or

```
[edit services service-set service-set-name]
user@host# set next-hop-service inside-service-interface interface-name
                        outside-service-interface interface-name
```

NOTE: If you have a Trio-based line card (MPC/MIC), you can use an inline-services interface that was configured on that card, as shown in this example:

```
[edit]
user@host# set interfaces si-0/0/0
[edit services service-set s1]
user@host# set interface-service service-interface si-0/0/0
```

For more information on interface service and next-hop service, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31.](#)

3. Configure a reference to the NAT rules or ruleset to be used with the service set.

```
[edit services service-set service-set-name]
user@host# set nat-rules rule-or-ruleset-name
```

4. (Optional) For NAT64, specify that the don't fragment (DF) bit for IPv4 packet headers is cleared when packet length is less than 1280 bytes.

```
[edit services service-set service-set-name]
user@host# set nat-options stateful-nat64 clear-dont-fragment-bit
```

Carrier-Grade NAT Implementation: Best Practices

The following topics present the best practices for carrier-grade NAT implementation on MS-DPCs using the Layer 3 services package:

- [Use APP and Round-Robin Address-Allocation on page 77](#)
- [Do Not Use EIM with SIP on page 77](#)
- [Do Not Use EIM with HTTP, DNS, or When Not Needed on page 78](#)
- [Define PBA Blocks Based on User Profiles on page 79](#)

- [Do Not Change the PBA Configuration on Running Systems on page 79](#)
- [Do Not Allocate Excessively Large NAT Pools on page 80](#)
- [Configure the System Log for PBA Only When Needed on page 81](#)
- [Use Redundant Service PIC \(RSP\) Interfaces for Failover on page 83](#)
- [Contain the Effects of Missing IP Fragments on page 84](#)
- [Do Not Use Configurations Prone to Routing Loops on page 84](#)

Use APP and Round-Robin Address-Allocation

Scenario:

- Address-pooling paired (APP) allows a private IP address to be mapped to the same public IP address from a NAT pool for all its sessions. The binding between private IP and public IP is triggered by the first packet seen from such private host.
- By default, an MS-DPC or MS-PIC allocates ports from a NAT pool in a sequential fashion from each consecutive IP address available in the pool.
- Sequential allocation, together with APP, can result in mapping multiple private hosts to the same public IP address, resulting in fast port exhaustion for the interested public IP address while other ports are still available from the remaining of NAT pool.

BEST PRACTICE: Configure round-robin address allocation for the NAT pool used by traffic served with APP. Round-robin allocation allocates ports from different IP addresses.

The following snippet provides an example of round-robin address allocation.

```
user@router# show services nat pool natpool-1
address-range low 9.9.9.1 high 9.9.9.10;
port {
    automatic;
}
address-allocation round-robin;
mapping-timeout 120;
```

Do Not Use EIM with SIP

Scenario:

- Session Initiation Protocol (SIP) traffic requires an Application Level Gateway (ALG) to allow SIP servers and clients on the public side of the CGNAT to communicate with the SIP hosts on the private side.
- The SIP ALG opens the pinholes in the CGNAT router to permit the forwarding of outbound traffic based on any supported SIP feature.
- Endpoint-independent mapping (EIM) is not needed by SIP to function, nor by the SIP ALG to create the flows for forwarding the SIP traffic

BEST PRACTICE: Do *not* configure EIM together with the SIP ALG; doing so adds processing overhead with no benefit.

```
user@router# show services nat rule natrule-1
match-direction input;
term 1 {
  from {
    applications junos-sip;
  }
  then {
    translated {
      source-pool natpool-3;
      translation-type {
        napt-44;
      }
    }
    address-pooling paired;
  }
}
```

Do Not Use EIM with HTTP, DNS, or When Not Needed

Scenario:

- Most Internet traffic uses HTTP, and there is no browser on any OS that reuses the same source port for sending traffic to different destinations. EIM provides no benefit for HTTP traffic.
- Because none of the junos-algs require EIM to work, avoid using EIM with the ALGs.
- EIM allocates memory for each mapping; this is in addition to the memory used for flow allocation. This reduces the maximum number of flows that can be established through the services PIC, and causes processing overhead for the creation and deletion of flows and mappings.

BEST PRACTICE:

- Don't enable EIM for applications that are defined ALGs or are known not to use Session Traversal Utilities for NAT (STUN) servers to discover the presence of a NAT router.
- Enable EIM for applications that do reuse the source ports and rely on a CGNAT device to maintain the same address:port mapping for all traffic sent to different destinations, such as on-line gaming applications like Xbox and PS3, or applications that use unilateral self-address fixing methods (UNSAF). see (*IETF RFC 3424 IAB Considerations for UNilateral Self-Address Fixing (UNSAF) Across Network Address Translation*).

Define PBA Blocks Based on User Profiles

Scenario:

- When a user connects to a website that requires the establishment of a significant number of sockets for a single HTML page, a corresponding number of new ports must be allocated. Port blocks should be large enough to prevent continual allocation of new blocks.
- If the number of concurrent sessions exceeds the number of ports available in the active port block, the other allocated port-blocks will be scanned for available ports to use or a new block will be allocated from the free block pool.
- The process of continually scanning the allocated port-blocks and/or allocating additional blocks from the free block pool could result in experienced latency for setting up new sessions and delay loading of web pages.
- Having a user continuously allocating or de-allocating from different PBA blocks impacts performance.

BEST PRACTICE: Define PBA blocks with a size that is a power of 2 or 4 related to the average number of sessions a user is expected to have active. For example, if a user is expected to have an average of approximately 200 to 250 sessions active, configuring the PBA block size to 512 or 1024 will provide a liberal allocation.

```
user@router# show services nat pool natpool-1
address-range low 9.9.9.1 high 9.9.9.10;
  port {
    automatic;
    secure-port-block-allocation {
      block-size 1024;
      max-blocks-per-user 8; /* Max 2048, default 8 */
      active-block-timeout 300;
    }
  }
mapping-timeout 300;
```

Do Not Change the PBA Configuration on Running Systems

Scenario:

- PBA settings in NAT pools are mapped to memory at the time of the Service PIC boot up and cannot be changed while processing traffic.
- Do not change the following settings:
 - Update any NAT pool PBA configuration.
 - Change a PBA NAT pool to a non-PBA NAT pool.
 - Change a non-PBA NAT pool to a PBA NAT pool.

Any of these changes result in the logging of the following message:

PBA_CATASTROPIC_CHANGE: The recent PBA configuration changes will reflect in the Service-PIC only after deactivate and activate of the service-set again

NOTE: Starting with Junos OS Release 14.1, when you deactivate a service-set that contains address pooling paired (APP) or endpoint independent mapping (EIM) mapping for that service-set, messages are displayed on the PIC console and the mappings are cleared for that service-set. These messages are triggered when the deletion of a service-set commences and again generated when the deletion of the service-set is completed. The following sample messages are displayed when deletion starts and ends:

- Nov 15 08:33:13.974 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion initiated
- Nov 15 08:33:14.674 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion completed

In a scaled environment that contains a large number of APP or EIM mappings in a service set, a heavy volume of messages is generated and this process takes some amount of time. We recommend that you wait until the console messages indicating the completion of deletion of the service set are completed before you reactivate the service-set again.

BEST PRACTICE: When changing PBA configurations, restart the services PIC if possible. Minimally, you must deactivate and reactivate the affected service set.

Do Not Allocate Excessively Large NAT Pools

Scenario:

- The maximum number of flows supported by the MS-DPC and each PIC on an MS-DPC is 8 million.
- Assuming that the 8 million flow maximum consists of 4 million sessions (1 reverse flow for each forward flow), these sessions would require a maximum of 4 million ports that are available from 64 IP addresses within the 1024 to 65,535 ports range (64K ports per IP address).
- Do not configure ports to support more than 8 million flows; they will never be needed.
- This scenario assumes that APP, EIM, and EIF are not enabled. When they *are* enabled, the total number of flows is lower, which means that you should configure the number of IP addresses in the NAT pool based on the maximum supported flows.

BEST PRACTICE: Do not configure NAT pools with more than 64 addresses (that is, a /26 network) and round-robin configured and 64K ports from each address.

On MS-MICs, do not configure NAT pools with more than 128 addresses (that is, a /25 network) and round-robin configured and 64K ports from each address. On MS-MICs, a maximum of up to 7 million sessions are supported. Assuming these 7 million sessions, such sessions would require maximum 7 million ports that are available from 128 IP addresses within the 1024-65535 ports range (64K ports per IP address).

On MS-MPCs, do not configure NAT pools with more than 256 addresses (that is, a /24 network) and round-robin configured and 64K ports from each address. On MS-MPCs, a maximum of up to 15 million sessions are supported. Assuming these 15 million sessions would require maximum 15 million ports that are available from 256 IP addresses within the 1024-65535 ports range (64K ports per IP address).

Configure the System Log for PBA Only When Needed

Scenario:

- Session logging can negatively affect performance depending on the frequency of creation and deletion of flows.
- PBA is meant to reduce the need for logging.
- Deterministic NAT is designed to eliminate the need for logging.
- All system log messages created by the services PIC constitutes traffic that will be sent to the Packet Forwarding Engine, competing with user traffic to reach the external destination.

BEST PRACTICE:

- Use logging to the system log at the service-set level rather than at the services PIC interface level when possible.
- Do not enable logging for redundant information. When using PBA, you don't need to configure logs per session because knowing the PBA block and the block size enables you to derive the ports allocated to each user. In this case, a log that reports all sessions created by that user with ports belonging to a block is redundant. If you have configured deterministic NAT (DetNat) a log is completely unnecessary because all information on port allocation can be deduced mathematically.
- Rate-limit the number of logs generated from an sp- interface. When not set, the default limits apply: 10K for the local host system log server (RE) and 200K for the external system log server.

```
user@router# show interfaces sp-1/1/0 services-options
```

```
system log {
  host 1.2.3.4 {
    services info;
  }
  message-rate-limit 1000;
}
```

- Always system log to an external server to avoid loading the Routing Engine and specify system log class to restrict logging.
 - If you do not specify system log class, all log messages are allowed (subject to priority check and rate limiting).
 - When you specify system log class, only messages meeting the class criteria are retained.
 - Use the `show services service-sets statistics system log detail` command to check what is being dropped by unconfigured classes.

```
user@router# show services service-set S-SET-1 system log
host 1.2.3.4 {
  services info;
  class {
    session-logs open close;
    packet-logs;
    stateful-firewall-logs;
    alg-logs;
    nat-logs;
    ids-logs;
  }
}
```

BEST PRACTICE: System log generation can be *rule-based* or *event-based*.

- Use rule-based system logging with care; it generates a log for every packet that enters the rule term, since rule-based logging is not subject to class or priority filtering.
- System log messages can be dropped only as a result of message rate limiting. Make sure you have set a realistic rate-limit that is unlikely to be exceeded.
- Use rule-based logging only for discarded traffic (a relatively small percentage of the traffic) or for troubleshooting. Since rule-based logging applies to all traffic that enters the PIC and creates a flow, logging can be excessive, resulting in reaching the configured induce rate limit with a consequent loss of needed logs.

```
cli# show services stateful-firewall
rule rule-sfw-accept {
  match-direction input-output;
  term term-sfw-accept {
    then {
      accept;
      system log;
    }
  }
}
```

```

}
rule rule-sfw-reject {
  match-direction input-output;
  term term-sfw-reject {
    then {
      reject;
      system log;
    }
  }
}

```

**BEST PRACTICE:**

All rule match logs are enabled by their respective rules:

- ASP_COS_RULE_MATCH (class-of-service rules)
- ASP_COS_RULE_MATCH (class-of-service rules)
- ASP_IDS_RULE_MATCH (ids rules)
- ASP_NAT_RULE_MATCH (nat rule)
- ASP_SFW_RULE_ACCEPT (stateful firewall rules)
- ASP_SFW_RULE_DISCARD
- ASP_SFW_RULE_REJECT

Use Redundant Service PIC (RSP) Interfaces for Failover

**BEST PRACTICE:**

- The usage of Redundant Service PIC (RSP) interfaces, allows the active services PIC to perform an immediated switchover to the secondary services PIC in case of major issues that require a services PIC reboot.
- This results in a minimal service impact for user traffic.
- There are two modes for redunancy: warm-standby (default) and hot-standby. Hot-standby provides 1:1 redundancy, while warm-standby provides 1:N redundancy. With both modes , there is no impact on the UDP forwarding.
- When the secondary services PIC is shared among multiple RSPs, only warm-standby is possible and the impact to traffic is limited to the time to load the appropriate configuration on the secondary PIC.

```

user@router# show interfaces rsp0
redundancy-options {
  primary sp-0/1/0;
  secondary sp-1/1/0;
  hot-standby;
}

```

Contain the Effects of Missing IP Fragments

Scenario:

- IP fragments are buffered as they arrive to facilitate the integrity check of the completely reassembled packet before being serviced by the services PIC.
- Missing fragments cause received fragments to be held until the internal buffer is full and are flushed out. This causes CPU usage overhead and reduced traffic forwarding.

BEST PRACTICE: Configure the `fragment-limit`, the maximum number of fragments for a packet, and `reassembly-timeout`, the maximum wait for a missing fragment, after which all other fragments for the same packet are flushed out.

```
user@router# show interfaces sp-0/0/0
services-options {
    open-timeout 5;
    close-timeout 5;
    inactivity-timeout 30;
    tcp-tickles 4;
    fragment-limit 10;
    reassembly-timeout 3;
    cgn-pic;
}
```

Do Not Use Configurations Prone to Routing Loops

Scenario:

- Sudden and persistent high CPU usage is most likely an indication of packet looping between the Packet Forwarding Engine and the services PIC. Depending on whether the configuration uses interface-style or next-hop-style service sets, different network flaps can lead to routing loops.

BEST PRACTICE:

Ensure that only the intended traffic is allowed to reach the services PIC and is serviced based on service set rule.

- Configure a firewall filter that accepts only the traffic meant to go to the services PIC on the output direction of the `sp-` interface. That is, accept only traffic identified in the NAT rule from option as received from the `source-address` that identifies the customer private network; discard and log all the rest.
- Allow only intended traffic to be serviced by the service set by configuring the stateful-firewall rules and NAT rules to translate only the traffic from the customer private source address ranges and intended applications. Although this does not prevent unintended traffic from being processed by the services PIC, it prevents the creation of flows, objects, and states

that are not consistent with the expected traffic and are likely to be problematic.

CHAPTER 7

Avoiding IPv4 Exhaustion Using Junos Address Aware Network Addressing and Stateful NAT64

- [Sample IPv6 Transition Scenarios on page 87](#)
- [Configuring Stateful NAT64 on page 89](#)

Sample IPv6 Transition Scenarios

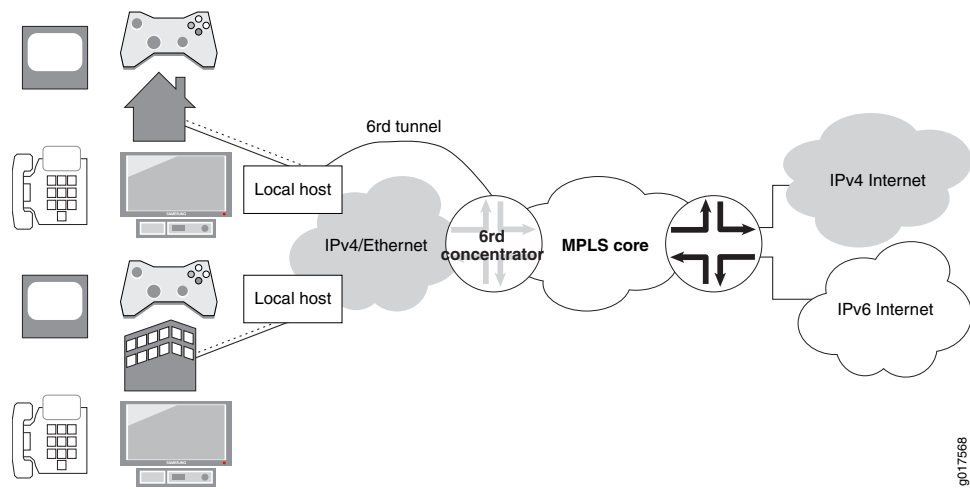

The Junos OS supports many IPv6 transition scenarios required by Junos OS customers. The following are selected examples:

- [Example 1: IPv4 Depletion with a Non-IPv6 Access Network on page 87](#)
- [Example 2: IPv4 Depletion with an IPv6 Access Network on page 88](#)
- [Example 3: IPv4 Depletion for Mobile Networks on page 89](#)

Example 1: IPv4 Depletion with a Non-IPv6 Access Network

[Figure 5 on page 88](#) depicts a scenario in which the Internet service provider (ISP) has not significantly changed its IPv4 network. This approach enables IPv4 hosts to access the IPv4 Internet and IPv6 hosts to access the IPv6 Internet. A dual-stack host can be treated as an IPv4 host when it uses the IPv4 access service, and as an IPv6 host when it uses the IPv6 access service.

Figure 5: IPv4 Depletion Solution - IPv4 Access Network

Two new types of devices must be deployed in this approach: a dual-stack home gateway and a dual-stack carrier-grade Network Address Translation (NAT). The dual-stack home gateway integrates IPv4 forwarding and v6-over-v4 tunneling functions. It can also integrate a v4-v4 NAT function. The dual-stack carrier-grade NAT (CGN) integrates v6-over-v4 tunneling and carrier-grade v4-v4 NAT functions.

Example 2: IPv4 Depletion with an IPv6 Access Network

In the scenario shown in [Figure 6 on page 88](#), the ISP network is IPv6-only.

Figure 6: IPv4 Depletion Solution - IPv6 Access Network

The dual-stack lite (DS-Lite) solution accommodates IPv6-only ISPs. The best business model for this approach is that the customer premises equipment (CPE) has integrated the functions for tunneling IPv6 to an IPv4 backbone, tunneling IPv4 to an IPv6 backbone, and can automatically detect which solution is required.

Not all customers of a given ISP must switch from IPv4 access to IPv6 access simultaneously; in fact, transition can be managed better by switching groups of

customers (for example, all those connected to a single point of presence) on an incremental basis. Such an incremental approach should prove easier to plan, schedule, and execute than an across-the-board conversion.

Example 3: IPv4 Depletion for Mobile Networks

The complexity of mobile networks necessitates a flexible migration approach to ensure minimal disruption and maximum backward compatibility during transition. NAT64 can be used to enable IPv6 devices to communicate to IPv4 hosts without modifying the clients.

Configuring Stateful NAT64

Stateful NAT64 is a mechanism used to move to an IPv6 network and at the same time deal with IPv4 address depletion. By allowing IPv6-only clients to contact IPv4 servers using unicast UDP, TCP, or ICMP, several IPv6-only clients can share the same public IPv4 server address. To allow sharing of the IPv4 server address, stateful NAT64 translates incoming IPv6 packets into IPv4, and vice versa.

To configure stateful NAT64, you must configure a rule at the **[edit services nat]** hierarchy level for translating the source address dynamically and the destination address statically.

BEST PRACTICE: When you configure the service set that includes your NAT rule, include the set `stateful-nat64 clear-dont-fragment-bit` at the **[edit services service-set service-set-name]** hierarchy level. This clears the DF (don't fragment) bit in order to prevent unnecessary creation of an IPv6 fragmentation header when translating IPv4 packets that are less than 1280 bytes. RFC 6145, *IP/ICMP Translation Algorithm*, provides a full discussion of the use of the DF flag to control generation of fragmentation headers. For more information on service sets for NAT, see [“Configuring Service Sets for Network Address Translation” on page 75](#).

To configure stateful NAT64:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Define the pool of source addresses to be used for dynamic translation.

```
[edit services nat]
user@host# set pool pool name address source addresses
user@host# set pool pool name port source ports
```

For example:

```
[edit services nat]
user@host# set pool src-pool-nat64 address 203.0.113.0/24
user@host# set pool src-pool-nat64 port automatic
```

NOTE: Starting with Junos OS release 14.2, the `sequential` option is introduced to enable you to configure sequential allocation of ports. The `sequential` and `random-allocation` options available with the `port automatic` statement at the `[edit services nat pool nat-pool-name]` hierarchy level are mutually exclusive. You can include the `sequential` option for sequential allocation and the `random-allocation` option for random delegation of ports. By default, sequential allocation of ports takes place if you include only the `port automatic` statement at the `[edit services nat pool nat-pool-name]` hierarchy level. The `auto` option is hidden and is deprecated in Junos OS Release 14.2 and later, and is only maintained for backward compatibility. It might be removed completely in a future software release.

3. Define a NAT rule for translating the source addresses. Set the `match-direction` statement of the rule as `input`. Then define a term that uses `stateful-nat64` as the translation type for translating the addresses of the pool defined in the previous step.

```
[edit services nat]
user@host# set rule rule name match-direction input
user@host# set rule rule name term term name from source-address source address
user@host# set rule rule name term term name from destination-address destination address
user@host# set rule rule name term term name then translated source-pool pool name
user@host# set rule rule name term term name then translated destination-prefix destination prefix
user@host# set rule rule name term term name then translated translation-type stateful-nat64
```

For example:

```
[edit services nat]
user@host# set rule stateful-nat64 match-direction input
user@host# set rule stateful-nat64 term t1 from source-address 2001:DB8::0/96
user@host# set rule stateful-nat64 term t1 from destination-address 64:FF9B::/96
user@host# set rule stateful-nat64 term t1 then translated source-pool src-pool-nat64
user@host# set rule stateful-nat64 term t1 then translated destination-prefix 64:FF9B::/96
user@host# set rule stateful-nat64 term t1 then translated translation-type stateful-nat64
```

The following example configures dynamic source address (IPv6-to-IPv4) and static destination address (IPv6-to-IPv4) translation.

```
[edit services]
user@host# show
nat {
    pool src-pool-nat64 {
        address 203.0.113.0/24;
        port {
            automatic;
        }
    }
    rule stateful-nat64 {
        match-direction input;
        term t1 {
```

```
        from {
            source-address {
                2001:db8::0/96;
            }
            destination-address {
                64:ff9b::/96;
            }
        }
        then {
            translated {
                source-pool src-pool-nat64;
                destination-prefix 64:ff9b::/96;
                translation-type {
                    stateful-nat64;
                }
            }
        }
    }
}
service-set sset-nat64 {
    nat-options {
        stateful-nat64 {
            clear-dont-fragment-bit;
        }
    }
    service-set-options;
    nat-rules stateful-nat64;
    interface-service {
        service-interface ms-0/1/0;
    }
}
```

.....

NOTE: If you configure two NAT64 rules and associate them with the same service set, along with stateful firewall rules, and apply the service set on two VLAN-tagged interfaces, for traffic that is transmitted matching both the NAT rules, the traffic that is destined to the second NAT rule is dropped. In such a scenario, traffic flows are not dropped on the Routing Engine. This behavior of traffic drop by the second NAT rule is expected. With Junos OS Extension-Provider packages installed on a device, because endpoint-independent mapping (EIM) is not supported, EIM per VLAN or per NAT rule term. The second session, which is dropped by the second NAT rule in the configuration scenario described here, is not created owing to the following sequence of events:

1. The first packet matching either rule creates an EIM and a session.
2. The second packet matches the EIM entry because the second packet is sent with the same source IP address and port as the first packet (but with a different destination address).

This condition causes allocation (reuse) of the same public IP address and port to the second packet as the first packet. The reverse flow for this session has the same 5-tuple data as the reverse flow of the first session. This behavior causes flow addition failure because a duplicate flow in the same service set is not permitted.

To work around this problem, disable EIM in both the NAT rules, which causes both the sessions to be established and processed correctly. Alternatively, to avoid this problem, specify the NAT rules on different service-sets configured on different units of the media interface with EIM enabled to successfully establish both the sessions.

.....

CHAPTER 8

Hiding Private Networks Using Static Source NAT

- [Configuring Static Source Translation in IPv4 Networks on page 93](#)
- [Configuring Static Source Translation in IPv6 Networks on page 99](#)
- [Example: Configuring Basic NAT44 on page 103](#)
- [Example: Configuring NAT for Multicast Traffic on page 105](#)

Configuring Static Source Translation in IPv4 Networks

To configure the translation type as **basic-nat44**, you must configure the NAT pool and rule, service set with service interface, and trace options. This topic includes the following tasks:

- [Configuring the NAT Pool and Rule on page 93](#)
- [Configuring the Service Set for NAT on page 95](#)
- [Configuring Trace Options on page 97](#)
- [Sample Configuration - Static Source NAT Using a Static Pool With An Address Prefix And An Address Range on page 98](#)
- [Sample Configuration - Static Source Nat for One-To-One Mapping Between a Private Subnet and a Public Subnet on page 98](#)

Configuring the NAT Pool and Rule

To configure the NAT pool, rule, and term:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool name address address
```

In the following example, the pool name is **src_pool** and the address is **10.10.10.2/32**.

```
[edit services nat]
user@host# set pool src_pool address 10.10.10.2/32
```

3. Configure the NAT rule and the match direction.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction
```

In the following example, the NAT rule name is **rule-basic-nat44** and the match direction is **input**.

```
[edit services nat]
user@host# set rule rule-basic-nat44 match-direction input
```

4. Configure the source address in the **from** statement.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term term-name from from
```

In the following example, the term name is **t1** and the input condition is **source-address 3.1.1.2/32**.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term t1 from source-address 3.1.1.2/32
```

5. Configure the NAT term action and properties of the translated traffic.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term t1 then term-action translated-property
```

In the following example, the term action is **translated** and the property of the translated traffic is **source-pool src_pool**.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term t1 then translated source-pool src_pool
```

6. Configure the translation type.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term t1 then translated translation-type
translation-type
```

In the following example, the translation type is **basic-nat44**.

```
[edit services nat]
user@host# set rule rule-basic-nat44 term t1 then translated translation-type
basic-nat44
```

7. Verify the configuration by using the **show** command at the **[edit services nat]** hierarchy level.

```
[edit services]
user@host# show
nat {
  pool src_pool {
    address 10.10.10.2/32;
  }
  rule rule-basic-nat44 {
    match-direction input;
    term t1 {
      from {
        source-address {
          3.1.1.2/32;
        }
      }
    }
    then {

```

```

        translated {
            source-pool src_pool;
            translation-type {
                basic-nat44;
            }
        }
    }
}

```

NOTE: If you don't configure a stateful firewall (SFW) rule for your traffic, then each packet is subjected to the following default stateful firewall rule:

- Allow any valid packets from inside to outside.
- Create forward and return flow based on packets 5-tuple.
- Allow only valid packets matching return flows from outside to inside.

The stateful firewall's packet validity checks are described in the *Stateful Firewall Anomaly Checking* in “[Junos Network Secure Overview](#)” on page 327. When a packets pass stateful firewall validity checking but are not matched by a NAT rule, they are not translated and may be forwarded if the NAT node has a valid route to the packets' destination IP addresses.

NOTE: When you add or delete a parameter in the from statement (NAT rule term match condition) at the [edit services service-set service-set-name nat-rules rule-name term term-name] hierarchy level, this configuration change triggers a deletion and addition of the NAT policy (which is equivalent to the deactivation and activation of a service set) that causes all existing NAT mappings to be deleted. Because the sessions are not closed owing to the change in the NAT policy, this behavior causes the mappings to timeout immediately after the sessions are closed. This behavior is expected and is applicable only with Junos OS Extension-Provider packages installed on a device. When a NAT policy is deleted and readdded, only EIM mappings are deleted. This NAT policy change does not deactivate and activate the service set. We recommend that you deactivate and reactivate the service set in such scenarios in Junos OS Release 14.2 and earlier.

Configuring the Service Set for NAT

To configure the service set for NAT:

1. In configuration mode, go to the [edit services] hierarchy level.

```

[edit]
user@host# edit services

```

2. Configure the service set.

```
[edit services]
user@host# edit service-set service-set-name
```

In the following example, the service set name is **s1**.

```
[edit services]
user@host# edit service-set s1
```

3. For the **s1** service set, set the reference to the NAT rules configured at the **[edit services nat]** hierarchy level.

```
[edit services service-set s1]
user@host# set nat-rules rule-name
```

In the following example, the rule name is **rule-basic-nat44**.

```
[edit services service-set s1]
user@host# set nat-rules rule-basic-nat44
```

4. Configure the service interface.

```
[edit services service-set s1]
user@host# set interface-service service-interface service-interface-name
```

In the following example, the service interface name is **ms-1/2/0**.

```
[edit services service-set s1]
user@host# set interface-service service-interface ms-1/2/0
```

NOTE: If you have a Trio-based line card, you can configure an inline-services interface on that card:

```
[edit]
user@host# set interfaces si-0/0/0
[edit services service-set s1]
user@host# set interface-service service-interface si-0/0/0
```

5. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
service-set s1 {
    nat-rules rule-basic-nat44;
    interface-service {
        service-interface ms-1/2/0;
    }
}
```

6. Associate the NAT service set with an **xe-** interface:

```
user@host# set interfaces xe-1/1/0 unit 0 family inet address 10.255.247.2/24
user@host# set interfaces xe-1/1/0 unit 0 family inet service input service-set s1
user@host# set interfaces xe-1/1/0 unit 0 family inet service output service-set s1
```

7. Verify the configuration by using the **show** command at the **[edit interfaces]** hierarchy level.

```
[edit interfaces]
user@host# show
```

```

xe-1/1/0 {
  unit 0 {
    family inet {
      service {
        input {
          service-set s1;
        }
        output {
          service-set s1;
        }
      }
      address 10.255.247.2/24;
    }
  }
}

```

Configuring Trace Options

To configure the trace options:

1. In configuration mode, go to the **[edit services adaptive-services-pics]** hierarchy level.

```

[edit]
user@host# edit services adaptive-services-pics

```

2. Configure the trace options.

```

[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter

```

In the following example, the tracing parameter is **all**.

```

[edit services adaptive-services-pics]
user@host# set traceoptions flag all

```

3. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```

[edit services]
user@host# show
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}

```

```

[edit]
user@host# show services
service-set s1 {
  nat-rules rule-basic-nat44;
  interface-service {
    service-interface ms-1/2/0;
  }
}
nat {
  pool src_pool {
    address 10.10.10.2/32;
  }
  rule rule-basic-nat44 {
    match-direction input;
    term t1 {

```

```

        from {
            source-address {
                3.1.1.2/32;
            }
        }
        then {
            translated {
                source-pool src_pool;
                translation-type {
                    basic-nat44;
                }
            }
        }
    }
}

adaptive-services-pics {
    traceoptions {
        flag all;
    }
}

```

Sample Configuration - Static Source NAT Using a Static Pool With An Address Prefix And An Address Range

```
[edit services nat]
pool p1 {

```

Configuring Static Source Translation in IPv6 Networks

To configure the translation type as **basic-nat66**, you must configure the NAT pool and rule, service set with service interface, and trace options. This topic includes the following tasks:

- [Configuring the NAT Pool and Rule on page 100](#)
- [Configuring the Service Set for NAT on page 101](#)
- [Configuring Trace Options on page 102](#)

Configuring the NAT Pool and Rule

To configure the NAT pool, rule, and term:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool name address address
```

In the following example, the pool name is **src_pool** and the address is **10.10.10.2/32**.

```
[edit services nat]
user@host# set pool src_pool address 10.10.10.2/32
```

3. Configure the NAT rule and the match direction.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction
```

In the following example, the rule name is **rule-basic-nat66** and the match direction is **input**.

```
[edit services nat]
user@host# set rule rule-basic-nat66 match-direction input
```

4. Configure the source address in the **from** statement.

```
[edit services nat]
user@host# set rule rule-basic-nat66 term term-name from from
```

In the following, the term name is **t1** and the input condition is **source-address 10:10:10::0/96**.

```
[edit services nat]
user@host# set rule rule-basic-nat66 term t1 from source-address 10:10:10::0/96
```

5. Configure the NAT term action and properties of the translated traffic.

```
[edit services nat]
user@host# set rule rule-basic-nat66 term t1 then term-action translated-property
```

In the following example, the term action is **translated** and the property of the translated traffic is **source-pool src_pool**.

```
[edit services nat]
user@host# set rule rule-basic-nat66 term t1 then translated source-pool src_pool
```

6. Configure the translation type.

```
[edit services nat]
user@host# set rule rule-basic-nat66 term t1 then translated translation-type
translation-type
```

In the following example, the translation type is **basic-nat66**.

```
[edit services nat]
```

```
user@host# set rule rule-basic-nat66 term t1 then translated translation-type
basic-nat66
```

7. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
nat {
  pool src_pool {
    address 10.10.10.2/32;
  }
  rule rule-basic-nat66 {
    match-direction input;
    term t1 {
      from {
        source-address {
          10:10:10::0/96;
        }
      }
      then {
        translated {
          source-pool src_pool;
          translation-type {
            basic-nat66;
          }
        }
      }
    }
  }
}
```

Configuring the Service Set for NAT

To configure the service set for NAT:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure the service set.

```
[edit services]
user@host# edit service-set service-set-name
```

In the following example, the service set name is **s1**.

```
[edit services]
user@host# edit service-set s1
```

3. For the **s1** service set, set the reference to the NAT rules configured at the **[edit services nat]** hierarchy level.

```
[edit services service-set s1]
user@host# set nat-rules rule-name
```

In the following example, the rule name is **rule-basic-nat66**.

```
[edit services service-set s1]
user@host# set nat-rules rule-basic-nat66
```

4. Configure the service interface.

```
[edit services service-set s1]
user@host# set interface-service service-interface service-interface-name
```

In the following example, the service interface name is **sp-1/2/0**.

```
[edit services service-set s1]
user@host# set interface-service service-interface sp-1/2/0
```

5. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-basic-nat66;
  interface-service {
    service-interface sp-1/2/0;
  }
}
```

Configuring Trace Options

To configure the trace options at the **[edit services adaptive-services-pics]** hierarchy level:

1. In configuration mode, go to the **[edit services adaptive-services-pics]** hierarchy level.

```
[edit]
user@host# edit services adaptive-services-pics
```

2. Configure the trace options.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter
```

In the following example, the tracing parameter is **all**.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag all
```

3. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following example configures the translation type as **basic-nat66**.

```
[edit]
user@host# show services
service-set s1 {
  nat-rules rule-basic-nat66;
  interface-service {
    service-interface sp-1/2/0;
  }
}
```

```

}
nat {
  pool src_pool {
    address 10.10.10.2/32;
  }
  rule rule-basic-nat66 {
    match-direction input;
    term t1 {
      from {
        source-address {
          10:10:10::0/96;
        }
      }
      then {
        translated {
          source-pool src_pool;
          translation-type {
            basic-nat66;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}

```

Example: Configuring Basic NAT44

This example describes how to implement a basic NAT44 configuration.

- [Requirements on page 103](#)
- [Overview on page 103](#)
- [Configuring Basic NAT44 on page 104](#)

Requirements

This example uses the following hardware and software components:

- An MX Series 3D Universal Edge router with a Services DPC or an M Series Multiservice Edge router with a services PIC
- A domain name server (DNS)
- Junos OS Release 11.4 or higher

Overview

This example shows a complete CGN NAT44 configuration and advanced options.

Configuring Basic NAT44

Chassis Configuration

Step-by-Step Procedure

To configure the service PIC (FPC 5 Slot 0) with the Layer 3 service package:

1. Go to the **[edit chassis]** hierarchy level.

```
user@host# edit chassis
```
2. Configure the Layer 3 service package.

```
[edit chassis]  
user@host# set fpc 5 pic 0 adaptive-services service-package layer-3
```

Interfaces Configuration

Step-by-Step Procedure

To configure interfaces to the private network and the public Internet:

1. Define the interface to the private network.

```
user@host# edit interfaces ge-1/3/5  
[edit interfaces ge-1/3/5]  
user@host# set description "Private"  
user@host# edit unit 0 family inet  
[edit interfaces ge-1/3/5 unit 0 family inet]  
user@host# set service input service-set ss2  
user@host# set service output service-set ss2  
user@host# set address 9.0.0.1/24
```
2. Define the interface to the public Internet.

```
user@host# edit interfaces ge-1/3/6  
[edit interfaces ge-1/3/6]  
user@host# set description "Public"  
user@host# set unit 0 family inet address 128.0.0.1/24
```
3. Define the service interface for NAT processing.

```
user@host# edit interfaces sp-5/0/0  
[edit interfaces sp-5/0/0]  
user@host# set unit 0 family inet
```

```

Results user@host# show interfaces ge-1/3/5
description Private;
unit 0 {
  family inet {
    service {
      input {
        service-set sset2;
      }
      output {
        service-set sset2;
      }
    }
    address 9.0.0.1/24;
  }
}

user@host# show interfaces ge-1/3/6
description Public;;
unit 0 {
  family inet {
    address 128.0.0.1/24;
  }
}

user@host# show interfaces sp-5/0/0
unit 0 {
  family inet;
}

```

Example: Configuring NAT for Multicast Traffic

Figure 7 on page 105 illustrates the network setup for the following configuration, which allows IP multicast traffic to be sent to the Multiservices PIC.

Figure 7: Configuring NAT for Multicast Traffic

- [Rendezvous Point Configuration on page 105](#)
- [Router 1 Configuration on page 108](#)

Rendezvous Point Configuration

On the rendezvous point (RP), all incoming traffic from the multicast source at **192.168.254.0/27** is sent to the static NAT pool **mcast_pool**, where its source is translated to **20.20.20.0/27**. The service set **nat_ss** is a next-hop service set that allows IP multicast traffic to be sent to the Multiservices DPC or Multiservices PIC. The inside interface on the PIC is **ms-1/1/0.1** and the outside interface is **ms-1/1/0.2**.

[edit services]

```
nat {
  pool mcast_pool {
    address 20.20.20.0/27;
  }
  rule nat_rule_1 {
    match-direction input;
    term 1 {
      from {
        source-address 192.168.254.0/27;
      }
    }
    then {
      translated {
        source-pool mcast_pool;
        translation-type basic-nat44;
      }
      syslog;
    }
  }
}
service-set nat_ss {
  allow-multicast;
  nat-rules nat_rule_1;
  next-hop-service {
    inside-service-interface ms-1/1/0.1;
    outside-service-interface ms-1/1/0.2;
  }
}
```

The Gigabit Ethernet interface **ge-0/3/0** carries traffic out of the RP to Router 1. The multiservices interface **ms-1/1/0** has two logical interfaces: **unit 1** is the inside interface for next-hop services and **unit 2** is the outside interface for next-hop services. Multicast source traffic comes in on the Fast Ethernet interface **fe-1/2/1**, which has the firewall filter **fbf** applied to incoming traffic.

```
[edit interfaces]
ge-0/3/0 {
  unit 0 {
    family inet {
      address 10.10.1.1/30;
    }
  }
}
ms-1/1/0 {
  unit 0 {
    family inet;
  }
  unit 1 {
    family inet;
    service-domain inside;
  }
  unit 2 {
    family inet;
    service-domain outside;
  }
}
```

```

}
fe-1/2/1 {
  unit 0 {
    family inet {
      filter {
        input fbf;
      }
      address 192.168.254.27/27;
    }
  }
}

```

Multicast packets can only be directed to the Multiservices DPC or the Multiservices PIC using a next-hop service set. In the case of NAT, you must also configure a VPN routing and forwarding instance (VRF). Therefore, the routing instance **stage** is created as a “dummy” forwarding instance. To direct incoming packets to **stage**, you configure filter-based forwarding through a firewall filter called **fbf**, which is applied to the incoming interface **fe-1/2/1**. A lookup is performed in **stage.inet.0**, which has a multicast static route that is installed with the next hop pointing to the PIC's inside interface. All multicast traffic matching this route is sent to the PIC.

```

[edit firewall]
filter fbf {
  term 1 {
    then {
      routing-instance stage;
    }
  }
}

```

The routing instance **stage** forwards IP multicast traffic to the inside interface **ms-1/1/0.1** on the Multiservices DPC or Multiservices PIC:

```

[edit]
routing-instances stage {
  instance-type forwarding;
  routing-options {
    static {
      route 224.0.0.0/4 next-hop ms-1/1/0.1;
    }
  }
}

```

You enable OSPF and Protocol Independent Multicast (PIM) on the Fast Ethernet and Gigabit Ethernet logical interfaces over which IP multicast traffic enters and leaves the RP. You also enable PIM on the outside interface (**ms-1/1/0.2**) of the next-hop service set.

```

[edit protocols]
ospf {
  area 0.0.0.0 {
    interface fe-1/2/1.0 {
      passive;
    }
    interface lo0.0;
    interface ge-0/3/0.0;
  }
}

```

```
    }  
  }  
  pim {  
    rp {  
      local {  
        address 10.255.14.160;  
      }  
    }  
    interface fe-1/2/1.0;  
    interface lo0.0;  
    interface ge-0/3/0.0;  
    interface ms-1/1/0.2;  
  }
```

As with any filter-based forwarding configuration, in order for the static route in the forwarding instance **stage** to have a reachable next hop, you must configure routing table groups so that all interface routes are copied from **inet.0** to the routing table in the forwarding instance. You configure routing tables **inet.0** and **stage.inet.0** as members of **fbf_rib_group**, so that all interface routes are imported into both tables.

```
[edit routing-options]  
interface-routes {  
  rib-group inet fbf_rib_group;  
}  
rib-groups fbf_rib_group {  
  import-rib [ inet.0 stage.inet.0 ];  
}  
multicast {  
  rpf-check-policy no_rpf;  
}
```

Reverse path forwarding (RPF) checking must be disabled for the multicast group on which source NAT is applied. You can disable RPF checking for specific multicast groups by configuring a policy similar to the one in the example that follows. In this case, the **no_rpf** policy disables RPF check for multicast groups belonging to **224.0.0.0/4**.

```
[edit policy-options]  
policy-statement no_rpf {  
  term 1 {  
    from {  
      route-filter 224.0.0.0/4 orlonger;  
    }  
    then reject;  
  }  
}
```

Router 1 Configuration

The Internet Group Management Protocol (IGMP), OSPF, and PIM configuration on Router 1 is as follows. Because of IGMP static group configuration, traffic is forwarded out **fe-3/0/0.0** to the multicast receiver without receiving membership reports from host members.

```
[edit protocols]  
igmp {
```

```
interface fe-3/0/0.0 {  
}  
}  
ospf {  
  area 0.0.0.0 {  
    interface fe-3/0/0.0 {  
      passive;  
    }  
    interface lo0.0;  
    interface ge-7/2/0.0;  
  }  
  pim {  
    rp {  
      static {  
        address 10.255.14.160;  
      }  
    }  
    interface fe-3/0/0.0;  
    interface lo0.0;  
    interface ge-7/2/0.0;  
  }  
}
```

The routing option creates a static route to the NAT pool, **mcast_pool**, on the RP.

```
[edit routing-options]  
static {  
  route 20.20.20.0/27 next-hop 10.10.1.1;  
}
```

CHAPTER 9

Making Private Servers Available Using Static Destination NAT

- [Configuring Static Destination Address Translation in IPv4 Networks on page 111](#)

Configuring Static Destination Address Translation in IPv4 Networks

In IPv4 networks, destination address translation is a mechanism used to implement address translation for destination traffic without port mapping. To use destination address translation, the size of the pool address space must be greater than or equal to the destination address space. You must specify a name for the **destination-pool** statement, which can contain multiple addresses, ranges, or prefixes, as long as the number of NAT addresses in the pool is larger than the number of destination addresses in the **from** statement.

To configure destination address translation in IPv4 networks:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure the service set and the NAT rule.

```
[edit services]
user@host# set service-set service-set-name nat-rules rule-name
```

In the following example, the name of the service set is **s1** and the name of the NAT rule is **rule-dnat44**.

```
[edit services]
user@host# set service-set s1 nat-rules rule-dnat44
```

3. Go to the **[interface-service]** hierarchy level of the service set.

```
[edit services]
user@host# edit service-set s1 interface-service
```

4. Configure the service interface.

```
[edit services service-set s1 interface-service]
user@host# set service-interface service-interface-name
```

In the following example, the name of the service interface is **ms-0/1/0**.

NOTE: If the service interface is not present in the router, or the specified interface is not functional, the following command can result in an error.

```
[edit services service-set s1 interface-service]
user@host# set service-interface ms-0/1/0
```

5. Go to the **[edit services nat]** hierarchy level. Issue the following command from the top of the services hierarchy, or use the **top** keyword.

```
[edit services service-set s1]
user@host# top edit services nat
```

6. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool-name address address
```

In the following example, **dest-pool** is used as the pool name and **4.1.1.2** as the address.

```
user@host# set pool dest-pool address 4.1.1.2
```

7. Configure the rule, match direction, term, and destination address.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction term term-name from
destination-address address
```

In the following example, the name of the rule is **rule-dnat44**, the match direction is **input**, the name of the term is **t1**, and the address is **20.20.20.20**.

```
[edit services nat]
user@host# set rule rule-dnat44 match-direction input term t1 from
destination-address 20.20.20.20
```

8. Go to the **[edit services nat rule rule-dnat44 term t1]** hierarchy level.

```
[edit services nat]
user@host# edit rule rule-dnat44 term t1
```

9. Configure the destination pool and the translation type.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then translated destination-pool dest-pool-name translation-type
translation-type
```

In the following example, the destination pool name is **dest-pool**, and the translation type is **dnat-44**.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then translated destination-pool dest-pool translation-type dnat-44
```

10. Go to the **[edit services adaptive-services-pics]** hierarchy level. In the following command, the **top** keyword ensures that the command is run from the top of the hierarchy.

```
[edit services nat rule rule-dnat44 term t1]
user@host# top edit services adaptive-services-pics
```

11. Configure the trace options.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter
```

In the following example, the tracing parameter is configured as **all**.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag all
```

12. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-dnat44;
  interface-service {
    service-interface ms-0/1/0;
  }
}
nat {
  pool dest-pool {
    address 4.1.1.2/32;
  }
  rule rule-dnat44 {
    match-direction input;
    term t1 {
      from {
        destination-address {
          20.20.20.20/32;
        }
      }
      then {
        translated {
          destination-pool dest-pool;
          translation-type {
            dnat-44;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following example configures the translation type as **dnat-44**.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-dnat44;
  interface-service {
    service-interface ms-0/1/0;
  }
}
nat {
  pool dest-pool {
    address 4.1.1.2/32;
  }
}
```

```

rule rule-dnat44 {
    match-direction input;
    term t1 {
        from {
            destination-address {
                20.20.20.20/32;
            }
        }
        then {
            translated {
                destination-pool dest-pool;
                translation-type {
                    dnat-44;
                }
            }
        }
    }
}

adaptive-services-pics {
    traceoptions {
        flag all;
    }
}

```

In the following configuration, **term1** configures source address translation for traffic from any private address to any public address. The translation is applied for all services. **term2** performs destination address translation for Hypertext Transfer Protocol (HTTP) traffic from any public address to the server's virtual IP address. The virtual server IP address is translated to an internal IP address.

```
[edit services nat]
rule my-nat-rule {
  match-direction input;
  term my-term1 {
    from {
      source-address private;
      destination-address public;
    }
    then {
      translated {
        source-pool my-pool; # pick address from a pool
        translation-type napt-44; # dynamic NAT with port translation
      }
    }
  }
}

rule my-nat-rule2 {
  match-direction input;
  term my-term2 {
    from {
      destination-address 192.168.137.3; # my server's virtual address
      application http;
    }
    then {
      translated {
        destination-pool nat-pool-name;
        translation-type dnat-44; # static destination NAT
      }
    }
  }
}
```

```
    }  
  }  
}  
}
```

The following configuration performs NAT using the destination prefix **20.20.10.0/32** without defining a pool.

```
[edit services nat]  
rule src-nat {  
  match-direction input;  
  term t1 {  
    from {  
      destination-address 10.10.10.10/32;  
      then {  
        translation-type dnat44;  
        destination-prefix 20.20.10.0/24;  
      }  
    }  
  }  
}
```

CHAPTER 10

Allowing Components of a Private Network to Share a Single Address Using NAT

- [Configuring Address Pools for Network Address Port Translation \(NAPT\) Overview on page 117](#)
- [Configuring Dynamic Source Address and Port Translation in IPv4 Networks on page 127](#)
- [Configuring Dynamic Source Address and Port Translation for IPv6 Networks on page 131](#)
- [Example: Configuring NAT with Port Translation on page 133](#)
- [Example: NAPT Configuration for the MS-MPC on page 134](#)
- [Example: Dynamic Source NAT as a Next-Hop Service on page 138](#)

Configuring Address Pools for Network Address Port Translation (NAPT) Overview

With Network Address Port Translation (NAPT), you can configure up to 32 address ranges with up to 65,536 addresses each.

The **port** statement specifies port assignment for the translated addresses. To configure automatic assignment of ports, include the **port automatic** statement at the **[edit services nat pool nat-pool-name]** hierarchy level. By default, sequential allocation of ports occurs. You can include the **sequential** option with the **port automatic** statement at the **[edit services nat pool nat-pool-name]** hierarchy level, starting with Junos OS Release 14.2 for sequenced allocation of ports from the specified range. To configure a specific range of port numbers, include the **port range low minimum-value high maximum-value** statement at the **[edit services nat pool nat-pool-name]** hierarchy level.

NOTE: When 99% of the total available ports in pool for napt-44 , no new flows are allowed on that NAT pool.

The **auto** option is hidden and is deprecated in Junos OS Release 14.2 and later, and is only maintained for backward compatibility. It might be removed completely in a future software release.

The Junos OS provides several alternatives for allocating ports:

- [Round-Robin Allocation for NAPT on page 118](#)
- [Sequential Allocation for NAPT on page 118](#)
- [Preserve Parity and Preserve Range for NAPT on page 119](#)
- [Address Pooling and Endpoint Independent Mapping for NAPT on page 119](#)
- [Port Block Allocation for NAPT on page 121](#)
- [Deterministic Port Block Allocation for NAPT on page 122](#)
- [Comparison of NAPT Implementation Methods on page 126](#)

Round-Robin Allocation for NAPT

To configure round-robin allocation for NAT pools, include the **address-allocation round-robin** configuration statement at the **[edit services nat pool *pool-name*]** hierarchy level. When you use round-robin allocation, one port is allocated from each address in a range before repeating the process for each address in the next range. After ports have been allocated for all addresses in the last range, the allocation process wraps around and allocates the next unused port for addresses in the first range.

- The first connection is allocated to the address:port 100.0.0.1:3333.
- The second connection is allocated to the address:port 100.0.0.2:3333.
- The third connection is allocated to the address:port 100.0.0.3:3333.
- The fourth connection is allocated to the address:port 100.0.0.4:3333.
- The fifth connection is allocated to the address:port 100.0.0.5:3333.
- The sixth connection is allocated to the address:port 100.0.0.6:3333.
- The seventh connection is allocated to the address:port 100.0.0.7:3333.
- The eighth connection is allocated to the address:port 100.0.0.8:3333.
- The ninth connection is allocated to the address:port 100.0.0.9:3333.
- The tenth connection is allocated to the address:port 100.0.0.10:3333.
- The eleventh connection is allocated to the address:port 100.0.0.11:3333.
- The twelfth connection is allocated to the address:port 100.0.0.12:3333.
- Wraparound occurs and the thirteenth connection is allocated to the address:port 100.0.0.1:3334.

Sequential Allocation for NAPT

With sequential allocation, the next available address in the NAT pool is selected only when all the ports available from an address are exhausted.

NOTE: This legacy implementation provides backward compatibility and is no longer a recommended approach.

The NAT pool called **napt** in the following configuration example uses the sequential implementation:

```
pool napt {  
  address-range low 100.0.0.1 high 100.0.0.3;  
  address-range low 100.0.0.4 high 100.0.0.6;  
  address-range low 100.0.0.8 high 100.0.0.10;  
  address-range low 100.0.0.12 high 100.0.0.13;  
  port {  
    range low 3333 high 3334;  
  }  
}
```

In this example, the ports are allocated starting from the first address in the first address-range, and allocation continues from this address until all available ports have been used. When all available ports have been used, the next address (in the same address-range or in the following address-range) is allocated and all its ports are selected as needed. In the case of the example **napt** pool, the tuple address, port 100.0.0.4:3333, is allocated only when all ports for all the addresses in the first range have been used.

- The first connection is allocated to the address:port 100.0.0.1:3333.
- The second connection is allocated to the address:port 100.0.0.1:3334.
- The third connection is allocated to the address:port 100.0.0.2:3333.
- The fourth connection is allocated to the address:port 100.0.0.2:3334, and so on.

Preserve Parity and Preserve Range for NAPT

The following options are available for NAPT:

- Preserving parity—Use the **preserve-parity** command to allocate even ports for packets with even source ports and odd ports for packets with odd source ports.
- Preserving range—Use the **preserve-range** command to allocate ports within a range from 0 to 1023, assuming the original packet contains a source port in the reserved range. This applies to control sessions, not data sessions.

Address Pooling and Endpoint Independent Mapping for NAPT

- [Address Pooling on page 119](#)
- [Endpoint Independent Mapping and Endpoint Independent Filtering on page 120](#)

Address Pooling

Address pooling, or address pooling paired (APP) ensures assignment of the same external IP address for all sessions originating from the same internal host. You can use this feature when assigning external IP addresses from a pool. This option does not affect port utilization

Address pooling solves the problems of an application opening multiple connections. For example, when Session Initiation Protocol (SIP) client sends Real-Time Transport Protocol (RTP) and Real-Time Control Protocol (RTCP) packets, the SIP generally server

requires that they come from the same IP address, even if they have been subject to NAT. If RTP and RTCP IP addresses are different, the receiving endpoint might drop packets. Any point-to-point (P2P) protocol that negotiates ports (assuming address stability) benefits from address pooling paired.

The following are use cases for address pooling:

- A site that offers instant messaging services requires that chat and their control sessions come from the same public source address. When the user signs on to chat, a control session authenticates the user. A different session begins when the user starts a chat session. If the chat session originates from a source address that is different from the authentication session, the instant messaging server rejects the chat session, because it originates from an unauthorized address.
- Certain websites such as online banking sites require that all connections from a given host come from the same IP address.

.....

NOTE: Starting with Junos OS Release 14.1, when you deactivate a service-set that contains address pooling paired (APP) for that service-set, messages are displayed on the PIC console and the mappings are cleared for that service-set. These messages are triggered when the deletion of a service-set commences and again generated when the deletion of the service-set is completed. The following sample messages are displayed when deletion starts and ends:

- Nov 15 08:33:13.974 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion initiated
- Nov 15 08:33:14.674 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion completed

In a scaled environment that contains a large number of APP in a service set, a heavy volume of messages is generated and this process takes some amount of time. We recommend that you wait until the console messages indicating the completion of deletion of the service set are completed before you reactivate the service-set again.

.....

Endpoint Independent Mapping and Endpoint Independent Filtering

Endpoint independent mapping (EIM) ensures the assignment of the same external address *and* port for all connections from a given host if they use the same internal port. This means if they come from a different source port, you are free to assign a different external address.

EIM and APP differ as follows:

- APP ensures assigning the same external IP address.
- EIM provides a stable external IP address and port (for a period of time) to which external hosts can connect. Endpoint independent filtering (EIF) controls which external hosts can connect to an internal host.

NOTE: Starting with Junos OS Release 14.1, when you deactivate a service-set that contains endpoint independent mapping (EIM) mapping for that service-set, messages are displayed on the PIC console and the mappings are cleared for that service-set. These messages are triggered when the deletion of a service-set commences and again generated when the deletion of the service-set is completed. The following sample messages are displayed when deletion starts and ends:

- Nov 15 08:33:13.974 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion initiated
- Nov 15 08:33:14.674 LOG: Critical] SVC-SET ss1 (iid 5) deactivate/delete: NAT Mappings and flows deletion completed

In a scaled environment that contains a large number of EIM mappings in a service set, a heavy volume of messages is generated and this process takes some amount of time. We recommend that you wait until the console messages indicating the completion of deletion of the service set are completed before you reactivate the service-set again.

Port Block Allocation for NAPT

Carriers track subscribers using the IP address (RADIUS or DHCP) log. If they use NAPT, an IP address is shared by multiple subscribers, and the carrier must track the IP address and port, which are part of the NAT log. Because ports are used and reused at a very high rate, tracking subscribers using the log becomes difficult due to the large number of messages, which are difficult to archive and correlate. By enabling the allocation of ports in blocks, port block allocation can significantly reduce the number of logs, making it easier to track subscribers.

Port block allocation is supported on MX series routers with MultiServices Dense Port Concentrators (MS-DPCs).

- [Secured Port Block Allocation for NAPT on page 121](#)
- [Interim Logging for Port Block Allocation on page 122](#)

Secured Port Block Allocation for NAPT

Secured port block allocation can be used for translation types **napt-44** and **stateful-nat64**.

When allocating blocks of ports, the most recently allocated block is the current active block. New requests for NAT ports are served from the active block. Ports are allocated randomly from the current active block.

When you configure secured port block allocation, you can specify the following:

- **block-size**
- **max-blocks-per-address**

- **active-block-timeout**

Interim Logging for Port Block Allocation

With port block allocation we generate one syslog log per set of ports allocated for a subscriber. These logs are UDP based and can be lost in the network, particularly for long-running flows. Interim logging triggers re-sending the above logs at a configured interval for active blocks that have traffic on at least one of the ports of the block.

Interim logging is activated by including the **pba-interim-logging-interval** statement under **services-options** for sp- interfaces.

Deterministic Port Block Allocation for NAT

You can configure NAT algorithm-based allocation of blocks of destination ports. By specifying **deterministic-port-block-allocation blocksize blocksize** at the **[edit services nat pool poolname port]** hierarchy level, you ensure that an incoming (source) IP address and port always map to the same destination IP address and port, thus eliminating the need for the address translation logging. You can also specify **include-boundary-addresses** if you want the lowest and highest addresses in the source address range of a NAT rule to be translated when the NAT pool is used. When you use deterministic port block allocation, you must specify **deterministic-nat44** as the **translation-type** in your NAT rule.

For detailed information on how to configure deterministic port block allocation, see [“Configuring Deterministic Port Block Allocation” on page 180](#).

- [Understanding Deterministic Port Block Allocation Algorithms on page 122](#)
- [Deterministic Port Block Allocation Algorithm Usage on page 123](#)
- [Deterministic Port Block Allocation Restrictions on page 125](#)

Understanding Deterministic Port Block Allocation Algorithms

The effectiveness of your implementation of deterministic port block allocation depends on your analysis of your subscriber requirements. The block size you provide indicates how many ports will be made available for each incoming subscriber address in the range the **from** clause specified in the applicable NAT rule. The allocation algorithm computes an offset value to determine the outgoing port. A reverse algorithm is used to derive the originating subscriber address.

NOTE: In order to track subscribers without using logs, an ISP must use a reverse algorithm to derive a subscriber (source) addresses from translated addresses.

Deterministic Port Block Allocation Algorithm Usage

When you have configured deterministic port block allocation, you can use the ***show services nat deterministic-nat internal-host*** and ***show services nat deterministic-nat nat-port-block*** commands to show forward and reverse mapping. However, mappings will change if you reconfigure your deterministic port block allocation block size or the **from** clause for your NAT rule. In order to provide historical information on mappings, we recommend that you write scripts that can show specific mappings for prior configurations.

The following variables are used in forward calculation (private subscriber IP address to public IP address) and reverse calculation (public IP address to private subscriber IP address):

- Pr_Prefix—Any pre-NAT IPv4 subscriber address
- Pr_Port—Any pre-NAT protocol port
- Block_Size—Number of ports configured to be available for each Pr_Prefix
- Base_PR_Prefix—First usable pre-NAT IPv4 subscriber address in a “from” clause match condition
- Base_PU_Prefix—First usable post-NAT IPv4 subscriber address configured in the NAT pool.
- Pu_Port_Range_Start—1024 (ports 0 through 1023 are not used when **port automatic** is configured)
- Pr_Offset—Pr_Prefix – Base_Pr_Prefix
- PR_Port_Offset—Pr_Offset * Block_Size
- Pu_Prefix—Post-NAT address for a given Pr_Prefix
- Pu_Start_Port—Post-NAT start port for a flow from a given Pr_Prefix
- Pu_Actual_Port—Post-NAT port seen on a reverse flow
- Nr_Addr_PR_Prefix — Number of usable pre-NAT IPv4 subscriber addresses in a “from” clause match condition
- Nr_Addr_PU_Prefix — Number of usable post-NAT IPv4 addresses configured in the NAT pool
- Rounded_Port_Range_Per_IP — $\text{ceil}[(\text{Nr_Addr_PR_Prefix}/\text{Nr_Addr_PU_Prefix})] * \text{Block_Size}$
- Pu_Offset—Pu_Prefix – Base_Pu_Prefix
- Pu_Port_Offset—(Pu_Offset * Port_Range_Per_Pu_IP) + (Pu_Actual_Port – Pu_Port_Start_Port)

NOTE: If `block-size` is configured as zero, the method for computing the block size has changed and is computed as follows:

$$\text{block-size} = \text{int}(\text{ceil}[(\text{Nr_Addr_PR_Prefix} / \text{Nr_Addr_PU_Prefix})])$$

where 64512 is the maximum available port range per public IP address.

Algorithm Usage—Assume the following configuration:

```
services {
  nat {
    pool src-pool {
      address-range low 32.32.32.1 high 32.32.32.254;
      port {
        automatic {
          random-allocation;
        }
        deterministic-block-allocation {
          block-size 249;
        }
      }
    }
  }
  rule det-nat {
    match-direction input;
    term t1 {
      from {
        source-address {
          10.1.0.0/16;
        }
      }
      then {
        translated {
          source-pool src-pool;
          translation-type {
            deterministic-napt44;
          }
        }
      }
    }
  }
}
```

Forward Translation

1. $\text{Pr_Offset} = \text{Pr_Prefix} - \text{Base_Pr_Prefix}$
2. $\text{Pr_Port_Offset} = \text{Pr_Offset} * \text{Block_Size}$
3. $\text{Rounded_Port_Range_Per_IP} = \text{ceil}[(\text{Nr_Addr_PR_Prefix} / \text{Nr_Addr_PU_Prefix})] * \text{Block_Size}$
4. $\text{Pu_Prefix} = \text{Base_Public_Prefix} + \text{floor}(\text{Pr_Port_Offset} / \text{Rounded_Port_Range_Per_IP})$
5. $\text{Pu_Start_Port} = \text{Pu_Port_Range_Start} + (\text{Pr_Port_Offset} \% \text{Rounded_Port_Range_Per_IP})$

Using the sample configuration and assuming a subscriber flow sourced from 10.1.1.250:5000:

1. $\text{Pr_Offset} = 10.1.1.250 - 10.1.0.1 = 505$
2. $\text{Pu_Port_Offset} = 505 * 249 = 125,745$
3. $\text{Rounded_Port_Range_Per_IP} = \text{ceil}[(65,533/254)] * 249 = 259 * 249 = 64,491$
4. $\text{Pu_Prefix} = 32.32.32.1 + \text{floor}(125,745 / 64,491) = 32.32.32.1 + 1 = 32.32.32.2$
5. $\text{Pu_Start_Port} = 1,024 + (125,745 \% 64,491) = 62278$
 - 10.1.1.250 is translated to 32.32.32.2.
 - The starting port is 62278. There are 249 ports available to the subscriber based on the configured block size. The available port range spans ports 62278 through 62526 (inclusive).
 - The specific flow 10.1.1.250:5000 randomly assigns any of the ports in its range because random allocation was specified.

Reverse Translation

1. $\text{Pu_Offset} = \text{Pu_Prefix} - \text{Base_Pu_Prefix}$
2. $\text{Pu_Port_Offset} = (\text{Pu_Offset} * \text{Rounded_Port_Range_Per_IP}) + (\text{Pu_Actual_Port} - \text{Pu_Port_Range_Start})$
3. $\text{Subscriber_IP} = \text{Base_Pr_Prefix} + \text{floor}(\text{Pu_Port_Offset} / \text{Block_Size})$

The reverse translation is determined as follows. Assume a flow returning to 32.32.32.2:62278.

1. $\text{Pu_Offset} = 32.32.32.2 - 32.32.32.1 = 1$
2. $\text{Pu_Port_Offset} = (1 * 64,491) + (62,280 - 1024) = 125,747$
3. $\text{Subscriber_IP} = 10.1.0.1 + \text{floor}(125,747 / 249) = 10.1.0.1 + 505 = 10.1.1.250$

NOTE: In reverse translation, only the original private IP address can be derived, and not the original port in use. This is sufficiently granular for law enforcement requirements.

Deterministic Port Block Allocation Restrictions

When you configure deterministic port block allocation, you must be aware of the following restrictions. Violation of any restriction results in a commit error. The restrictions and their error messages are shown in [Table 10 on page 126](#).

Table 10: Deterministic Port Block Allocation Commit Constraints

Restriction	Error Message
The total number of deterministic NAT blocks must be greater than or equal to the 'from' clause addresses configured. This means that the Rounded_Port_Range_Per_IP value must be less than or equal to 64,512.	Number of addresses and port blocks combination in the NAT pool is less than number of addresses in 'from' clause
IPv6 addresses should not be used in deterministic NAT pool/from clause.	Invalid IP address in pool p1 with translation type deterministic-napt44 OR There is already a range configured with v4 address range
The from clause addresses should be same if the same deterministic NAT pool is used across multiple terms/rules. Only one from clause address/range should be specified if the same deterministic NAT pool is used across multiple terms/rules.	With translation-type deterministic-napt44, same 'from' address/range should be configured if pool is shared by multiple rules or terms
There shouldn't be address overlap between except entries in the from clause addresses.	overlapping address, in the 'from' clause between 'except' entries
A deterministic NAT pool cannot be used with other translation-types	Deterministic NAT pool cannot be used with other translation-types
Deterministic NAPT44 must use a source pool with deterministic-port-block-allocation configuration	Deterministic NAPT44 must use a source pool with deterministic-port-block-allocation configuration
If address-allocation round-robin is configured, a commit results in display of a warning indicating that this technique is not needed with translation-type deterministic-napt44 and is ignored.	Address allocation round-robin is not needed with translation-type deterministic-napt44
The total number of IP addresses assigned to a deterministic NAT pool should be less than or equal to 2^{24} (16777216).	Number of addresses in pool with deterministic-napt44 translation are limited to at most 16777216 (2^{24})

Comparison of NAPT Implementation Methods

Table 11 on page 126 provides a feature comparison of available NAPT implementation methods.

Table 11: Comparison of NAPT Implementation Methods

Feature/Function	Dynamic Port Allocation	Secured Port Block Allocation	Deterministic Port Block Allocation
Users per IP	High	Medium	Low
Security Risk	Low	Medium	Medium
Log Utilization	High	Low	None (no logs necessary)
Security Risk Reduction	Random allocation	active-block-timeout feature	n/a

Table 11: Comparison of NAT Implementation Methods (*continued*)

Feature/Function	Dynamic Port Allocation	Secured Port Block Allocation	Deterministic Port Block Allocation
Increasing Users per IP	n/a	Configure multiples of smaller port blocks to maximize users/ public IP	Algorithm-based port allocation

Configuring Dynamic Source Address and Port Translation in IPv4 Networks

Network Address Port Translation (NAPT) is a method by which many network addresses and their TCP/UDP ports are translated into a single network address and its TCP/UDP ports. This translation can be configured in both IPv4 and IPv6 networks. This section describes the steps for configuring NAPT in IPv4 networks.

To configure NAPT, you must configure a rule at the **[edit services nat]** hierarchy level for dynamically translating the source IPv4 addresses.

To configure the NAPT in IPv4 networks:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure the service set and NAT rule.

```
[edit services]
user@host# set service-set service-set-name nat-rules rule-name
```

In the following example, the name of the service set is **s1** and the name of the NAT rule is **rule-napt-44**.

```
[edit services]
user@host# set service-set s1 nat-rules rule-napt-44
```

3. Go to the **[interface-service]** hierarchy level of the service set.

```
[edit services]
user@host# edit service-set s1 interface-service
```

4. Configure the service interface.

```
[edit services service-set s1 interface service]
user@host# set service-interface service-interface-name
```

In the following example, the name of the service interface is **ms-0/1/0**.

NOTE: If the service interface is not present in the router, or the specified interface is not functional, the following command can result in an error.

```
[edit services service-set s1 interface service]
user@host# set service-interface ms-0/1/0
```

5. Go to the **[edit services nat]** hierarchy level. Issue the command from the top of the services hierarchy, or use the **top** keyword.

```
[edit services service-set s1 interface service]
user@host# top edit services nat
```

6. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool-name address address
```

In the following example, the name of the pool is **napt-pool** and the address is **10.10.10.0**.

```
[edit services nat]
user@host# set pool napt-pool address 10.10.10.0
```

7. Configure the port.

```
[edit services nat]
user@host# set pool pool-name port port-type
```

In the following example, the port type is selected as **sequential** or **auto**.

```
[edit services nat]
user@host# set pool napt-pool port automatic
```

NOTE: Starting with Junos OS release 14.2, the **sequential** option is introduced to enable you to configure sequential allocation of ports. The **sequential** and **random-allocation** options available with the **port automatic** statement at the `[edit services nat pool nat-pool-name]` hierarchy level are mutually exclusive. You can include the **sequential** option for sequential allocation and the **random-allocation** option for random delegation of ports. By default, sequential allocation of ports takes place if you include only the **port automatic** statement at the `[edit services nat pool nat-pool-name]` hierarchy level. The **auto** option is hidden and is deprecated in Junos OS Release 14.2 and later, and is only maintained for backward compatibility. It might be removed completely in a future software release.

8. Configure the rule and the match direction.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction
```

In the following example, the name of the rule is **rule-napt-44** and the match direction is **input**.

```
[edit services nat]
user@host# set rule rule-napt-44 match-direction input
```

9. Configure the term, the action for the translated traffic, and the translation type.

```
[edit services nat]
user@host# set rule rule-name term term-name then translated translated-action
translation-type translation-type
```

In the following example, the name of the term is **t1**, the action for the translated traffic is **translated**, the name of the source pool is **napt-pool**, and the translation type is **napt-44**.

```
[edit services nat]
```

```
user@host# set rule rule-napt-44 match-direction input term t1 then translated
source-pool napt-pool translation-type napt-44
```

10. Go to the `[edit services adaptive-services-pics]` hierarchy level. In the command, the `top` keyword ensures that the command is run from the top of the hierarchy.

```
[edit services nat]
user@host# top edit services adaptive-services-pics
```

11. Configure the trace options.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter
```

In the following example, the tracing parameter is configured as `all`.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag all
```

12. Verify the configuration by using the `show` command at the `[edit services]` hierarchy level.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-napt-44;
  interface-service {
    service-interface ms-0/1/0;
  }
}
nat {
  pool napt-pool {
    address 10.10.10.0/32;
    port {
      automatic;
    }
  }
  rule rule-napt-44 {
    match-direction input;
    term t1 {
      then {
        translated {
          source-pool napt-pool;
          translation-type {
            napt-44;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following example configures the translation type as `napt-44`.

```
[edit services]
user@host# show
service-set s1 {
```

```
    nat-rules rule-napt-44;
    interface-service {
        service-interface ms-0/1/0;
    }
}
nat {
    pool napt-pool {
        address 10.10.10.0/32;
        port {
            automatic auto;
        }
    }
    rule rule-napt-44 {
        match-direction input;
        term t1 {
            then {
                translated {
                    source-pool napt-pool;
                    translation-type {
                        napt-44;
                    }
                }
            }
        }
    }
}
adaptive-services-pics {
    traceoptions {
        flag all;
    }
}
```

Dynamic Address Translation to a Small Pool with Fallback to NAT

The following configuration shows dynamic address translation from a large prefix to a small pool, translating a /24 subnet to a pool of 10 addresses. When the addresses in the source pool (**src-pool**) are exhausted, NAT is provided by the NAPT overload pool (**pat-pool**).

```
[edit services nat]
pool src-pool {
    address-range low 192.16.2.1 high 192.16.2.10;
}
pool pat-pool {
    address-range low 192.16.2.11 high 192.16.2.12;
    port automatic auto;
    rule myrule {
        match-direction input;
        term myterm {
            from {
                source-address 10.150.1.0/24;
            }
            then {
                translated {
                    source-pool src-pool;
                    overload-pool pat-pool;
                    translation-type napt-44;
                }
            }
        }
    }
}
```

**Dynamic Address
Translation with Small
Pool**

}
The following configuration shows dynamic address translation from a large prefix to a small pool, translating a /24 subnet to a pool of 10 addresses. Sessions from the first 10 host sessions are assigned an address from the pool on a first-come, first-served basis, and any additional requests are rejected. Each host with an assigned NAT can participate in multiple sessions.

```
[edit services nat]
pool my-pool {
  address-range low 10.10.10.1 high 10.10.10.10;
}
rule src-nat {
  match-direction input;
  term t1 {
    from {
      source-address 192.168.1.0/24;
    }
    then {
      translated {
        translation-type dynamic-nat44;
        source-pool my-pool;
      }
    }
  }
}
```

Configuring Dynamic Source Address and Port Translation for IPv6 Networks

Network Address Port Translation (NAPT) is a method by which many network addresses and their TCP/UDP ports are translated into a single network address and its TCP/UDP ports. This translation can be configured in both IPv4 and IPv6 networks. This section describes the steps for configuring NAPT in IPv6 networks. For information about configuring NAPT in IPv4 networks, see [“Configuring Dynamic Source Address and Port Translation in IPv4 Networks” on page 127](#).

To configure NAPT, you must configure a rule at the **[edit services nat]** hierarchy level for dynamically translating the source IPv6 addresses.

To configure NAPT in IPv6 networks:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Define the pool of IPv6 source addresses that must be used for dynamic translation. For NAPT, also specify port numbers when configuring the source pool.

```
[edit services nat]
user@host# set pool pool name address IPv6 source addresses
user@host# set pool pool name port source ports
```

For example:

```
[edit services nat]
```

```
user@host# set pool IPV6-NAPT-Pool address 2002::1/96
user@host# set pool IPV6-NAPT-Pool port automatic sequential
```

3. Define a NAT rule for translating the source addresses. To do this, set the **match-direction** statement of the rule as **input**. In addition, define a term that uses **napt-66** as the translation type for translating the addresses of the pool defined in the previous step.

```
[edit services nat]
user@host# set rule rule name match-direction input
user@host# set rule rule name term term name then translated source-pool pool name
user@host# set rule rule name term term name then translated translation-type napt-66
```

For example:

```
[edit services nat]
user@host# set rule IPV6-NAPT-Rule match-direction input
user@host# set rule IPV6-NAPT-Rule term t1 then translated source-pool
  IPV6-NAPT-Pool
user@host# set rule IPV6-NAPT-Rule term t1 then translated translation-type napt-66
```

4. Enter the **up** command to navigate to the **[edit services]** hierarchy level.

```
[edit services nat]
user@host# up
```

5. Define a service set to specify the services interface that must be used, and reference the NAT rule implemented for NAPT translation.

```
[edit services]
user@host# set service-set service-set name interface-service service interface
  services interface
user@host# set service-set service-set name nat-rules rule name
```

For example:

```
[edit services]
user@host# set service-set IPV6-NAPT-ServiceSet interface-service service interface
  ms-0/1/0
user@host# set service-set IPV6-NAPT-ServiceSet nat-rules IPV6-NAPT-Rule
```

6. Define the trace options for the adaptive services PIC.

```
[edit services]
user@host# set adaptive-services-pics traceoptions flag tracing parameter
```

For example:

```
[edit services]
user@host# set adaptive-services-pics traceoptions flag all
```

The following example configures dynamic source (address and port) translation or NAPT for an IPv6 network.

```
[edit services]
user@host# show
  service-set IPV6-NAPT-ServiceSet {
    nat-rules IPV6-NAPT-Rule;
    interface-service {
      service-interface ms-0/1/0;
    }
  }
```

```
}
nat {
  pool IPV6-NAPT-Pool {
    address 2002::1/96;
    port automatic sequential;
  }
  rule IPV6-NAPT-Rule {
    match-direction input;
    term term1 {
      then {
        translated {
          source-pool IPV6-NAPT-Pool;
          translation-type {
            napt-66;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

Example: Configuring NAT with Port Translation

This example shows how to configure NAT with port translation.

- [Requirements on page 133](#)
- [Overview on page 133](#)
- [Configuring NAT with Port Translation on page 133](#)

Requirements

This example uses the following hardware and software components:

- An MX Series 3D Universal Edge router with a Services DPC or an M Series Multiservice Edge router with a services PIC
- A domain name server (DNS)
- Junos OS Release 11.4 or higher

Overview

This example shows a complete CGN NAT44 configuration and advanced options.

Configuring NAT with Port Translation

Step-by-Step Procedure

To configure the service set:

1. Configure a service set.

```
user@host# edit services service-set ss2
```

2. Specify the NAT rule to be used.

```
[edit services service-set ss2]  
host# set nat-rules r1
```

3. Specify the interface service.

```
[edit services service-set ss2]  
host# set interface-service service-interface sp-5/0/0
```

Results user@host# show services service-sets sset2

```
nat-rules r1;  
interface-service {  
    service-interface sp-5/0/0;  
}
```

Example: NAPT Configuration for the MS-MPC

This example shows how to configure network address translation with port translation (NAPT) on an MX series router using a MultiServices Modular Port Concentrator (MS-MPC) as a services interface card.

- [Requirements on page 134](#)
- [Overview on page 134](#)
- [Configuration on page 134](#)

Requirements

This example uses the following hardware and software components:

- MX-series router
- MultiServices Modular Port Concentrator (MS-MPC)
- Junos OS Release 13.2R1 or higher

Overview

A service provider has chosen an MS-MPC as a platform to provide NAT services to accommodate new subscribers.

Configuration

To configure NAPT⁴⁴ using the MS-MPC as a services interface card, perform these tasks:

- [Configuring Interfaces on page 135](#)
- [Configure an Application Set of Acceptable ALG traffic on page 136](#)
- [Configuring a Stateful Firewall Rule on page 136](#)

- [Configuring NAT Pool and Rule on page 137](#)
- [Configuring the Service Set on page 138](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set interfaces ge-0/2/0 unit 0 family inet address 10.255.248.2/24
set interfaces xe-1/1/0 unit 0 family inet address 10.255.247.2/24
set interfaces xe-1/1/0 unit 0 family inet service input service-set sset1
set interfaces xe-1/1/0 unit 0 family inet service output service-set sset1
set interfaces ms-3/0/0 unit 0 family inet
set applications application-set accept-algs application junos-http
set applications application-set accept-algs application junos-ftp
set applications application-set accept-algs application junos-tftp
set applications application-set accept-algs application junos-telnet
set applications application-set accept-algs application junos-sip
set applications application-set accept-algs application junos-rtcp
set services stateful-firewall rule sf-rule1 match-direction input-output
set services stateful-firewall rule sf-rule1 term sf-term1 from source-address
  10.255.247.0/24
set services stateful-firewall rule sf-rule1 term sf-term1 from application-sets accept-algs
set services stateful-firewall rule sf-rule1 term sf-term1 then accept
set services nat pool napt-pool address 1.1.1.0/24
set services nat pool napt-pool port automatic
* nat rule for napt
set services nat rule nat-rule1 match-direction input
set services nat rule nat-rule1 term nat-term1 from source-address 10.255.247.0/24
set services nat rule nat-rule1 term nat-term1 from application-sets accept-algs
set services nat rule nat-rule1 term nat-term1 then translated source-pool napt-pool
set services nat rule nat-rule1 term nat-term1 then translated translation-type napt-44
* nat rule for basic nat
set services service-set sset1 stateful-firewall-rules sf-rule1
set services service-set sset1 nat-rules nat-rule1
set services service-set sset1 interface-service service-interface ms-3/0/0
```

[Configuring Interfaces](#)

Step-by-Step Procedure

Configure the interfaces required for NAT processing. You will need the following interfaces:

- A customer-facing interface that handles traffic from and to the customer.
- An internet-facing interface.
- A services interface that provides NAT and stateful firewall services to the customer-facing interface

1. Configure the interface for the customer-facing interface.

```
user@host# edit
[edit ]
user@host# set interfaces xe-1/1/0 unit 0 family inet address 10.255.247.2/24
user@host# set interfaces xe-1/1/0 unit 0 family inet service input service-set sset1
user@host# set interfaces xe-1/1/0 unit 0 family inet service output service-set sset1
```

2. Configure the interface for the Internet-facing interface.

```
[edit ]  
set interfaces ge-0/2/0 unit 0 family inet address 10.255.248.2/24
```
3. Configure the interface for the service set that will connect services to the customer-facing interface. In our example, the interface resides on an MS-MPC.

```
[edit ]  
user@host# set interfaces ms-3/0/0 unit 0 family inet
```

Configure an Application Set of Acceptable ALG traffic

Step-by-Step Procedure

Identify the acceptable ALGs for incoming traffic.

1. Specify an application set that contains acceptable incoming ALG traffic.

```
user@host# set applications application-set accept-algs application junos-http  
user@host# set applications application-set accept-algs application junos-ftp  
user@host# set applications application-set accept-algs application junos-tftp  
user@host# set applications application-set accept-algs application junos-telnet  
user@host# set applications application-set accept-algs application junos-sip  
user@host# set applications application-set accept-algs application junos-rtcp
```

Results

```
user@host#edit services applications application-set accept-algs  
user@host#show  
application junos-http;  
application junos-ftp;  
application junos-tftp;  
application junos-telnet;  
application junos-sip;  
application junos-
```

Configuring a Stateful Firewall Rule

Step-by-Step Procedure

Configure a stateful firewall rule that will accept all incoming traffic.

1. Specify firewall matching for all input and output

```
user@host# set services stateful-firewall rule sf-rule1 match-direction input-output
```
2. Identify source-address and acceptable ALG traffic from the customer-facing interface.

```
user@host# set services stateful-firewall rule sf-rule1 term sf-term1 from  
source-address 10.255.247.0/24  
user@host# set services stateful-firewall rule sf-rule1 term sf-term1 from  
application-sets accept-algs  
user@host# set services stateful-firewall rule sf-rule1 term sf-term1 then accept
```

Results

```
user@host# edit services stateful-firewall
user@host# show
rule sf-rule1 {
  match-direction input-output;
  term sf-term1 {
    from {
      source-address {
        10.255.247.0/24;
      }
      application-sets accept-algs;
    }
    then {
      accept;
    }
  }
}
```

Configuring NAT Pool and Rule

Step-by-Step Procedure Configure a NAT pool and rule for address translation with automatic port assignment.

1. Configure the NAT pool with automatic port assignment.

```
user@host# set services nat pool napt-pool address 1.1.1.0/24
user@host# set services nat pool napt-pool port automatic auto
```

2. Configure a NAT rule that applies translation type **napt-44** using the defined NAT pool.

```
user@host# set services nat rule nat-rule1 term nat-term1 from application-sets
accept-algs
user@host# set services nat rule nat-rule1 term nat-term1 then translated source-pool
napt-pool
user@host# set services nat rule nat-rule1 term nat-term1 then translated
translation-type napt-44
```

Results

```
user@host#edit services nat
user@host#show

pool napt-pool {
    address 1.1.1.0/24;
    port {
        automatic;
    }
}
rule nat-rule1 {
    match-direction input;
    term nat-term1 {
        from {
            source-address {
                10.255.247.0/24;
            }
            application-sets accept-algs;
        }
        then {
            translated {
                source-pool napt-pool;
                translation-type {
                    napt-44;
                }
            }
        }
    }
}
```

Configuring the Service Set

Step-by-Step Procedure Configure an interface type service set.

1. Specify the NAT and stateful firewall rules that apply to customer traffic.

```
user@host set services service-set sset1 stateful-firewall-rules sf-rule1
user@host set services service-set sset1 nat-rules bat-rule1
```
2. Specify the services interface that applies the rules to customer traffic.

```
set services service-set sset1 interface-service service-interface ms-3/0/0
```

Results

```
user@host# edit services service-set sset1
user@host# show
set services service-set sset1 stateful-firewall-rules sf-rule1
set services service-set sset1 nat-rules nat-rule1
set services service-set sset1 interface-service service-interface ms-3/0/0
```

Securing Traffic Using NAT-PT and ALGs

- ALGs Available by Default for Junos OS Address Aware NAT on page 141
- Configuring Protocol Translation Between IPv6 and IPv4 Networks - NAT-PT on page 143
- Example: Configuring NAT-PT on page 150

ALGs Available by Default for Junos OS Address Aware NAT

The following application-level gateways (ALGs) listed in [Table 12 on page 141](#) are supported for NAT processing on the listed platforms.

To view the implementation details (port, protocol, and so on) for these Junos OS default applications, locate the Junos OS Default ALG Name in the table and then look up the listed name in the **groups**. For example, for details about TFTP, look up **junos-tftp** as shown.

TIP: The Junos OS provides the **junos-alg**, which enables other ALGs to function by handling ALG registrations, causing slow path packets to flow through registered ALGs, and transferring ALG events to the ALG plug-ins. The **junos-alg** ALG is automatically available on the MS-MPC and MS-MIC platforms and does not require further configuration.

```
user@host# show groups junos-defaults applications application junos-tftp
application-protocol tftp;
protocol udp;
destination-port 69;
```

Table 12: ALGs Available by Default

ALG	MS-DPC	MS-MPC, MS-MIC	Junos OS Default ALG Name
Basic TCP ALG	yes	yes	NOTE: Specific Junos ALGs are not supported. However, a feature called TCP tracker, available by default, performs segment ordering and retransmit and connection tracking, validations for TCP connections.
Basic UDP ALG	yes	yes	NOTE: TCP tracker performs limited integrity and validation checks for UDP.

Table 12: ALGs Available by Default (*continued*)

Configuring Protocol Translation Between IPv6 and IPv4 Networks - NAT-PT

To configure the translation type as **basic-nat-pt**, you must configure the DNS ALG application, the NAT pools and rules, a service set with a service interface, and trace options. This topic includes the following tasks:

- [Configuring the DNS ALG Application on page 144](#)
- [Configuring the NAT Pool and NAT Rule on page 144](#)
- [Configuring the Service Set for NAT on page 147](#)
- [Configuring Trace Options on page 148](#)

Configuring the DNS ALG Application

To configure the DNS ALG application:

1. In configuration mode, go to the **[edit applications]** hierarchy level.

```
[edit]
user@host# edit applications
```

2. Configure the ALG to which the DNS traffic is destined at the **[edit applications]** hierarchy level. Define the application name and specify the application protocol to use in match conditions in the first NAT rule or term.

```
[edit applications]
user@host# set application application-name application-protocol application-protocol
```

In the following example, the application name is **dns-alg** and application protocol is **dns**.

```
[edit applications]
user@host# set application dns-alg application-protocol dns
```

3. Verify the configuration by using the **show** command at the **[edit applications]** hierarchy level.

```
[edit applications]
user@host# show
application dns-alg {
    application-protocol dns;
}
```

Configuring the NAT Pool and NAT Rule

To configure the NAT pool and NAT rule:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Configure the NAT pool and its address.

```
[edit services nat]
user@host# set pool pool-name address address
```

In the following example, the name of the NAT pool is **p1** and the address is **10.10.10.2/32**.

```
[edit services nat]
user@host# set pool p1 address 10.10.10.2/32
```

3. Configure the source pool and its address.

```
[edit services nat]
user@host# set pool source-pool-name address address
```

In the following example, the name of the source pool is **src_pool0** and the source pool address is **20.1.1.1/32**.

```
[edit services nat]
```

```
user@host# set pool src_pool0 address 20.1.1.1/32
```

4. Configure the destination pool and its address.

```
[edit services nat]
user@host# set pool destination-pool-name address address
```

In the following example, the name of the destination pool is **dst_pool0** and the destination pool address is **50.1.1.2/32**.

```
[edit services nat]
user@host# set pool dst_pool0 address 50.1.1.2/32
```

5. Configure the rule and the match direction.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction
```

In the following example, the rule name is **rule-basic-nat-pt** and the match direction is **input**.

```
[edit services nat]
user@host# set rule basic-nat-pt match-direction input
```

6. Configure the term and the input conditions for the NAT term.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term term from from
```

In the following example, the term is **t1** and the input conditions are **source-address 2000::2/128**, **destination-address 4000::2/128**, and **applications dns_alg**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 from source-address 2000::2/128
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 from destination-address 4000::2/128
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 from applications dns_alg
```

7. Configure the NAT term action and the properties of the translated traffic.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then term-action translated-property
```

In the following example, the term action is **translated** and the properties of the translated traffic are **source-pool src_pool0**, **destination-pool dst_pool0**, and **dns-alg-prefix 10:10:10::0/96**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then translated source-pool src_pool0
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then translated destination-pool
dst_pool0
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then translated dns-alg-prefix
10:10:10::0/96
```

8. Configure the translation type.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then translated translation-type
translation-type
```

In the following example, the translation type is **basic-nat-pt**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t1 then translated translation-type
basic-nat-pt
```

9. Configure another term and the input conditions for the NAT term.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term term-name from from
```

In the following example, the term name is **t2** and the input conditions are **source-address 2000::2/128** and **destination-address 10:10:10::0/96**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 from source-address 2000::2/128
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 from destination-address 10:10:10::0/96
```

10. Configure the NAT term action and the property of the translated traffic.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 then term-action translated-property
```

In the following example, the term action is **translated** and the property of the translated traffic is **source-prefix 19.19.19.1/32**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 then translated source-prefix
19.19.19.1/32
```

11. Configure the translation type.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 then translated translation-type
translation-type
```

In the following example, the translation type is **basic-nat-pt**.

```
[edit services nat]
user@host# set rule rule-basic-nat-pt term t2 then translated translation-type
basic-nat-pt
```

12. Verify the configuration by using the **show** command at the **[edit services nat]** hierarchy level.

```
[edit services nat]
user@host# show
pool p1 {
    address 10.10.10.2/32;
}
pool src_pool0 {
    address 20.1.1.1/32;
}
pool dst_pool0 {
    address 50.1.1.2/32;
}
rule rule-basic-nat-pt {
    match-direction input;
    term t1 {
        from {
            source-address {
```

```

        2000::2/128;
    }
    destination-address {
        4000::2/128;
    }
    applications dns_alg;
}
then {
    translated {
        source-pool src_pool0;
        destination-pool dst_pool0;
        dns-alg-prefix 10:10:10::0/96;
        translation-type {
            basic-nat-pt;
        }
    }
}
}
term t2 {
    from {
        source-address {
            2000::2/128;
        }
        destination-address {
            10:10:10::0/96;
        }
    }
    then {
        translated {
            source-prefix 19.19.19.1/32;
            translation-type {
                basic-nat-pt;
            }
        }
    }
}
}
}

```

Configuring the Service Set for NAT

To configure the service set for NAT:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```

[edit]
user@host# edit services

```

2. Configure the service set.

```

[edit services]
user@host# edit service-set service-set-name

```

In the following example, the name of the service set is **ss_dns**.

```

[edit services]
user@host# edit service-set ss_dns

```

3. Configure the service set with NAT rules.

```

[edit services service-set ss_dns]
user@host# set nat-rules rule-name

```

In the following example, the rule name is **rule-basic-nat-pt**.

```
[edit services service-set ss_dns]
user@host# set nat-rules rule-basic-nat-pt
```

4. Configure the service interface.

```
[edit services service-set ss_dns]
user@host# set interface-service service-interface service-interface-name
```

In the following example, the name of service interface is **sp-1/2/0**.

```
[edit services service-set ss_dns]
user@host# set interface-service service-interface sp-1/2/0
```

5. Verify the configuration by using the **show services** command from the **[edit]** hierarchy level.

```
[edit]
user@host# show services
  service-set ss_dns {
    nat-rules rule-basic-nat-pt;
    interface-service {
      service-interface sp-1/2/0;
    }
  }
```

Configuring Trace Options

To configure the trace options:

1. In configuration mode, go to the **[edit services adaptive-services-pics]** hierarchy level.

```
[edit]
user@host# edit services adaptive-services-pics
```

2. Configure the trace options.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter
```

In the following example, the tracing parameter is **all**.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag all
```

3. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following example configures the translation type as **basic-nat-pt**.

```
[edit]
user@host# show services
```

```

service-set ss_dns {
    nat-rules rule-basic-nat-pt;
    interface-service {
        service-interface sp-1/2/0;
    }
}
nat {
    pool p1 {
        address 10.10.10.2/32;
    }
    pool src_pool0 {
        address 20.1.1.1/32;
    }
    pool dst_pool0 {
        address 50.1.1.2/32;
    }
    rule rule-basic-nat-pt {
        match-direction input;
        term t1 {
            from {
                source-address {
                    2000::2/128;
                }
                destination-address {
                    4000::2/128;
                }
                applications dns_alg;
            }
            then {
                translated {
                    source-pool src_pool0;
                    destination-pool dst_pool0;
                    dns_alg-prefix 10:10:10::0/96;
                    translation-type {
                        basic-nat-pt;
                    }
                }
            }
        }
        term t2 {
            from {
                source-address {
                    2000::2/128;
                }
                destination-address {
                    10:10:10::0/96;
                }
            }
            then {
                translated {
                    source-prefix 19.19.19.1/32;
                    translation-type {
                        basic-nat-pt;
                    }
                }
            }
        }
    }
}
adaptive-services-pics {
    traceoptions {

```

```
        flag all;  
    }  
}
```

Example: Configuring NAT-PT

A Domain Name System application-level gateway (DNS ALG) is used with Network Address Translation-Protocol Translation (NAT-PT) to facilitate name-to-address mapping. You can configure the DNS ALG to map addresses returned in the DNS response to an IPv6 address.

When you configure NAT-PT with DNS ALG support, you must configure two NAT rules or one rule with two terms. In this example, you configure two rules. The first NAT rule ensures that the DNS query and response packets are translated correctly. For this rule to work, you must configure a DNS ALG application and reference it in the rule. The second rule is required to ensure that NAT sessions are destined to the address mapped by the DNS ALG.

Then, you must configure a service set, and then apply the service set to the interfaces.

This example describes how to configure NAT-PAT with DNS ALG:

- [Requirements on page 150](#)
- [Overview and Topology on page 150](#)
- [Configuration of NAT-PT with DNS ALGs on page 152](#)

Requirements

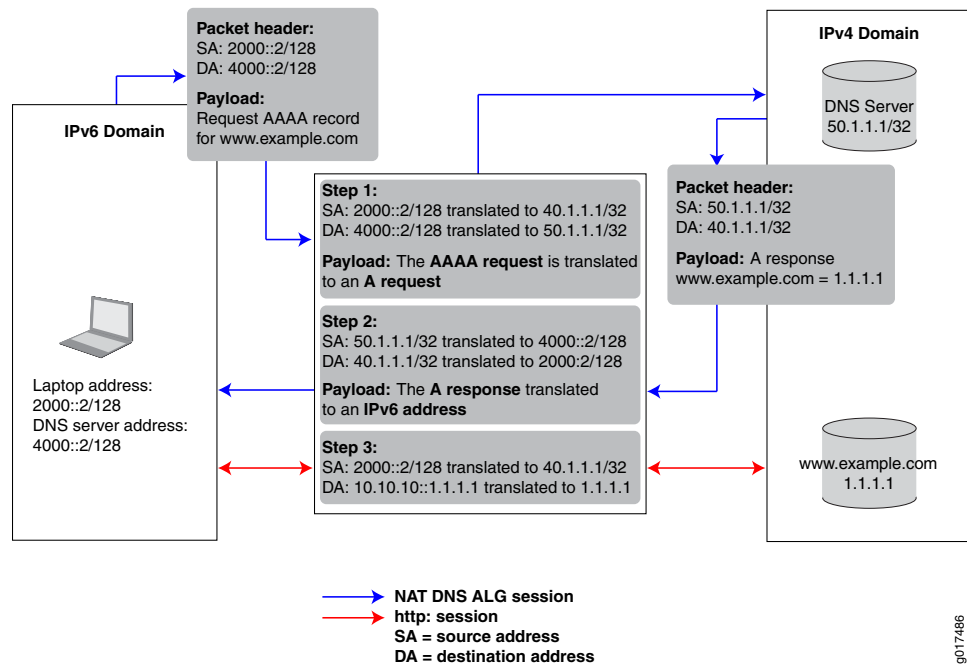

This example uses the following hardware and software components:

- Junos OS Release 11.2
- A multiservices interface (**ms-**)

Overview and Topology

The following scenario shows the process of NAT-PT with DNS ALG when a laptop in an IPv6-only domain requests access to a server in an IPv4-only domain.

Figure 8: Configuring DNS ALGs with NAT-PT Network Topology

The Juniper Networks router in the center of the illustration performs address translation in two steps. When the laptop requests a session with the **www.example.com** server that is in an IPv4-only domain, the Juniper Networks router performs the following:

- Translates the IPv6 laptop and DNS server addresses into IPv4 addresses.
- Translates the AAAA request from the laptop into an A request so that the DNS server can provide the IPv4 address.

When the DNS server responds with the A request, the Juniper Networks router performs the following:

- Translates the IPv4 DNS server address back into an IPv6 address.
- Translates the A request back into a AAAA request so that the laptop now has the 96-bit IPv6 address of the **www.example.com** server.

After the laptop receives the IPv6 version of the **www.example.com** server address, the laptop initiates a second session using the 96-bit IPv6 address to access that server. The Juniper Networks router performs the following:

- Translates the laptop IPv4 address directly into its IPv4 address.
- Translates the 96-bit IPv6 **www.example.com** server address into its IPv4 address.

Configuration of NAT-PT with DNS ALGs

To configure NAT-PT with DNS ALG, perform the following tasks:

- [Configuring the Application-Level Gateway on page 152](#)
- [Configuring the NAT Pools on page 153](#)
- [Configuring the DNS Server Session: First NAT Rule on page 154](#)
- [Configuring the HTTP Session: Second NAT Rule on page 157](#)
- [Configuring the Service Set on page 159](#)
- [Configuring the Stateful Firewall Rule on page 161](#)
- [Configuring Interfaces on page 162](#)

Configuring the Application-Level Gateway

Step-by-Step Procedure

Configure the DNS application as the ALG to which the DNS traffic is destined. The DNS application protocol closes the DNS flow as soon as the DNS response is received. When you configure the DNS application protocol, you must specify the UDP protocol as the network protocol to match in the application definition.

To configure the DNS application:

1. In configuration mode, go to the **[edit applications]** hierarchy level.

```
user@host# edit applications
```

2. Define the application name and specify the application protocol to use in match conditions in the first NAT rule.

```
[edit applications]
user@host# set application application-name application-protocol protocol-name
```

For example:

```
[edit applications]
user@host# set application dns_alg application-protocol dns
```

3. Specify the protocol to match, in this case UDP.

```
[edit applications]
user@host# set application application-name protocol type
```

For example:

```
[edit applications]
user@host# set application dns_alg protocol udp
```

4. Define the UDP destination port for additional packet matching, in this case the domain port.

```
[edit applications]
user@host# set application application-name destination-port value
```

For example:

```
[edit applications]
user@host# set application dns_alg destination-port 53
```

Results [edit applications]
 user@host# show
 application dns_alg {
 application-protocol dns;
 protocol udp;
 destination-port 53;
 }

Configuring the NAT Pools

Step-by-Step Procedure In this configuration, you configure two pools that define the addresses (or prefixes) used for NAT. These pools define the IPv4 addresses that are translated into IPv6 addresses. The first pool includes the IPv4 address of the source. The second pool defines the IPv4 address of the DNS server. To configure NAT pools:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.
 user@host# edit services nat
2. Specify the name of the first pool and the IPv4 source address (laptop).
 [edit services nat]
 user@host# set pool *nat-pool-name* address *ip-prefix*

For example:

```
[edit services nat]
user@host# set pool pool1 address 40.1.1.1/32
```

3. Specify the name of the second pool and the IPv4 address of the DNS server.
 [edit services nat]
 user@host# set pool *nat-pool-name* address *ip-prefix*

For example:

```
[edit services nat]
user@host# set pool pool2 address 50.1.1.1/32
```

Results The following sample output shows the configuration of NAT pools.

```
[edit services nat]
user@host# show
pool pool1 {
  address 40.1.1.1/32;
}
pool pool2 {
  address 50.1.1.1/32;
}
```

Configuring the DNS Server Session: First NAT Rule

Step-by-Step Procedure The first NAT rule is applied to DNS traffic going to the DNS server. This rule ensures that the DNS query and response packets are translated correctly. For this rule to work, you must configure a DNS ALG application and reference it in the rule. The DNS application was configured in [“Configuring the DNS ALG Application” on page 144](#). In addition, you must specify the direction in which traffic is matched, the source address of the laptop, the destination address of the DNS server, and the actions to take when the match conditions are met.

To configure the first NAT rule:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
user@host# edit services nat
```

2. Specify the name of the NAT rule.

```
[edit services nat]
user@host# edit rule rule-name
```

For example:

```
[edit services nat]
user@host# edit rule rule1
```

3. Specify the name of the NAT term.

```
[edit services nat rule rule-name]
user@host# edit term term-name
```

For example:

```
[edit services nat rule rule1]
user@host# edit term term1
```

4. Define the match conditions for this rule.

- a. Specify the IPv6 source address of the device (laptop) attempting to access an IPv4 address.

```
[edit services nat rule rule-name term term-name]
user@host# set from source-address source-address
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set from source-address 2000::2/128
```

- b. Specify the IPv6 destination address of the DNS server.

```
[edit services nat rule rule-name term term-name]
user@host# set from destination-address prefix
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set from destination-address 4000::2/128
```

- c. Reference the DNS application to which the DNS traffic destined for port 53 is applied.

```
[edit services nat rule rule1 term term1]
user@host# set from applications application-name
```

In this example, the application name configured in the *Configuring the DNS Application* step is `dns_alg`:

```
[edit services nat rule rule1 term term1]
user@host# set from applications dns_alg
```

5. Define the actions to take when the match conditions are met. The source and destination pools you configured in “[Configuring the NAT Pools](#)” on page 153 are applied here.

- a. Apply the NAT pool configured for source translation.

```
[edit services nat rule rule-name term term-name]
user@host# set then translated source-pool nat-pool-name
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set then translated source-pool pool1
```

- b. Apply the NAT pool configured for destination translation.

```
[edit services nat rule rule-name term term-name]
user@host# set then translated destination-pool nat-pool-name
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set then translated source-pool pool2
```

6. Define the DNS ALG 96-bit prefix for IPv4-to-IPv6 address mapping.

```
[edit services nat rule rule-name term term-name]
user@host# set then translated dns-alg-prefix dns-alg-prefix
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set then translated dns-alg-prefix 10:10:10::0/96
```

7. Specify the type of NAT used for source and destination traffic.

```
[edit services nat rule rule-name term term-name]
user@host# set then translated translation-type basic-nat-pt
```

For example:

```
[edit services nat rule rule1 term term1]
user@host# set then translated translation-type basic-nat-pt
```

NOTE: In this example, since NAT is achieved using address-only translation, the `basic-nat-pt` translation type is used. To achieve NAT using address and port translation (NAPT), use the `napt-pt` translation type.

8. Specify the direction in which to match traffic that meets the rule conditions.

```
[edit services nat rule rule-name]  
user@host# set match-direction (input | output)
```

For example:

```
[edit services nat rule rule1]  
user@host# set match-direction input
```

9. Configure system logging to record information from the services interface to the `/var/log` directory.

```
[edit services nat rule rule-name term term-name]  
user@host# set then syslog
```

For example:

```
[edit services nat rule rule1 term term1]  
user@host# set then syslog
```

Results The following sample output shows the configuration of the first NAT rule that goes to the DNS server.

```
[edit services nat]
user@host# show
rule rule1 {
  match-direction input;
  term term1 {
    from {
      source-address {
        2000::2/128;
      }
      destination-address {
        4000::2/128;
      }
      applications dns_alg;
    }
    then {
      translated {
        source-pool pool1;
        destination-pool pool2;
        dns-alg-prefix 10:10:10::0/96;
        translation-type {
          basic-nat-pt;
        }
      }
    }
    syslog;
  }
}
```

Configuring the HTTP Session: Second NAT Rule

Step-by-Step Procedure

The second NAT rule is applied to destination traffic going to the IPv4 server (www.example.com). This rule ensures that NAT sessions are destined to the address mapped by the DNS ALG. For this rule to work, you must configure the DNS ALG address map that correlates the DNS query or response processing done by the first rule with the actual data sessions processed by the second rule. In addition, you must specify the direction in which traffic is matched: the IPv4 address for the IPv6 source address (laptop), the 96-bit prefix to prepend to the IPv4 destination address (www.example.com), and the translation type.

To configure the second NAT rule:

1. In configuration mode, go to the following hierarchy level.

```
user@host# edit services nat
```

2. Specify the name of the NAT rule and term.

```
[edit services nat]
user@host# edit rule rule-name term term-name
```

For example:

```
[edit services nat]
user@host# edit rule rule2 term term1
```

3. Define the match conditions for this rule:
 - a. Specify the IPv6 address of the device attempting to access the IPv4 server.

```
[edit services nat rule rule-name term term-name]  
user@host# set from source-address source-address
```

For example:

```
[edit services nat rule rule2 term term1]  
user@host# set from source-address 2000::2/128
```

- b. Specify the 96-bit IPv6 prefix to prepend to the IPv4 server address.

```
[edit services nat rule rule-name term term-name]  
user@host# set from destination-address prefix
```

For example:

```
[edit services nat rule rule2 term term1]  
user@host# set from destination-address 10:10:10::c0a8:108/128
```

4. Define the actions to take when the match conditions are met.
 - Specify the prefix for the translation of the IPv6 source address.

```
[edit services nat rule rule-name term term-name]  
user@host# set then translated source-prefix source-prefix
```

For example:

```
[edit services nat rule rule2 term term1]  
user@host# set then translated source-prefix 19.19.19.1/32
```

5. Specify the type of NAT used for source and destination traffic.

```
[edit services nat rule rule-name term term-name]  
user@host# set then translated translation-type basic-nat-pt
```

For example:

```
[edit services nat rule rule2 term term1]  
user@host# set then translated translation-type basic-nat-pt
```

NOTE: In this example, since NAT is achieved using address-only translation, the *basic-nat-pt* translation type is used. To achieve NAT using address and port translation (NAPT), you must use the *napt-pt* translation type.

6. Specify the direction in which to match traffic that meets the conditions in the rule.

```
[edit services nat rule rule-name]  
user@host# set match-direction (input | output)
```

For example:

```
[edit services nat rule rule2]  
user@host# set match-direction input
```

Results The following sample output shows the configuration of the second NAT rule.

```
[edit services nat]
user@host# show
rule rule2 {
  match-direction input;
  term term1 {
    from {
      source-address {
        2000::2/128;
      }
      destination-address {
        10:10:10::c0a8:108/128;
      }
    }
    then {
      translated {
        source-prefix 19.19.19.1/32;
        translation-type {
          basic-nat-pt;
        }
      }
    }
  }
}
```

Configuring the Service Set

Step-by-Step Procedure This service set is an interface service set used as an action modifier across the entire services (**ms-**) interface. Stateful firewall and NAT rule sets are applied to traffic processed by the services interface.

To configure the service set:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
user@host# edit services
```

2. Define a service set.

```
[edit services]
user@host# edit service-set service-set-name
```

For example:

```
[edit services]
user@host# edit service-set ss
```

3. Specify properties that control how system log messages are generated for the service set.

```
[edit services service-set ss]
user@host# set syslog host local services severity-level
```

The example below includes all severity levels.

```
[edit services service-set ss]
user@host# set syslog host local services any
```

4. Specify the stateful firewall rule included in this service set.

```
[edit services service-set ss]
user@host# set stateful-firewall-rules rule1 severity-level
```

The example below references the stateful firewall rule defined in [“Configuring the Stateful Firewall Rule” on page 161](#).

```
[edit services service-set ss]
user@host# set stateful-firewall-rules rule1
```

5. Define the NAT rules included in this service set.

```
[edit services service-set ss]
user@host# set nat-rules rule-name
```

The example below references the two rules defined in this configuration example.

```
[edit services service-set ss]
user@host# set nat-rules rule1
user@host# set nat-rules rule2
```

6. Configure an adaptive services interface on which the service is to be performed.

```
[edit services service-set ss]
user@host# set interface-service service-interface interface-name
```

For example:

```
[edit services service-set ss]
user@host# interface-service service-interface ms-2/0/0
```

Only the device name is needed, because the router software manages logical unit numbers automatically. The services interface must be an adaptive services interface for which you have configured **unit 0 family inet** at the `[edit interfaces interface-name]` hierarchy level in [“Configuring Interfaces” on page 162](#).

Results The following sample output shows the configuration of the service set.

```
[edit services]
user@host# show
service-set ss {
  syslog {
    host local {
      services any;
    }
  }
  stateful-firewall-rules rule1;
  nat-rules rule1;
  nat-rules rule2;
  interface-service {
    service-interface ms-2/0/0;
  }
}
```

Configuring the Stateful Firewall Rule

Step-by-Step Procedure This example uses a stateful firewall to inspect packets for state information derived from past communications and other applications. The NAT-PT router checks the traffic flow matching the direction specified by the rule, in this case both input and output. When a packet is sent to the services (**ms-**) interface, direction information is carried along with it.

To configure the stateful firewall rule:

1. In configuration mode, go to the **[edit services stateful firewall]** hierarchy level.

```
user@host# edit services stateful firewall
```

2. Specify the name of the stateful firewall rule.

```
[edit services stateful-firewall]
user@host# edit rule rule-name
```

For example:

```
[edit services stateful-firewall]
user@host# edit rule rule1
```

3. Specify the direction in which traffic is to be matched.

```
[edit services stateful-firewall rule rule-name]
user@host# set match-direction (input | input-output | output)
```

For example:

```
[edit services stateful-firewall rule rule1]
user@host# set match-direction input-output
```

4. Specify the name of the stateful firewall term.

```
[edit services stateful-firewall rule rule-name]
user@host# edit term term-name
```

For example:

```
[edit services stateful-firewall rule rule1]
user@host# edit term term1
```

5. Define the terms that make up this rule.

```
[edit services stateful-firewall rule rule-name term term-name]  
user@host# set then accept
```

For example:

```
[edit services stateful-firewall rule rule1 term term1]  
user@host# set then accept
```

Results The following sample output shows the configuration of the services stateful firewall.

```
[edit services]  
user@host# show  
stateful-firewall {  
  rule rule1 {  
    match-direction input-output;  
    term term1 {  
      then {  
        accept;  
      }  
    }  
  }  
}
```

Configuring Interfaces

Step-by-Step Procedure After you have defined the service set, you must apply services to one or more interfaces installed on the router. In this example, you configure one interface on which you apply the service set for input and output traffic. When you apply the service set to an interface, it automatically ensures that packets are directed to the services (**ms-**) interface.

To configure the interfaces:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level.

```
user@host# edit interfaces
```

2. Configure the interface on which the service set is applied to automatically ensure that packets are directed to the services (**ms-**) interface.

- a. For IPv4 traffic, specify the IPv4 address.

```
[edit interfaces]  
user@host# set ge-1/0/9 unit 0 family inet address 30.1.1.1/24
```

- b. Apply the service set defined in [“Configuring Interfaces” on page 162](#).

```
[edit interfaces]  
user@host# set ge-1/0/9 unit 0 family inet6 service input service-set ss  
user@host# set ge-1/0/9 unit 0 family inet6 service output service-set ss
```

- c. For IPv6 traffic, specify the IPv6 address.

```
[edit interfaces]  
user@host# set ge-1/0/9 unit 0 family inet6 address 2000::1/64
```

3. Specify the interface properties for the services interface that performs the service.

```
[edit interfaces]
user@host# set ms-2/0/0 services-options syslog host local services any
user@host# set ms-2/0/0 unit 0 family inet
user@host# set ms-2/0/0 unit 0 family inet6
```

Results The following sample output shows the configuration of the interfaces for this example.

```
[edit interfaces]
user@host# show

ge-1/0/9 {
  unit 0 {
    family inet {
      address 30.1.1.1/24;
    }
    family inet6 {
      service {
        input {
          service-set ss;
        }
        output {
          service-set ss;
        }
      }
      address 2000::1/64;
    }
  }
}

ms-2/0/0 {
  services-options {
    syslog {
      host local {
        services any;
      }
    }
  }
  unit 0 {
    family inet;
    family inet6;
  }
}
```

Reducing Traffic and Bandwidth Requirements Using Port Control Protocol

- [Port Control Protocol Overview on page 165](#)
- [Configuring Port Control Protocol on page 167](#)
- [Example: Configuring Port Control Protocol with NAPT44 on page 170](#)

Port Control Protocol Overview

The Port Control Protocol (PCP) provides a mechanism to control the forwarding of incoming packets by upstream devices such as NAT44, and firewall devices, and a mechanism to reduce application keep-alive traffic. PCP is designed to be implemented in the context of both Carrier-Grade NATs (CGNs) and small NATs (for example, residential NATs). PCP allows hosts to operate servers for a long time (as in the case of a webcam) or a short time (for example, while playing a game or on a phone call) when behind a NAT device, including when behind a CGN operated by their Internet service provider. PCP allows applications to create mappings from an external IP address and port to an internal IP address and port. These mappings are required for successful inbound communications destined to machines located behind a NAT or a firewall. After creating a mapping for incoming connections, it is necessary to inform remote computers about the IP address and port for the incoming connection. This is usually done in an application-specific manner.

PCP consists of the following components:

- **PCP client**—A host or gateway that issues PCP requests to a PCP server in order to obtain and control resources.
- **PCP server**—Typically a CGN gateway or co-located server that receives and processes PCP requests

Many NAT-friendly applications send frequent application-level messages to ensure their session are not be timed out by a NAT. These applications can reduce the frequency of such NAT keep-alive messages by using PCP to learn and influence the NAT mapping lifetime. This helps reduce bandwidth on the subscriber's access network, traffic to the server, and battery consumption on mobile devices.

The Junos OS enables configuring PCP servers for mapping flows using NAPT44 capabilities such as port forwarding and port block allocation. Flows can be processed from these sources:

- Traffic containing PCP requests received directly from UEs as shown in [Figure 9 on page 166](#).

Figure 9: Basic PCP NAPT44 Topology

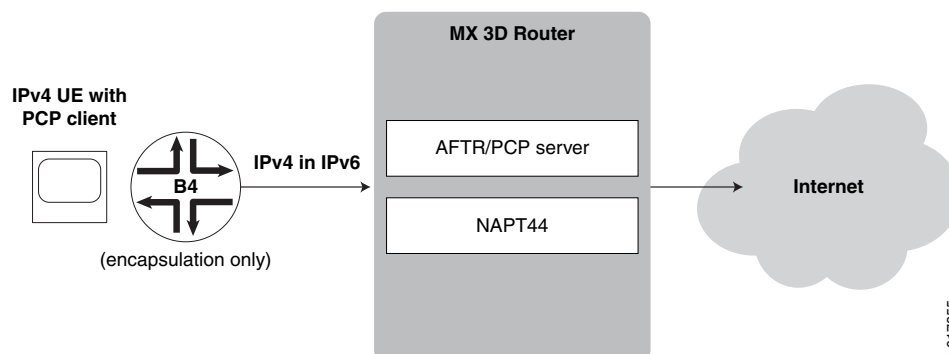

- Mapping of traffic containing PCP requests added by a router functioning as a DS-Lite software initiator (B4). This mode, known as *DS-Lite plain mode*, is shown in [Figure 10 on page 166](#)

Figure 10: PCP with DS-Lite Plain Mode

- Mapping of traffic containing PCP requests initiated directly by UEs and encapsulated by a router functioning as a DS-Lite software initiator (B4). This mode, known as *DS-Lite tunnel mode*, is shown in [Figure 11 on page 167](#).

Figure 11: PCP with DS-Lite Tunnel Mode

NOTE: The Junos OS does not support deterministic port block allocation for PCP-originated traffic.

Configuring Port Control Protocol

This topic describes the following configuration tasks:

- [Configuring PCP Server Options on page 167](#)
- [Configuring a PCP Rule on page 168](#)
- [Configuring a Service Set to Apply PCP on page 169](#)
- [SYSLOG Message Configuration on page 169](#)

Configuring PCP Server Options

1. Go to the `[edit services pcp pcp-server server-name]` hierarchy level and specify a PCP server name.

```
user @host# edit services pcp pcp-server server-name
```

2. Set the IPv4 or IPv6 addresses of the server. For PCP DS-Lite, the **ipv6-address** must match the address of the AFTR (Address Family Transition Router or software concentrator).

```
[edit services pcp pcp-server s1]
user @host# set ipv6-address ipv6-address
```

or

```
[edit services pcp pcp-server s1]
user @host# set ipv4-address ipv4-address
```

3. For PCP DS-Lite, provide the name of the DS-Lite software concentrator configuration.

```
[edit services pcp pcp-server s1]
user @host# set software-concentrator software-concentrator-name
```

- Specify the minimum and maximum mapping lifetimes for the server.

```
[edit services pcp pcp-server s1]
user @host# set mapping-lifetime-minimum mapping-lifetime-minimum
user @host# set mapping-lifetime-maximum mapping-lifetime-maximum
```

- Specify the time limits for generating short lifetime or long lifetime errors.

```
[edit services pcp pcp-server s1]
user @host# set short-lifetime-error short-lifetime-error
user @host# set long-lifetime-error long-lifetime-error
```

- (Optional)—Enable PCP options on the specified PCP server. The following options are available—**third-party** and **prefer-failure**. The third-party option is required to enable third-party requests by the PCP client. DS-Lite requires the **third-party** option. The **prefer-failure** option requests generation of an error message when the PCP client requests a specific IP address/port that is not available, rather than assigning another available address from the NAT pool. If **prefer-failure** is not specified NAPT44 assigns an available address/port from the NAT pool based on the configured NAT options.

```
[edit services pcp pcp-server s1]
user @host# set pcp-options third-party
user @host# set pcp-options prefer-failure
```

- (Optional)—Specify which NAT pool to use for mapping.

```
[edit services pcp pcp-server s1]
user @host# set nat-options pcp-nat-pool pool-name1 <poolname2...>
```

NOTE: When you do not explicitly specify a NAT pool for mapping, the Junos OS performs a partial rule match based on source IP, source port and protocol; the Junos OS uses the NAT pool configured for the first matching rule to allocate mappings for PCP.

You *must* use explicit configuration in order to use multiple NAT pools.

- (Optional)—Configure the maximum number of mappings per client. The default is 32 and maximum is 128.

```
[edit services pcp pcp-server s1]
user @host# set max-mappings-per-client max-mappings-per-client
```

Configuring a PCP Rule

A PCP rule is has the same basic options as all service set rules:

- A **term** option that allows a single rule to have multiple applications.
 - A **from** option that identifies the traffic that is subject to the rule.
 - A **then** option that identifies what action is to be taken. In the case of a PCP rule, this option identifies the pcp server that handles selected traffic
- Go to the **[edit services pcp rule *rulename*]** hierarchy level and specify **match-direction** input.

```
user @host# edit services pcp rule rulename
user @host# set match-direction input
```

2. Go to the `[edit services pcp rule rulename term termname]` hierarchy level and provide a *termname*.

```
user @host# edit term termname
```

3. (Optional)—Provide a **from** option to filter the traffic to be selected for processing by the rule. When you omit the **from** option, all traffic handled by the service set's service interface is subject to the rule.
4. Set the **then** option to identify the target pcp server.

```
[edit services pcp rule rulename term termname]
user @host# set then pcp-server server-name
```

Configuring a Service Set to Apply PCP

To use PCP, you must provide the rule-name (or name of a list of rulenames) in the **pcp-rule *rulename*** option.

1. Go to the `[edit services service-set service-set-name]` hierarchy level.

```
user @host# edit services service-set service-set-name
```

2. If this is a new service set, provide basic service set information, including interface information and any other rules that may apply.
3. Specify the name of the PCP rule or rule list used to send traffic to the specified PCP server.

```
[edit services service-set service-set-name ]
user @host# set pcp-rule rule-name | rule-listname
```

NOTE: Your service set must also identify any required **nat-rule** and **software-rule**.

SYSLOG Message Configuration

A new syslog class, configuration option, **pcp-logs**, has been provided to control PCP log generation. It provides the following levels of logging:

- **protocol**—All logs related to mapping creation, deletion are included at this level of logging.
- **protocol-error**—All protocol error related logs (such as mapping refresh failed, PCP look up failed, mapping creation failed). are included in this level of logging.
- **system-error**—Memory and infrastructure errors are included in this level of logging.

Example: Configuring Port Control Protocol with NAPT44

- [Requirements on page 170](#)
- [Overview on page 170](#)
- [PCP Configuration on page 170](#)

Requirements

Hardware Requirements

- UEs with PCP clients.
- An MX 3D Router with an MS-DPC services PIC.

Software Requirements

- Junos OS 13.2
- Layer-3 Services Package

Overview

An ISP wants to enable UEs with PCP clients to maintain connections to servers without timing out. The PCP clients generate PCP requests for the type and duration of the connection they require. Connections may be of a long duration, such as applications using a webcam, or a shorter duration, such as online games. An MX 3D router provides a PCP server to interpret PCP client requests, and NAPT44. [Figure 12 on page 170](#) shows the basic topology for this example.

Figure 12: PCP with NAPT44

PCP Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```

set chassis fpc 2 pic 0 adaptive-services service-package layer-3
set interfaces sp-2/0/0 services-options inactivity-timeout 180 cgn-pic
set interfaces sp-2/0/0 unit 0 family inet
  
```

```

set interfaces xe-3/2/0 unit 0 family inet service input service-set sset_0
set interfaces xe-3/2/0 unit 0 family inet service output service-set sset_0
set interfaces xe-3/2/0 unit 0 family inet address 30.0.0.1/24
set interfaces xe-5/0/0 unit 0 family inet address 25.0.0.1/24
set services nat pool pcp-pool address 44.0.0.0/16
set services nat pool pcp-pool port automatic random-allocation address-allocation
    round-robin
set services nat pool pcp-pool address-allocation round-robin
set services nat rule pcp-rule match-direction input
set services nat rule pcp-rule term t0 then translated source-pool pcp-pool
    translation-type napt-44
set services nat rule pcp-rule term t0 then translated mapping-type endpoint-independent
    filtering-type endpoint-independent
set services nat rule pcp-rule term t0 then translated mapping-type endpoint-independent
    filtering-type endpoint-independent
set services pcp server pcp-s1 ipv4-address 124.124.124.122 mapping-lifetime-minimum
    600 mapping-lifetime-maximum 600
set services pcp server pcp-s1 mapping-lifetime-minimum 600
    mapping-lifetime-maximum 86500
set services pcp server pcp-s1 short-lifetime-error 120 long-lifetime-error 1200
set services pcp server pcp-s1 max-mappings-per-client 128 pcp-options third-party
    prefer-failure
set services service-set sset_0 pcp-rules r1
set services service-set sset_0 nat-rules pcp-rule
set services service-set sset_0 interface-service service-interface sp-2/0/0.0

```

Chassis Configuration

Step-by-Step Procedure

To configure the service PIC (FPC 2 Slot 0) with the Layer 3 service package:

1. Go to the [edit chassis] hierarchy level.

```
user@host# edit chassis
```
2. Configure the Layer 3 service package.

```
[edit chassis]
user@host# set fpc 2 pic 0 adaptive-services service-package layer-3
```

Results `user@host# show chassis fpc 2 pic 0`

```

pcp-rules pcp-napt44-rule;
nat-rules pcp-rule;
interface-service {
    service-interface sp-2/0/0.0;
}

```

Interface Configuration

Step-by-Step Procedure

1. Configure the services MS-DPC.

```
user@host# set interfaces sp-2/0/0 services-options inactivity-timeout 180 cgn-pic
user@host# set interfaces sp-2/0/0 unit 0 family inet
```
2. Configure the customer-facing interface used for NAT and PCP services.

```
user@host# set interfaces xe-3/2/0 unit 0 family inet service input service-set
sset_0
user@host# set interfaces xe-3/2/0 unit 0 family inet service output service-set
sset_0
user@host# set interfaces xe-3/2/0 unit 0 family inet address 30.0.0.1/24
```

3. Configure the Internet-facing interface.

```
user@host# set interfaces xe-5/0/0 unit 0 family inet address 25.0.0.1/24
```

Results

```
user@host#
sp-2/0/0 {
  services-options {
    inactivity-timeout 180;
    cgn-pic;
  }
  unit 0 {
    family inet;
  }
}
xe-3/2/0 {
  unit 0 {
    family inet {
      service {
        input {
          service-set sset_0;
        }
        output {
          service-set sset_0;
        }
      }
      address 30.0.0.1/24;
    }
  }
}
xe-5/0/0 {
  unit 0 {
    family inet {
      address 25.0.0.1/24;
    }
  }
}
```

NAT Configuration

Step-by-Step Procedure

1. Go the **[edit services nat]** hierarchy.

```
user@host# edit services nat
```
2. Configure a NAT pool called **pcp-pool**.

```
[edit services nat]
user@host# set pool pcp-pool address 44.0.0.0/16
user@host# set pool pcp-pool port automatic random-allocation
user@host# set pool pcp-pool address-allocation round-robin
```
3. Configure a NAT rule called **pcp-rule**.

```
[edit services nat]
```

```

user@host# set rule pcp-rule term t0 then translated source-pool pcp-pool
translation-type napt-44
user@host# set rule pcp-rule term t0 then translated mapping-type
endpoint-independent filtering-type endpoint-independent

```

Results

```

user@host# show services nat
pool pcp-pool {
  address 44.0.0.0/16;
  port {
    automatic {
      random-allocation;
    }
  }
  address-allocation round-robin;
}
rule pcp-rule {
  match-direction input;
  term t0 {
    then {
      translated {
        source-pool pcp-pool;
        translation-type {
          napt-44;
        }
        mapping-type endpoint-independent;
        filtering-type {
          endpoint-independent;
        }
      }
    }
  }
}

```

PCP Configuration

Step-by-Step Procedure To configure the PCP server and PCP rule options.

1. Go to the **edit services pcp** hierarchy level for server **pcp-s1**

```

user@host# edit services pcp server pcp-s1

```
2. Configure the PCP server options.

```

[edit services pcp server pcp-s1]
user@host# set ipv4-address 124.124.124.122
user@host# set mapping-lifetime-minimum 600
user@host# set mapping-lifetime-maximum 86500
user@host# set short-lifetime-error 120
user@host# set long-lifetime-error 1200
user@host# set max-mappings-per-client 128
user@host# set pcp-options third-party prefer-failure

```
3. Create the PCP rule.

```

[edit services pcp rule pcp-napt44-rule
user@host# edit rule pcp-napt44-rule

```
4. Configure the PCP rule options.

```
[edit services pcp rule pcp-napt44-rule]
user@host# set match-direction input
user@host# set term t0 then pcp-server pcp-s1
```

Results regress@montag# show services pcp

```
server pcp-s1 {
  ipv4-address 124.124.124.122;
  mapping-lifetime-minimum 600;
  mapping-lifetime-maximum 86500;
  short-lifetime-error 120;
  long-lifetime-error 1200;
  max-mappings-per-client 128;
  pcp-options third-party prefer-failure;
}
rule pcp-napt44-rule {
  match-direction input;
  term t0 {
    then {
      pcp-server pcp-s1;
    }
  }
}
```

Service Set Configuration

Step-by-Step Procedure

1. Create a service set, **sset_0**, at the **edit services service-set** hierarchy level.

```
user@router# edit services service-set sset_0

service-set sset_0 {
  pcp-rules pcp-napt44-rule;
  nat-rules pcp-rule;
  interface-service {
    service-interface sp-2/0/0.0;
  }
}
```

2. Identify the NAT rule associated with the service set.

```
[edit services service-set sset_0]
user@router# set nat-rules pcp-rule
```

3. Identify the PCP rule associated with the service set.

```
[edit services service-set sset_0]
user@router# set pcp-rules r1
```

4. Identify the service interface associated with the service set.

```
[edit services service-set sset_0]
user@router# set interface-service service-interface sp-2/0/0.0
```

Results user@host# show
pcp-rules pcp-napt44-rule;
nat-rules pcp-rule;
interface-service {
 service-interface sp-2/0/0.0;
}

Automatically Assigning Ports Using Port Block Allocation

- [Secured Port Block Allocation for NAPT on page 177](#)
- [Interim Logging for Port Block Allocation on page 177](#)
- [Configuring Secured Port Block Allocation on page 178](#)
- [Configuring Deterministic Port Block Allocation on page 180](#)

Secured Port Block Allocation for NAPT

Secured port block allocation can be used for translation types **napt-44** and **stateful-nat64**.

When allocating blocks of ports, the most recently allocated block is the current active block. New requests for NAT ports are served from the active block. Ports are allocated randomly from the current active block.

When you configure secured port block allocation, you can specify the following:

- **block-size**
- **max-blocks-per-address**
- **active-block-timeout**

Related Documentation

- [Configuring Secured Port Block Allocation on page 178](#)

Interim Logging for Port Block Allocation

With port block allocation we generate one syslog log per set of ports allocated for a subscriber. These logs are UDP based and can be lost in the network, particularly for long-running flows. Interim logging triggers re-sending the above logs at a configured interval for active blocks that have traffic on at least one of the ports of the block.

Interim logging is activated by including the **pba-interim-logging-interval** statement under **services-options**.

- Related Documentation**
- [Configuring NAT Session Logs on page 209](#)
 - [Secured Port Block Allocation for NAT on page 177](#)

Configuring Secured Port Block Allocation

To configure secured port block allocation:

1. At the **[edit services nat pool *poolname*]** hierarchy level, create a pool.

```
user@host# edit services nat pool poolname
```

For example:

```
user@host# edit services nat pool pba-pool1
```

2. Define the range of addresses to be translated, specifying the upper and lower limits of the range or an address prefix that describes the range.

```
[edit services nat pool pba-pool1]  
user@host# set address-range low address high address
```

Or

```
user@host# set address address-prefix
```

For example:

```
[edit services nat pool pba-pool1]  
user@host# set address 203.0.113.0/24
```

3. Define the range of ports to be used in the translation, or use automatic port assignment by the Junos OS. You can optionally specify random assignment of ports (sequential assignment is the default).

```
[edit services nat pool pba-pool1]  
user@host# set port range low address high address random
```

Or

```
user@host# set port automatic random-allocation
```

For example:

```
[edit services nat pool pba-pool1]  
user@host# set port range low 256 high 511 random
```

Or

```
[edit services nat pool pba-pool1]  
user@host# set port automatic random-allocation
```

NOTE: When you configure a port range, the range should be a multiple of the port block-size value (see Step 4). When the NAT pool port range is *not* a multiple of the port block-size value, the number of ports or port-blocks that are effectively available for use is less than the configured number of ports and port-blocks. The port block allocation mechanism uses ports in the range 0 through 1023 of a NAT address.

When you configure automatic assignment of ports, the available port range for allocation is 1024 through 65535. Automatic allocation can result in no ports being available for use. Use the `show services nat pool` command on the Routing Engine after you configure the port block allocation method to determine the number of ports and port blocks available for allocation to users.

4. Configure secured port block allocation. Specify **active-block-timeout**, **block-size**, and **max-blocks-per-address**, or accept the default values for those options.

```
[edit services nat pool pba-pool1]
user@host# set secured-port-block-allocation active-block-timeout
active-block-timeout block-size block-size max-blocks-per-address
max-blocks-per-address
```

For example:

```
[edit services nat pool pba-pool1]
user@host# set secured-port-block-allocation active-block-timeout 120 block-size
256 max-blocks-per-address 12
```

NOTE: In order for secured-port-block-allocation configuration changes to take effect, you must reboot the services PIC whenever you change any of the following nat pool options:

- *pool-name*
- address or address-range
- port range
- port secured-port-block-allocation block-size
- port secured-port-block-allocation max-blocks-per-address.
- port secured-port-block-allocation active-block-timeout.
- from hierarchy in the nat rule

NOTE: MS-MICs and MS-MPCs support up to a maximum of nine million port blocks per NPU. If your configuration exceeds this maximum supported number, one or more service sets might not be activated on that NPU.

Related Documentation • [Network Address Translation Configuration Overview on page 65](#)

Configuring Deterministic Port Block Allocation

To configure deterministic port block allocation:

1. At to the `[edit services nat pool poolname]` hierarchy level, create a pool.

```
user@host# edit services nat pool poolname
```

For example:

```
user@host# edit services nat pool pba-pool2
```

2. Define the range of addresses to be translated, specifying the upper and lower limits of the range or an address prefix that describes the range.

```
[edit services nat pool pba-pool1]
user@host# set address-range low address high address
```

Or

```
user@host# set address address-prefix
```

For example:

```
[edit services nat pool pba-pool1]
user@host# set address-range low 32.32.32.1 high 32.32.32.253
```

3. Specify automatic port assignment by the Junos OS.

```
[edit services nat pool pba-pool1]
user@host# set port automatic sequential
```

NOTE: Starting with Junos OS release 14.2, the `sequential` option is introduced to enable you to configure sequential allocation of ports. The `sequential` and `random-allocation` options available with the `port automatic` statement at the `[edit services nat pool nat-pool-name]` hierarchy level are mutually exclusive. You can include the `sequential` option for sequential allocation and the `random-allocation` option for random delegation of ports. By default, sequential allocation of ports takes place if you include only the `port automatic` statement at the `[edit services nat pool nat-pool-name]` hierarchy level. The `auto` option is hidden and is deprecated in Junos OS Release 14.2 and later, and is only maintained for backward compatibility. It might be removed completely in a future software release.

4. Configure deterministic port block allocation. Specify `block-size` or accept the default value of 512.

. You can also specify `include-boundary-addresses` if you want the lowest and highest addresses in the source address range of a NAT rule to be translated when the NAT pool is used.

```
[edit services nat pool pba-pool1]
```

```
user@host# set port deterministic-port-block-allocation block-size block-size  
include-boundary-addresses
```

For example:

```
[edit services nat pool pba-pool1]  
user@host# set port deterministic-port-block-allocation block-size 256
```

NOTE: In order for deterministic-port-block-allocation configuration changes to take effect, you must reboot the services PIC whenever you change any of the following nat pool options:

- address or address-range
- port range
- port deterministic-port-block-allocation block-size

Configuring Port Forwarding for Static Destination Address Translation

Starting with Junos OS Release 11.4, you can map an external IP address and port with an IP address and port in a private network. This allows the destination address and port of a packet to be changed to reach the correct host in a Network Address Translation (NAT) gateway. The translation facilitates reaching a host within a masqueraded, typically private, network, based on the port number on which the packet was received from the originating host. Port forwarding allows remote computers, such as public machines on the Internet, to connect to a non-standard port (port other than 80) of a specific computer within a private network. An example of this type of destination is the host of a public HTTP server within a private network. Port forwarding is supported only with **dnat-44** and **twice-napt-44** on IPv4 networks. Port forwarding works only with the FTP application-level gateway (ALG). Port forwarding also supports endpoint-independent mapping (EIM), endpoint-independent filtering (EIF), and address pooling paired (APP). Port forwarding has no support for technologies such as IPv6 rapid deployment (6rd) and dual-stack lite (DS-Lite) that offer IPv6 services over IPv4 infrastructure.

To configure destination address translation with port forwarding in IPv4 networks:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool-name address address
```

In the following example, **dest-pool** is used as the pool name and **4.1.1.2** as the address.

```
user@host# set pool dest-pool address 4.1.1.2
```

3. Configure the rule, match direction, term, and destination address.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction term term-name from
destination-address address
```

In the following example, the name of the rule is **rule-dnat44**, the match direction is **input**, the name of the term is **t1**, and the address is **20.20.20.20**.

```
[edit services nat]
user@host# set rule rule-dnat44 match-direction input term t1 from
destination-address 20.20.20.20
```

4. Configure the destination port range.

```
[edit services nat]
user@host# set rule rule-dnat44 match-direction match-direction term term-name from
destination-port range range high | low
```

In the following example, the upper port range is **50** and the lower port range is **20**.

```
[edit services nat]
user@host# set rule rule-dnat44 match-direction input term t1 from destination-port
range range high 50 low 20
```

5. Go to the **[edit services nat rule rule-dnat44 term t1]** hierarchy level.

```
[edit services nat]
user@host# edit rule rule-dnat44 term t1
```

6. Configure the destination pool.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then translated destination-pool dest-pool-name
```

In the following example, the destination pool name is **dest-pool**, and the translation type is **dnat-44**.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then translated destination-pool dest-pool
```

7. Configure the mapping for port forwarding and the translation type.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then port-forwarding-mappings map-name translation-type
translation-type
```

In the following example, the port forwarding map name is **map1**, and the translation type is **dnat-44**.

```
[edit services nat rule rule-dnat44 term t1]
user@host# set then port-forwarding-mappings map1 translation-type dnat-44
```

8. Go to the **[edit services nat port-forwarding map1]** hierarchy level.

```
[edit services nat]
user@host# edit port-forwarding map1
```

9. Configure the mapping for port forwarding.

```
[edit port-forwarding map1]
user@host# set destined-port port-id
user@host# set translated-port port-id
```

In the following example, the destination port is **45** and the translated port is **23**.

```
[edit port-forwarding map1]
user@host# set destined-port 23
user@host# set translated-port 45
```

**NOTE:**

- Multiple port mappings are supported with port forwarding. Up to 32 port maps can be configured for port forwarding.
- The destination port should not overlap the port range configured for NAT.

10. Verify the configuration by using the **show** command at the **[edit services nat]** hierarchy level.

```
[edit services]
user@host# show
nat {
  pool dest-pool {
    address 4.1.1.2/32;
  }
  rule rule-dnat44 {
    match-direction input;
    term t1 {
      from {
        destination-address {
          20.20.20.20/32;
        }
        destination-port {
          range low 20 high 50;
        }
      }
      then {
        port-forwarding-mappings map1;
        translated {
          destination-pool dest-pool;
          translation-type {
            dnat-44;
          }
        }
      }
    }
  }
}
port-forwarding map1 {
  destined-port 45;
  translated-port 23;
}
```

**NOTE:**

- A similar configuration is possible with twice NAT for IPv4. See [“Example: Configuring Port Forwarding with Twice NAT”](#) on page 187.
- Port forwarding and stateful firewall can be configured together. Stateful firewall has precedence over port forwarding.

Related Documentation • [Configuring Static Destination Address Translation in IPv4 Networks on page 111](#)

Configuring Port Forwarding Without Destination Address Translation

Starting with Junos OS Release 12.1, you can configure port forwarding without translating a destination address.

To configure port forwarding without destination address translation in IPv4 networks:

1. In configuration mode, go to the **[edit services nat]** hierarchy level.

```
[edit]
user@host# edit services nat
```

2. Configure the rule, match direction, term, and destination address.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction term term-name
```

In the following example, the name of the rule is **rule-port-forwarding**, the match direction is **input**, and the name of the term is **t1**.

```
[edit services nat]
user@host# set rule rule-port-forwarding match-direction input term t1
```

3. Go to the **[edit services nat rule rule-port-forwarding term t1]** hierarchy level.

```
[edit services nat]
user@host# edit rule rule-port-forwarding term t1
```

4. Specify that there is no address translation for this rule.

```
[edit services nat rule rule-port-forwarding term t1]
user@host# set then no-translation
```

5. Configure the mapping for port forwarding and the translation type.

```
[edit services nat rule rule-port-forwarding term t1]
user@host# set then port-forwarding-mappings map-name
```

In the following example, the port forwarding map name is **map1**.

```
[edit services nat rule rule-port-forwarding term t1]
user@host# set then port-forwarding-mappings map1
```

6. Go to the **[edit services nat port-forwarding map1]** hierarchy level.

```
[edit services nat]
user@host# edit port-forwarding map1
```

7. Configure the mapping for port forwarding.

```
[edit port-forwarding map1]
user@host# set destined-port port-id
user@host# set translated-port port-id
```

In the following example, the destination port is **45** and the translated port is **23**.

```
[edit port-forwarding map1]
user@host# set destined-port 23
user@host# set translated-port 45
```

**NOTE:**

- Multiple port mappings are supported with port forwarding. Up to 32 port maps can be configured for port forwarding.
- The destination port should not overlap the port range configured for NAT.

8. Verify the configuration by using the **show** command at the **[edit services nat]** hierarchy level.

```
[edit services]
user@host# show
nat {
  rule rule-port-forwarding {
    match-direction input;
    term t1 {
      then {
        port-forwarding-mappings map1;
        no-translation      }
      }
    }
  }
  port-forwarding map1 {
    destined-port 45;
    translated-port 23;
  }
}
```

NOTE: Port forwarding and stateful firewall can be configured together. Stateful firewall has precedence over port forwarding.

Example: Configuring Port Forwarding with Twice NAT

The following example configures port forwarding with **twice-napt-44** as the translation type. The example also has stateful firewall and multiple port maps configured.

```
[edit services]
user@host# show
service-set in {
  syslog {
    host local {
      services any;
    }
  }
  stateful-firewall-rules r;
  nat-rules r;
  interface-service {
    service-interface sp-10/0/0.0;
  }
}
stateful-firewall {
  rule r {
    match-direction input;
    term t {
```

```
        from {
            destination-port {
                range low 20 high 5000;
            }
        }
        then {
            reject;
        }
    }
}
nat {
    pool x {
        address 12.0.0.2/32;
    }
    rule r {
        match-direction input;
        term t {
            from {
                destination-address {
                    14.0.0.2/32;
                }
                destination-port {
                    range low 10 high 20000;
                }
            }
            then {
                port-forwarding-mappings y;
                translated {
                    destination-pool x;
                    translation-type {
                        twice-napt-44;
                    }
                }
            }
        }
    }
}
port-forwarding y {
    destined-port 45;
    translated-port 23;
    destined-port 55;
    translated-port 33;
    destined-port 65;
    translated-port 43;
}
}
adaptive-services-pics {
    traceoptions {
        file sp-trace;
        flag all;
    }
}
```

NOTE:

- Stateful firewall has precedence over port forwarding. In this example, for instance, no traffic destined to any port between 20 and 5000 will be translated.
- Up to 32 port maps can be configured.

Configuring Dynamic Address-Only Source Translation in IPv4 Networks

In IPv4 networks, dynamic address translation (dynamic NAT) is a mechanism to dynamically translate the destination traffic without port mapping. To use dynamic NAT, you must specify a source pool name, which includes an address configuration.

To configure dynamic NAT in IPv4 networks:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure the service set and NAT rule.

```
[edit services]
user@host# set service-set service-set-name nat-rules rule-name
```

In the following example, the name of the service set is **s1**, and the name of the NAT rule is **rule-dynamic-nat44**.

```
[edit services]
user@host# set service-set s1 nat-rules rule-dynamic-nat44
```

3. Go to the **[interface-service]** hierarchy level for the service set.

```
[edit services]
user@host# edit service-set s1 interface-service
```

4. Configure the service interface.

```
[edit services service-set s1 interface-service]
user@host# set service-interface service-interface-name
```

In the following example, the name of the service interface is **ms-0/1/0**.

NOTE: If the service interface is not present in the router, or the specified interface is not functional, the following command can result in an error.

```
[edit services service-set s1 interface-service]
user@host# set service-interface ms-0/1/0
```

5. Go to the **[edit services nat]** hierarchy level. Issue the following command from the top of the services hierarchy, or use the **top** keyword.

```
[edit services service-set s1 interface-service]
user@host# top edit services nat
```

6. Configure the NAT pool with an address.

```
[edit services nat]
user@host# set pool pool-name address address
```

In the following example, the name of the pool is **source-dynamic-pool**, and the address is **10.10.10.0**.

```
[edit services nat]
user@host# set pool source-dynamic-pool address 10.10.10.0
```

7. Configure the rule, match direction, term, and source address.

```
[edit services nat]
user@host# set rule rule-name match-direction match-direction term term-name from
source-address address
```

In the following example, the name of the rule is **rule-dynamic-nat44**, the match direction is **input**, the name of the term is **t1**, and the source address is **3.1.1.0**.

```
[edit services nat]
user@host# set rule rule-dynamic-nat44 match-direction input term t1 from
source-address 3.1.1.0
```

8. Go to the **[edit rule rule-dynamic-nat-44 term t1]** hierarchy level.

```
[edit services nat]
user@host# edit rule rule-dynamic-nat44 term t1
```

9. Configure the source pool and the translation type.

```
[edit services nat rule rule-dynamic-nat44 term t1]
user@host# set then translated source-pool src-pool-name translation-type
translation-type
```

In the following example, the name of the source pool is **source-dynamic-pool** and the translation type is **dynamic-nat44**.

```
[edit services nat rule rule-dynamic-nat44 term t1]
user@host# set then translated source-pool source-dynamic-pool translation-type
dynamic-nat44
```

10. Go to the **[edit services adaptive-services-pics]** hierarchy level. In the following command, the **top** keyword ensures that the command is run from the top of the hierarchy.

```
[edit services nat rule rule-dynamic-nat44 term t1]
```

```
user@host# top edit services adaptive-services-pics
```

11. Configure the trace options.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag tracing parameter
```

In the following example, the tracing parameter is configured as **all**.

```
[edit services adaptive-services-pics]
user@host# set traceoptions flag all
```

12. Verify the configuration by using the **show** command at the **[edit services]** hierarchy level.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-dynamic-nat44;
  interface-service {
    service-interface ms-0/1/0;
  }
}
nat {
  pool source-dynamic-pool {
    address 10.1.1.0/24;
  }
  rule rule-dynamic-nat44 {
    match-direction input;
    term t1 {
      from {
        source-address {
          3.1.1.0/24;
        }
      }
      then {
        translated {
          destination-pool source-dynamic-pool;
          translation-type {
            dynamic-nat44;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following example configures the translation type as **dynamic-nat44**.

```
[edit services]
user@host# show
service-set s1 {
  nat-rules rule-dynamic-nat44;
  interface-service {
    service-interface ms-0/1/0;
  }
}
```

```
nat {
  pool source-dynamic-pool {
    address 10.1.1.0/24;
  }
  rule rule-dynamic-nat44 {
    match-direction input;
    term t1 {
      from {
        source-address {
          3.1.1.0/24;
        }
      }
      then {
        translated {
          destination-pool source-dynamic-pool;
          translation-type {
            dynamic-nat44;
          }
        }
      }
    }
  }
}
adaptive-services-pics {
  traceoptions {
    flag all;
  }
}
```

The following configuration specifies that NAT is not performed on incoming traffic from the source address **192.168.20.24/32** by providing a NAT rule term **t0** that configures **no-translation**. Dynamic NAT is performed on all other incoming traffic, as configured by term **t1** of the NAT rule.

```
[edit services nat]
pool my-pool {
  address-range low 10.10.10.1 high 10.10.10.16;
  port automatic;
}
rule src-nat {
  match-direction input;
  term t0 {
    from {
      source-address 192.168.20.24/32;
    }
    then {
      no-translation;
    }
  }
  term t1 {
    then {
      translated {
        translation-type dynamic-nat44;
        source-pool my-pool;
      }
    }
  }
}
```

The following configuration performs NAT using the source prefix **20.20.10.0/24** without defining a pool.

```
[edit services nat]
rule src-nat {
  match-direction input;
  term t1 {
    then {
      translation-type dynamic-nat44;
      source-prefix 20.20.10.0/24;
    }
  }
}
```

The following configuration performs NAT using the destination prefix **20.20.10.0/32** without defining a pool.

```
[edit services nat]
rule src-nat {
  match-direction input;
  term t1 {
    from {
      destination-address 10.10.10.10/32;
    }
    then {
      translation-type dnat44;
      destination-prefix 20.20.10.0/24;
    }
  }
}
```

Example: Dynamic Source NAT as a Next-Hop Service

The following example shows dynamic-source NAT applied as a next-hop service:

```
[edit interfaces]
ge-0/2/0 {
  unit 0 {
    family mpls;
  }
}
sp-1/3/0 {
  unit 0 {
    family inet;
  }
  unit 20 {
    family inet;
  }

Example: Assigning Addresses from a Dynamic Pool for Static Use

The following configuration statically assigns a subset of addresses that are configured as part of a dynamic pool (**dynamic-pool**) to two separate static pools (**static-pool** and **static-pool2**).

```
[edit services nat]
pool dynamic-pool {
  address 20.20.10.0/24;
}
pool static-pool {
  address-range low 20.20.10.10 high 10.20.10.12;
}
pool static-pool2 {
  address 20.20.10.15/32;
}
rule src-nat {
  match-direction input;
  term t1 {
    from {
      source-address 30.30.30.0/24;
    }
    then {
      translation-type dynamic-nat44;
      source-pool dynamic-pool;
    }
  }
  term t2 {
    from {
      source-address 10.10.10.2;
    }
    then {
      translation-type basic-nat44;
      source-pool static-pool;
    }
  }
  term t3 {
    from {
      source-address 10.10.10.10;
    }
    then {
      translation-type basic-nat44;
      source-pool static-pool2;
    }
  }
}
```

Achieving Line-Rate, Low-Latency Translations Using Inline NAT

- [Inline Network Address Translation Overview for MPC Types 1, 2, and 3 on page 199](#)
- [Example: Configuring Inline Network Address Translation - Interface-Service Service Set on page 201](#)

Inline Network Address Translation Overview for MPC Types 1, 2, and 3

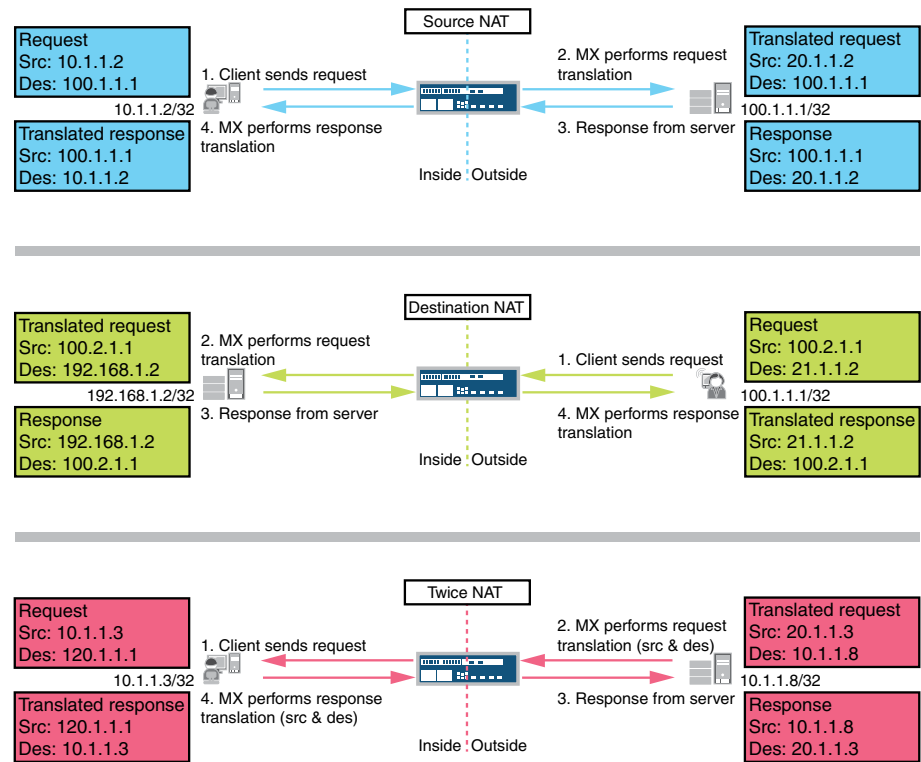

Inline network address translation (NAT) uses the capabilities of the Modular Port Concentrator (MPC) line card, eliminating the need for a MultiServices Dense Port Concentrator (MS-DPC) for NAT. Consequently, you can achieve line-rate, low-latency address translations (up to 120 Gbps per slot). The current implementation provides:

- 1:1 static address mapping
- Bidirectional mapping - source NAT for outbound traffic and destination NAT for inbound traffic
- No limit on number of flows
- Support for Source, destination, and twice NAT, as shown in [Figure 13 on page 200](#)

NOTE: Inline NAT is generally only the `basic-nat44` translation type, and implements destination NAT and twice NAT by applying NAT at the egress interface or to back-to-back, as shown in the following figure.

Figure 13: Supported Inline NAT Types

g041381

To configure inline NAT, you define your service interface as type **si-** (service-inline) interface. You must also reserve adequate bandwidth for the inline interface. This enables you to configure both interface or next-hop service-sets used for NAT. The **si-** interface serves as a “virtual service PIC”.

NOTE: Only static source NAT is supported. Port translation and dynamic NAT are not supported. An MS-DPC or MS-PIC will still be needed for any stateful-firewall processing.

Example: Configuring Inline Network Address Translation - Interface-Service Service Set

- [Requirements on page 201](#)
- [Overview on page 201](#)
- [Configuration on page 203](#)

Requirements

This example uses the following hardware and software components:

- MX-series router
- Modular Port Concentrator (MPC) with Trio chipset
- Junos OS Release 11.4R1 or higher

Overview

This example is configured for the network of a large financial services firm. This Application Service Provider (ASP) has an IP/MPLS-based backbone and provides L3VPN connectivity. In our example, the ASP acts like an Internet Service Provider (ISP) and its servers have public IPv4 addresses.

A large subscriber base relies heavily on the market data feeds that the ASP provides. Like many of the enterprise networks today, a private addressing scheme has been in place for majority of ASP's customers. NAT is required to maintain access to ASP's shared services.

Requirements for the solution include:

- Ease subscriber addressing challenges of their by providing NAT services in ASP's network.
- Support access to common services by a large number of customers, even when these are hosted across in different VRFs and use overlapping addresses.
- Provide high throughput, low latency packet forwarding with NAT enabled.
- Provide operational simplicity and efficiency.
- Reduce cost of operations.

By deploying Juniper's MX's inline NAT service, the ASP can offer scalable solutions with uncompromised performance that fit the requirements of financial markets customers. Operational cost can be dramatically reduced by eliminating the need for a dedicated services PIC. Enabling subscribers to keep their existing addressing scheme by outsourcing the address translation function to the ASP greatly simplifies their network operations.

Topology

The topology for this application is show in [Figure 14 on page 202](#)

The ASP's shared services are located on LAN segment 101.1.1.0/24 behind PE3. PE1 and PE2 are used to connect subscribers. Traditional MPLS-VPN is deployed between provider edge routers. In the case of PE1, subscriber A and B have overlapping addressing schemes of 10.1.1.0/24; NAT is needed so the subscribers can access the same server. NAT pools 192.168.1.0/24 and 192.168.2.0/24 have been allocated to customer A and B respectively.

We will use host 10.1.1.2 from customer A to illustrate packet flow at a high level, as shown in Figure 14 on page 202

Figure 14: Deploy Inline NAT within L3VPN

1. CE1 forwards request from host 10.1.1.2 with a server destination of 101.1.1.2
2. With configured service set on PE1 for VRF_A, source address of 10.1.1.2 will be translated into 192.168.1.2. VPN label and IGP label will be imposed after the translation.
3. Packets will then be forwarded to PE3 using IGP label
4. PE3 receives the packet and performs a lookup in its VPN routing table. It then forwards the packets to server 101.1.1.2 after label disposition.
5. The server returns the packet with destination address of 192.168.1.2.
6. PE3 imposes VPN and IGP labels for the above destination and label switched the packets to PE1.
7. PE1 sends the packet to VRF_A after a FIB lookup. Destination address 192.168.1.2 will be translated 10.1.1.2.
8. CE1 receives the packets for host 10.1.1.2 and forwards them on.

Configuration

By using a **si-** (service-inline) interface, the operator can configure both **interface-service** and **next-hop** service-sets to perform inline NAT. This example uses the **interface-service** service set.

To configure inline NAT, perform these tasks:

- [Configure Interfaces on page 203](#)
- [Configuring Bandwidth for the Service Inline \(si-\) Interface on page 205](#)
- [Configuring NAT Pool and Rule on page 206](#)
- [Configuring the Service Set on page 207](#)

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set interfaces si-0/0/0 unit 0 family inet
set interfaces ge-1/0/0 unit 0 family inet service input service-set nat1
set interfaces ge-1/0/0 unit 0 family inet service output service-set nat1
set interfaces ge-1/0/0 unit 0 family inet address 100.1.1.252/30
set interfaces ge-1/0/0 unit 1 family inet service input service-set nat2
set interfaces ge-1/0/0 unit 1 family inet service output service-set nat2
set interfaces ge-1/0/0 unit 1 family inet address 100.1.1.250/30
set interfaces ge-3/0/0 unit 0 family inet service input service-set nat3
set interfaces ge-3/0/0 unit 0 family inet service output service-set nat3
set interfaces ge-3/0/0 unit 0 family inet address 100.1.1.252/30
set chassis fpc 0 pic 0 inline-services bandwidth 10g
set services nat pool p1 address 192.1.68.1.0/24
set services nat pool p2 address 192.1.68.2.0/24
set services nat rule r1 match-direction input
set services nat rule r1 term t1 from source-address 10.1.1.0/24
set services nat rule r1 term t1 then translated source-pool p1 translation-type basic-nat44
set services nat rule r2 match-direction input
set services nat rule r2 term t1 from source-address 10.1.3.0/24
set services nat rule r2 term t1 then translated source-pool p2 translation-type basic-nat44
set services service-set nat1 nat-rules r1
set services service-set nat1 interface-service service-interface si-0/0/0.0
set services service-set nat2 nat-rules r2
set services service-set nat2 interface-service service-interface si-0/0/0.0
```

Configure Interfaces

Step-by-Step Procedure

To configure interfaces required for inline NAT:

1. Configure the inline interface for NAT services.

```
user@host# edit interfaces si-0/0/0
[edit interfaces si-0/0/0]
user@host# set unit 0 family inet
```
2. Configure the interface for traffic to be handled by service set nat1

```
user@host# edit interfaces ge-1/0/0
[edit interfaces ge-1/0/0]
user@host# edit unit 0 family inet service
[edit unit 0 family inet service]
user@host# set input service-set nat1 output service-set nat1
user@host# set address 100.1.1.252/30
```

3. Configure the interface for traffic to be handled by service set nat2

```
user@host# edit interfaces ge-1/0/0
[edit interfaces ge-1/0/0]
user@host# edit unit 1 family inet service input service
[edit unit 0 family inet service]
user@host# set input service-set nat2 output service-set nat2
user@host# set address 100.1.1.250/30
```

4. Configure the interface for traffic to be handled by service set nat3

```
user@host# edit interfaces ge-3/0/0
[edit interfaces ge-3/0/0]
user@host# edit unit 0 family inet service input service
[edit unit 0 family inet service]
user@host# set input service-set nat3 output service-set nat3
user@host# set address 100.1.1.252/30
```

```

Results si-0/0/0 {
        unit 0 {
            family inet;
        }
    }
    ge-1/0/0 {
        unit 0 {
            family inet {
                service {
                    input {
                        service-set nat1;
                    }
                    output {
                        service-set nat1;
                    }
                }
            }
            address 100.1.1.252/30;
        }
    }
    ge-1/0/0 {
        unit 1 {
            family inet {
                service {
                    input {
                        service-set nat2;
                    }
                    output {
                        service-set nat2;
                    }
                }
            }
            address 100.1.1.250/30;
        }
    }
    ge-3/0/0 {
        unit 0 {
            family inet {
                service {
                    input {
                        service-set nat3;
                    }
                    output {
                        service-set nat3;
                    }
                }
            }
            address 100.1.1.252/30;
        }
    }
}

```

Configuring Bandwidth for the Service Inline (si-) Interface

Step-by-Step Procedure

1. Go to the configuration hierarchy for the fpc and pic used for inline NAT services.

```

user@host# edit chassis fpc 0 pic 0
[edit chassis fpc - pic 0]

```
2. Set the bandwidth for inline services.

```

[edit chassis fpc 0 pic 0]

```

```
user@host# set inline-services bandwidth 10g
```

Configuring NAT Pool and Rule

Step-by-Step Procedure

1. Go to the services NAT hierarchy.

```
user@host# edit services nat
```
2. Configure two NAT pools.

```
[edit services nat]  
user@host# set nat pool p1 address 192.168.1.0/24  
user@host# set nat pool p2 address 192.168.2.0/24
```
3. Configure NAT rule for source pool p1.

```
[edit services nat]  
user@host# set nat rule r1 match-direction input  
user@host# set nat rule r1 term t1 from source-address 10.1.1.0/24 then  
[nat pool r1 term t1 from source-address 10.1.1.0/24 then]  
user@host# set translated source-pool p1 translation-type basic-nat44
```
4. Configure NAT rule for source pool p2.

```
[edit services nat]  
user@host# set nat rule r2 match-direction input  
user@host# edit nat rule r2 term t1 from source-address 10.1.3.0/24 then  
[nat pool r1 term t1 from source-address 10.1.3.0/24 then]  
user@host# set translated source-pool p3 translation-type basic-nat44
```

```

Results user@host# edit services nat
user@host# show

pool p1 {
    address 192.168.1.0/24;
}
pool p2 {
    address 192.168.2.0/24;
}

rule r1 {
    match-direction input;
    term t1 {
        from {
            source-address {
                10.1.1.0/24;
            }
        }
        then {
            translated {
                source-pool p1;
                translation-type {
                    basic-nat44;
                }
            }
        }
    }
}

rule r2 {
    match-direction input;
    term t1 {
        from {
            source-address {
                10.1.3.0/24;
            }
        }
        then {
            translated {
                source-pool p2;
                translation-type {
                    basic-nat44;
                }
            }
        }
    }
}

```

Configuring the Service Set

Step-by-Step Procedure

1. Configure a service set using NAT rule r1, associated with NAT pool p1.

```

user@host# edit services service-set nat1
[edit services service-set nat1]
user@host# set nat rules r1
user@host# set interface-service service-interface si-0/0/0.0

```
2. Configure a service set using NAT rule r2, associated with NAT pool p2.

```

user@host# edit services service-set nat2
[edit services service-set nat1]

```

```
user@host# set nat rules r2
user@host# set interface-service service-interface si-0/0/0.0
```

Results

```
user@host# edit services service-set nat1
user@host# show
nat-rules r1;
interface-service {
    service-interface si-0/0/0.0;
}
```

```
user@host# edit services service-set nat2
user@host# show
nat-rules r2;
interface-service {
    service-interface si-0/0/0.0;
}
```

Monitoring NAT

- [Configuring NAT Session Logs on page 209](#)
- [Monitoring NAT Pool Usage on page 210](#)

Configuring NAT Session Logs

You can configure session logs for NAT from the CLI. By default, session open and close logs are produced. However, you can request that only one type of log be produced.

To configure NAT session logs:

1. Go to the `[edit services service-set service-set-name syslog host class classname]` hierarchy level.

```
user@host# edit services service-set service-set-name syslog host class classname
```
2. Configure NAT logging using the `nat-logs` configuration statement.

```
[edit services service-set service-set-name syslog host class classname]
user@host# set nat-logs.
```
3. Configure session logging using the `session-logs` statement. Open and close logs are produced by default. Specify `open` or `close` to produce only one type of log.

```
[edit services service-set service-set-name syslog host class classname]
user@host# set session-logs.
```

Or

```
[edit services service-set service-set-name syslog host class classname]
user@host# set session-logs open.
```

Or

```
[edit services service-set service-set-name syslog host class classname]
user@host# set session-logs close.
```
4. For NAT sessions that use secured port block allocation (PBA), enter the `pba-interim-logging interval` option.

```
[edit services service-set service-set-name syslog host class classname]
user@host# top.
[edit]
user@host# set interfaces interface-name service-options
pba-interim-logging-intervale.
```

Monitoring NAT Pool Usage

Purpose Use the **show services nat pool detail** command to find global NAT statistics related to pool usage. This command is frequently used in conjunction with the **show services stateful-firewall statistics** command.

Action user@host# **show services nat pool detail**

```
Interface: ms-1/0/0, Service set: s1
  NAT pool: dest-pool, Translation type: DNAT-44
    Address range: 10.10.10.2-10.10.10.2
  NAT pool: napt-pool, Translation type: NAPT-44
    Address range: 50.50.50.1-50.50.50.254
    Port range: 1024-63487, Ports in use: 0, Out of port errors: 0, Max ports
used: 0
  NAT pool: source-dynamic-pool, Translation type: DYNAMIC NAT44
    Address range: 40.40.40.1-40.40.40.254
    Out of address errors: 0, Addresses in use: 0
  NAT pool: source-static-pool, Translation type: BASIC NAT44
    Address range: 30.30.30.1-30.30.30.254
```

CHAPTER 18

Softwires Overview

- [Tunneling Services for IPv4-to-IPv6 Transition Overview on page 213](#)

Tunneling Services for IPv4-to-IPv6 Transition Overview

The Junos OS enables service providers to transition to IPv6 by using softwire encapsulation and decapsulation techniques. A softwire is a tunnel that is created between softwire Customer Premises Equipment (CPE). A softwire CPE can share a unique common internal state for multiple softwires, making it a very light and scalable solution. When you use softwires, you need not maintain an interface infrastructure for each softwire, unlike a typical mesh of generic routing encapsulation (GRE) tunnels that would require you to do so. A softwire initiator at the customer end encapsulates native packets and tunnels them to a softwire concentrator at the service provider. The softwire concentrator decapsulates the packets and sends them to their destination. A softwire is created when a softwire concentrator receives the first tunneled packet of a flow and prepares for flow processing. The softwire exists as long as the softwire concentrator is providing flows for routing. A flow counter is maintained; when the number of active flows is 0, the softwire is deleted. Statistics are kept for both flows and softwires.

Softwire addresses are not specifically configured under any physical or virtual interface. Therefore, the number of established softwires does not affect throughput, and scalability is independent of the number of interfaces. The scalability is only limited to the number of flows that the platform (services DPC or PIC) can support.

This topic contains the following sections:

- [6to4 Overview on page 213](#)
- [DS-Lite Softwires—IPv4 over IPv6 on page 215](#)
- [6rd Softwires—IPv6 over IPv4 on page 216](#)

6to4 Overview

- [Basic 6to4 on page 214](#)
- [6to4 Anycast on page 214](#)
- [6to4 Provider-Managed Tunnels on page 215](#)

Basic 6to4

6to4 is an Internet transition mechanism for migrating from IPv4 to IPv6, a system that allows IPv6 packets to be transmitted over an IPv4 network (generally the IPv4 Internet) without the need to configure explicit tunnels. 6to4 is described in RFC 3056, *Connection of IPv6 Domains via IPv4 Clouds*. 6to4 is especially relevant during the initial phases of deployment to full, native IPv6 connectivity, since IPv6 is not required on nodes between the host and the destination. However, it is intended only as a transition mechanism and is not meant to be used permanently.

6to4 can be used by an individual host, or by a local IPv6 network. When used by a host, it must have a global IPv4 address connected, and the host is responsible for the encapsulation of outgoing IPv6 packets and the decapsulation of incoming 6to4 packets. If the host is configured to forward packets for other clients, often a local network, it is then a router.

There are two kinds of 6to4 virtual routers: border routers and relay routers. A 6to4 border router is an IPv6 router supporting a 6to4 pseudointerface, and is normally the border router between an IPv6 site and a wide-area IPv4 network. A relay router is a 6to4 router configured to support transit routing between 6to4 addresses and pure native IPv6 addresses.

In order for a 6to4 host to communicate with the native IPv6 Internet, its IPv6 default gateway must be set to a 6to4 address which contains the IPv4 address of a 6to4 relay router. To avoid the need for users to set this up manually, the Anycast address of 192.88.99.1 has been allocated to send packets to a 6to4 relay router. Note that when wrapped in 6to4 with the subnet and hosts fields set to zero, this IPv4 address (192.88.99.1) becomes the IPv6 address 2002:c058:6301::. To ensure BGP routing propagation, a short prefix of 192.88.99.0/24 has been allocated for routes pointed at 6to4 relay routers that use this Anycast IP address. Providers willing to provide 6to4 service to their clients or peers should advertise the Anycast prefix like any other IP prefix, and route the prefix to their 6to4 relay.

Packets from the IPv6 Internet to 6to4 systems must be sent to a 6to4 relay router by normal IPv6 routing methods. The specification states that such relay routers must only advertise 2002::/16 and not subdivisions of it to prevent IPv4 routes from polluting the routing tables of IPv6 routers. From there they can then be sent over the IPv4 Internet to the destination.

6to4 Anycast

Router 6to4 assumes that 6to4 routers and relays are managed and configured cooperatively. In particular, 6to4 sites must configure a relay router to carry the outbound traffic, which becomes the default IPv6 router (except for 2002::/16). The objective of the Anycast variant, defined in RFC 3068, *An Anycast Prefix for 6to4 Relay Routers*, is to avoid the need for such configuration. This makes the solution available for small or domestic users, even those with a single host or simple home gateway instead of a border router. This is achieved by defining 192.88.99.1 as the default IPv4 address for a 6to4 relay, and 2002:c058:6301:: as the default IPv6 router prefix (“well-known prefix”) for a 6to4 site.

RFC 6343, *Advisory Guidelines for 6to4 Deployment*, published in August 2011, identifies a wide range of problems associated with the use of unmanaged 6to4 Anycast relay routers.

6to4 Provider-Managed Tunnels

A solution to many problems associated with unmanaged Anycast 6to4 is presented in IETF informational draft draft-kuarsingh-v6ops-6to4-provider-managed-tunnel-02, *6to4 Provider-Managed Tunnels (PMT)*. That document, a “work in progress,” proposes a solution that allows providers to exercise greater control over the routing of 6to4 traffic.

Anycast 6to4 implies a default configuration for the user site. It does not require any particular user action. It does require an IPv4 Anycast route to be in place to a relay at 192.88.99.1. Traffic does not necessarily return to the same 6to4 gateway because of the the “well-known” 6to4 prefix used and advertised by all 6to4 traffic.

6to4 provider-managed tunnels (PMTs) facilitate the management of 6to4 tunnels using an Anycast configuration. 6to4 PMT enables service providers to improve 6to4 operation when network conditions provide suboptimal performance or break normal 6to4 operation. 6to4 PMT provides a stable provider prefix and forwarding environment by utilizing existing 6to4 relays with an added function of IPv6 prefix translation that controls the flow of return traffic.

The 6to4 managed tunnel model behaves like a standard 6to4 service between the customer IPv6 host or gateway and the 6to4 PMT relay (within the provider domain). The 6to4-PMT relay shares properties with 6rd (RFC5969) by decapsulating and forwarding embedded IPv6 flows, within an IPv4 packet, to the IPv6 Internet. The model provides an additional function which translates the source 6to4 prefix to a provider assigned prefix which is not found in 6rd (RFC5969) or traditional 6to4 operation. The 6to4-PMT relay provides a stateless (or stateful) mapping of the 6to4 prefix to a provider-supplied prefix by mapping the embedded IPv4 address in the 6to4 prefix to the provider prefix.

DS-Lite Softwires—IPv4 over IPv6

When an Internet service provider (ISP) begins to allocate new subscriber home IPv6 addresses and IPv6-capable equipment, dual-stack lite (DS-Lite) provides a method for the private IPv4 addresses behind the IPv6 customer edge (CE) WAN equipment to reach the IPv4 network. DS-Lite enables IPv4 customers to continue to access the Internet using their current hardware by using a softwire initiator, referred to as a Basic Bridging Broadband (B4), at the customer edge to encapsulate IPv4 packets into IPv6 packets and tunnel them over an IPv6 network to a softwire concentrator, referred to as an Address Family Transition Router (AFTR), for decapsulation. DS-Lite creates the IPv6 softwires that terminate on the services PIC. Packets coming out of the softwire can then have other services such as NAT applied on them.

DS-Lite is supported on Multiservices 100, 400, and 500 PICs on M Series routers and on MX Series routers equipped with Multiservices Dense Port Concentrator (DPCs).

NOTE: IPv6 Provider Edge (6PE), or MPLS-enabled IPv6, is available for ISPs with MPLS-enabled networks. These networks now can use Multiprotocol BGP (MP-BGP) to provide connectivity between the DS-Lite B4 and AFTR (or any two IPv6 nodes). DS-Lite properly handles encapsulation and decapsulation despite the presence of additional MPLS header information.

For more information on DS-Lite softwires, see the IETF draft *Dual Stack Lite Broadband Deployments Following IPv4 Exhaustion*.

NOTE: The most recent IETF draft documentation for DS-Lite uses new terminology:

- The term *software initiator* has been replaced by *B4*.
- The term *software concentrator* has been replaced by *AFTR*.

The Junos OS documentation generally uses the original terms when discussing configuration in order to be consistent with the command-line interface (CLI) statements used to configure DS-Lite.

6rd Softwires—IPv6 over IPv4

6rd software flow is shown in [Figure 15 on page 216](#).

Figure 15: 6rd Software Flow

The Junos OS supports a 6rd software concentrator on a services DPC or PIC to facilitate rapid deployment of IPv6 service to subscribers on native IPv4 CE WANs. IPv6 packets are encapsulated in IPv4 packets by a software initiator at the CE WAN. These packets are tunneled to a software concentrator residing on a multiservices DPC (branch relay). A software is created when IPv4 packets containing IPv6 destination information are received at the software concentrator, which decapsulates IPv6 packets and forwards them for IPv6 routing. All of these functions are performed in a single pass of the services PIC.

In the reverse path, IPv6 packets are sent to the Services DPC where they are encapsulated in IPv4 packets corresponding to the proper software and sent to the CE WAN.

The software concentrator creates softwires as the IPv4 packets are received from the CE WAN side or IPv6 packets are received from the Internet. A 6rd software on the Services DPC is identified by the 3-tuple containing the service set ID, CE software initiator IPv4 address, and software concentrator IPv4 address. IPv6 flows are also created for the encapsulated IPv6 payload, and are associated with the specific software that carried

them in the first place. When the last IPv6 flow associated with a softwire ends, the softwire is deleted. This simplifies configuration and there is no need to create or manage tunnel interfaces.

6rd is supported on Multiservices 100, 400, and 500 PICs on M Series and T Series routers, and on MX Series platforms equipped with Multiservices DPCs.

For more information on 6rd softwires, see RFC 5969, *IPv6 Rapid Deployment on IPv4 Infrastructures (6rd) -- Protocol Specification*.

Softwires Configuration Overview

- [Configuring Software Rules on page 219](#)
- [Configuring Service Sets for Software on page 220](#)

Configuring Software Rules

You configure software rules to instruct the router how to direct traffic to the addresses specified for 6rd or DS-Lite software concentrators. Software rules do not perform any filtration of the traffic. They do not include a **from** statement, and the only option in the **then** statement is to specify the address of the 6rd or DS-Lite software concentrator.

You can create a software rule consisting of one or more terms and associate a particular 6rd or DS-Lite software concentrator with each term. You can include the software rule in service sets along with other services rules.

To configure a software rule:

1. Assign a name to the rule.

```
[edit services software ]  
user@host# edit rule rule-name
```

2. Specify the match direction.

```
[edit services software rule rule-name]  
user@host# set match-direction (input | output)
```

3. Assign a name for the first term.

```
[edit services software rule rule-name]  
user@host# edit term term-name
```

4. Associate a 6rd or DS-Lite software concentrator with this term.

```
[edit services software rule rule-name term term-name]  
user@host# set then ds-lite name
```

Or

```
user@host# set then v6rd v6rd-software-concentrator
```

5. Repeat Steps 3 and 4 for as many additional terms as needed.

- [Configuring a 6rd Software Concentrator on page 245](#)
- [Configuring a DS-Lite Software Concentrator on page 227](#)
- [Configuring IPv6 Multicast Interfaces](#)
- [Configuring Service Sets for Software on page 220](#)

Configuring Service Sets for Software

You must include software rules or a software rule set in a service set to enable software processing. You must include a stateful firewall rule for DS-Lite.

To configure service sets for software:

1. Include a software rule or rule set in the service set.

```
[edit services service-set service-set-name]  
user@host# set software-rules rule software-rule-name
```

2. When using a 6rd software, include a stateful-firewall rule.

```
[edit services service-set service-set-name]  
user@host# set stateful-firewall-rules software-rule-name
```

3. You can include a NAT rule for flows originated by DS-Lite softwares.

NOTE:

Currently a NAT rule configuration is required with a DS-Lite software configuration when you use interface service set configurations; NAT is not required when using next-hop service set configurations. NAT processing from IPv4 to IPv6 address pools and vice versa is not currently supported. FTP, HTTP, and RSTP are supported.

NOTE: With a DS-Lite software concentrator, if you configure stateful firewall rules without configuring NAT rules, using an interface service set causes the ICMP echo reply messages to be not sent correctly to DS-Lite. This behavior occurs if you apply a service set to both inet and inet6 families. In such a scenario, the traffic that is not destined to the DS-Lite software concentrator is also processed by the service set and the packets might be dropped, although the service set must not process such packets.

To prevent the problem to incorrect processing of traffic applicable for DS-Lite, you must configure a next-hop style service set and not an interface style service set. This problem does not occur when you configure NAT rules with interface service sets for DS-Lite.

For further information, see ““[Configuring Service Rules](#)” on page 36.”

Transitioning to IPv6 Using 6to4 Softwires

- [Configuring a 6to4 Provider-Managed Tunnel on page 223](#)

Configuring a 6to4 Provider-Managed Tunnel

When configuring a 6to4 provider-managed tunnel (PMT), replace the Anycast destination with the address of a managed relay in the provider network.

To configure a 6to4 PMT:

1. Configure the ingress interface for 6to4 traffic. Include the name of the service set that identifies the rules for input and output service on this interface.

```
[edit interfaces ge-0/2/1]
user@host# set unit logical-unit-number family family service input service-set-name
user@host# set unit logical-unit-number family family service output service-set-name
user@host# set unit logical-unit-number family family address address
```

For example:

```
[edit interfaces ge-0/2/1]
user@host# set unit 0 family inet service input service-set v6to4-pmt
user@host# set unit 0 family inet service output service-set v6to4-pmt
user@host# set unit 0 family inet address 130.130.130.1/24
```

2. Configure the egress interface.

```
[edit interfaces ge-0/2/2]
user@host# set unit logical-unit-number family family address address
```

For example:

```
[edit interfaces ge-0/2/2]
user@host# set unit 0 family inet6 address 4ABC::1/16
```

3. Configure the service interface that contains the rules for processing incoming traffic. Include a syslog option and associate a logical unit.

```
[edit interfaces sp-2/0/0]
user@host# edit services-options syslog host host-name services any
user@host# edit unit logical-unit-number family family
user@host# edit unit 0 family family
```

For example:

```
[edit interfaces sp-2/0/0]
```

```
user@host# set services-options syslog host local services any
user@host# set unit 0 family inet
user@host# set unit 0 family inet6
```

4. Configure the softwire concentrator and softwire rule for 6to4. In the Junos OS, 6to4 PMT configuration uses the same options as 6rd.

```
[edit services softwire softwire-concentrator v6rd v6to4]
user@host# set softwire-address softwire-address
user@host# set ipv4-prefix ipv4-prefix
user@host# set v6rd-prefix v6rd-prefix
user@host# set mtu-v4 mtu-v4
```

For example:

```
[edit services softwire softwire-concentrator v6rd v6to4]
user@host# set softwire-address 192.88.99.1
user@host# set ipv4-prefix 130.130.130.2/32
user@host# set v6rd-prefix 2002::0/16
user@host# set mtu-v4 9192
```

5. Define the softwire rule that will process traffic on the ingress interface.

```
[edit services softwire rule v6to4-r1]
user@host# set match-direction input
user@host# set term term-name then v6rd softwire-concentrator
```

For example:

```
[edit services softwire rule v6to4-r1]
user@host# set match-direction input
user@host# set term t1 then v6rd v6to4
```

6. Define a stateful firewall rule that will accept all incoming traffic on the ingress interface.

```
[edit services stateful-firewall rule sfw-r1]
user@host# set match-direction direction
user@host# set term term-name then accept
user@host# set term term-name then syslog
```

For example:

```
[edit services stateful-firewall rule sfw-r1]
user@host# set match-direction input-output
user@host# set term t1 then accept
user@host# set term t1 then syslog
```

7. Define the NAT pool to be used for IPv6 NAT translation. This pool supports translation of the Anycast 6to4 relay addresses to addresses at the provider-managed relay.

```
[edit services nat pool v6to4-pmt]
user@host# set address address
user@host# port automatic
```

For example:

```
[edit services nat pool v6to4-pmt]
user@host# set address 3ABC::1/128
user@host# set port automatic
```

8. Define the NAT rule for translation.

```
[edit services nat rule rule-name]  
user@host# set match-direction input  
user@host# set term term-name then translated source-pool pool-name  
user@host# set term t1 then translated translation-type translation-type
```

For example:

```
[edit services nat rule v6to4-pmt-r1]  
user@host# set match-direction input  
user@host# set term t1 then translated source-pool v6to4-pmt  
user@host# set term t1 then translated translation-type napt-66
```

9. Define the service set that specifies the softwire rule and NAT rule.

```
[edit services service-set v6to4-pmt]  
user@host# set softwire-rules rule-name  
user@host# set stateful-firewall-rules rule-name  
user@host# set nat-rules rule-name  
user@host# set interface-service service-interface interface-name
```

For example:

```
[edit services service-set v6to4-pmt]  
user@host# set softwire-rules v6to4-r1  
user@host# set stateful-firewall-rules sfw-r1  
user@host# set nat-rules v6to4-pmt-r1  
user@host# set interface-service service-interface sp-2/0/0
```

Transitioning to IPv6 Using DS-Lite Softwires

- [Configuring a DS-Lite Softwire Concentrator on page 227](#)
- [Example: Basic DS-Lite Configuration on page 228](#)
- [Example: Configuring DS-Lite and 6rd in the Same Service Set on page 234](#)
- [Protecting CGN Devices Against Denial of Service \(DOS\) Attacks on page 241](#)
- [DS-Lite Subnet Limitation on page 242](#)

Configuring a DS-Lite Softwire Concentrator

To configure a DS-Lite softwire concentrator:

1. Assign a name to the DS-Lite softwire concentrator.

```
[edit services softwire softwire-concentrator]
user@host# edit ds-lite ds-lite-softwire-concentrator
```

2. Specify the address of the softwire tunnel.

```
[edit services softwire softwire-concentrator ds-lite ds-lite-softwire-concentrator]
user@host# set softwire-address address
```

3. Specify the MTU for the softwire tunnel.

```
[edit services softwire softwire-concentrator ds-lite ds-lite-softwire-concentrator]
user@host# set mtu-v6 mtu-v6
```

NOTE: This option sets the maximum transmission unit when encapsulating IPv4 packets into IPv6. If the final length is greater than the MTU, the IPv6 packet will be fragmented. This option is mandatory since it depends on other network parameters under administrator control.

4. To copy DSCP information from the IPv6 header into the decapsulated IPv4 header, include the **copy-dscp** statement.

```
[edit services softwire softwire-concentrator ds-lite ds-lite-softwire-concentrator]
user@host# set copy-dscp
```

5. Specify the maximum number of flows for the softwire

```
[edit services software-concentrator ds-lite ds-lite-software-concentrator]  
user@host# set flow-limit 1000
```

Example: Basic DS-Lite Configuration

- [Requirements on page 228](#)
- [Configuration Overview and Topology on page 228](#)
- [Configuration on page 229](#)

Requirements

The following hardware components can perform DS-Lite:

- M Series Multiservice Edge routers with Multiservices PICs
- T Series Core routers with Multiservices PICs
- MX Series 3D Universal Edge routers with Multiservices DPCs

Configuration Overview and Topology

This example describes how to configure an MX Series router with an MS-DPC as an AFTR to facilitate the flow shown in [Figure 16 on page 229](#).

Figure 16: DS-Lite Topology

In this example, the DS-Lite softwire concentrator, or AFTR, is an MX Series router with two Gigabit interfaces and a Services DPC. The interface facing the B4 element is ge-3/1/5 and the interface facing the Internet is ge-3/1/0.

Configuration

- [Chassis Configuration on page 229](#)
- [Interfaces Configuration on page 229](#)
- [Network Address and Port Translation Configuration on page 231](#)
- [Softwire Configuration on page 232](#)
- [Service Set Configuration on page 233](#)

Chassis Configuration

Step-by-Step Procedure

To configure the service PIC (FPC 0 Slot 0) with the Layer 3 service package:

1. Enter the **edit chassis** hierarchy level.

```
user@host# edit chassis
```
2. Configure the Layer 3 service package.

```
[edit chassis]
user@host# set fpc 0 pic 0 adaptive-services service-package layer-3
```

Interfaces Configuration

Step-by-Step Procedure

To configure interfaces facing the B4 (softwire initiator) and facing the Internet:

1. Go the **[edit interfaces]** edit hierarchy level for ge-3/1/0, which faces the Internet.

```
host# edit interfaces ge-3/1/0
```

2. Define the interface.

```
[edit interfaces ge-3/1/0]
user@host# set description AFTR-Internet
user@host# set unit 0 family inet address 128.0.0.2/24
```

3. Go to the **[edit interfaces]** hierarchy level for ge-3/1/5, which faces the B4.

```
user@host# up 1
[edit]
user@host# edit interfaces ge-3/1/5
```

4. Define the interface.

```
[edit interfaces ge-3/1/5]
user@host# set description AFTR-B4
user@host# set unit 0 family inet
user@host# edit unit 0 family inet6
[edit unit 0 family inet6]
user@host# set service input service-set sset
user@host# set service output service-set sset
user@host# set address 2001:0:0:2::1/48
```

5. Go to the **[edit interfaces]** hierarchy level for sp-0/0/0, used to host the DS-Lite AFTR.

```
[edit]
user@host# edit interfaces sp-0/0/0
```

6. Define the interface.

```
[edit interfaces sp-0/0/0]
user@host# set description AFTR-B4
user@host# set unit 0 family inet
user@host# edit unit 0 family inet6
```

```

Results user@host# show interfaces ge-3/1/0
description AFTR-Internet;
unit 0 {
    family inet {
        address 128.0.0.2/24;
    }
}

user@host# show interfaces ge-3/1/5
description AFTR-B4;
unit 0 {
    family inet;
    family inet6 {
        service {
            input {
                service-set sset;
            }
            output {
                service-set sset;
            }
        }
        address 2001:0:0:2::1/48;
    }
}

user@host# show interfaces sp-o/o/o
unit 0 {
    family inet;
    family inet6;
}

```

Network Address and Port Translation Configuration

Step-by-Step Procedure

To configure NAPT:

1. Go to the **[edit services nat]** hierarchy level.

```

user@host# edit services nat
[edit services nat]

```
2. Define a NAT pool p1.

```

user@host# set pool p1 address 129.0.0.1/32 port automatic

```
3. Define a NAT rule, beginning with the match direction.

```

[edit services nat]
user@host# set rule r1 match-direction input

```
4. Define a **term** for the rule, beginning with a **from** clause.

```

[edit services nat]
user@host# set rule r1 term t1 from source-address 10.0.0.0/16

```
5. Define the desired translation in a **then** clause. In this case, use dynamic source translation.

```

[edit services nat]
user@host# set rule r1 term t1 then translated source-pool p1 translation-type napt-44

```
6. (Optional) Configure logging of translation information for the rule.

```
[edit services nat]
user@host# set rule r1 term t1 then syslog
```

```
Results user@host# show services nat
pool p1 {
  address 129.0.0.1/32;
  port {
    automatic;
  }
}
rule r1 {
  match-direction input;
  term t1 {
    from {
      source-address {
        10.0.0.0/16;
      }
    }
    then {
      translated {
        source-pool p1;
        translation-type {
          napt-44;
        }
      }
      syslog;
    }
  }
}
```

Software Configuration

Step-by-Step Procedure To configure the DS-Lite software concentrator and associated rules:

1. Go to the **[edit services software]** hierarchy level.

```
user@host# edit services software
```
2. Define the DS-Lite software concentrator.

```
[edit services software]
user@host# set software-concentrator ds-lite ds-1 software-address 1001::1 mtu-v6 1460
```
3. Define the software rule.

```
[edit services software]
user@host# set rule r1 match-direction input term t1 then ds-lite ds1.
```

Results

```

user@host# show services software
software-concentrator {
  ds-lite ds1 {
    software-address 1001::1;
    mtu-v6 1460;
  }
}
rule r1 {
  match-direction input;
  term t1 {
    then {
      ds-lite ds1;
    }
  }
}

```

Service Set Configuration

Step-by-Step Procedure Configure a service set that includes software and NAT rules and specifies either interface-service or next-hop service. This example uses a next-hop service.

1. Go to the **[edit services service-set]** hierarchy level, naming the service set.

```
user@host# edit services service-set sset
```

2. Define the NAT rule to be used for IPv4-to-IPv4 translation.

```

[edit services service-set sset]
user@host# set nat-rules r1

```

3. Define the software rule to define the software tunnel.

```

[edit services service-set sset]
user@host# set software-rules r1

```

4. Define the interface service,

```

[edit services service-set sset]
user@host# set interface-service service-interface sp-0/0/0.0

```

TIP: In order to avoid or minimize IPv6 fragmentation, you can configure a TCP maximum segment size (MSS) for your service set.

5. (Optional) Define a TCP MSS.

```

[edit services service-set sset]
user@host# set tcp-mss 1024

```

Results `user@host# show services service-set`

```
syslog {
  host local {
    services any;
  }
}
software-rules r1;
nat-rules r1;
interface-service {
  service-interface sp-0/0/0;
}
```

- T Series Core routers with Multiservices PICs
- MX Series 3D Universal Edge routers with Multiservices DPCs

Overview

This example describes a software solution that includes DS-Lite and 6rd in the same service set.

Configuration

Chassis Configuration

Step-by-Step Procedure

To configure the chassis:

1. Configure the ingress interface.

```
user@host# edit interfaces ge-1/2/0
[edit interfaces ge-1/2/0]
```

```

user@host# set unit 0 family inet service input service-set v6rd-dslite-service-set
user@host# set unit 0 family inet service output service-set v6rd-dslite-service-set
user@host# set unit 0 family inet address address 10.10.10.1/24
user@host# set unit 0 family inet6 service input service-set v6rd-dslite-service-set
user@host# set unit 0 family inet6 service output service-set v6rd-dslite-service-set
user@host# set unit 0 family inet6 address address address 2001::1/16

```

Here the service set is applied on the inet (IPv4) and inet6 (IPv6) families of subunit 0. Both DS-Lite IPv6 traffic and 6rd IPv4 traffic hits the service filter and is sent to the services PIC.

2. Configure the egress interface (IPv6 Internet). The IPv4 server that the DS-Lite clients are trying to reach is at 200.200.200.2/24, and the IPv6 server is at 3ABC::2/16.

```

user@host# edit interfaces ge-1/2/2
[edit interfaces ge-1/2/2]
user@host# set unit 0 family inet address 200.200.200.1/24
user@host# set unit 0 family inet6 address 3ABC::1/16

```

3. Configure the services PIC.

```

user@host# edit interfaces sp-3/0/0
[edit interfaces sp-3/0/0]
user@host# set unit 0 family inet
user@host# set unit 0 family inet6

```

Results [edit interfaces]
user@host# show
ge-1/2/0 {
 unit 0 {
 family inet {
 service {
 input {
 service-set v6rd-dslite-service-set;
 }
 output {
 service-set v6rd-dslite-service-set;
 }
 }
 address 10.10.10.1/24;
 }
 family inet6 {
 service {
 input {
 service-set v6rd-dslite-service-set;
 }
 output {
 service-set v6rd-dslite-service-set;
 }
 }
 address 2001::1/16;
 }
 }
}
ge-1/2/2 {
 unit 0 {
 family inet {
 address 200.200.200.1/24;
 }
 family inet6 {
 address 3ABC::1/16;
 }
 }
}
sp-3/0/0 {
 unit 0 {
 family inet;
 family inet6;
 }
}

Software Concentrator, Software Rule, Stateful Firewall Rule Configuration

Step-by-Step Procedure

To configure the software concentrator, software rule, and stateful firewall rule:

1. Configure the DS-Lite and 6rd software concentrators.

```
user@host# edit services software software-concentrator ds-lite ds1
[edit services software software-concentrator ds-lite ds1]
user@host# set software-address 1001::1
user@host# mtu-v6 9192
user@host# up 1
user@host# edit v6rd v6rd-dom1
[edit services software software-concentrator v6rd v6rd-dom1]
user@host# set software-address 30.30.30.1
```

```

user@host# set ipv4-prefix 10.10.10.0/24
user@host# set v6rd-prefix 3040::0/16
user@host# set mtu-v4 9192

```

2. Configure the softwire rules.

```

user@host# edit services softwire rule v6rd-r1]
[edit services softwire rule v6rd-r1]
user@host# set match-direction input
user@host# set term t1 then v6rd v6rd-dom1
user@host# up 1
user@host# edit services softwire]
[edit services softwire]
user@host# edit rule dslite-r1
[edit services softwire rule dslite-r1]
user@host# set term dslite-t1 then ds-lite ds1

```

The following routes are added by the services PIC daemon on the Routing Engine:

```

user@router# run show route 30.30.30.1
inet.0: 43 destinations, 46 routes (42 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

30.30.30.1/32      *[Static/786432] 00:24:11
                  Service to v6rd-dslite-service-set

```

```
[edit]
```

```
user@router# run show route 3040::0/16
```

```

inet6.0: 23 destinations, 33 routes (23 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

3040::/16          *[Static/786432] 00:24:39
                  Service to v6rd-dslite-service-set

```

```

user@router# run show route 1001::1
inet6.0: 33 destinations, 43 routes (33 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

```

1001::1/128       *[Static/1] 1w2d 22:05:41
                  Service to v6rd-dslite-service-set

```

3. Configure a stateful firewall rule.

```

user@host# edit services stateful-firewall rule r1
[edit services stateful-firewall rule r1]
user@host# set match-direction input-output
user@host# set term t1 then accept

[edit services stateful-firewall]
rule r1 {
  match-direction input-output;
  term t1 {
    then {
      accept;
    }
  }
}

```

Results [edit services software]
user@host# **show**
software-concentrator {
 ds-lite ds1 {
 software-address 1001::1;
 mtu-v6 9192;
 }
 v6rd v6rd-dom1 {
 software-address 30.30.30.1;
 ipv4-prefix 10.10.10.0/24;
 v6rd-prefix 3040::0/16;
 mtu-v4 9192;
 }
}
rule v6rd-r1 {
 match-direction input;
 term t1 {
 then {
 v6rd v6rd-dom1;
 }
 }
}
rule dslite-r1 {
 match-direction input;
 term dslite-t1 {
 then {
 ds-lite ds1;
 }
 }
}
}

[edit services stateful-firewall]
user@host# **show**
rule r1 {
 match-direction input-output;
 term t1 {
 then {
 accept;
 }
 }
}

NAT Configuration for DS-Lite

Step-by-Step Procedure

To configure NAT for DS-Lite:

1. Configure a NAT pool for DS-Lite.

```
user@host# edit services nat pool dslite-pool  
[edit services nat pool dslite-pool]  
user@host# set address-range low 33.33.33.1 high 33.33.33.32  
user@host# set port automatic
```
2. Configure a NAT rule.

```
user@host# up 1  
[edit services nat rule dslite-nat-r1]  
user@host# set match-direction input
```

```
user@host# set term dslite-nat-t1 from source-address 20.20.0.0/16 then translated  
translation-type napt-44
```

Results [edit services nat]
user@host# show
pool dslite-pool {
 address-range low 33.33.33.1 high 33.33.33.32;
 port {
 automatic;
 }
}
rule dslite-nat-r1 {
 match-direction input;
 term dslite-nat-t1 {
 from {
 source-address {
 20.20.0.0/16;
 }
 }
 then {
 translated {
 source-pool dslite-pool;
 translation-type {
 source dynamic;
 }
 }
 }
 }
}

Because of this NAT rule, the following NAT routes are installed for the reverse DS-Lite traffic:

```
user@router# run show route 33.33.33.0/24
inet.0: 48 destinations, 52 routes (47 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

33.33.33.1/32      *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
33.33.33.2/31      *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
33.33.33.4/30      *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
33.33.33.8/29      *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
33.33.33.16/28     *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
33.33.33.32/32     *[Static/1] 1w2d 23:08:38
                  Service to v6rd-dslite-service-set
```

The NAT rule triggers address translation for the traffic coming from 20.20.0.0/16 to public address range 33.33.33.1 to 33.33.33.32.

Service Set Configuration

Step-by-Step Procedure

This service set has a stateful firewall rule and 6rd rule for 6rd service. The service set also includes a softwire rule for DS-Lite and a NAT rule to perform address translation for all DS-Lite traffic. The NAT rule performs NAPT translation in the forward direction on the source address and port of the DS-Lite traffic.

To configure the service set:

1. Define the service set.

```
user@host# edit services service-set v6rd-dslite-service-set
```
2. Configure the service set rules.

```
[edit services service-set v6rd-dslite-service-set]  
user@host# set software-rules dslite-r1  
user@host# set stateful-firewall-rules r1  
user@host# set nat-rules dslite-nat-r1
```
3. Configure the service set interface-service.

```
[edit services service-set v6rd-dslite-service-set]  
user@host# set interface-service service-interface sp-3/0/0
```

Results

```
[edit services service-set]  
user@host# show  
v6rd-dslite-service-set {  
  software-rules v6rd-r1;  
  software-rules dslite-r1;  
  stateful-firewall-rules r1;  
  nat-rules dslite-nat-r1;  
  interface-service {  
    service-interface sp-3/0/0;  
  }  
}
```

Protecting CGN Devices Against Denial of Service (DOS) Attacks

You can now choose configuration options that help prevent or minimize the effect of attempted denial of service (DOS) attacks.

- [Mapping Refresh Behavior on page 241](#)
- [EIF Inbound Flow Limit on page 242](#)

Mapping Refresh Behavior

Prior to the implementation of the new options for configuring NAT mapping refresh behavior, described in this topic, a conversation was kept alive when either inbound or outbound flows were active. This remains the default behavior. You can now also specify mapping refresh for only inbound flows or only outbound flows. To configure mapping refresh behavior, include the **mapping-refresh (inbound | outbound | inbound-outbound)** statement at the **[edit services nat rule *rule-name* term *term-name* then translated secure-nat-mapping]** hierarchy level.

EIF Inbound Flow Limit

Previously, the number of inbound connections on an EIF mapping was limited only by the maximum flows allowed on the system. You can now configure the number of inbound flows allowed for an EIF. To limit the number of inbound connections on an EIF mapping, include the **eif-flow-limit *number-of-flows*** statement at the **[edit services nat rule *rule-name* term *term-name* then translated secure-nat-mapping]** hierarchy level.

DS-Lite Subnet Limitation

- [DS-Lite Per Subnet Limitation Overview on page 242](#)
- [Configuring DS-Lite Per Subnet Session Limitation to Prevent Denial of Service Attacks on page 243](#)

DS-Lite Per Subnet Limitation Overview

Junos OS enables you to limit the number of software flows from a subscriber's basic bridging broadband (B4) device at a given point in time, preventing subscribers from excessive use of addresses within the subnet. This limitation reduces the risk of denial-of-service (DoS) attacks.

A household using IPv6 with DS-Lite is a subnet, not just an individual IP address. The subnet limitation feature associates a subscriber and mapping with an IPv6 prefix instead of an IPv6 address. A subscriber can use any IPv6 addresses in that prefix as a DS-Lite B4 address and potentially exhaust carrier-grade NAT resources. The subnet limitation feature enables greater control of resource utilization by identifying a subscriber with a prefix instead of a specific address.

The subnet limit provides the following features:

- Flows utilize the complete B4 address.
- Prefix length can be configured per service set under software-options for the individual service-set.
- Port blocks are allocated per prefix of the subscriber B4 device, and not on each B4 address (if the prefix length is less than 128). If prefix the length is 128, then each IPv6 address is treated as a B4. Port blocks are allocated per 128-bit V6 address.
- Session limit, defined under the DSLite software concentrator configuration, limits the number of IPv4 sessions for the prefix.
- EIM, EIF, and PCP mappings are created per software tunnel (full 128 bit IPv6 address). Stale mappings time out based on timeout values.
- If prefix length is configured, then PCP **max-mappings-per-subscriber** (configurable under **pcp-server**) is based on the prefix only, and not the full B4 address.
- SYSLOGS for PBA allocation and release contain the prefix portion of the address completed with all zeros. SYSLOGS for PCP alloc and release, Flow creation and deletion will still contain the complete IPv6 address.

The **show services nat mappings address-pooling-paired** operational command output now shows the mapping for the prefix. The mapping shows the address of the active B4.

The **show services softwire statistics ds-lite** output includes a new field that displays the number of times the session limit was exceeded for the MPC.

Configuring DS-Lite Per Subnet Session Limitation to Prevent Denial of Service Attacks

To configure DS-Lite per subnet session limitation:

1. Configure the size of the subnet prefix to which limiting is applied. Specify a prefix length of 56, 64, 96, or 128.

```
[edit]
user@router# set services service-set service-set-name softwire-options
                        dslite-ipv6-prefix-length 56.
```

NOTE: Ensure that all mappings are cleared before changing the prefix length.

2. Configure the maximum number of subscriber sessions allowed per prefix. You can configure from 0 through 16,384 sessions.

```
[edit]
user@router# set services softwire softwire-concentrator dslite
                        dslite-concentrator-name session-limit-per-prefix 12
```

NOTE: You cannot use **flow-limit** and **session-limit-per-prefix** in the same **dslite** configuration.

Transitioning to IPv6 Using 6rd Softwires

- [Configuring a 6rd Software Concentrator on page 245](#)
- [Configuring Stateful Firewall Rules for 6rd Software on page 246](#)
- [Example: Basic 6rd Configuration on page 247](#)
- [Inter-Chassis High Availability for MS-MIC and MS-MPC on page 252](#)
- [High Availability and Load Balancing for 6rd Softwires on page 264](#)

Configuring a 6rd Software Concentrator

To configure a 6rd software concentrator:

1. Assign a name to the 6rd software concentrator.

```
[edit services software software-concentrator]  
user@host# edit v6rd v6rd-software-concentrator
```

2. Specify the address of the software tunnel.

```
[edit services software software-concentrator v6rd v6rd-software-concentrator]  
user@host# set software-address address
```

3. Specify the MTU for the software tunnel.

```
[edit services software software-concentrator v6rd v6rd-software-concentrator]  
user@host# set mtu-v4 mtu-v4
```

TIP: In this release there is no support for fragmentation and reassembly, therefore the MTUs on the IPv6 and IPV4 network must be properly configured by the administrator.

NOTE: Configuration changes to 6rd software concentrators do not become effective in the Packet Forwarding Engine. This is a known limitation. If you attempt to add the new configuration of software concentrators by overriding the existing configuration of 1024 software concentrators, which is the maximum limit of software concentrators that the system supports, the new configuration is not updated. To work around this limitation, you must delete the existing configuration and commit the settings, and then add the new configuration of software concentrators and commit the settings.

NOTE: For 6rd software concentrators, packet drops are observed and error messages logged on the virtual terminal session (VTY) console, if one inline services (si-) interface is replaced with another si- interface without stopping the traffic during the replacement of the interface. In a scenario in which an si- interface is associated with a service set that has a large number of software concentrators, replacing that interface without halting the traffic causes traffic disruption. You must stop the traffic and restart it during such a replacement of si- interfaces with 6rd software concentrators. The following error messages are displayed on the VTY console of the FPC:

packet discarded because no ifl or not SI ifl

- [Example: Basic 6rd Configuration on page 247](#)
- [Example: Configuring DS-Lite and 6rd in the Same Service Set on page 234](#)

Configuring Stateful Firewall Rules for 6rd Software

You must configure a stateful firewall rule for use with 6rd softwires. The stateful firewall service is used only to direct packets to the software, not for firewalling purposes. The 6rd software service itself must be stateless. To support stateless processing, you must include an **allow** term in both directions of the stateful firewall policy.

To include a stateful firewall rule for 6rd software processing:

1. Assign a name to the rule.

```
[edit services stateful-firewall]  
user@host# edit rule rule-name
```

2. Specify the match direction.

```
[edit services stateful-firewall rule-name]
```

```
user@host# set match-direction input-output
```

3. Assign a name for the term.

```
[edit services stateful-firewall rule-name]
```

```
user@host# edit term term-name
```

4. Specify that all traffic in both directions should be accepted for the software process.

```
[edit services stateful-firewall rule-name term term-name]
```

```
user@host# set then accept
```

Example: Basic 6rd Configuration

- [Requirements on page 247](#)
- [Overview on page 247](#)
- [Configuration on page 247](#)

Requirements

This example describes how a 6rd concentrator can be configured for a 6rd domain, D1, to provide IPv6 Internet connectivity.

The following hardware components can perform 6rd:

- M Series Multiservice Edge routers with Multiservices PICs
- T Series Core routers with Multiservices PICs
- MX Series 3D Universal Edge routers with Multiservices DPCs

Overview

This configuration example describes how to configure a basic 6rd tunneling solution.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-1/2/0 unit 0 family inet service input service-set v6rd-dom1-service-set
set interfaces ge-1/2/0 unit 0 family inet service output service-set v6rd-dom1-service-set
```

```
set interfaces ge-1/2/0 unit 0 family inet address 10.10.10.1/24
set interfaces ge-1/2/0 unit 0 family inet6 service input service-set v6rd-dom1-service-set
set interfaces ge-1/2/0 unit 0 family inet6 service output service-set v6rd-dom1-service-set
set interfaces ge-1/2/2 unit 0 family inet6 address 3abc::1/16
set interfaces sp-0/2/0 unit 0 family inet
set interfaces sp-0/2/0 unit 0 family inet6
set services software software-concentrator v6rd v6rd-dom1 software-address 30.30.30.1
set services software software-concentrator v6rd v6rd-dom1 ipv4-prefix 10.10.10.0/24
set services software software-concentrator v6rd v6rd-dom1 v6rd-prefix 3040::0/16
set services software software-concentrator v6rd v6rd-dom1 mtu-v4 9192
set services software rule v6rd-dom1 match-direction input
set services software rule v6rd-dom1 term t1 then v6rd v6rd-dom1
set services service-set v6rd-dom1-service-set software-rules v6rd-dom1
set services service-set v6rd-dom1-service-set stateful-firewall-rules r1
set services service-set v6rd-dom1-service-set interface-service service-interface sp-0/2/0
set services stateful-firewall rule r1 match-direction input-output
set services stateful-firewall rule r1 term t1 then accept
```

Chassis Configuration

Step-by-Step Procedure

To configure the chassis:

1. Define the ingress interface.

```
user@host# edit interfaces ge-1/2/0
```
2. Configure the ingress interface logical unit and input/output service options.

```
[edit interfaces ge-1/2/0]
user@host# set unit 0 family inet service input service-set v6rd-dom1-service-set
user@host# set unit 0 family inet service output service-set v6rd-dom1-service-set
user@host# set unit 0 family inet6 service input service-set v6rd-dom1-service-set
user@host# set unit 0 family inet6 service output service-set v6rd-dom1-service-set
```
3. Configure the address of the ingress interface.

```
[edit interfaces ge-1/2/0]
user@host# set unit 0 family inet address 10.10.10.1/24
```
4. Define the egress interface.

```
user@host# up
[edit interfaces]
user@host# edit ge-1/2/2
```
5. Define the logical unit and address for the egress interface.

```
[edit interfaces ge-1/2/2]
user@host# set unit 0 family inet6 address 3ABC::1/16
```
6. Define the services PIC.

```
[edit interfaces ge-1/2/2]
user@host# up
[edit interfaces]
user@host# edit sp-0/2/0
```
7. Configure the logical unit for the services PIC.

```
[edit interfaces sp-0/2/0]
```

```

user@host# up
[edit interfaces]
user@host# set unit 0 family inet
user@host# set unit 0 family inet6

```

Results

```

[edit interfaces]
user@router# show
sp-0/2/0 {
    unit 0 {
        family inet;
        family inet6;
    }
}
ge-1/2/0 {
    unit 0 {
        family inet {
            service {
                input {
                    service-set v6rd-dom1-service-set;
                }
                output {
                    service-set v6rd-dom1-service-set;
                }
            }
            address 10.10.10.1/24;
        }
        family inet6 {
            service {
                input {
                    service-set v6rd-dom1-service-set;
                }
                output {
                    service-set v6rd-dom1-service-set;
                }
            }
        }
    }
}
ge-1/2/2 {
    unit 0 {
        family inet6 {
            address 3abc::1/16;
        }
    }
}

```

Software Concentrator, Software Rule, and Stateful Firewall Rule Configuration

Step-by-Step Procedure

To configure the software concentrator, software rule, and stateful firewall rule:

1. Define the 6rd software concentrator.

```

user@host# top
user@host# edit services software software-concentrator v6rd v6rd-dom1

```

2. Configure the software concentrator properties. Here, software address 30.30.30.1 is the software concentrator IPv4 address, 10.10.10.0/24 is the IPv4 prefix of the CE WAN side, and 3040::0/16 is the IPv6 prefix of the 6rd domain D1.

```
[edit services software software-concentrator v6rd v6rd-dom1]
user@host# set software-address 30.30.30.1
user@host# set ipv4-prefix 10.10.10.0/24
user@host# set v6rd-prefix 3040::0/16
user@host# set mtu-v4 9192
```

3. Define the software rule.

```
[edit services software software-concentrator v6rd v6rd-dom1]
user@host# up 2
[edit services software]
user@host# edit rule v6rd-dom1
[edit services software rule v6rd-dom1]
user@host# set match-direction input
[edit services software rule v6rd-dom1]
user@host# set term t1 then v6rd v6rd-dom1
```

4. Define a stateful firewall rule and properties. You must configure a stateful firewall rule that accepts all traffic in both the input and output direction in order for 6rd to work; however, this is not enforced through the CLI. This is because in IPv6, gratuitous IPv6 packets are expected (due to Anycast) and should not be dropped. The service PIC can handle reverse traffic without seeing all forward traffic. This can also happen with service PIC switchover in the middle of a session. By default, the stateful firewall on the service PIC will drop all traffic unless a rule is configured explicitly to allow it.

```

Service Set Configuration

Step-by-Step Procedure To configure the service set:

1. Define the service set for 6rd processing.

```
user@host# top
user@host# edit services service-set v6rd-dom1-service-set
```
2. Define the software and stateful firewall rules for the service set.

```
[edit services service-set v6rd-dom1-service-set]
user@host# set software-rules v6rd-dom1
user@host# set stateful-firewall-rules r1
```
3. Define the interface-service for the service set.

```
[edit services service-set v6rd-dom1-service-set]
user@host# set interface-service service-interface sp-0/2/0
```

Results [edit service-set v6rd-dom1-service-set]
 user@host# show
 software-rules v6rd-dom1-r1
 interface-service {
 service-interface sp-0/2/0;
 }

Inter-Chassis High Availability for MS-MIC and MS-MPC

Inter-chassis high availability supports stateful synchronization of services using a switchover to a backup services PIC on a different chassis. The feature is described in the following topics:

- [Inter-Chassis High Availability for Stateful Firewall and NAPT44 Overview \(MS-MIC, MS-MPC\) on page 252](#)
- [Configuring Inter-Chassis High Availability for Stateful Firewall and NAPT44 \(MS-MPC, MS-MIC\) on page 253](#)
- [Example: Inter-Chassis Stateful High Availability for NAT and Stateful Firewall \(MS-MIC, MS-MPC\) on page 254](#)

Inter-Chassis High Availability for Stateful Firewall and NAPT44 Overview (MS-MIC, MS-MPC)

Carrier-grade NAT (CGN) deployments can use dual-chassis implementations to provide a redundant data path and redundancy for key components in the router. Although intra-chassis high availability can be used in dual-chassis environments, it deals only with service PIC failures. If traffic is switched to a backup router due to some other failure in the router, state is lost. Inter-chassis high availability preserves state and provides redundancy using fewer service PICs than intra-chassis high availability. Only long-lived flows are synchronized between the master and backup chassis in the high availability pair. The service PICs do not replicate state until an explicit CLI command, **request services redundancy (synchronize | no-synchronize)**, is issued to start or stop the state replication. Stateful firewall, NAPT44, and APP state information can be synchronized.

NOTE: When both the master and backup PICs are up, replication starts immediately when the **request services redundancy** command is issued.

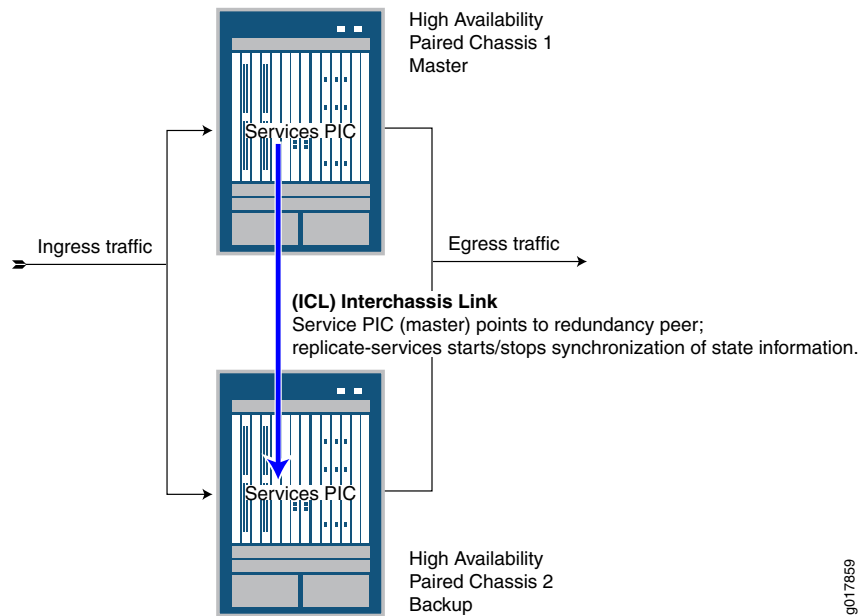

In order to use Inter-chassis high availability, you must use service sets configured for next-hop service interfaces. Inter-chassis high availability works with ms- service interfaces configured on MS-MIC or MS-MPC interface cards. A unit other than unit 0 must be configured with the **ip-address-owner service-plane** option.

The following restrictions apply:

- NAPT44 is the only translation type supported.
- Checkpointing is not supported for ALGs, PBA port block allocation (PBA), endpoint-independent mapping (EIM), or endpoint-independent filters (EIF).

[Figure 17 on page 253](#) shows the inter-chassis high availability topology.

Figure 17: Inter-Chassis High Availability Topology

Configuring Inter-Chassis High Availability for Stateful Firewall and NAPT44 (MS-MPC, MS-MIC)

To configure inter-chassis availability for stateful firewall and NAPT44 on MS-MIC or MS-MPC service PICs, perform the following configuration steps on each chassis of the high availability pair:

1. At the `[edit interfaces interface-name redundancy-options]` hierarchy level, set the **ipaddress** for the **redundancy-peer**. This IPv4 address specifies one of the hosted IP addresses of the remote PIC. This address is used by the TCP channel between the HA pairs.

```
[edit interfaces interface-name redundancy-options]
user@host# set redundancy-peer ipaddress ipaddress
```

NOTE: When you enable or disable high availability of MS-MICs or MS-MPCs by configuring or removing the primary and backup adaptive services PICs by using the `redundancy-options redundancy-peer ipaddress address` statement at the `[edit interfaces interface-name]` hierarchy level, the configuration change is treated as a catastrophic event for each service-set that refers to the affected interface at the `[edit services service-set name interface-service service-interface interface-name]` hierarchy level. A catastrophic event at the service-set level has the effect of deactivating the service set, applying the change, and then reactivating the service set.

2. Specify the name of a special routing instance, or VRF, you want applied to the HA synchronization traffic between the high availability pair.

```
[edit interfaces interface-name redundancy-options]
```

```
user@host# set routing-instance instance-name
```

3. For the service set defining an interface that is a member of the high availability pair, configure the service replication options using the *replicate-services* option.

```
[edit services service-set service-set-name replicate-services]  
user@host# set replication-threshold threshold-value  
stateful-firewall  
nat
```

Example: Inter-Chassis Stateful High Availability for NAT and Stateful Firewall (MS-MIC, MS-MPC)

This example shows how to configure inter-chassis high availability for stateful firewall and NAT services.

- [Requirements on page 254](#)
- [Overview on page 254](#)
- [Configuration on page 255](#)

Requirements

This example uses the following hardware and software components:

- Two MX480 routers with MS-MPC line cards
- Junos OS Release 13.3 or later

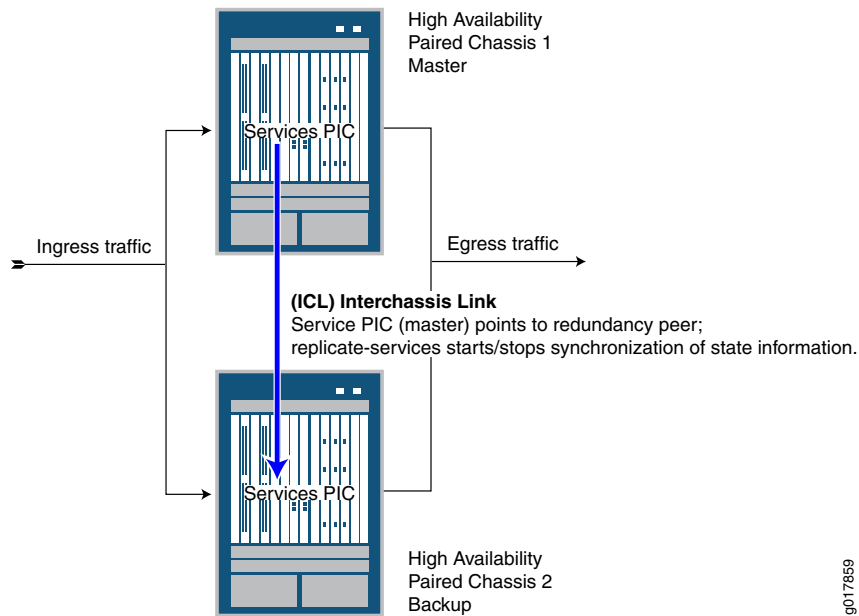

Overview

Two MX 3D routers are identically configured to facilitate stateful failover for firewall and NAT services in case of a chassis failure.

Topology

[Figure 18 on page 255](#) shows the inter-chassis high availability topology.

Figure 18: Inter-Chassis High Availability Topology

g017859

Configuration

To configure inter-chassis high availability for this example, perform these tasks:

- [Configuring Interfaces for Chassis 1 on page 257](#)
- [Configure Routing Information for Chassis 1 on page 258](#)
- [Configuring NAT and Stateful Firewall for Chassis 1 on page 259](#)
- [Configuring the Service Set on page 260](#)
- [Configuring Interfaces for Chassis 2 on page 261](#)
- [Configure Routing Information for Chassis 2 on page 263](#)

CLI Quick Configuration

To quickly configure this example on the routers, copy the following commands and paste them into the router terminal window after removing line breaks and substituting interface information specific to your site.

NOTE: The following configuration is for chassis 1.

```
[edit]
set interfaces ms-4/0/0 redundancy-options redundancy-peer ipaddress 5.5.5.2
set interfaces ms-4/0/0 redundancy-options routing-instance HA
set interfaces ms-4/0/0 unit 10 ip-address-owner service-plane

```

Configuring Interfaces for Chassis 1.

Step-by-Step Procedure

The interfaces for each of the HA pair of routers are configured identically with the exception of the following service PIC options:

- `redundancy-options redundancy-peer ipaddress address`
- `unit unit-number family inet address address` of a unit, other than 0, that contains the `ip-address-owner service-plane` option

To configure interfaces:

1. Configure the redundant service PIC on chassis 1.

```

[edit interfaces]
user@host# set interfaces ms-4/0/0 redundancy-options redundancy-peer
ipaddress 5.5.5.2
user@host# set interfaces ms-4/0/0 redundancy-options routing-instance HA
user@host# set interfaces ms-4/0/0 unit 10 ip-address-owner service-plane
user@host# set interfaces ms-4/0/0 unit 10 family inet address 5.5.5.1/32
user@host# set interfaces ms-4/0/0 unit 20 family inet
user@host# set interfaces ms-4/0/0 unit 20 service-domain inside
user@host# set interfaces ms-4/0/0 unit 30 family inet
user@host# set interfaces ms-4/0/0 unit 30 service-domain outside

```

2. Configure the interfaces for chassis 1 that are used as interchassis links for synchronization traffic.

```

user@host# set interfaces ge-2/0/0 vlan-tagging

```

```
user@host# set interfaces ge-2/0/0 unit 0 vlan-id 100 family inet address 20.1.1.1/24
```

3. Configure remaining interfaces as needed.

Results

```
user@host# show interfaces
ge-2/0/0 {
    vlan-tagging;
    unit 0 {
        vlan-id 100;
        family inet {
            address 20.1.1.1/24;
        }
    }
}
ms-4/0/0 {
    redundancy-options {
        redundancy-peer {
            ipaddress 5.5.5.2;
        }
        routing-instance HA;
    }
    unit 10 {
        ip-address-owner service-plane;
        family inet {
            address 5.5.5.1/32;
        }
    }
    unit 20 {
        family inet;
        family inet6;
        service-domain inside;
    }
    unit 30 {
        family inet;
        family inet6;
        service-domain outside;
    }
}
```

Configure Routing Information for Chassis 1

Step-by-Step Procedure Detailed routing configuration is not included for this example. A routing instance is required for the HA synchronization traffic between the chassis as follows:

- Configure routing instances for Chassis 1.

```
user@host# set routing-instances HA instance-type vrf
user@host# set routing-instances HA interface ge-2/0/0.0
user@host# set routing-instances HA interface ms-4/0/0.10
user@host# set routing-instances HA route-distinguisher 1:1
user@host# set policy-options policy-statement dummy term 1 then reject
user@host# set routing-instances HA vrf-import dummy
user@host# set routing-instances HA vrf-export dummy
@user@host# set routing-instances HA routing-options static route route 5.5.5.1/32
next-hop ms-4/0/0.10
user@host# set routing-instances HA routing-options static route route 5.5.5.2/32
next-hop 20.1.1.2
```

```

Results  @user@host# show routing-instances
HA {
    instance-type vrf;
    interface ge-2/0/0.0;
    interface ms-4/0/0.10;
    route-distinguisher 1:1;
    vrf-import dummy;
    vrf-export dummy;
    routing-options {
        static {
            route 5.5.5.1/32 next-hop ms-4/0/0.10;
            route 5.5.5.2/32 next-hop 20.1.1.2;
        }
    }
}

```

Configuring NAT and Stateful Firewall for Chassis 1

Step-by-Step Procedure Configure NAT and stateful firewall identically on both routers. To configure NAT and stateful firewall:

1. Configure NAT as needed.

```

user@host# set services nat pool p2 address 32.0.0.0/24
user@host# set services nat pool p2 port automatic random-allocation
user@host# set services nat pool p2 address-allocation round-robin
user@host# set services nat rule r2 match-direction input
user@host# set services nat rule r2 term t1 from source-address 129.0.0.0/8
user@host# set services nat rule r2 term t1 from source-address 128.0.0.0/8
user@host# set services nat rule r2 term t1 then translated source-pool p2
user@host# set services nat rule r2 term t1 then translated translation-type napt-44
user@host# set services nat rule r2 term t1 then translated address-pooling paired
user@host# set services nat rule r2 term t1 then syslog

```

2. Configure stateful firewall as needed.

```

user@host# set services stateful-firewall rule r2 match-direction input
user@host# set services stateful-firewall rule r2 term t1 from source-address
any-unicast
user@host# set services stateful-firewall rule r2 term t1 then accept
user@host# set services stateful-firewall rule r2 term t1 then syslog

```

```
Results user@host# show services nat
nat {
    pool p2 {
        address 32.0.0.0/24;
        port {
            automatic {
                random-allocation;
            }
        }
        address-allocation round-robin;
    }
    rule r2 {
        match-direction input;
        term t1 {
            from {
                source-address {
                    129.0.0.0/8;
                    128.0.0.0/8;
                }
            }
            then {
                translated {
                    source-pool p2;
                    translation-type {
                        napt-44;
                    }
                    address-pooling paired;
                }
                syslog;
            }
        }
    }
}

user@host# show services stateful-firewall
rule r2 {
    match-direction input;
    term t1 {
        from {
            source-address {
                any-unicast;
            }
        }
        then {
            accept;
            syslog;
        }
    }
}
```

Configuring the Service Set

Step-by-Step Procedure Configure the the service set identically on both routers. To configure the service set:

1. Configure the service set replication options.

```
user@host# set services service-set ss2 replicate-services replication-threshold
180
```

```
user@host# set services service-set ss2 replicate-services stateful-firewall
user@host# set services service-set ss2 replicate-services nat
```

2. Configure references to NAT and stateful firewall rules for the service set.

```
user@host# set services service-set ss2 stateful-firewall-rules r2
user@host# set services service-set ss2 nat-rules r2
```

3. Configure next-hop service interface on the MS-PIC.

```
user@host# set services service-set ss2 next-hop-service inside-service-interface
ms-4/0/0.20
user@host# set services service-set ss2 next-hop-service outside-service-interface
ms-4/0/0.30
```

4. Configure desired logging options.

```
user@host# set services service-set ss2 syslog host local class session-logs
user@host# set services service-set ss2 syslog host local class stateful-firewall-logs
user@host# set services service-set ss2 syslog host local class nat-logs
```

Results

```
user@host# show services service-set ss2
syslog {
    host local {
        class {
            session-logs;
            inactive: stateful-firewall-logs;
            nat-logs;
        }
    }
}
replicate-services {
    replication-threshold 180;
    stateful-firewall;
    nat;
}
stateful-firewall-rules r2;
inactive: nat-rules r2;
next-hop-service {
    inside-service-interface ms-3/0/0.20;
    outside-service-interface ms-3/0/0.30;
}
}
```

Configuring Interfaces for Chassis 2

Step-by-Step Procedure The interfaces for each of the HA pair of routers are configured identically with the exception of the following service PIC options:

- **redundancy-options redundancy-peer ipaddress address**
- **unit unit-number family inet address address** of a unit, other than 0, that contains the **ip-address-owner service-plane** option

1. Configure the redundant service PIC on chassis 2.

The **redundancy-peer ipaddress** points to the address of the unit (unit 10) on ms-4/0/0 on chassis 1 that contains the **ip-address-owner service-plane** statement.

```
[edit interfaces]
set interfaces ms-4/0/0 redundancy-options redundancy-peer ipaddress 5.5.5.1
user@host# set interfaces ms-4/0/0 redundancy-options routing-instance HA
user@host# set interfaces ms-4/0/0 unit 10 ip-address-owner service-plane
user@host# set interfaces ms-4/0/0 unit 10 family inet address 5.5.5.2/32
user@host# set interfaces ms-4/0/0 unit 20 family inet
user@host# set interfaces ms-4/0/0 unit 20 service-domain inside
user@host# set interfaces ms-4/0/0 unit 30 family inet
user@host# set interfaces ms-4/0/0 unit 30 service-domain outside
```

2. Configure the interfaces for chassis 2 that are used as interchassis links for synchronization traffic

```
user@host# set interfaces ge-2/0/0 vlan-tagging
user@host# set interfaces ge-2/0/0 unit 0 vlan-id 100 family inet address 20.1.1.2/24
```

3. Configure remaining interfaces for chassis 2 as needed.

Results

```

user@host# show interfaces
ms-4/0/0 {
    redundancy-options {
        redundancy-peer {
            ipaddress 5.5.5.1;
        }
        routing-instance HA;
    }
    unit 0 {
        family inet;
    }
    unit 10 {
        ip-address-owner service-plane;
        family inet {
            address 5.5.5.2/32;
        }
    }
}
ge-2/0/0 {
    vlan-tagging;
    unit 0 {
        vlan-id 100;
        family inet {
            address 20.1.1.2/24;
        }
    }
    unit 10 {
        vlan-id 10;
        family inet {
            address 2.10.1.2/24;
        }
    }
}

```

Configure Routing Information for Chassis 2

Step-by-Step Procedure Detailed routing configuration is not included for this example. A routing instance is required for the HA synchronization traffic between the two chassis and is included here.

- Configure routing instances for chassis 2.

```

user@host# set routing-instances HA instance-type vrf
user@host# set routing-instances HA interface ge-2/0/0.0
user@host# set routing-instances HA interface ms-4/0/0.10
user@host# set routing-instances HA route-distinguisher 1:1
user@host# set policy-options policy-statement dummy term 1 then reject
user@host# set routing-instances HA vrf-import dummy
user@host# set routing-instances HA vrf-export dummy
user@host# set routing-instances HA routing-options static route 5.5.5.2/32 next-hop ms-4/0/0.10
user@host# set routing-instances HA routing-options static route 5.5.5.1/32 next-hop 20.1.1.1

```

NOTE: The following configuration steps are *identical* to the steps shown for chassis 1.

- Configuring NAT and Stateful Firewall
- Configuring the Service Set

Results @user@host# **show services routing-instances**

```
HA {
    instance-type vrf;
    interface xe-2/2/0.0;
    interface ms-4/0/0.10;
    route-distinguisher 1:1;
    vrf-import dummy;
    vrf-export dummy;
    routing-options {
        static {
            route 5.5.5.2/32 next-hop ms-4/0/0.10;
            route 5.5.5.1/32 next-hop 20.1.1.1;
        }
    }
}
```

High Availability and Load Balancing for 6rd Softwires

- [Load Balancing a 6rd Domain Across Multiple Services PICs on page 264](#)
- [Example: Load Balancing a 6rd Domain Across Multiple Services PICs on page 264](#)
- [Configuring High Availability for 6rd Using 6rd Anycast on page 269](#)

Load Balancing a 6rd Domain Across Multiple Services PICs

The 6rd domain is an IPv6 network, which can potentially be very large. A single PIC, or network processing unit (NPU) on a Multiservices DPC, might not be able to handle all the traffic for the 6rd domain. To alleviate load problems, you can load-balance the 6rd domain traffic across multiple PICs. To do so, assign the same software rule to different services sets that use different interfaces. Configure explicit routes and equal-cost multipath (ECMP) to load-balance the 6rd traffic.

Example: Load Balancing a 6rd Domain Across Multiple Services PICs

- [Hardware and Software Requirements on page 264](#)
- [Overview on page 265](#)
- [Configuration on page 265](#)

Hardware and Software Requirements

This example requires the following hardware:

- An MX Series 3D Universal Edge router with a services DPC with two available NPUs or an M Series Multiservice Edge router with two services PICs available for 6rd software concentrator processing
- A domain name server (DNS)

This example uses the following software:

- Junos OS Release 11.4 or higher

Overview

Because of anticipated volume, a provider needs to balance 6rd software traffic between two services PICs.

Configuration

- [Chassis Configuration on page 265](#)
- [Software Concentrator and Software Rule Configuration on page 266](#)
- [Stateful Firewall Configuration on page 266](#)
- [Service Set Configuration on page 267](#)
- [Load-Balancing Configuration on page 267](#)

Chassis Configuration

Step-by-Step Procedure

To configure the chassis:

1. Define the ingress interface and its properties.

```
user@host# edit interfaces ge-1/2/0
user@host# set unit 0 family inet address 10.10.10.1/16
```
2. Define the egress interface and its properties. In this example, the IPv6 clients try to reach the IPv6 server at 3abc::2/16.

```
user@host# edit interfaces ge-1/2/2
user@host# set unit 0 family inet6 address 3ABC::1/16
```
3. Define the services PICs for selection as software concentrators by the load-balancing process. This configuration uses two PICs/NPUs: sp-3/0/0 and sp-3/1/0. A next-hop style service set is configured (shown in the next section).

```
user@host# edit interfaces sp-3/0/0
[edit interfaces ge-3/0/0]
user@host# set services-options syslog host local services any
user@host# set unit 0 family inet
user@host# set unit 0 family inet6
user@host# set unit 1 family inet service-domain inside
user@host# set unit 1 family inet service-domain outside
user@host# set unit 2 family inet service-domain inside
user@host# set unit 2 family inet service-domain outside
user@host# up 1
[edit]
user@host# edit interfaces sp-3/1/0
[edit interfaces sp-3/1/0]
user@host# set services-options syslog host local services any
user@host# set unit 0 family inet
user@host# set unit 0 family inet6
user@host# set unit 1 family inet service-domain inside
user@host# set unit 1 family inet service-domain outside
user@host# set unit 2 family inet service-domain inside
user@host# set unit 2 family inet service-domain outside
```

Software Concentrator and Software Rule Configuration

Step-by-Step Procedure The software configuration is straightforward. In this example, the 6rd domain prefix is 3040::0/16, the 6rd software concentrator IPv4 address is 30.30.30.1, and the customer IPv4 network is 10.10.0.0/16. In the customer premises equipment (CPE) network, all customer edge (CE) devices have addresses that belong to the 10.10.0.0/16 network. To configure the software:

1. Go to the **[edit services software]** hierarchy level.
`user@host# edit services software`
2. Configure IPv6 multicast.
`[edit services software]
user@host# set ipv6-multicast-interfaces all`
3. Go to the software concentrator v6rd hierarchy level and name the software concentrator **shenick01-rd1**.
`[edit services software]
user@host# edit software-concentrator v6rd shenick01-rd1`
4. Configure the software concentrator properties.
`[edit services software software-concentrator v6rdshenick01-rd1]
user@host# set software-address 30.30.30.1
user@host# set ipv4-prefix 10.10.0.0/16
user@host# set v6rd-prefix 3040::/16
user@host# set mtu-v4 9192`
5. Configure a software rule for incoming 6rd traffic.
`[edit services software software-concentrator v6rd shenick01-rd1]
user@host# up 1
[edit services software]
user@host# edit rule shenick01-r1
[edit services software rule shenick01-r1]
user@host# set match-direction input
user@host# set term t1 then v6rd shenick01-rd1`

Stateful Firewall Configuration

Step-by-Step Procedure To configure the stateful firewall rule:

1. Go to the stateful firewall hierarchy level and define a rule.
`user@host# edit services stateful-firewall rule r1`
2. Set the match direction.
`[edit services stateful-firewall rule r1]
user@host# set match-direction input-output`
3. Configure a term that accepts all traffic.
`[edit services stateful-firewall rule r1]
user@host# set term t1 then accept`

Service Set Configuration

Step-by-Step Procedure This configuration provides two service sets, each pointing to a different network processing unit (NPU). Both service sets use the same stateful firewall and softwire rules. Because they use the same softwire rule, they refer to same 6rd softwire concentrator. This results in the software concentrator being hosted on both the NPUs.

To configure the service set:

1. Define a service set for the first NPU.

```
user@host# edit services service-set v6rd-sset1
```
2. Configure the softwire and stateful firewall rules for the first NPU.

```
[edit services service-set v6rd-sset1]
user@host# set softwire-rules shenick01-r1
user@host# set stateful-firewall-rules r1
```
3. Configure the inside and outside interfaces for the next-hop service.

```
[edit services service-set v6rd-sset1]
user@host# set next-hop-service inside-service-interface sp-3/0/0.1
user@host# set next-hop-service outside-service-interface sp-3/0/0.2
```
4. Define a service set for the second NPU.

```
user@host# edit services service-set v6rd-sset2
```
5. Configure the softwire and stateful firewall rules for the second NPU.

```
[edit services service-set v6rd-sset2]
user@host# set softwire-rules shenick01-r1
user@host# set stateful-firewall-rules r1
```
6. Configure the inside and outside interfaces for the next-hop service.

```
[edit services service-set v6rd-sset1]
user@host# set next-hop-service inside-service-interface sp-3/1/0.1
user@host# set next-hop-service outside-service-interface sp-3/1/0.2
```

Load-Balancing Configuration

Step-by-Step Procedure To configure load balancing:
 Configure explicit routes and ECMP to load-balance the 6rd traffic. Configure explicit routes for both the 6rd concentrator IPv4 address and the 6rd domain prefix, so that they point to both NPUs.

1. To configure static routes for the 6rd domain using the routing-table inet6.0, go to the **[edit forwarding-options rib inet6.0 static]** hierarchy level and set the routes for the 6rd domain and the 6rd concentrator IPv4 address.

```
user@host edit forwarding-options rib inet6.0 static
[edit forwarding-options rib inet6.0 static]
user@host# set route 3040::0/16 next-hop [ sp-3/0/0.2 sp-3/1/0.2 ]
user@host# set route 30.30.30.1/32 next-hop [ sp-3/0/0.1 sp-3/1/0.1 ]
```

The service PIC daemon (spd) also adds default routes to these addresses pointing to the NPUs. However, the routes added by the spd use different metrics, which are computed based on the FPC, PIC, slot numbers, and subunit of the services PIC if used in the service set configuration. The static routes configured in this sample configuration will have metrics of 5 and therefore a higher preference than the spd-added routes.

The explicitly configured routes are as follows:

```
root@router# run show route 30.30.30.1
inet.0: 37 destinations, 40 routes (36 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
30.30.30.1/32      *[Static/5] 00:00:10
                   > via sp-3/0/0.1
                   via sp-3/1/0.1
                   [Static/786433] 00:23:03
                   > via sp-3/0/0.1
                   [Static/851969] 00:00:09
                   > via sp-3/1/0.1
```

```
root@router# run show route 3040::/16
inet6.0: 20 destinations, 33 routes (20 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
3040::/16         *[Static/5] 00:00:15
                   via sp-3/0/0.2
                   > via sp-3/1/0.2
                   [Static/786434] 00:23:08
                   > via sp-3/0/0.2
                   [Static/851970] 00:00:14
                   > via sp-3/1/0.2
```

BEST PRACTICE: The spd-installed routes have higher metric values (hence a low preference) and the metrics are different. If the metrics are different and ECMP is not enabled, even though multiple routes exist for the same destination, only one of the routes is picked up all the time (based on the metric). For ECMP you must configure equal-cost routes, and hence a manual configuration of routes is needed as shown above.

2. Configure equal-cost multipath (ECMP) load balancing by configuring the hash key at the **[edit forwarding-options hash-key]** hierarchy level.

```
user@host# forwarding-options hash-key
[edit forwarding-options hash-key]
user@host# set family inet layer-3 destination-address
user@host# set family inet layer-3 source-address
user@host# set family inet6 layer-3 destination-address
user@host# set family inet6 layer-3 source-address
```

3. Verify your configuration by displaying **forwarding-options**.

```
user@host# show forwarding-options
hash-key {
    family inet { <== IPv4 traffic from CEs uses this
```

```

        layer-3 {
            destination-address;
            source-address;
        }
    }
    family inet6 { <== IPv6 traffic from Internet uses this
        layer-3 {
            destination-address;
            source-address;
        }
    }
}

```

TIP: Both IPv4 and IPv6 hash keys must be configured. The IPv4 hash key is used to distribute the traffic coming from CPE devices to the 6rd branch relay. The IPv6 hash key is used to distribute the traffic coming from the IPv6 Internet to the 6rd domain. Because the hash in the forward and reverse direction is for different families, different flows from the same session can reside on different NPUs. However, 6rd processing is stateless (as far as mapping IPv6 packets to softwires is concerned), so this should not be a problem.

Configuring High Availability for 6rd Using 6rd Anycast

You configure 6rd Anycast by defining two service sets that use the same softwire rule in both service sets, just as you do when you configure load balancing for 6rd. However, you do not configure ECMP, and as a result, the services PIC daemon (spd) installs two routes *each* for the softwire concentrator address and 6rd domain pointing to each service interface. The forwarding plane can select any route based on the priority, which is computed when the spd installs the routes. The priority is computed based on the FPC, PIC, slot numbers, and subunit number used on the sp- interface. *Only one PIC is used* based on the route priority, and that PIC gets all of the 6rd traffic. If the PIC goes down, the route pointing to it is also deleted and the forwarding plane automatically selects the alternate available PIC.

6rd Anycast is completely stateless. The spd installs the route and doesn't run any state machine for the PIC. Because the routes are pre-installed and service sets are already on the PIC, there is no service delay if a failover occurs.

Monitoring and Troubleshooting Softwires

- [Ping and Traceroute for DS-Lite on page 271](#)
- [Monitoring Softwire Statistics on page 271](#)
- [Monitoring CGN, Stateful Firewall, and Softwire Flows on page 273](#)

Ping and Traceroute for DS-Lite

With Junos OS Release 11.4, you can use the **ping** and **traceroute** commands to determine the status of the DS-Lite softwire tunnels:

- **IPv6 ping**—The softwire address endpoint on the DS-Lite softwire terminator (AFTR) is usually configured only at the **[edit services softwire]** hierarchy level; it need not be hosted on any interface. Previous releases of the Junos OS software did not provide replies to pings to the IPv6 softwire address when the AFTR was not configured on a specific interface or loopback. An IPv6 ping enables the softwire initiator (B4) to verify the softwire address of the AFTR before creating a tunnel.
- **IPv4 ping**—A special IPv4 address, 192.0.0.1, is reserved for the AFTR. Previous releases of the Junos OS did not respond to any pings sent to this address. A B4 and other IPv4 nodes can now ping to this address to determine whether the DS-Lite tunnel is working.
- **Traceroute**—The AFTR now generates and forwards traceroute packets over the DS-Lite tunnel.

NOTE: No additional CLI configuration is necessary to use the new functionality.

Monitoring Softwire Statistics

Purpose You can review softwire global statistics by using the **show services softwire** or **show services softwire statistics** command.

```
Action user@host# show services software

Monitoring CGN, Stateful Firewall, and Softwire Flows

Purpose Use the following commands to check the creation of the softwires, pre-NAT flows, and post-NAT flows. Output can be filtered using more specific fields such as AFTR or B4 address or both for DS-Lite, and softwire-concentrator or softwire-initiator or both for 6rd.

- [show services stateful-firewall flows](#)
- [show services softwire flows](#)

Action user@host# **show services stateful-firewall flows**
 Interface: sp-0/1/0, Service set: dslite-svc-set2

Basic TCP ALG

This ALG performs basic sanity checking on TCP packets. If it finds errors, it generates the following anomaly events and system log messages:

- TCP source or destination port zero
- TCP header length check failed
- TCP sequence number zero and no flags are set
- TCP sequence number zero and FIN/PSH/RST flags are set
- TCP FIN/RST or SYN(URG|FIN|RST) flags are set

The TCP ALG performs the following steps:

1. When the router receives a SYN packet, the ALG creates TCP forward and reverse flows and groups them in a *conversation*. It tracks the TCP three-way handshake.
2. The SYN-defense mechanism tracks the TCP connection establishment state. It expects the TCP session to be established within a small time interval (currently 4 seconds). If the TCP three-way handshake is not established in that period, the session is terminated.
3. A keepalive mechanism detects TCP sessions with nonresponsive endpoints.
4. ICMP errors are allowed only if there is a flow that matches the selector information specified in the ICMP data.

Basic UDP ALG

This ALG performs basic sanity checking on UDP headers. If it finds errors, it generates the following anomaly events and system log messages:

- UDP source or destination port 0
- UDP header length check failed

The UDP ALG performs the following steps:

1. When it receives the first packet, the ALG creates bidirectional flows to accept forward and reverse UDP session traffic.
2. If the session is idle for more than the maximum allowed idle time (the default is 30 seconds), the flows are deleted.
3. ICMP errors are allowed only if there is a flow that matches the selector information specified in the ICMP data.

BOOTP

The Bootstrap Protocol (BOOTP) client retrieves its networking information from a server across the network. It sends out a general broadcast message to request the information, which is returned by the BOOTP server. For the protocol specification, see <ftp://ftp.isi.edu/in-notes/rfc951.txt>.

Stateful firewall support requires that you configure the BOOTP ALG on UDP server port 67 and client port 68. If the client sends a broadcast message, you should configure the broadcast address in the **from** statement of the service rule. Network Address Translation (NAT) is not performed on the BOOTP traffic, even if the NAT rule matches the traffic. If the BOOTP relay feature is activated on the router, the remote BOOTP server is assumed to assign addresses for clients masked by NAT translation.

DCE RPC Services

Distributed Computing Environment (DCE) Remote Procedure Call (RPC) services are mainly used by Microsoft applications. The ALG uses well-known TCP port 135 for port mapping services, and uses the universal unique identifier (UUID) instead of the program number to identify protocols. The main application-based DCE RPC is the Microsoft Exchange Protocol.

Support for stateful firewall and NAT services requires that you configure the DCE RPC portmap ALG on TCP port 135. The DCE RPC ALG uses the TCP protocol with application-specific UUIDs.

DNS

The Domain Name Service (DNS) ALG handles data associated with locating and translating domain names into IP addresses. The ALG typically runs on port 53. The ALG monitors DNS query and reply packets and supports only UDP traffic. The ALG does not support payload translations. The DNS ALG will only close the session when a reply is received or an idle timeout is reached.

FTP

FTP is the File Transfer Protocol, specified in RFC 959. In addition to the main control connection, data connections are also made for any data transfer between the client

and the server; and the host, port, and direction are negotiated through the control channel.

For non-passive-mode FTP, Junos OS stateful firewall service scans the client-to-server application data for the PORT command, which provides the IP address and port number to which the server connects. For passive-mode FTP, Junos OS stateful firewall service scans the client-to-server application data for the PASV command and then scans the server-to-client responses for the 227 response, which contains the IP address and port number to which the client connects.

There is an additional complication: FTP represents these addresses and port numbers in ASCII. As a result, when addresses and ports are rewritten, the TCP sequence number might be changed, and thereafter the NAT service needs to maintain this delta in SEQ and ACK numbers by performing sequence NAT on all subsequent packets.

Support for stateful firewall and NAT services requires that you configure the FTP ALG on TCP port 21 to enable the FTP control protocol. The ALG performs the following tasks:

- Automatically allocates data ports and firewall permissions for dynamic data connection
- Creates flows for the dynamically negotiated data connection
- Monitors the control connection in both active and passive modes
- Rewrites the control packets with the appropriate NAT address and port information

On MS-MPCs and MS-MICs, for passive FTP to work properly without FTP application layer gateway (ALG) enabled (by not specifying the **application junos-ftp** statement at the **[edit services stateful-firewall rule rule-name term term-name from]** and the **[edit services nat rule rule-name term term-name from]** hierarchy levels), you must enable the address pooling paired (APP) functionality enabled (by including the **address-pooling** statement at the **[edit services nat rule rule-name term term-name then translated]** hierarchy level). Such a configuration causes the data and control FTP sessions to receive the same NAT address.

H323

H323 is a suite of ITU protocols for audio and video conferencing and collaboration applications. H323 consists of H.225 call signaling protocols and H.245 control protocol for media communication. During H.225 negotiation, the endpoints create a call by exchanging call signaling messages on the control channel and negotiate a new control channel for H.245. A new control connection is created for H.245 messages. Messages are exchanged on the H.245 control channel to open media channels.

Stateful firewall monitors the H.225 control channel to open the H.245 control channel. After the H.245 channel is created, stateful firewall also monitors this channel for media channel information and allows the media traffic through the firewall.

H323 ALG supports static destination, static and dynamic source NAT by rewriting the appropriate addresses and ports in the H.225 and H.245 messages.

ICMP

The Internet Control Message Protocol (ICMP) is defined in RFC 792. The Junos OS stateful firewall service allows ICMP messages to be filtered by specific type or specific type code value. ICMP error packets that lack a specifically configured type and code are matched against any existing flow in the opposite direction to check for the legitimacy of the error packet. ICMP error packets that pass the filter matching are subject to NAT translation.

The ICMP ALG always tracks ping traffic statefully using the ICMP sequence number. Each echo reply is forwarded only if there is an echo request with the corresponding sequence number. For any ping flow, only 20 echo requests can be forwarded without receiving an echo reply. When you configure dynamic NAT, the PING packet identifier is translated to allow additional hosts in the NAT pool to use the same identifier.

Support for stateful firewall and NAT services requires that you configure the ICMP ALG if the protocol is needed. You can configure the ICMP type and code for additional filtering.

IIOP

The Oracle Application Server NameServer Internet Inter-ORB Protocol (IIOP). This ALG is used in Common Object Request Broker Architecture (CORBA) based on distributed computing. Even though CORBA and IIOP are Object Management Group (OMG) standards, there is no fixed port assigned for IIOP. Each vendor implementing CORBA chooses a port. Java Virtual machine uses port 1975 by default, while ORBIX uses port 3075 as a default.

Stateful firewall and NAT require ALG IIOP be configured for TCP port 1975 for Java VM IIOP, and 3075 for CORBA applications ORBIX, a CORBA framework from Iona Technologies.

IP

The IP ALG is used to create uni-directional flows only. In case of TCP traffic, it does not check the 3-way handshake process. This ALG is useful in case of stateful firewall only service sets, where it allows traffic to flow uni-directionally only. When configuring in conjunction with **match-direction input-output** it allows the return traffic to flow through the stateful firewall as well. Typical scenarios are static NAT, destination NAT or scenarios where traffic is expected to traverse the stateful firewall in the presence of asymmetric routing. The Junos IP ALG is not intended for use with NAT, which will cause matching traffic to be discarded through the creation of a drop flow.

NetBIOS

A NetBIOS ALG translates NetBIOS IP addresses and port numbers when NAT is used.

NetBIOS supports the TCP and UDP transport protocols. Support for stateful firewall and NAT services requires that you configure the NetBIOS ALG on UDP port 138 and TCP port 139.

NetShow

The Microsoft protocol ms-streaming is used by NetShow, the Microsoft media server. This protocol supports several transport protocols: TCP, UDP, and HTTP. The client starts a TCP connection on port 1755 and sends the PORT command to the server. The server then starts UDP on that port to the client. Support for stateful firewall and NAT services requires that you configure the NetShow ALG on UDP port 1755.

ONC RPC Services

Open Networks Computing (ONC) RPC services function similarly to DCE RCP services. However, the ONC RPC ALG uses TCP/UDP port 111 for port mapping services, and uses the program number to identify protocols rather than the UUID.

Support for stateful firewall and NAT services requires that you configure the ONC RPC portmap ALG on TCP port 111. The ONC RPC ALG uses the TCP protocol with application-specific program numbers.

PPTP

The Point-to-Point Tunneling Protocol (PPTP) ALG is a TCP-based ALG. PPTP allows the Point-to-Point Protocol (PPP) to be tunneled through an IP network. PPTP defines a client-server architecture, a PPTP Network Server, and a PPTP Access Concentrator. The PPTP ALG requires a control connection and a data tunnel. The control connection uses TCP to establish and disconnect PPP sessions, and runs on port 1723. The data tunnel carries PPP traffic in generic routing encapsulated (GRE) packets that are carried over IP.

RealAudio

Real Networks PNA protocol RealVideo is not a separate service. It is part of the RealPlayer and most likely uses another channel for video. The RealPlayer versions G2, 7, and 8 use PNA and RTSP. For this version to work, the ALG must allow both PNA(7070) and RTSP(554). For the media, the server selects from a range of UDP ports(6970 through 7170), or TCP port 7071, or HTTP. The client can be configured to use a particular port. The RealPlayer versions 4.0 and 5.0 use control channel 7070 media UDP ports 6970 through 7170, or TCP port 7071, or HTTP. RealAudio player version 3.0 uses control channel 7070 media, UDP ports 6770-7170, or TCP port 7071.

Real products use the ports and ranges of ports shown in [Table 14 on page 283](#).

Table 14: RealAudio Product Port Usage

Real Product	Port Usage
4.0 and 5.0 Servers/Players	Control channel (bidirectional) on TCP port 7070. Data channel from server to player on TCP port 7070 or UDP port 6970-7170.
4.0 and 5.0 Servers/Encoders	Control channel (bidirectional) on TCP port 7070. Data channel from encoder or server on TCP port 7070.
G2 Servers/Players	Control channel (bidirectional) on TCP port 80, 554, 7070, or 8080. Data channel from server to player on TCP port 80, 554, 7070, 8080 or UDP port 6970-32,000.

Table 14: RealAudio Product Port Usage (*continued*)

Real Product	Port Usage
G2 Server/3.1, and 5.x Encoders	Control channel (bidirectional) on TCP port 7070. Data channel from encoder to server on TCP port 7070.
G2 Server/G2 Producer	Control channel (bidirectional) on TCP port 4040. Data channel from encoder to server on TCP port 4040 and UDP port 6970-32,000.
2 Server/G2 Producer (TCP ONLY)	Control channel (bidirectional) on TCP port 4040 Data channel from encoder to server on TCP port 4040. Note: TCP-ONLY option available in version 6.1 or above.

NOTE: RealAudio was the original protocol by RealPlayers. Newer versions of RealPlayer use RTSP. Stateful firewall and NAT require ALG RealAudio to be programmed on TCP port 7070.

Sun RPC and RPC Portmap Services

The Remote Procedure Call (RPC) ALG uses well-known ports TCP 111 and UDP 111 for port mapping, which dynamically assigns and opens ports for RPC services. The RPC Portmap ALG keeps track of port requests and dynamically opens the firewall for these requested ports. The RPC ALG can further restrict the RPC protocol by specifying allowed program numbers.

The ALG includes the RPC services listed in [Table 15 on page 284](#).

Table 15: Supported RPC Services

Name	Description	Comments
rpc-mountd	Network File Server (NFS) mount daemon; for details, see the UNIX man page for rpc.mountd(8) .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050).
rpc-nfsprog	Used as part of NFS. For details, see RFC 1094. See also RFC1813 for NFS v3.	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050).
rpc-nisplus	Network Information Service Plus (NIS+), designed to replace NIS; it is a default naming service for Sun Solaris and is not related to the old NIS. No protocol information is available.	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050).
rpc-nlockmgr	Network lock manager.	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-nlockmgr service can be allowed or blocked based on RPC program 100021.
rpc-pcnfsd	Kernel statistics server. For details, see the UNIX man pages for rstatd and rpc.rstatd .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-rstat service can be allowed or blocked based on RPC program 150001.

Table 15: Supported RPC Services (*continued*)

Name	Description	Comments
rpc-rwall	Used to write a message to users; for details, see the UNIX man page for rpc.rwalld .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-rwall service can be allowed or blocked based on RPC program 150008.
rpc-ybind	NIS binding process. For details, see the UNIX man page for ybind .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-ybind service can be allowed or blocked based on RPC program 100007.
rpc-yppasswd	NIS password server. For details, see the UNIX man page for yppasswd .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-yppasswd service can be allowed or blocked based on RPC program 100009.
rpc-ybserv	NIS server. For details, see the UNIX man page for ybserv .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-ybserv service can be allowed or blocked based on RPC program 100004.
rpc-ypupdated	Network updating tool.	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-ypupdated service can be allowed or blocked based on RPC program 100028.
rpc-ypxfrd	NIS map transfer server. For details, see the UNIX man page for rpc.ypxfrd .	The base support is RPC v2 and the port mapper service on port 111 (see RFC 1050). Once the RPC program table is built, rpc-ypxfrd service can be allowed or blocked based on RPC program 100069.

Support for stateful firewall and NAT services that use port mapping requires that you configure the RPC portmap ALG on TCP/UDP destination port 111 and the RPC ALG for both TCP and UDP. You can specify one or more **rpc-program-number** values to further restrict allowed RPC protocols.

RTSP

The Real-Time Streaming Protocol (RTSP) controls the delivery of data with real-time properties such as audio and video. The streams controlled by RTSP can use RTP, but it is not required. Media can be transmitted on the same RTSP control stream. This is an HTTP-like text-based protocol, but client and server maintain session information. A session is established using the SETUP message and terminated using the TEARDOWN message. The transport (the media protocol, address, and port numbers) is negotiated in the setup and the setup-response.

Support for stateful firewall and NAT services requires that you configure the RTSP ALG for TCP port 554.

The ALG monitors the control connection, opens flows dynamically for media (RTP/RTSP) streams, and performs NAT address and port rewrites.

SIP

The Session Initiation Protocol (SIP) is an application layer protocol that can establish, maintain, and terminate media sessions. It is a widely used voice over IP (VoIP) signaling protocol. The SIP ALG monitors SIP traffic and dynamically creates and manages pinholes on the signaling and media paths. The ALG only allows packets with the correct permissions. The SIP ALG also performs the following functions:

- Manages parent-child session relationships.
- Enforces security policies.
- Manages pinholes for VoIP traffic.

The SIP ALG supports the following features:

- Stateful firewall
- Static source NAT
- Dynamic address only source NAT
- Network Address Port Translation (NAPT)

NOTE: SIP sessions are limited to 12 hours (720 minutes) for NAT processing on the MS-MIC and MS-MPC interface cards. There is no time limit for SIP sessions on the MS-DPC.

SNMP

SNMP is a communication protocol for managing TCP/IP networks, including both individual network devices and aggregated devices. The protocol is defined by RFC 1157. SNMP runs on top of UDP.

The Junos OS stateful firewall service implements the SNMP ALG to inspect the SNMP type. SNMP does not enforce stateful flow. Each SNMP type needs to be specifically enabled. Full SNMP support of stateful firewall services requires that you configure the SNMP ALG on UDP port 161. This enables the SNMP **get** and **get-next** commands, as well as their response traffic in the reverse direction: UDP port 161 enables the SNMP **get-response** command. If SNMP traps are permitted, you can configure them on UDP port 162, enabling the SNMP **trap** command.

SQLNet

The SQLNet protocol is used by Oracle SQL servers to execute SQL commands from clients, including load balancing and application-specific services.

Support of stateful firewall and NAT services requires that you configure the SQLNet ALG for TCP port 1521.

The ALG monitors the control packets, opens flows dynamically for data traffic, and performs NAT address and port rewrites.

TFTP

The Trivial File Transfer Protocol (TFTP) is specified in RFC 1350. The initial TFTP requests are sent to UDP destination port 69. Additional flows can be created to **get** or **put** individual files. Support of stateful firewall and NAT services requires that you configure the TFTP ALG for UDP destination port 69.

Traceroute

Traceroute is a tool for displaying the route that packets take to a network host. It uses the IP time-to-live (TTL) field to trigger ICMP time-exceeded messages from routers or gateways. It sends UDP datagrams to destination ports that are believed to be not in use; destination ports are numbered using the formula: $+ n\text{hops} - 1$. The default base port is 33434. To support traceroute through the firewall, two types of traffic must be passed through:

1. UDP probe packets (UDP destination port > 33000 , IP TTL < 30)
2. ICMP response packets (ICMP type time-exceeded)

When NAT is applied, the IP address and port within the ICMP error packet also must be changed.

Support of stateful firewall and NAT services requires you to configure the Traceroute ALG for UDP destination port 33434 to 33450. In addition, you can configure the TTL threshold to prevent UDP flood attacks with large TTL values.

UNIX Remote-Shell Services

Three protocols form the basis for UNIX remote-shell services:

- **Exec**—Remote command execution; enables a user on the client system to execute a command on the remote system. The first command from client (**rcmd**) to server (**rshd**) uses well-known TCP port 512. A second TCP connection can be opened at the request of **rcmd**. The client port number for the second connection is sent to the server as an ASCII string.
- **Login**—Better known as **rlogin**; uses well-known TCP port 513. For details, see RFC 1282. No special firewall processing is required.
- **Shell**—Remote command execution; enables a user on the client system to execute a command on the remote system. The first command from client (**rcmd**) to server (**rshd**) uses well-known TCP port 514. A second TCP connection can be opened at the request of **rcmd**. The client port number for the second connection is sent to the server as an ASCII string.

Support of stateful firewall services requires that you configure the Exec ALG on TCP port 512, the Login ALG on TCP port 513, and the Shell ALG on TCP port 514. NAT remote-shell services require that any dynamic source port assigned be within the port range 512 to 1023. If you configure a NAT pool, this port range is reserved exclusively for remote shell applications.

Winframe

WinFrame application server software provides access to virtually any Windows application, across any type of network connection to any type of client.

This protocol is mainly used by Citrix Windows applications.

Stateful firewall and NAT require the ALG Winframe to be configured on TCP destination port 1494 and UDP port 1604.

Juniper Networks Defaults

The Junos OS provides a default, hidden configuration group called **junos-defaults** that is automatically applied to the configuration of your router. The **junos-defaults** group contains preconfigured statements that contain predefined values for common applications. Some of the statements must be referenced to take effect, such as applications like FTP or Telnet. Other statements are applied automatically, such as terminal settings. All of the preconfigured statements begin with the reserved name **junos-**.

NOTE: You can override the Junos default configuration values, but you cannot delete or edit them. If you delete a configuration, the defaults return when a new configuration is added.

You cannot use the **apply-groups** statement with the Junos defaults group.

To view the full set of available preset statements from the Junos default group, issue the **show groups junos-defaults** configuration mode command. The following example displays the list of Junos default groups that use application protocols (ALGs).

```
user@host# show groups junos-defaults
applications {
  #
  # File Transfer Protocol
  #
  application junos-ftp {
    application-protocol ftp;
    protocol tcp;
    destination-port 21;
  }
  #
  # Trivial File Transfer Protocol
  #
  application junos-tftp {
    application-protocol tftp;
    protocol udp;
    destination-port 69;
  }
  #
  # RPC portmapper on TCP
  #
  application junos-rpc-portmap-tcp {
```

```
    application-protocol rpc-portmap;
    protocol tcp;
    destination-port 111;
}
#
# RPC portmapper on UDP
#
application junos-rpc-portmap-udp {
    application-protocol rpc-portmap;
    protocol udp;
    destination-port 111;
}
#
# SNMP get
#
application junos-snmp-get {
    application-protocol snmp;
    protocol udp;
    destination-port 161;
    snmp-command get;
}
#
# SNMP get next
#
application junos-snmp-get-next {
    application-protocol snmp;
    protocol udp;
    destination-port 161;
    snmp-command get-next;
}
#
# SNMP response
#
application junos-snmp-response {
    application-protocol snmp;
    protocol udp;
    source-port 161;
    snmp-command get-response;
}
#
# SNMP trap
#
application junos-snmp-trap {
    application-protocol snmp;
    protocol udp;
    destination-port 162;
    snmp-command trap;
}
#
# remote exec
#
application junos-rexec {
    application-protocol exec;
    protocol tcp;
    destination-port 512;
}
```

```
#
# remote login
#
application junos-rlogin {
    application-protocol shell;
    protocol tcp;
    destination-port 513;
}
#
# remote shell
#
application junos-rsh {
    application-protocol shell;
    protocol tcp;
    destination-port 514;
}
#
# Real Time Streaming Protocol
#
application junos-rtsp {
    application-protocol rtsp;

    application junos-http;
    application junos-https;
    application junos-xnm-ssl;
    application junos-xnm-clear-text;
}
#
# 'junos-routing-inbound' represents routing protocols that might
# need to access the router from public network.
#

```

```
# Set is intended for a UI to display routing involvement choices.
#
# NOTE: It is not recommended the user to use the entire set
# directly in a firewall rule and open up firewall to all
# of these applications. Also, the user should always
# specify the source and destination prefixes when using
# each application.
#
# NOTE: the contents of this set might grow in future JUNOS OS versions.
#
application-set junos-routing-inbound {
    application junos-bgp;
    application junos-rip;
    application junos-ldp-tcp;
    application junos-ldp-udp;
}
```

To reference statements available from the **junos-defaults** group, include the selected **junos-default-name** statement at the applicable hierarchy level. To configure application protocols, see [“Configuring Application Protocol Properties” on page 303](#); for details about a specific protocol, see [“ALG Descriptions” on page 277](#).

Examples: Referencing the Preset Statement from the Junos Default Group

The following example is a preset statement from the Junos default groups that is available for FTP in a stateful firewall:

```
[edit]
groups {
  junos-defaults {
    applications {
      application junos-ftp { # Use FTP default configuration
        application-protocol ftp;
        protocol tcp;
        destination-port 21;
      }
    }
  }
}
```

To reference a preset Junos default statement from the Junos default groups, include the **junos-default-name** statement at the applicable hierarchy level. For example, to reference the Junos default statement for FTP in a stateful firewall, include the **junos-ftp** statement at the **[edit services stateful-firewall rule rule-name term term-name from applications]** hierarchy level.

```
[edit]
services {
  stateful-firewall {
    rule my-rule {
      term my-term {
        from {
          applications junos-ftp; #Reference predefined statement, junos-ftp,
        }
      }
    }
  }
}
```

```

    }
  }

```

The following example shows configuration of the default Junos IP ALG:

```

[edit]
services {
  stateful-firewall {
    rule r1 {
      match-direction input;
      term t1 {
        from {
          applications junos-ip;
        }
        then {
          accept;
          syslog;
        }
      }
    }
  }
}

```

If you configure the IP ALG in the stateful firewall rule, it is matched by any IP traffic, but if there is any other more specific application that matches the same traffic, the IP ALG will not be matched. For example, in the following configuration, both the ICMP ALG and the IP ALG are configured, but traffic is matched for ICMP packets, because it is the more specific match.

```

[edit]
services {
  stateful-firewall {
    rule r1 {
      match-direction input;
      term t1 {
        from {
          applications [ junos-ip junos-icmp-all ];
        }
        then {
          accept;
          syslog;
        }
      }
    }
  }
}

```

ALGs Available by Default for Junos OS Address Aware NAT

The following application-level gateways (ALGs) listed in [Table 12 on page 141](#) are supported for NAT processing on the listed platforms.

To view the implementation details (port, protocol, and so on) for these Junos OS default applications, locate the Junos OS Default ALG Name in the table and then look up the listed name in the **groups**. For example, for details about TFTP, look up **junos-tftp** as shown.

TIP: The Junos OS provides the **junos-alg**, which enables other ALGs to function by handling ALG registrations, causing slow path packets to flow through registered ALGs, and transferring ALG events to the ALG plug-ins. The **junos-alg** ALG is automatically available on the MS-MPC and MS-MIC platforms and does not require further configuration.

```
user@host# show groups junos-defaults applications application junos-tftp
application-protocol tftp;
protocol udp;
destination-port 69;
```

Table 16: ALGs Available by Default

ALG	MS-DPC	MS-MPC, MS-MIC	Junos OS Default ALG Name
Basic TCP ALG	yes	yes	NOTE: Specific Junos ALGs are not supported. However, a feature called TCP tracker, available by default, performs segment ordering and retransmit and connection tracking, validations for TCP connections.
Basic UDP ALG	yes	yes	NOTE: TCP tracker performs limited integrity and validation checks for UDP.
BOOTP	yes	no	<ul style="list-style-type: none"> junos-bootpc junos-bootps
DCE RPC Services	yes	yes	<ul style="list-style-type: none"> junos-dce-rpc-portmap junos-dcerpc-endpoint-mapper-service junos-dcerpc-msexchange-directory-nsp junos-dcerpc-msexchange-directory-rfr junos-dcerpc-msexchange-information-store

Configuring Application Sets

You can group the applications you have defined into a named object by including the **application-set** statement at the **[edit applications]** hierarchy level with an **application** statement for each application:

```
[edit applications]
  application-set application-set-name {
    application application;
  }
```

For an example of a typical application set, see “[Examples: Configuring Application Protocols](#)” on page 321.

Configuring Application Protocol Properties

To configure application properties, include the **application** statement at the **[edit applications]** hierarchy level:

```
[edit applications]
  application application-name {
    application-protocol protocol-name;
    destination-port port-number;
    icmp-code value;
    icmp-type value;
```

```

inactivity-timeout value;
protocol type;
rpc-program-number number;
snmp-command command;
source-port port-number;
ttl-threshold value;
uuid hex-value;
}

```

You can group application objects by configuring the **application-set** statement; for more information, see “Configuring Application Sets” on page 303.

This section includes the following tasks for configuring applications:

- [Configuring an Application Protocol on page 304](#)
- [Configuring the Network Protocol on page 306](#)
- [Configuring the ICMP Code and Type on page 307](#)
- [Configuring Source and Destination Ports on page 309](#)
- [Configuring the Inactivity Timeout Period on page 312](#)
- [Configuring SIP on page 312](#)
- [Configuring an SNMP Command for Packet Matching on page 320](#)
- [Configuring an RPC Program Number on page 320](#)
- [Configuring the TTL Threshold on page 320](#)
- [Configuring a Universal Unique Identifier on page 320](#)

Configuring an Application Protocol

The **application-protocol** statement allows you to specify which of the supported application protocols (ALGs) to configure and include in an application set for service processing. To configure application protocols, include the **application-protocol** statement at the **[edit applications application application-name]** hierarchy level:

```

[edit applications application application-name]
application-protocol protocol-name;

```

[Table 17 on page 304](#) shows the list of supported protocols. For more information about specific protocols, see “ALG Descriptions” on page 277.

Table 17: Application Protocols Supported by Services Interfaces

Protocol Name	CLI Value	Comments
Bootstrap protocol (BOOTP)	bootp	Supports BOOTP and dynamic host configuration protocol (DHCP).
Distributed Computing Environment (DCE) remote procedure call (RPC)	dce-rpc	Requires the protocol statement to have the value udp or tcp . Requires a uuid value. You cannot specify destination-port or source-port values.
DCE RPC portmap	dce-rpc-portmap	Requires the protocol statement to have the value udp or tcp . Requires a destination-port value.

Table 17: Application Protocols Supported by Services Interfaces (*continued*)

Protocol Name	CLI Value	Comments
Domain Name System (DNS)	dns	Requires the protocol statement to have the value udp . This application protocol closes the DNS flow as soon as the DNS response is received.
Exec	exec	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port value.
FTP	ftp	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port value.
H.323	h323	—
Internet Control Message Protocol (ICMP)	icmp	Requires the protocol statement to have the value icmp or to be unspecified.
Internet Inter-ORB Protocol	iiop	—
IP	ip	—
Login	login	—
NetBIOS	netbios	Requires the protocol statement to have the value udp or to be unspecified. Requires a destination-port value.
NetShow	netshow	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port value.
Point-to-Point Tunneling Protocol	pptp	—
RealAudio	realaudio	—
Real-Time Streaming Protocol (RTSP)	rtsp	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port value.
RPC User Datagram Protocol (UDP) or TCP	rpc	Requires the protocol statement to have the value udp or tcp . Requires a rpc-program-number value. You cannot specify destination-port or source-port values.
RPC port mapping	rpc-portmap	Requires the protocol statement to have the value udp or tcp . Requires a destination-port value.
Shell	shell	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port value.
Session Initiation Protocol	sip	—
SNMP	snmp	Requires the protocol statement to have the value udp or to be unspecified. Requires a destination-port value.

Table 17: Application Protocols Supported by Services Interfaces (*continued*)

Protocol Name	CLI Value	Comments
SQLNet	sqlnet	Requires the protocol statement to have the value tcp or to be unspecified. Requires a destination-port or source-port value.
Talk Program	talk	
Trace route	traceroute	Requires the protocol statement to have the value udp or to be unspecified. Requires a destination-port value.
Trivial FTP (TFTP)	tftp	Requires the protocol statement to have the value udp or to be unspecified. Requires a destination-port value.
WinFrame	winframe	—

NOTE: You can configure application-level gateways (ALGs) for ICMP and trace route under stateful firewall, NAT, or CoS rules when twice NAT is configured in the same service set. These ALGs cannot be applied to flows created by the Packet Gateway Controller Protocol (PGCP). Twice NAT does not support any other ALGs. NAT applies only the IP address and TCP or UDP headers, but not the payload.

For more information about configuring twice NAT, see *Junos Address Aware Carrier Grade NAT and IPv6 Feature Guide*.

Related Documentation

- [ALGs Available by Default for Junos OS Address Aware NAT on page 141](#)

Configuring the Network Protocol

The **protocol** statement allows you to specify which of the supported network protocols to match in an application definition. To configure network protocols, include the **protocol** statement at the **[edit applications application *application-name*]** hierarchy level:

```
[edit applications application application-name]
  protocol type;
```

You specify the protocol type as a numeric value; for the more commonly used protocols, text names are also supported in the command-line interface (CLI). [Table 18 on page 306](#) shows the list of the supported protocols.

Table 18: Network Protocols Supported by Services Interfaces

Network Protocol Type	CLI Value	Comments
IP Security (IPsec) authentication header (AH)	ah	—

Table 18: Network Protocols Supported by Services Interfaces (*continued*)

Network Protocol Type	CLI Value	Comments
External Gateway Protocol (EGP)	egp	—
IPsec Encapsulating Security Payload (ESP)	esp	—
Generic routing encapsulation (GR)	gre	—
ICMP	icmp	Requires an application-protocol value of icmp .
ICMPv6	icmp6	Requires an application-protocol value of icmp .
Internet Group Management Protocol (IGMP)	igmp	—
IP in IP	ipip	—
OSPF	ospf	—
Protocol Independent Multicast (PIM)	pim	—
Resource Reservation Protocol (RSVP)	rsvp	—
TCP	tcp	Requires a destination-port or source-port value unless you specify application-protocol rcp or dce-rcp .
UDP	udp	Requires a destination-port or source-port value unless you specify application-protocol rcp or dce-rcp .

For a complete list of possible numeric values, see RFC 1700, *Assigned Numbers (for the Internet Protocol Suite)*.

NOTE: IP version 6 (IPv6) is not supported as a network protocol in application definitions.

By default, the twice NAT feature can affect IP, TCP, and UDP headers embedded in the payload of ICMP error messages. You can include the **protocol tcp** and **protocol udp** statements with the application statement for twice NAT configurations. For more information about configuring twice NAT, see *Junos Address Aware Carrier Grade NAT and IPv6 Feature Guide*.

Configuring the ICMP Code and Type

The ICMP code and type provide additional specification, in conjunction with the network protocol, for packet matching in an application definition. To configure ICMP settings,

include the **icmp-code** and **icmp-type** statements at the **[edit applications application application-name]** hierarchy level:

```
[edit applications application application-name]
icmp-code value;
icmp-type value;
```

You can include only one ICMP code and type value. The **application-protocol** statement must have the value **icmp**. [Table 19 on page 308](#) shows the list of supported ICMP values.

Table 19: ICMP Codes and Types Supported by Services Interfaces

CLI Statement	Description
icmp-code	<p>This value or keyword provides more specific information than icmp-type. Because the value's meaning depends upon the associated icmp-type value, you must specify icmp-type along with icmp-code. For more information, see the <i>Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices</i>.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <p>parameter-problem: ip-header-bad (0), required-option-missing (1)</p> <p>redirect: redirect-for-host (1), redirect-for-network (0), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2)</p> <p>time-exceeded: ttl-eq-zero-during-reassembly (1), ttl-eq-zero-during-transit (0)</p> <p>unreachable: communication-prohibited-by-filtering (13), destination-host-prohibited (10), destination-host-unknown (7), destination-network-prohibited (9), destination-network-unknown (6), fragmentation-needed (4), host-precedence-violation (14), host-unreachable (1), host-unreachable-for-TOS (12), network-unreachable (0), network-unreachable-for-TOS (11), port-unreachable (3), precedence-cutoff-in-effect (15), protocol-unreachable (2), source-host-isolated (8), source-route-failed (5)</p>
icmp-type	<p>Normally, you specify this match in conjunction with the protocol match statement to determine which protocol is being used on the port. For more information, see the <i>Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices</i>.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply (0), echo-request (8), info-reply (16), info-request (15), mask-request (17), mask-reply (18), parameter-problem (12), redirect (5), router-advertisement (9), router-solicit (10), source-quench (4), time-exceeded (11), timestamp (13), timestamp-reply (14), or unreachable (3).</p>

NOTE: If you configure an interface with an input firewall filter that includes a reject action and with a service set that includes stateful firewall rules, the router executes the input firewall filter before the stateful firewall rules are run on the packet. As a result, when the Packet Forwarding Engine sends an ICMP error message out through the interface, the stateful firewall rules might drop the packet because it was not seen in the input direction.

Possible workarounds are to include a forwarding-table filter to perform the reject action, because this type of filter is executed after the stateful firewall in the input direction, or to include an output service filter to prevent the locally generated ICMP packets from going to the stateful firewall service.

Configuring Source and Destination Ports

The TCP or UDP source and destination port provide additional specification, in conjunction with the network protocol, for packet matching in an application definition. To configure ports, include the **destination-port** and **source-port** statements at the [edit applications application *application-name*] hierarchy level:

```
[edit applications application application-name]
destination-port value;
source-port value;
```

You must define one source or destination port. Normally, you specify this match in conjunction with the **protocol** match statement to determine which protocol is being used on the port; for constraints, see [Table 17 on page 304](#).

You can specify either a numeric value or one of the text synonyms listed in [Table 20 on page 309](#).

Configuring the Inactivity Timeout Period

You can specify a timeout period for application inactivity. If the software has not detected any activity during the duration, the flow becomes invalid when the timer expires. To configure a timeout period, include the `inactivity-timeout` statement at the `[edit applications application application-name]` hierarchy level:

```
[edit applications application application-name]
  inactivity-timeout seconds;
```

The default value is 30 seconds. The value you configure for an application overrides any global value configured at the `[edit interfaces interface-name service-options]` hierarchy level; for more information, see “[Configuring Default Timeout Settings for Services Interfaces](#)” on page 19.

Configuring SIP

The Session Initiation Protocol (SIP) is a generalized protocol for communication between endpoints involved in Internet services such as telephony, fax, video conferencing, instant messaging, and file exchange.

The Junos OS provides ALG services in accordance with the standard described in RFC 3261, *SIP: Session Initiation Protocol*. SIP flows under the Junos OS are as described in RFC 3665, *Session Initiation Protocol (SIP) Basic Call Flow Examples*.

NOTE: Before implementing the Junos OS SIP ALG, you should be familiar with certain limitations, discussed in “[Junos OS SIP ALG Limitations](#)” on page 319

The use of NAT in conjunction with the SIP ALG results in changes in SIP header fields due to address translation. For an explanation of these translations, refer to “[SIP ALG Interaction with Network Address Translation](#)” on page 313.

To implement SIP on adaptive services interfaces, you configure the **application-protocol** statement at the **[edit applications application *application-name*]** hierarchy level with the value **sip**. For more information about this statement, see [“Configuring an Application Protocol” on page 304](#). In addition, there are two other statements you can configure to modify how SIP is implemented:

- You can enable the router to accept any incoming SIP calls for the endpoint devices that are behind the NAT firewall. When a device behind the firewall registers with the proxy that is outside the firewall, the AS or Multiservices PIC maintains the registration state. When the **learn-sip-register** statement is enabled, the router can use this information to accept inbound calls. If this statement is not configured, no inbound calls are accepted; only the devices behind the firewall can call devices outside the firewall.

To configure SIP registration, include the **learn-sip-register** statement at the **[edit applications application *application-name*]** hierarchy level:

```
[edit applications application application-name]  
learn-sip-register;
```

You can also manually inspect the SIP register by issuing the **show services stateful-firewall sip-register** command; for more information, see the *Junos OS System Basics and Services Command Reference*.

- You can specify a timeout period for the duration of SIP calls that are placed on hold. When a call is put on hold, there is no activity and flows might time out after the configured **inactivity-timeout** period expires, resulting in call state teardown. To avoid this, when a call is put on hold, the flow timer is reset to the **sip-call-hold-timeout** cycle to preserve the call state and flows for longer than the **inactivity-timeout** period.

To configure a timeout period, include the **sip-call-hold-timeout** statement at the **[edit applications application *application-name*]** hierarchy level:

```
[edit applications application application-name]  
sip-call-hold-timeout seconds;
```

The default value is 7200 seconds and the range is from 0 through 36,000 seconds (10 hours).

SIP ALG Interaction with Network Address Translation

The Network Address Translation (NAT) protocol enables multiple hosts in a private subnet to share a single public IP address to access the Internet. For outgoing traffic, NAT replaces the private IP address of the host in the private subnet with the public IP address. For incoming traffic, the public IP address is converted back into the private address, and the message is routed to the appropriate host in the private subnet.

Using NAT with the Session Initiation Protocol (SIP) service is more complicated because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When using NAT with the SIP service, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. The device translates SDP information for allocating resources to send and receive the media.

How IP addresses and port numbers in SIP messages are replaced depends on the direction of the message. For an outgoing message, the private IP address and port number of the client are replaced with the public IP address and port number of the Juniper Networks firewall. For an incoming message, the public address of the firewall is replaced with the private address of the client.

When an INVITE message is sent out across the firewall, the SIP Application Layer Gateway (ALG) collects information from the message header into a call table, which it uses to forward subsequent messages to the correct endpoint. When a new message arrives, for example an ACK or 200 OK, the ALG compares the "From:", "To:", and "Call-ID:" fields against the call table to identify the call context of the message. If a new INVITE message arrives that matches the existing call, the ALG processes it as a REINVITE.

When a message containing SDP information arrives, the ALG allocates ports and creates a NAT mapping between them and the ports in the SDP. Because the SDP requires sequential ports for the Real-Time Transport Protocol (RTP) and Real-Time Control Protocol (RTCP) channels, the ALG provides consecutive even-odd ports. If it is unable to find a pair of ports, it discards the SIP message.

This topic contains the following sections:

- [Call Cancellation on page 316](#)
- [Forking on page 316](#)
- [SIP Messages on page 316](#)
- [SIP Headers on page 316](#)
- [SIP Body on page 319](#)

Outgoing Calls

When a SIP call is initiated with a SIP request message from the internal to the external network, NAT replaces the IP addresses and port numbers in the SDP and binds the IP addresses and port numbers to the Juniper Networks firewall. Via, Contact, Route, and Record-Route SIP header fields, if present, are also bound to the firewall IP address. The ALG stores these mappings for use in retransmissions and for SIP response messages.

The SIP ALG then opens pinholes in the firewall to allow media through the device on the dynamically assigned ports negotiated based on information in the SDP and the Via, Contact, and Record-Route header fields. The pinholes also allow incoming packets to reach the Contact, Via, and Record-Route IP addresses and ports. When processing return traffic, the ALG inserts the original Contact, Via, Route, and Record-Route SIP fields back into packets.

Incoming Calls

Incoming calls are initiated from the public network to public static NAT addresses or to interface IP addresses on the device. Static NATs are statically configured IP addresses that point to internal hosts; interface IP addresses are dynamically recorded by the ALG as it monitors REGISTER messages sent by internal hosts to the SIP registrar. When the device receives an incoming SIP packet, it sets up a session and forwards the payload of the packet to the SIP ALG.

The ALG examines the SIP request message (initially an INVITE) and, based on information in the SDP, opens gates for outgoing media. When a 200 OK response message arrives, the SIP ALG performs NAT on the IP addresses and ports and opens pinholes in the outbound direction. (The opened gates have a short time-to-live, and they time out if a 200 OK response message is not received quickly.)

When a 200 OK response arrives, the SIP proxy examines the SDP information and reads the IP addresses and port numbers for each media session. The SIP ALG on the device performs NAT on the addresses and port numbers, opens pinholes for outbound traffic, and refreshes the timeout for gates in the inbound direction.

When the ACK arrives for the 200 OK, it also passes through the SIP ALG. If the message contains SDP information, the SIP ALG ensures that the IP addresses and port numbers are not changed from the previous INVITE—if they are, the ALG deletes old pinholes and creates new pinholes to allow media to pass through. The ALG also monitors the Via, Contact, and Record-Route SIP fields and opens new pinholes if it determines that these fields have changed.

Forwarded Calls

A forwarded call is when, for example, user A outside the network calls user B inside the network, and user B forwards the call to user C outside the network. The SIP ALG processes the INVITE from user A as a normal incoming call. But when the ALG examines the forwarded call from B to C outside the network and notices that B and C are reached using the same interface, it does not open pinholes in the firewall, because media will flow directly between user A and user C.

Call Termination

The BYE message terminates a call. When the device receives a BYE message, it translates the header fields just as it does for any other message. But because a BYE message must be acknowledged by the receiver with a 200 OK, the ALG delays call teardown for five seconds to allow time for transmission of the 200 OK.

Call Re-INVITE Messages

Re-INVITE messages add new media sessions to a call and remove existing media sessions. When new media sessions are added to a call, new pinholes are opened in the firewall and new address bindings are created. The process is identical to the original call setup. When one or more media sessions are removed from a call, pinholes are closed and bindings released just as with a BYE message.

Call Session Timers

The SIP ALG uses the Session-Expires value to time out a session if a Re-INVITE or UPDATE message is not received. The ALG gets the Session-Expires value, if present, from the 200 OK response to the INVITE and uses this value for signaling timeout. If the ALG receives another INVITE before the session times out, it resets all timeout values to this new INVITE or to default values, and the process is repeated.

As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the device is protected should one of the following events occur:

- End systems crash during a call and a BYE message is not received.
- Malicious users never send a BYE in an attempt to attack a SIP ALG.
- Poor implementations of SIP proxy fail to process Record-Route and never send a BYE message.
- Network failures prevent a BYE message from being received.

Call Cancellation

Either party can cancel a call by sending a CANCEL message. Upon receiving a CANCEL message, the SIP ALG closes pinholes through the firewall—if any have been opened—and releases address bindings. Before releasing the resources, the ALG delays the control channel age-out for approximately five seconds to allow time for the final 200 OK to pass through. The call is terminated when the five second timeout expires, regardless of whether a 487 or non-200 response arrives.

Forking

Forking enables a SIP proxy to send a single INVITE message to multiple destinations simultaneously. When the multiple 200 OK response messages arrive for the single call, the SIP ALG parses but updates call information with the first 200 OK messages it receives.

SIP Messages

The SIP message format consists of a SIP header section and the SIP body. In request messages, the first line of the header section is the request line, which includes the method type, request-URI, and protocol version. In response messages, the first line is the status line, which contains a status code. SIP headers contain IP addresses and port numbers used for signaling. The SIP body, separated from the header section by a blank line, is reserved for session description information, which is optional. Junos OS currently supports the SDP only. The SIP body contains IP addresses and port numbers used to transport the media.

SIP Headers

In the following sample SIP request message, NAT replaces the IP addresses in the header fields to hide them from the outside network.

```
INVITE bob@10.150.20.5 SIP/2.0
Via: SIP/2.0/UDP 10.150.20.3:5434
```

From: alice@10.150.20.3
To: bob@10.150.20.5
Call-ID: a12abcde@10.150.20.3
Contact: alice@10.150.20.3:5434
Route: <sip:netscreen@10.150.20.3:5060>
Record-Route: <sip:netscreen@10.150.20.3:5060>

How IP address translation is performed depends on the type and direction of the message. A message can be any of the following:

- Inbound request
- Outbound response
- Outbound request
- Inbound response

Table 21 on page 317 shows how NAT is performed in each of these cases. Note that for several of the header fields the ALG determine more than just whether the messages comes from inside or outside the network. It must also determine what client initiated the call, and whether the message is a request or response.

Table 21: Requesting Messages with NAT Table

Inbound Request (from public to private)	To:	Replace domain with local address
	From:	None
	Call-ID:	None
	Via:	None
	Request-URI:	Replace ALG address with local address
	Contact:	None
	Record-Route:	None
	Route:	None

Table 21: Requesting Messages with NAT Table (*continued*)

Outbound Response (from private to public)	To:	Replace ALG address with local address
	From:	None
	Call-ID:	None
	Via:	None
	Request-URI:	N/A
	Contact:	Replace local address with ALG address
	Record-Route:	Replace local address with ALG address
	Route:	None
Outbound Request (from private to public)	To:	None
	From:	Replace local address with ALG address
	Call-ID:	None
	Via:	Replace local address with ALG address
	Request-URI:	None
	Contact:	Replace local address with ALG address
	Record-Route:	Replace local address with ALG address
	Route:	Replace ALG address with local address
Outbound Response (from public to private)	To:	None
	From:	Replace ALG address with local address
	Call-ID:	None
	Via:	Replace ALG address with local address
	Request-URI:	N/A
	Contact:	None
	Record-Route:	Replace ALG address with local address
	Route:	Replace ALG address with local address

SIP Body

The SDP information in the SIP body includes IP addresses the ALG uses to create channels for the media stream. Translation of the SDP section also allocates resources, that is, port numbers to send and receive the media.

The following excerpt from a sample SDP section shows the fields that are translated for resource allocation.

```
o=user 2344234 55234434 IN IP4 10.150.20.3
c=IN IP4 10.150.20.3
m=audio 43249 RTP/AVP 0
```

SIP messages can contain more than one media stream. The concept is similar to attaching multiple files to an e-mail message. For example, an INVITE message sent from a SIP client to a SIP server might have the following fields:

```
c=IN IP4 10.123.33.4
m=audio 33445 RTP/AVP 0
c=IN IP4 10.123.33.4
m=audio 33447 RTP/AVP 0
c=IN IP4 10.123.33.4
m=audio 33449 RTP/AVP 0
```

Junos OS supports up to 6 SDP channels negotiated for each direction, for a total of 12 channels per call. For more information, see *SDP Session Descriptions*.

Junos OS SIP ALG Limitations

The following limitations apply to configuration of the SIP ALG:

- Only the methods described in RFC 3261 are supported.
- Only SIP version 2 is supported.
- TCP is not supported as a transport mechanism for signaling messages.
- *Do not configure the SIP ALG when using STUN.* If clients use STUN/TURN to detect the firewall or NAT devices between the caller and responder or proxy, the client attempts to best-guess the NAT device behavior and act accordingly to place the call.
- Do not use the endpoint-independent mapping NAT pool option in conjunction with the SIP ALG. Errors will result.
- IPv6 signaling data is not supported.
- Authentication is not supported.
- Encrypted messages are not supported.
- SIP fragmentation is not supported.
- The maximum UDP packet size containing a SIP message is assumed to be 4 KB. SIP messages larger than this are not supported.
- The maximum number of media channels in a SIP message is assumed to be six.
- Fully qualified domain names (FQDNs) are not supported in critical fields.

- QoS is not supported.
- High availability is not supported, except for warm standby.
- A timeout setting of never is not supported on SIP or NAT.
- Multicast (forking proxy) is not supported.

Configuring an SNMP Command for Packet Matching

You can specify an SNMP command setting for packet matching. To configure SNMP, include the **snmp-command** statement at the **[edit applications application application-name]** hierarchy level:

```
[edit applications application application-name]
snmp-command value;
```

The supported values are **get**, **get-next**, **set**, and **trap**. You can configure only one value for matching. The **application-protocol** statement at the **[edit applications application application-name]** hierarchy level must have the value **snmp**. For information about specifying the application protocol, see [“Configuring an Application Protocol” on page 304](#).

Configuring an RPC Program Number

You can specify an RPC program number for packet matching. To configure an RPC program number, include the **rpc-program-number** statement at the **[edit applications application application-name]** hierarchy level:

```
[edit applications application application-name]
rpc-program-number number;
```

The range of values used for DCE or RPC is from 100,000 through 400,000. The **application-protocol** statement at the **[edit applications application application-name]** hierarchy level must have the value **rpc**. For information about specifying the application protocol, see [“Configuring an Application Protocol” on page 304](#).

Configuring the TTL Threshold

You can specify a trace route time-to-live (TTL) threshold value, which controls the acceptable level of network penetration for trace routing. To configure a TTL value, include the **ttl-threshold** statement at the **[edit applications application application-name]** hierarchy level:

```
[edit applications application application-name]
ttl-threshold value;
```

The **application-protocol** statement at the **[edit applications application application-name]** hierarchy level must have the value **traceroute**. For information about specifying the application protocol, see [“Configuring an Application Protocol” on page 304](#).

Configuring a Universal Unique Identifier

You can specify a Universal Unique Identifier (UUID) for DCE RPC objects. To configure a UUID value, include the **uuid** statement at the **[edit applications application application-name]** hierarchy level:

```
[edit applications application application-name]
  uuid hex-value;
```

The **uuid** value is in hexadecimal notation. The **application-protocol** statement at the **[edit applications **application** *application-name*** hierarchy level must have the value **dce-rpc**. For information about specifying the application protocol, see “[Configuring an Application Protocol](#)” on page 304. For more information on UUID numbers, see <http://www.opengroup.org/onlinepubs/9629399/apdxa.htm>.

Examples: Configuring Application Protocols

The following example shows an application protocol definition describing a special FTP application running on port 78:

```
[edit applications]
application my-ftp-app {
  application-protocol ftp;
  protocol tcp;
  destination-port 78;
  timeout 100; # inactivity timeout for FTP service
}
```

The following example shows a special ICMP protocol (**application-protocol icmp**) of type 8 (ICMP echo):

```
[edit applications]
application icmp-app {
  application-protocol icmp;
  protocol icmp;
  icmp-type icmp-echo;
}
```

The following example shows a possible application set:

```
[edit applications]
application-set basic {
  http;
  ftp;
  telnet;
  nfs;
  icmp;
}
```

The software includes a predefined set of well-known application protocols. The set includes applications for which the TCP and UDP destination ports are already recognized by stateless firewall filters.

ICMP, Ping, and Traceroute ALGs for MS-MICs and MS-MPCs

Starting with Junos OS Release 14.2, Junos OS extension-provider packages that are preinstalled and preconfigured on the MS-MIC and MS-MPC offer support for ping, traceroute, and ICMP ALGs in a consistent manner that is identical to the support that the uKernel service provides. Parity and uniformity of support is established for these ALGs between MS-MICs/MS-MPCs and the uKernel service. Until Junos OS Release 14.1, ICMP ALGs, ping ALGs, and traceroute ALGs were not entirely supported on MX Series routers with MS-MICs and MS-MPCs in comparison with the uKernel service that enables Network Address Translation (NAT) with stateful firewall (SFW) on the uKernel PIC. Support was available for handling of ICMP error response packets that match any existing flow in the opposite direction and NAT processing of ICMP packets with NAT processing of ping packets.

On MX Series routers with MS-MICs and MS-MPCs, tracking of ping traffic states wholly using the ICMP sequence numbers (for example, forwarding an echo reply only if the echo request with the corresponding sequence number is identified) is supported. ICMP application layer gateway (ALG) is enhanced to provide detailed logging information. Also, the traceroute ALGs enable UDP probe packets to be processed with the UDP destination port number greater than 33000 and the IP time-to-live (TTL) is less than 30 seconds. Traceroute ALGs enable ICMP response packets for which the ICMP type is time-exceeded to be processed and support a traceroute TTL threshold value, which controls the acceptable level of network penetration for trace routing.

You can configure ICMP and ping messages with the **application junos-icmp-all**, **application junos-icmp-ping**, and **application icmp-code** statements at the **[edit services stateful-firewall rule rule-name term term-name from]** and the **[edit services nat rule rule-name term term-name from]** hierarchy levels to define the match condition for the stateful firewall and NAT rules. Until Junos OS Release 14.1, a restriction or a validation on the applications that you could define for ICMP messages was not present. MS-MICs and MS-MPCs function the same way as the uKernel service, which causes the ping traffic to be tracked statefully using the ICMP sequence numbers (an echo reply is forwarded only if echo request with the corresponding sequence number matches). Also, MS-MICs and MS-MPCs impose a limit on the outstanding ping requests and drop the subsequent ping requests when the limit is reached.

Similarly, for traceroute messages, you can configure the **application junos-traceroute** and **application junos-traceroute-ttl-1** statements at the **[edit services stateful-firewall rule rule-name term term-name from]** and the **[edit services nat rule rule-name term term-name from]** hierarchy levels to define the match condition for traceroute messages for the stateful firewall and NAT rules.

Traceroute and ICMP messages are supported for both IPv4 and IPv6 packets. For the traceroute functionality to work, you only need to ensure that the user-defined applications are working as expected with the inactivity timeout period and the TTL threshold values are configured to be the same period of time as configured by using the **session-timeout seconds** statement at the **[edit services application-identification application application-name]** hierarchy level. During the logging of ICMP messages, the ALG information for ping and ICMP utilities is displayed in the output of the relevant show

commands, such as **show sessions** and **show conversations**, in the same manner as displayed for uKernel logging.

Monitoring Port Control Protocol Operations

You can monitor Port Control Protocol (PCP) operations with the following operational commands:

- **show services nat mappings pcp**
- **show services nat mappings endpoint-independent**
- **show services pcp statistics protocol**

The following are examples of the output of these commands.

```
user@host> show services nat mappings pcp
```

```
Interface: sp-0/0/0, Service set: in
```

```
NAT pool: p
PCP Client      : 10.1.1.2          PCP lifetime : 995
Mapping         : 10.1.1.2          : 9000 --> 8.8.8.8      : 1025
Session Count   : 1
Mapping State    : Active
```

```
DS-LITE output:
```

```
=====
PCP Client      : 2222::1          PCP lifetime : 106
Mapping         : 88.1.0.47        : 47 --> 70.70.70.1    :41972

Junos Network Secure Overview

Routers use firewalls to track and control the flow of traffic. The following platforms employ a type of firewall called a *stateful firewall*.

- MultiServices Dense Port Concentrators (MS-DPCs)
- MS-100, MS-400, and MS-500 MultiServices PICs
- MultiServices Modular Port Concentrators (MS-MPCs), and Multiservices Modular Interface Cards (MS-MICs)

The stateful firewall capabilities provided by the Junos OS are collectively known as *Junos Network Secure*.

Contrasted with a *stateless* firewall that inspects packets in isolation, a stateful firewall provides an extra layer of security by using state information derived from past communications and other applications to make dynamic control decisions for new communication attempts.

Stateful firewalls group relevant *flows* into *conversations*. A flow is identified by the following five properties:

- Source address
- Source port
- Destination address
- Destination port
- Protocol

A typical Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) conversation consists of two flows: the initiation flow and the responder flow. However, some conversations, such as an FTP conversation, might consist of two control flows and many data flows.

Firewall rules govern whether the conversation is allowed to be established. If a conversation is allowed, all flows within the conversation are permitted, including flows that are created during the life cycle of the conversation.

You configure stateful firewalls using a powerful rule-driven conversation handling path. A *rule* consists of direction, source address, source port, destination address, destination port, IP protocol value, and application protocol or service. In addition to the specific values you configure, you can assign the value **any** to rule objects, addresses, or ports, which allows them to match any input value. Finally, you can optionally negate the rule objects, which negates the result of the type-specific match.

Firewall rules are directional. For each new conversation, the router software checks the initiation flow matching the direction specified by the rule.

Firewall rules are ordered. The software checks the rules in the order in which you include them in the configuration. The first time the firewall discovers a match, the router implements the action specified by that rule. Rules still unchecked are ignored.

NOTE: Starting with Junos OS Release 14.2, MS-MPC and MS-MIC interface cards support IPv6 traffic for Junos Network Secure Stateful Firewall.

For more information, see [“Configuring Stateful Firewall Rules” on page 331](#).

Stateful Firewall Support for Application Protocols

By inspecting the application protocol data, the Junos Network Secure stateful firewall can intelligently enforce security policies and allow only the minimal required packet traffic to flow through the firewall.

The firewall rules are configured in relation to an interface. By default, the stateful firewall allows all sessions initiated from the hosts behind the interface to pass through the router.

Stateful Firewall Anomaly Checking

The stateful firewall recognizes the following events as anomalies and sends them to the IDS software for processing:

- IP anomalies:
 - IP version is not correct.
 - IP header length field is too small.
 - IP header length is set larger than the entire packet.
 - Bad header checksum.
 - IP total length field is shorter than header length.
 - Packet has incorrect IP options.

- Internet Control Message Protocol (ICMP) packet length error.
- Time-to-live (TTL) equals 0.
- IP address anomalies:
 - IP packet source is a broadcast or multicast.
 - Land attack (source IP equals destination IP).
- IP fragmentation anomalies:
 - IP fragment overlap.
 - IP fragment missed.
 - IP fragment length error.
 - IP packet length is more than 64 kilobytes (KB).
 - Tiny fragment attack.
- TCP anomalies:
 - TCP port 0.
 - TCP sequence number 0 and flags 0.
 - TCP sequence number 0 and FIN/PSH/RST flags set.
 - TCP flags with wrong combination (TCP FIN/RST or SYN/(URG|FIN|RST)).
 - Bad TCP checksum.
- UDP anomalies:
 - UDP source or destination port 0.
 - UDP header length check failed.
 - Bad UDP checksum.
- Anomalies found through stateful TCP or UDP checks:
 - SYN followed by SYN-ACK packets without ACK from initiator.
 - SYN followed by RST packets.
 - SYN without SYN-ACK.
 - Non-SYN first flow packet.
 - ICMP unreachable errors for SYN packets.
 - ICMP unreachable errors for UDP packets.
- Packets dropped according to stateful firewall rules.

If you employ stateful anomaly detection in conjunction with stateless detection, IDS can provide early warning for a wide range of attacks, including these:

- TCP or UDP network probes and port scanning

- SYN flood attacks
- IP fragmentation-based attacks such as teardrop, bonk, and boink

- [Example: Virtual Routing and Forwarding \(VRF\) and Service Configuration on page 351](#)

Configuring Stateful Firewall Rules

To configure a stateful firewall rule, include the **rule** *rule-name* statement at the **[edit services stateful-firewall]** hierarchy level:

```
[edit services stateful-firewall]
rule rule-name {
  match-direction (input | output | input-output);
  term term-name {
    from {
      application-sets set-name;
      applications [ application-names ];
      destination-address address <except>;
      destination-address-range low minimum-value high maximum-value <except>;
      destination-prefix-list list-name <except>;
      source-address address <except>;
      source-address-range low minimum-value high maximum-value <except>;
      source-prefix-list list-name <except>;
    }
    then {
      (accept | discard | reject);
      allow-ip-options [ values ];
      syslog;
    }
  }
}
```

Each stateful firewall rule consists of a set of terms, similar to a filter configured at the **[edit firewall]** hierarchy level. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded. The **from** statement is optional in stateful firewall rules.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software. The **then** statement is mandatory in stateful firewall rules.

The following sections explain how to configure the components of stateful firewall rules:

- [Configuring Match Direction for Stateful Firewall Rules on page 332](#)
- [Configuring Match Conditions in Stateful Firewall Rules on page 332](#)
- [Configuring Actions in Stateful Firewall Rules on page 334](#)

Configuring Match Direction for Stateful Firewall Rules

Each rule must include a **match-direction** statement that specifies the direction in which the rule match is applied. To configure where the match is applied, include the **match-direction** statement at the **[edit services stateful-firewall rule rule-name]** hierarchy level:

```
[edit services stateful-firewall rule rule-name]
match-direction (input | output | input-output);
```

If you configure **match-direction input-output**, sessions initiated from both directions might match this rule.

The match direction is used with respect to the traffic flow through the AS or Multiservices PIC. When a packet is sent to the PIC, direction information is carried along with it.

With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.

With a next-hop service set, packet direction is determined by the interface used to route the packet to the AS or Multiservices PIC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the PIC, the packet direction is output. For more information on inside and outside interfaces, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).

On the PIC, a flow lookup is performed. If no flow is found, rule processing is performed. Rules in this service set are considered in sequence until a match is found. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that matches the packet direction are considered. Most packets result in the creation of bidirectional flows.

Configuring Match Conditions in Stateful Firewall Rules

To configure stateful firewall match conditions, include the **from** statement at the **[edit services stateful-firewall rule rule-name term term-name]** hierarchy level:

```
[edit services stateful-firewall rule rule-name term term-name]
```

```

from {
  application-sets set-name;
  applications [ application-names ];
  destination-address (address | any-unicast) <except>;
  destination-address-range low minimum-value high maximum-value <except>;
  destination-prefix-list list-name <except>;
  source-address (address | any-unicast) <except>;
  source-address-range low minimum-value high maximum-value <except>;
  source-prefix-list list-name <except>;
}

```

The source address and destination address can be either IPv4 or IPv6. You can use either the source address or the destination address as a match condition, in the same way that you would configure a firewall filter; for more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*. You can use the wildcard value **any-unicast**, which denotes matching all unicast addresses.

Alternatively, you can specify a list of source or destination prefixes by configuring the **prefix-list** statement at the **[edit policy-options]** hierarchy level and then including either the **destination-prefix-list** or the **source-prefix-list** statement in the stateful firewall rule. For an example, see “[Examples: Configuring Stateful Firewall Rules](#)” on page 335.

If you omit the **from** term, the stateful firewall accepts all traffic and the default protocol handlers take effect:

- User Datagram Protocol (UDP), Transmission Control Protocol (TCP), and Internet Control Message Protocol (ICMP) create a bidirectional flow with a predicted reverse flow.
- IP creates a unidirectional flow.

You can also include application protocol definitions you have configured at the **[edit applications]** hierarchy level; for more information, see “[Configuring Application Protocol Properties](#)” on page 303.

- To apply one or more specific application protocol definitions, include the **applications** statement at the **[edit services stateful-firewall rule rule-name term term-name from]** hierarchy level.
- To apply one or more sets of application protocol definitions you have defined, include the **application-sets** statement at the **[edit services stateful-firewall rule rule-name term term-name from]** hierarchy level.

NOTE: If you include one of the statements that specifies application protocols, the router derives port and protocol information from the corresponding configuration at the **[edit applications]** hierarchy level; you cannot specify these properties as match conditions.

Configuring Actions in Stateful Firewall Rules

To configure stateful firewall actions, include the **then** statement at the **[edit services stateful-firewall rule *rule-name* term *term-name*]** hierarchy level:

```
[edit services stateful-firewall rule rule-name term term-name]  
then {  
  (accept | discard | reject);  
  allow-ip-options [ values ];  
  syslog;  
}
```

You must include one of the following three possible actions:

- **accept**—The packet is accepted and sent on to its destination.
- **discard**—The packet is not accepted and is not processed further.
- **reject**—The packet is not accepted and a rejection message is returned; UDP sends an ICMP unreachable code and TCP sends RST. Rejected packets can be logged or sampled.

You can optionally configure the firewall to record information in the system logging facility by including the **syslog** statement at the **[edit services stateful-firewall rule *rule-name* term *term-name* then]** hierarchy level. This statement overrides any **syslog** setting included in the service set or interface default configuration.

Configuring IP Option Handling

You can optionally configure the firewall to inspect IP header information by including the **allow-ip-options** statement at the **[edit services stateful-firewall rule *rule-name* term *term-name* then]** hierarchy level. When you configure this statement, all packets that match the criteria specified in the **from** statement are subjected to additional matching criteria. A packet is accepted only when all of its IP option types are configured as values in the **allow-ip-options** statement. If you do not configure **allow-ip-options**, only packets without IP header options are accepted.

The additional IP header option inspection applies only to the **accept** and **reject** stateful firewall actions. This configuration has no effect on the **discard** action. When the IP header inspection fails, reject frames are not sent; in this case, the **reject** action has the same effect as **discard**.

If an IP option packet is accepted by the stateful firewall, Network Address Translation (NAT) and intrusion detection service (IDS) are applied in the same way as to packets without IP option headers. The IP option configuration appears only in the stateful firewall rules; NAT applies to packets with or without IP options.

When a packet is dropped because it fails the IP option inspection, this exception event generates both IDS event and system log messages. The event type depends on the first IP option field rejected.

[Table 22 on page 335](#) lists the possible values for the **allow-ip-options** statement. You can include a range or set of numeric values, or one or more of the predefined IP option

settings. You can enter either the option name or its numeric equivalent. For more information, refer to <http://www.iana.org/assignments/ip-parameters>.

Table 22: IP Option Values

IP Option Name	Numeric Value	Comment
any	0	Any IP option
ip-security	130	–
ip-stream	136	–
loose-source-route	131	–
route-record	7	–
router-alert	148	–
strict-source-route	137	–
timestamp	68	–

Configuring Stateful Firewall Rule Sets

The **rule-set** statement defines a collection of stateful firewall rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then, you specify the order of the rules by including the **rule-set** statement at the **[edit services stateful-firewall]** hierarchy level with a **rule** statement for each rule:

```
[edit services stateful-firewall]
rule-set rule-set-name {
  rule rule-name;
}
```

The router software processes the rules in the order in which you specify them in the configuration. If a term in a rule matches the packet, the router performs the corresponding action and the rule processing stops. If no term in a rule matches the packet, processing continues to the next rule in the rule set. If none of the rules matches the packet, the packet is dropped by default.

Examples: Configuring Stateful Firewall Rules

The following example show a stateful firewall configuration containing two rules, one for input matching on a specified application set and the other for output matching on a specified source address:

```
[edit services]
stateful-firewall {
```

```
rule Rule1 {
  match-direction input;
  term 1 {
    from {
      application-sets Applications;
    }
    then {
      accept;
    }
  }
  term accept {
    then {
      accept;
    }
  }
}
rule Rule2 {
  match-direction output;
  term Local {
    from {
      source-address {
        10.1.3.2/32;
      }
    }
    then {
      accept;
    }
  }
}
```

The following example has a single rule with two terms. The first term rejects all traffic in **my-application-group** that originates from the specified source address, and provides a detailed system log record of the rejected packets. The second term accepts Hypertext Transfer Protocol (HTTP) traffic from anyone to the specified destination address.

```
[edit services stateful-firewall]
rule my-firewall-rule {
  match-direction input-output;
  term term1 {
    from {
      source-address 10.1.3.2/32;
      application-sets my-application-group;
    }
    then {
      reject;
      syslog;
    }
  }
  term term2 {
    from {
      destination-address 10.2.3.2/32;
      applications http;
    }
    then {
      accept;
    }
  }
}
```

```

    }
  }
}

```

The following example shows use of source and destination prefix lists. This requires two separate configuration items.

You configure the prefix list at the **[edit policy-options]** hierarchy level:

```

[edit]
policy-options {
  prefix-list p1 {
    1.1.1.1/32;
    2.2.2.0/24;
  }
  prefix-list p2 {
    3.3.3.3/32;
    4.4.4.0/24;
  }
}

```

You reference the configured prefix list in the stateful firewall rule:

```

[edit]
services {
  stateful-firewall {
    rule r1 {
      match-direction input;
      term t1 {
        from {
          source-prefix-list {
            p1;
          }
          destination-prefix-list {
            p2;
          }
        }
        then {
          accept;
        }
      }
    }
  }
}

```

This is equivalent to the following configuration:

```

[edit]
services {
  stateful-firewall {
    rule r1 {
      match-direction input;
      term t1 {
        from {
          source-address {
            1.1.1.1/32;
            2.2.2.0/24;
          }
        }
      }
    }
  }
}

```

```
    }
    destination-address {
        3.3.3.3/32;
        4.4.4.0/24;
    }
}
then {
    accept;
}
}
}
```

You can use the **except** qualifier with the prefix lists, as in the following example. In this case, the **except** qualifier applies to all prefixes included in prefix list **p2**.

```
[edit]
services {
    stateful-firewall {
        rule r1 {
            match-direction input;
            term t1 {
                from {
                    source-prefix-list {
                        p1;
                    }
                    destination-prefix-list {
                        p2 except;
                    }
                }
                then {
                    accept;
                }
            }
        }
    }
}
```

For additional examples that combine stateful firewall configuration with other services and with virtual private network (VPN) routing and forwarding (VRF) tables, see the configuration examples.

Related Documentation

- [Example: BOOTP and Broadcast Addresses on page 338](#)

Example: BOOTP and Broadcast Addresses

The following example supports Bootstrap Protocol (BOOTP) and broadcast addresses:

```

[edit applications]
application bootp {
  application-protocol bootp;
  protocol udp;
  destination-port 67;
}
[edit services]
stateful-firewall bootp-support {
  rule bootp-allow {
    direction input;
    term bootp-allow {
      from {
        destination-address {
          any-unicast;
          255.255.255.255;
        }
        application bootp;
      }
      then {
        accept;
      }
    }
  }
}
}

```

Example: Configuring Layer 3 Services and the Services SDK on Two PICs

You can configure the Layer 3 service package and the Services SDK on two PICs. For this example, you must configure an FTP or HTTP client and a server. In this configuration, the client side of the router interface is ge-1/2/2.1 and the server side of the router interface is ge-1/1/0.48. This configuration enables Network Address Translation (NAT) with stateful firewall (SFW) on the uKernel PIC and application identification (APPID), application-aware access list (AACL), and intrusion detection and prevention (IDP) on the Services SDK PIC for FTP or HTTP traffic.

NOTE: The Services SDK does not support NAT yet. When NAT is required, you can configure the Layer 3 service package to deploy NAT along with the Services SDK such as APPID, AACL, or IDP.

To deploy the Layer 3 service package and the Services SDK on two PICs:

1. In configuration mode, go to the following hierarchy level:

```

[edit services]
user@host# edit stateful-firewall

```

2. In the hierarchy level, configure the conditions for the stateful firewall rule r1.

```

[edit services stateful-firewall]
user@host# set rule rule-name match-direction input-output term term from
  applications application-name
user@host# set rule rule-name match-direction input-output term term then accept
  syslog

```

In this example, the stateful firewall term is **ALLOWED-SERVICES**. Enclose the application names—`junos-ftp`, `junos-http`, and `junos-icmp-ping`—in brackets for *application-name*.

```
[edit services stateful-firewall]
user@host# set rule r1 match-direction input-output term ALLOWED-SERVICES from
  applications [ junos-ftp junos-http junos-icmp-ping ]
user@host# set rule r1 match-direction input-output term ALLOWED-SERVICES then
  accept syslog
```

3. Configure the conditions for the stateful firewall rule `r2`.

```
[edit services stateful-firewall]
user@host# set rule rule-name match-direction input-output term term then discard
user@host# set rule rule-name match-direction input-output term term then syslog
```

In this example, the stateful firewall term is `term1`.

```
[edit services stateful-firewall]
user@host# set rule r2 match-direction input-output term term1 then discard
user@host# set rule r2 match-direction input-output term term1 then syslog
```

4. Go to the following hierarchy level and verify the configuration:

```
[edit services stateful-firewall]
user@host# show
rule r1 {
  match-direction input-output;
  term ALLOWED-SERVICES {
    from {
      applications [ junos-ftp junos-http junos-icmp-ping ];
    }
    then {
      accept;
      syslog;
    }
  }
}
rule r2 {
  match-direction input-output;
  term term1 {
    then {
      discard;
      syslog;
    }
  }
}
```

5. Go to the following hierarchy level:

```
[edit services]
user@host# edit nat
```

6. In the hierarchy level, configure the NAT pool.

```
[edit services nat]
user@host# set pool pool-name address ip-address
user@host# set pool pool-name port automatic
```

In this example, the NAT pool is **OUTBOUND-SERVICES** and the IP address is **10.48.0.2/32**.

```
[edit services nat]
user@host# set pool OUTBOUND-SERVICES address 10.48.0.2/32
user@host# set pool OUTBOUND-SERVICES port automatic
```

7. Configure the NAT rule.

```
[edit services nat]
user@host# set rule rule-name match-direction output term term from applications
application-name
user@host# set rule rule-name match-direction output term term then translated
source-pool source-pool translation-type source dynamic
```

In this example, the NAT rule is **SET-MSR-ADDR**, the NAT term is **TRANSLATE-SOURCE-ADDR**, and the source pool is **OUTBOUND-SERVICES**. Enclose the application names—**junos-ftp**, **junos-http**, and **junos-icmp-ping**—in parentheses for *application-name*.

```
[edit services nat]
user@host# set rule SET-MSR-ADDR match-direction output term
TRANSLATE-SOURCE-ADDR from applications [ junos-ftp junos-http
junos-icmp-ping ]
user@host# set rule SET-MSR-ADDR match-direction output term
TRANSLATE-SOURCE-ADDR then translated source-pool OUTBOUND-SERVICES
translation-type source dynamic
```

8. Go to the following hierarchy level and verify the configuration:

```
[edit services nat]
user@host# show
pool OUTBOUND-SERVICES {
    address 11.48.0.2/32;
    port {
        automatic;
    }
}
rule SET-MSR-ADDR {
    match-direction output;
    term TRANSLATE-SOURCE-ADDR {
        from {
            applications [ junos-ftp junos-http junos-icmp-ping ];
        }
        then {
            translated {
                source-pool OUTBOUND-SERVICES;
                translation-type {
                    source dynamic;
                }
            }
        }
    }
}
```

9. Go to the following hierarchy level:

```
[edit security]
user@host# edit idp
```

10. In the hierarchy level, configure the IDP policy.

```
[edit security idp]
user@host# set idp-policy policy-name rulebase-ips rule rule-name match application
    default attacks predefined-attacks attack-name
user@host# set idp-policy policy-name rulebase-ips rule rule-name match application
    default attacks predefined-attack-groups attack-group--name
user@host# set idp-policy policy-name rulebase-ips rule rule-name then action
    no-action
user@host# set idp-policy policy-name rulebase-ips rule rule-name then notification
    log-attacks alert
```

In this example, the IDP policy is **test1**, the rule is **r1**, the predefined attack is **FTP:USER:ROOT**, and the predefined attack group is **"Recommended Attacks"**.

```
[edit security idp]
user@host# set idp-policy test1 rulebase-ips rule r1 match application default attacks
    predefined-attacks FTP:USER:ROOT
user@host# set idp-policy test1 rulebase-ips rule r1 match application default attacks
    predefined-attack-groups [ "Recommended Attacks" ]
user@host# set idp-policy test1 rulebase-ips rule r1 then action no-action
user@host# set idp-policy test1 rulebase-ips rule r1 then notification log-attacks alert
```

11. Configure the trace options for IDP services.

```
[edit security idp]
user@host# set traceoptions file filename
user@host# set traceoptions flag all
user@host# set traceoptions level all
```

In this example, the log file name is **idp-demo.log**.

```
[edit security idp]
user@host# set traceoptions file idp-demo.log
user@host# set traceoptions flag all
user@host# set traceoptions level all
```

12. Go to the following hierarchy level and verify the configuration:

```
[edit security idp]
user@host# show
idp-policy test1 {
    rulebase-ips {
        rule r1 {
            match {
                application default;
                attacks {
                    predefined-attacks FTP:USER:ROOT;
                    predefined-attack-groups "Recommended Attacks";
                }
            }
            then {
                action {
                    no-action;
                }
                notification {
                    log-attacks {
                        alert;
                    }
                }
            }
        }
    }
}
```

```

}
traceoptions {
  file idp-demo.log;
  flag all;
  level all;
}

```

13. Go to the following hierarchy level:

```

[edit services]
user@host# edit aacl

```

14. In the hierarchy level, configure the AACL rules.

```

[edit services aacl]
user@host# set rule rule-name match-direction input-output term term from
  application-group-any
user@host# set rule rule-name match-direction input-output term term then count
  application accept

```

In this example, the AACL rule is **app-aware** and the term is **t1**.

```

[edit services aacl]
user@host# set rule app-aware match-direction input-output term t1 from
  application-group-any
user@host# set rule app-aware match-direction input-output term t1 then count
  application accept

```

15. Go to the following hierarchy level and verify the configuration:

```

[edit services aacl]
user@host# show
rule app-aware {
  match-direction input-output;
  term t1 {
    from {
      application-group-any;
    }
    then {
      count application;
      accept;
    }
  }
}

```

16. Go to the following hierarchy level:

```

[edit services]
user@host# edit service-set App-Aware-Set

```

17. Configure the APPID profile.

```

[edit services service-set App-Aware-Set]
user@host# set application-identification-profile application-identification-profile

```

In this example, the APPID profile is **dummy-profile**.

```

[edit services service-set App-Aware-Set]
user@host# set application-identification-profile dummy-profile

```

18. Configure the IDP profile.

```

[edit services service-set App-Aware-Set]

```

```
user@host# set idp-profile idp-profile
```

In this example, the IDP profile is **test1**.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set idp-profile test1
```

19. Configure the policy decision statistics profile.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set policy-decision-statistics-profile profile-name
```

In this example, the policy decision statistics profile is **lpdf-stats**.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set policy-decision-statistics-profile lpdf-stats
```

20. Configure the AACL rules.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set aacl-rules rule-name
```

In this example, the AACL rule name is **app-aware**.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set aacl-rules app-aware
```

21. Configure two stateful firewall rules.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set stateful-firewall-rules rule-name
```

```
user@host# set stateful-firewall-rules rule-name
```

In this example, the first rule is **r1** and the second rule is **r2**.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set stateful-firewall-rules r1
```

```
user@host# set stateful-firewall-rules r2
```

22. In the hierarchy level, configure the service set to bypass traffic on service PIC failure.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set service-set-options bypass-traffic-on-pic-failure
```

23. Configure interface-specific service set options.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set interface-service service-interface service-interface
```

In this example, the services interface is **ms-0/1/0**.

```
[edit services service-set App-Aware-Set]
```

```
user@host# set interface-service service-interface ms-0/1/0
```

24. Go to the following hierarchy level and verify the configuration:

```
[edit services service-set App-Aware-Set]
```

```
user@host# show
```

```
application-identification-profile dummy-profile;
```

```
idp-profile test1;
```

```
policy-decision-statistics-profile {
```

```
  lpdf-stats;
```

```
}
```

```
aacl-rules app-aware;
```

```

stateful-firewall-rules r1;
stateful-firewall-rules r2;
service-set-options {
    bypass-traffic-on-pic-failure;
}
interface-service {
    service-interface ms-0/1/0;
}

```

25. Go to the following hierarchy level:

```

[edit services]
user@host# edit service-set NAT-SFW-SET

```

26. In the hierarchy level, configure optional notification parameters for the services interface. Note that it is required only for debugging.

```

[edit services service-set NAT-SFW-SET]
user@host# set syslog host host-name services any

```

In this example, the host to notify is **local**.

```

[edit services service-set NAT-SFW-SET]
user@host# set services-options syslog host local services any

```

27. Configure two stateful firewall rules.

```

[edit services service-set NAT-SFW-SET]
user@host# set stateful-firewall-rules rule-name
user@host# set stateful-firewall-rules rule-name

```

In this example, the first rule is **r1** and the second rule is **r2**.

```

[edit services service-set NAT-SFW-SET]
user@host# set stateful-firewall-rules r1
user@host# set stateful-firewall-rules r2

```

28. Configure NAT rules.

```

[edit services service-set NAT-SFW-SET]
user@host# set nat-rules rule-name

```

In this example, the NAT rule is **SET-MSR-ADDR**.

```

[edit services service-set NAT-SFW-SET]
user@host# set nat-rules SET-MSR-ADDR

```

29. Configure interface-specific service set options.

```

[edit services service-set NAT-SFW-SET]
user@host# set interface-service service-interface

```

In this example, the services interface is **sp-3/1/0**.

```

[edit services service-set NAT-SFW-SET]
user@host# set interface-service service-interface sp-3/1/0

```

30. Go to the following hierarchy level and verify the configuration:

```

[edit services service-set NAT-SFW-SET]
user@host# show
syslog {
    host local {
        services any;
    }
}

```

```
    }  
  }  
  stateful-firewall-rules r1;  
  stateful-firewall-rules r2;  
  interface-service {  
    service-interface sp-3/1/0;  
  }
```

31. Go to the following hierarchy level:

```
user@host# edit interfaces
```

32. In the hierarchy level, configure the interface.

```
[edit interfaces]  
user@host# set interface
```

In this example, the interface is **ge-1/2/2.1**.

```
[edit interfaces]  
user@host# set ge-1/2/2.1
```

33. Go to the following hierarchy level:

```
[edit interfaces]  
user@host# edit ge-1/2/2.1
```

34. In the hierarchy level, configure the service set for received packets.

```
[edit interfaces ge-1/2/2 unit 1]  
user@host# set family inet service input service-set service-set-name
```

In this example, the input service set is **App-Aware-Set**.

```
[edit interfaces ge-1/2/2 unit 1]  
user@host# set family inet service input service-set App-Aware-Set
```

35. Configure the service set for transmitted packets.

```
[edit interfaces ge-1/2/2 unit 1]  
user@host# set family inet service output service-set service-set-name
```

In this example, the output service set is **App-Aware-Set**.

```
[edit interfaces ge-1/2/2 unit 1]  
user@host# set family inet service output service-set App-Aware-Set
```

36. Go to the following hierarchy level:

```
[edit interfaces ge-1/2/2 unit 1]  
user@host# edit family inet
```

37. In the hierarchy level, configure the interface address.

```
[edit interfaces ge-1/2/2 unit 1 family inet]  
user@host# set address source
```

In this example, the interface address is **10.10.9.10/30**.

```
[edit interfaces]  
user@host# set address 10.10.9.10/30
```

38. Go to the following hierarchy level and verify the configuration:

```
[edit interfaces ge-1/2/2 unit 1]
user@host# show
family inet {
  service {
    input {
      service-set App-Aware-Set;
    }
    output {
      service-set App-Aware-Set;
    }
  }
  address 10.10.9.10/30;
}
```

39. Go to the following hierarchy level:

```
user@host# edit interfaces
```

40. In the hierarchy level, configure the interface.

```
[edit interfaces]
user@host# set interface
```

In this example, the interface is **ge-1/1/0.48**.

```
[edit interfaces]
user@host# set ge-1/1/0.48
```

41. Go to the following hierarchy level:

```
[edit interfaces]
user@host# edit ge-1/1/0.48
```

42. In the hierarchy level, configure the service set for received packets.

```
[edit interfaces ge-1/1/0 unit 48]
user@host# set family inet service input service-set service-set-name
```

In this example, the service set is **NAT-SFW-SET**.

```
[edit interfaces ge-1/1/0 unit 48]
user@host# set family inet service input service-set NAT-SFW-SET
```

43. Configure the service set for transmitted packets.

```
[edit interfaces ge-1/1/0 unit 48]
user@host# set family inet service output service-set service-set-name
```

In this example, the service set is **NAT-SFW-SET**.

```
[edit interfaces ge-1/1/0 unit 48]
user@host# set family inet service output service-set NAT-SFW-SET
```

44. Go to the following hierarchy level:

```
[edit interfaces ge-1/1/0 unit 48]
user@host# edit family inet
```

45. Configure the interface address.

```
[edit interfaces ge-1/1/0 unit 48 family inet]
user@host# set address source
```

In this example, the interface address is **10.48.0.1/31**.

```
[edit interfaces ge-1/1/0 unit 48 family inet]
user@host# set address 10.48.0.1/31
```

46. Go to the following hierarchy level and verify the configuration:

```
[edit interfaces ge-1/1/0 unit 48]
user@host# show
family inet {
  service {
    input {
      service-set NAT-SFW-SET;
    }
    output {
      service-set NAT-SFW-SET;
    }
  }
  address 10.48.0.1/31;
}
```

47. Go to the following hierarchy level:

```
user@host# edit interfaces
```

48. In the hierarchy level, configure the interface.

```
[edit interfaces]
set interface
```

In this example, the interface is **ms-0/1/0.0**.

```
[edit interfaces]
user@host# set ms-0/1/0.0
```

49. Go to the following hierarchy level:

```
[edit interfaces]
user@host# edit ms-0/1/0.0
```

50. In the hierarchy level, configure the protocol family.

```
[edit interfaces ms-0/1/0 unit 0]
user@host# set family inet
```

51. Go to the following hierarchy level and verify the configuration:

```
[edit interfaces ms-0/1/0]
user@host# show
unit 0 {
  family inet;
}
```

52. Go to the following hierarchy level:

```
user@host# edit interfaces
```

53. In the hierarchy level, configure the interface.

```
[edit interfaces]
set interface
```

In this example, the interface is **sp-3/1/0.0**.

```
[edit interfaces]
```

```
user@host# set sp-3/1/0.0
```

54. Go to the following hierarchy level:

```
[edit interfaces]
user@host# edit sp-3/1/0
```

55. In the hierarchy level, configure optional notification parameters for the services interface. Note that it is required only for debugging.

```
[edit interfaces sp-3/1/0]
user@host# set services-options syslog host host-name services any
```

In this example, the host to notify is **local**.

```
[edit interfaces sp-3/1/0]
user@host# set services-options syslog host local services any
```

56. Go to the following hierarchy level:

```
[edit interfaces]
user@host# edit sp-3/1/0.0
```

57. In the hierarchy level, configure the protocol family.

```
[edit interfaces sp-3/1/0 unit 0]
user@host# set family inet
```

58. Go to the following hierarchy level and verify the configuration:

```
[edit interfaces sp-3/1/0]
user@host# show
services-options {
  syslog {
    host local {
      services any;
    }
  }
}
unit 0 {
  family inet;
}
```

59. Go to the following hierarchy level:

```
[edit chassis]
```

60. In the hierarchy level, configure the redundancy settings.

```
[edit chassis]
user@host# set no-service-pic-restart-on-failover
user@host# set redundancy graceful-switchover
```

61. Configure the FPC and PIC.

```
[edit chassis]
user@host# edit fpc slot pic slot
```

In this example, the FPC is in slot 0 and the PIC is in slot 1.

```
[edit chassis]
user@host# edit fpc 0 pic 1
```

62. Configure the number of cores dedicated to run control functionality.

```
[edit chassis fpc slot pic slot]
user@host# set adaptive-services service-package extension-provider control-cores
control-cores
```

In this example, the number of control cores is 1.

```
[edit chassis fpc 1 pic 0]
user@host# set adaptive-services service-package extension-provider control-cores
1
```

63. Configure the number of processing cores dedicated to data.

```
[edit chassis fpc slot pic slot]
user@host# set adaptive-services service-package extension-provider data-cores
data-cores
```

In this example, the number of data cores is 7.

```
[edit chassis fpc 1 pic 0]
user@host# set adaptive-services service-package extension-provider data-cores 7
```

64. Configure the size of the object cache in megabytes. Only values in increments of 128 MB are allowed and the maximum value of object cache can be 1280 MB. On MS-100, the value is 512 MB.

```
[edit chassis fpc slot pic slot]
user@host# set adaptive-services service-package extension-provider
object-cache-size object-cache-size
```

In this example, the size of the object cache is 1280 MB.

```
[edit chassis fpc 1 pic 0]
user@host# set adaptive-services service-package extension-provider
object-cache-size 1280
```

65. Configure the size of the policy database in megabytes.

```
[edit chassis fpc slot pic slot]
user@host# set adaptive-services service-package extension-provider policy-db-size
policy-db-size
```

In this example, the size of the policy database is 64 MB.

```
[edit chassis fpc 1 pic 0]
user@host# set adaptive-services service-package extension-provider policy-db-size
64
```

66. Configure the packages.

```
[edit chassis fpc slot pic slot]
user@host# set adaptive-services service-package extension-provider package
package
```

In this example, the first package is **jservices-appid**, the second package is **jservices-aacl**, the third package is **jservices-llpdf**, the fourth package is **jservices-idp**, and the fifth package is **jservices-sfw**. **jservices-sfw** is available only in Junos OS Release 10.1 and later.

```
[edit chassis fpc 1 pic 0]
user@host# set adaptive-services service-package extension-provider package
jservices-appid
```

```

user@host# set adaptive-services service-package extension-provider package
jservices-aac1
user@host# set adaptive-services service-package extension-provider package
jservices-llpdf
user@host# set adaptive-services service-package extension-provider package
jservices-idp
user@host# set adaptive-services service-package extension-provider package
jservices-sfw

```

67. Configure the IP network services.

```

[edit chassis]
user@host# set network-services ip

```

68. Go to the following hierarchy level and verify the configuration:

```

[edit chassis]
user@host# show chassis
no-service-pic-restart-on-failover;
filter-memory-enhanced;
redundancy {
    graceful-switchover;
}
fpc 0 {
    pic 1 {
        adaptive-services {
            service-package {
                extension-provider {
                    control-cores 1;
                    data-cores 7;
                    object-cache-size 1280;
                    policy-db-size 64;
                    package jservices-appid;
                    package jservices-aac1;
                    package jservices-llpdf;
                    package jservices-idp;
                    package jservices-sfw;
                }
            }
        }
    }
}
network-services ip;

```

Example: Virtual Routing and Forwarding (VRF) and Service Configuration

The following example combines virtual routing and forwarding (VRF) and services configuration:

```

[edit policy-options]
policy-statement test-policy {
    term t1 {
        then reject;
    }
}
[edit routing-instances]
test {
    interface ge-0/2/0.0;
    interface sp-1/3/0.20;
}

```

```
instance-type vrf;
route-distinguisher 10.58.255.1:37;
vrf-import test-policy;
vrf-export test-policy;
routing-options {
    static {
        route 0.0.0.0/0 next-table inet.0;
    }
}
[edit interfaces]
ge-0/2/0 {
    unit 0 {
        family inet {
            service {
                input service-set nat-me;
                output service-set nat-me;
            }
        }
    }
}
sp-1/3/0 {
    unit 0 {
        family inet;
    }
    unit 20 {
        family inet;
        service-domain inside;
    }
    unit 21 {
        family inet;
        service-domain outside;
    }
}
[edit services]
stateful-firewall {
    rule allow-any-input {
        match-direction input;
        term t1 {
            then accept;
        }
    }
}
nat {
    pool hide-pool {
        address 10.58.16.100;
        port automatic;
    }
    rule hide-all-input {
        match-direction input;
        term t1 {
            then {
                translated {
                    source-pool hide-pool;
                    translation-type source napt-44;
                }
            }
        }
    }
}
```

```
    }  
  }  
}  
service-set nat-me {  
  stateful-firewall-rules allow-any-input;  
  nat-rules hide-all-input;  
  interface-service {  
    service-interface sp-1/3/0.20;  
  }  
}
```

CHAPTER 28

IDS Configuration Overview

- [Configuring IDS Rules on page 355](#)
- [Configuring IDS Rule Sets on page 363](#)
- [Examples: Configuring IDS Rules on page 364](#)

Configuring IDS Rules

IDS rules identify traffic for which you want the router software to count events. Because IDS is based on stateful firewall properties, you must configure at least one stateful firewall rule and include it in the service set with the IDS rules; for more information, see [“Configuring Stateful Firewall Rules” on page 331](#).

To configure an IDS rule, include the **rule** *rule-name* statement at the **[edit services ids]** hierarchy level:

```
[edit services ids]
rule rule-name {
  match-direction (input | output | input-output);
  term term-name {
    from {
      application-sets set-name;
      applications [ application-names ];
      destination-address (address | any-unicast) <except>;
      destination-address-range low minimum-value high maximum-value <except>;
      destination-prefix-list list-name <except>;
      source-address (address | any-unicast) <except>;
      source-address-range low minimum-value high maximum-value <except>;
      source-prefix-list list-name <except>;
    }
    then {
      aggregation {
        destination-prefix prefix-value | destination-prefix-ipv6 prefix-value;
        source-prefix prefix-value | source-prefix-ipv6 prefix-value;
      }
      (force-entry | ignore-entry);
      logging {
        syslog;
        threshold rate;
      }
      session-limit {
        by-destination {
```

```

        hold-time seconds;
        maximum number;
        packets number;
        rate number;
    }
    by-pair {
        hold-time seconds;
        maximum number;
        packets number;
        rate number;
    }
    by-source {
        hold-time seconds;
        maximum number;
        packets number;
        rate number;
    }
}
syn-cookie {
    mss value;
    threshold rate;
}
}
}

```

Each IDS rule consists of a set of terms, similar to a filter configured at the **[edit firewall]** hierarchy level. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

The following sections describe IDS rule content in more detail:

- [Configuring Match Direction for IDS Rules on page 356](#)
- [Configuring Match Conditions in IDS Rules on page 357](#)
- [Configuring Actions in IDS Rules on page 358](#)

Configuring Match Direction for IDS Rules

Each rule must include a **match-direction** statement that specifies whether the match is applied on the input or output side of the interface. To configure where the match is applied, include the **match-direction (input | input-output | output)** statement at the **[edit services ids rule *rule-name*]** hierarchy level:

```

[edit services ids rule rule-name]
  match-direction (input | output | input-output);

```

If you configure **match-direction input-output**, bidirectional rule creation is allowed.

The match direction is used with respect to the traffic flow through the AS or Multiservices PIC. When a packet is sent to the PIC, direction information is carried along with it.

With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.

With a next-hop service set, packet direction is determined by the interface used to route the packet to the AS or Multiservices PIC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the PIC, the packet direction is output. For more information on inside and outside interfaces, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).

On the AS or Multiservices PIC, a flow lookup is performed. If no flow is found, rule processing is performed. All rules in the service set are considered. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that match the packet direction are considered.

Configuring Match Conditions in IDS Rules

To configure IDS match conditions, include the **from** statement at the **[edit services ids rule rule-name term term-name]** hierarchy level:

```
[edit services ids rule rule-name term term-name]
from {
  application-sets set-name;
  applications [ application-names ];
  destination-address (address | any-unicast) <except>;
  destination-address-range low minimum-value high maximum-value <except>;
  destination-prefix-list list-name <except>;
  source-address (address | any-unicast) <except>;
  source-address-range low minimum-value high maximum-value <except>;
  source-prefix-list list-name <except>;
}
```

If you omit the **from** statement, the software accepts all events and places them in the IDS cache for processing.

The source address and destination address can be either IPv4 or IPv6. You can use the destination address, a range of destination addresses, a source address, or a range of source addresses as a match condition, in the same way that you would configure a firewall filter; for more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Alternatively, you can specify a list of source or destination prefixes by including the **prefix-list** statement at the **[edit policy-options]** hierarchy level and then including either the **destination-prefix-list** or **source-prefix-list** statement in the IDS rule. For an example, see [“Examples: Configuring Stateful Firewall Rules” on page 335](#).

You can also include application protocol definitions that you have configured at the **[edit applications]** hierarchy level; for more information, see [“Configuring Application Protocol Properties” on page 303](#).

- To apply one or more specific application protocol definitions, include the **applications** statement at the **[edit services ids rule rule-name term term-name from]** hierarchy level.

- To apply one or more sets of application protocol definitions that you have defined, include the **application-sets** statement at the **[edit services ids rule *rule-name* term *term-name* from]** hierarchy level.

NOTE: If you include one of the statements that specifies application protocols, the router derives port and protocol information from the corresponding configuration at the **[edit applications]** hierarchy level; you cannot specify these properties as match conditions.

If a match occurs on an application, the application protocol is displayed separately in the **show services ids** command output. For more information, see the [CLI Explorer](#).

Configuring Actions in IDS Rules

To configure IDS actions, include the **then** statement at the **[edit services ids rule *rule-name* term *term-name*]** hierarchy level:

```
[edit services ids rule rule-name term term-name]
then {
  aggregation {
    destination-prefix prefix-value | destination-prefix-ipv6 prefix-value;
    source-prefix prefix-value | source-prefix-ipv6 prefix-value;
  }
  (force-entry | ignore-entry);
  logging {
    syslog;
    threshold rate;
  }
  session-limit {
    by-destination {
      hold-time seconds;
      maximum number;
      packets number;
      rate number;
    }
    by-pair {
      hold-time seconds;
      maximum number;
      packets number;
      rate number;
    }
    by-source {
      hold-time seconds;
      maximum number;
      packets number;
      rate number;
    }
  }
  syn-cookie {
    mss value;
    threshold rate;
  }
}
```

You can configure the following possible actions:

- **aggregation**—The router aggregates traffic labeled with the specified source or destination prefixes before passing the events to IDS processing. This is helpful if you want to examine all the traffic connected with a particular source or destination host. To collect traffic with some other marker, such as a particular application or port, configure that value in the match conditions.

To configure aggregation prefixes, include the **aggregation** statement at the **[edit services ids rule rule-name term term-name then]** hierarchy level and specify values for **source-prefix**, **destination-prefix**, **source-prefix-ipv6**, or **destination-prefix-ipv6**:

```
[edit services ids rule rule-name term term-name then]
  aggregation {
    destination-prefix prefix-value | destination-prefix-ipv6 prefix-value;
    source-prefix prefix-value | source-prefix-ipv6 prefix-value;
  }
```

The value of **source-prefix** and **destination-prefix** must be an integer between 1 and 32. The value of **source-prefix-ipv6** and **destination-prefix-ipv6** must be an integer between 1 and 128.

- **(force-entry | ignore-entry)**—**force-entry** provides a permanent spot in IDS caches for subsequent events after one event is registered. By default, the IDS software does not record information about “good” packets that do not exhibit suspicious behavior. You can use the **force-entry** statement to record all traffic from a suspect host, even traffic that would not otherwise be counted.

ignore-entry ensures that all IDS events are ignored. You can use this statement to disregard all traffic from a host you trust, including any temporary anomalies that IDS would otherwise count as events.

To configure an entry behavior different from the default, include the **force-entry** or **ignore-entry** statement at the **[edit services ids rule rule-name term term-name then]** hierarchy level:

```
[edit services ids rule rule-name term term-name then]
  (force-entry | ignore-entry);
```

- **logging**—The event is logged in the system log file.

To configure logging, include the **logging** statement at the **[edit services ids rule rule-name term term-name then]** hierarchy level:

```
[edit services ids rule rule-name term term-name then]
  logging {
    syslog;
    threshold rate;
  }
```

You can optionally include a threshold rate to trigger the generation of system log messages. The threshold rate is specified in events per second. IDS logs are generated once every 60 seconds for each anomaly that is reported. The logs are generated as long as the events continue.

- **session-limit**—The router limits open sessions when the specified threshold is reached.

To configure a threshold, include the **session-limit** statement at the **[edit services ids rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ids rule rule-name term term-name then]
session-limit {
  by-destination {
    hold-time seconds;
    maximum number;
    packets number;
    rate number;
  }
  by-pair {
    hold-time seconds;
    maximum number;
    packets number;
    rate number;
  }
  by-source {
    hold-time seconds;
    maximum number;
    packets number;
    rate number;
  }
}
```

You configure the thresholds for flow limitation based on traffic direction:

- To limit the number of outgoing sessions from one internal host or subnet, configure the **by-source** statement.
- To limit the number of sessions between a pair of IP addresses, subnets, or applications, configure the **by-pair** statement.
- To limit the number of incoming sessions to one external public IP address or subnet, configure the **by-destination** statement.

For each direction, you can configure the following threshold values:

- **hold-time *seconds***—When the **rate** or **packets** measurement reaches the threshold value, stop all new flows for the specified number of seconds. Once **hold-time** is in effect, the traffic is blocked for the specified time even if the rate subsides below the specified limit. By default, **hold-time** has a value of 0; the range is 0 through 60 seconds.
- **maximum *number***—Maximum number of open sessions per IP address or subnet per application. The range is 1 through 32,767.
- **packets *number***—Maximum number of packets per second (pps) per IP address or subnet per application. The range is 4 through 2,147,483,647.
- **rate *number***—Maximum number of sessions per second per IP address or subnet per application. The range is 4 through 32,767.

If you include more than one source address in the match conditions configured at the **[edit services ids rule *rule-name* term *term-name* from]** hierarchy level, limits are applied for each source address independently. For example, the following

configuration allows 20 connections from each source address (10.1.1.1 and 10.1.1.2), not 20 connections total. The same logic applies to the **applications** and **destination-address** match conditions.

```
[edit services ids rule rule-name term term-name]
  from {
    source-address 10.1.1.1;
    source-address 10.1.1.2;
  }
  then {
    session-limit by-source {
      maximum 20;
    }
  }
}
```

NOTE: IDS limits are applied to packets that are accepted by stateful firewall rules. They are not applied to packets discarded or rejected by stateful firewall rules. For example, if the stateful firewall accepts 75 percent of the incoming traffic and the remaining 25 percent is rejected or discarded, the IDS limit applies only to 75 percent of the traffic.

- **syn-cookie**—The router activates SYN-cookie defensive mechanisms.

To configure SYN-cookie values, include the **syn-cookie** statement at the **[edit services ids rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ids rule rule-name term term-name then]
  syn-cookie {
    mss value;
    threshold rate;
  }
```

If you enable SYN-cookie defenses, you must include both a threshold rate to trigger SYN-cookie activity and a Transmission Control Protocol (TCP) maximum segment size (MSS) value for TCP delayed binding. The threshold rate is specified in SYN attacks per second. By default, the TCP MSS value is 1500; the range is from 128 through 8192.

Handling of SYN Flood Attacks and SYN Cookie Protection

The main purpose of a SYN flood attack is to consume all new network connections at a site and thereby prevent authorized and legitimate users from being able to connect to network resources. The SYN (synchronize sequence number) packet is the first request to connect sent to a system. The SYN packet contains an ID to which the receiver is required to respond. If the packet contains an illegal ID, the receiving system does receive a connection acknowledgment when it responds to the intended connection initiator. Eventually, this half-open connection times out and the incoming channel on the receiver becomes available again to normally handle another request. A SYN flood attack sends so many such requests that all incoming connections are continuously tied up waiting for acknowledgments that are never received. This condition causes the server to be unavailable to legal users (except in cases where a user session is established when it is exactly at the moment when one of the tied-up connections times out). A SYN flood attack is a connectionless attack. It does not require a real source IP addresses and, because it uses legitimate destination IP or port addresses, is practically impossible to distinguish from legitimate packets. Therefore, it is very difficult to prevent this type of

attack by using only filters or stateful firewall rules. Basically, there are only three methods to protect from this type of attack:

- Intercept (delayed binding)—The firewall intercepts incoming TCP synchronization requests and establishes a connection with the client on the server's behalf, and with the server on the client's behalf. If both connections are successful, the firewall transparently merges the two connections. The firewall usually has aggressive timeouts to prevent its own resources from being consumed by a SYN attack. This is the most intensive solution in terms of processing and memory requirements.
- Watch (SYN defense)—The firewall passively watches half-open connections and actively closes connections on the server after a configurable length of time.
- SYN cookie—SYN cookies are particular choices for the initial TCP sequence number chosen by the TCP server. A host requesting a connection must answer with the cookie to connect to an open TCP socket while a SYN-flood has been detected as in progress by the IDS.

Juniper Networks routers support the combination of stateful firewall and IDS mechanisms to support the SYN cookie and watch (SYN defense) methods. The key to the SYN flood attack is the filling of the SYN queue of the victim or the attacked network element. The SYN cookie defense method enables the victim to continue accepting connection requests when the SYN queue is full or, in the case of the firewall or IDS applications, when a certain threshold has been reached. After the threshold is reached, a cryptographic cookie (a 32-bit number) is created from information in the SYN segment and the SYN segment is dropped. The cookie is used as the initial sequence number in the SYN-ACK sent to the client. The cookie (plus one) is returned to the firewall or IDS application as the acknowledgment number in the ACK from a legitimate client. The returned cookie can be validated and the most important parts of the SYN segment can be reconstructed from the cookie, thereby allowing a connection to be established. Because the spoofed clients of the SYN flood never send ACKs, no resources are allocated for them in any state when SYN cookies are in use. It is preferred that you use SYN flood countermeasures only for hosts under attack. The anomaly table can be used for reliable attack recognition or they can be enabled within the stateful firewall. Such a type of configuration also helps prevent the depletion of system resources (especially the flow table) in case of attacks.

When combining multiple services, the general path is an important factor for consideration in the forward and reverse directions. This is especially true when NAT is deployed to determine whether the pre-NAT or post-NAT address must be used to match a rule. In the forward path from a LAN interface to a WAN interface, IDS and stateful firewall are performed first, then NAT, and finally IPsec. This sequence of processing of services denotes that the stateful firewall must match on a pre-NAT address, whereas the IPsec tunnel matches on the post-NAT address. In the return path, the IPsec packet is processed first, then NAT, and finally the stateful firewall. This order of processing still allows IPsec to match a public address and the stateful firewall to match on a private address. You must separately configure the firewall, NAT, and IDS services. The processing of packets becomes much more complicated when IPsec over GRE is implemented in the router with other services turned on. This behavior occurs because Junos OS treats GRE packets in a unique fashion after GRE encapsulation. After a packet is encapsulated in a GRE packet, it is marked with an input interface as the next-hop outgoing interface.

This method of marking causes GRE packets to be blocked if any input filters or input services are allowed that do not allow for this service.

Junos OS services support a limited set of IDS rules to help detect attacks such as port scanning and anomalies in traffic patterns. It also supports some attack prevention by limiting the number of flows, sessions, and rates. In addition, it protects against SYN attacks by implementing a SYN cookie mechanism. Because the intrusion detection and prevention (IDP) service does not support higher-layer application signatures, an effective approach against attacks is that protection against a SYN attack can be configured. The IDP solution is largely a monitoring tool and not an essential prevention tool. To prevent a SYN attack, the router will operate as a type of SYN “proxy” and utilizes cookie values. When this feature is turned on, the router responds to the initial SYN packet with a SYN-ACK packet that contains a unique cookie value in the sequence number field. If the initiator responds with the same cookie in the sequence field, the TCP flow is accepted; if the responder does not respond or if it responds with the wrong cookie, the flow is dropped. To trigger this defense, you must configure a SYN cookie threshold. To enable the SYN cookie defense, an IDS rule action must contain a threshold that indicates when the feature should be enabled and an MSS value to avoid having the router manage segmented fragments when acting as a SYN proxy:

```
[edit]
user@host# set services ids rule simple-ids term 1 then syn-cookie
```

- [Configuring IDS Rule Sets on page 363](#)
 - [Examples: Configuring IDS Rules on page 364](#)

Configuring IDS Rule Sets

The **rule-set** statement defines a collection of IDS rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then, you specify the order of the rules by including the **rule-set** statement at the **[edit services ids]** hierarchy level with a **rule** statement for each rule:

```
[edit services ids]
rule-set rule-set-name {
  rule rule-name;
}
```

The router software processes the rules in the order in which you specify them in the configuration. If a term in a rule matches the packet, the router performs the corresponding action and the rule processing stops. If no term in a rule matches the packet, processing continues to the next rule in the rule set. If none of the rules matches the packet, the packet is dropped by default.

 - [Examples: Configuring IDS Rules on page 364](#)

Examples: Configuring IDS Rules

The following configuration adds a permanent entry to the IDS anomaly table when it encounters a flow with the destination address 10.410.6.2:

```
[edit services ids]
rule simple_ids {
  term 1 {
    from {
      destination-address 10.410.6.2/32;
    }
    then {
      force-entry;
      logging {
        threshold 1;
        syslog;
      }
    }
  }
  term default {
    then {
      aggregation {
        source-prefix 24;
      }
    }
  }
  match-direction input;
}
```

The IDS configuration works in conjunction with the stateful firewall mechanism and relies heavily on the anomalies reported by the stateful firewall. The following configuration example shows this relationship:

```
[edit services ids]
rule simple_ids {
  term 1 {
    from {
      source-address 10.30.20.2/32;
      destination-address {
        10.30.10.2/32;
        10.30.1.2/32 except;
      }
      applications appl-ftp;
    }
    then {
      force-entry;
      logging {
        threshold 5;
        syslog;
      }
      syn-cookie {
        threshold 10;
      }
    }
  }
}
```

```

    }
    match-direction input;
}

[edit services stateful-firewall]
rule my-firewall-rule {
  match-direction input-output;
  term term1 {
    from {
      source-address 10.30.20.2/32;
      applications appl-ftp ;
      destination-address {
        10.30.10.2/32;
        10.30.1.2/32 except;
      }
    }
    then {
      accept;
      syslog;
    }
  }
}

```

The stateful firewall or NAT service is used to generate the input data for the IDS application. When you enable and configure an IDS service, you must also enable stateful firewall with at least one rule (accept or discard all traffic). When the system is under an attack, the stateful firewall sends the correct and complete list of attack events to the IDS system. In your network environment, you can ensure that the system is wholly protected against a whole range of attacks so that the IDS system reports all such attacks. You must exercise caution when you configure the system to be protected from all attacks and unauthenticated access scenarios so that the traffic bandwidth that the system handles is not burdened. It is also important to verify the correlation between the firewall syslog messages corresponding to the attacks and IDS tables. The IDS tables must have the same or slightly less number of anomalies or errors compared to the firewall-based syslog messages. You can use the appropriate show commands are used to display the IDS tables.

A default stateful firewall rule can be as simple as only allowing connection initiation from the inside interface to the outside interface and discarding all other packets. However, in a real-world network environment, rules are generally more complex, such as configuring only a certain tributary unit ports are allowed to be opened, using application layer gateways (ALGs) for complicated protocols, and using NAT for both outgoing connections and inside hosts such as HTTP servers. Therefore, it is necessary to also configure the system as needed to interwork with simple and complicated rules. For example, if a SYN attack is directed towards an inside address that is simply discarded, no anomalies need to be reported to the IDS system. But if the SYN attack is directed towards the real HTTP server, anomalies must be reported. The IDS system can mitigate SYN attacks by using the TCP SYN cookie defense capability. You can enable the SYN cookie protection methodology by setting a threshold for SYNs per second for a given host and also a maximum segment size (MSS). Because the IDS system uses the stateful firewall, a firewall rule must be defined in the service-set. If you do not configure the **from** statement in a stateful firewall (rule term match condition) at the **[edit services service-set**

service-set-name stateful-firewall-rules *rule-name* term *term-name*] hierarchy level, it signifies that all events are placed into the IDS cache.

The following example shows configuration of flow limits:

```
[edit services ids]
rule ids-all {
  match-direction input;
  term t1 {
    from {
      application-sets alg-set;
    }
    then {
      aggregation {
        destination-prefix 30; /* IDS action aggregation */
      }
      logging {
        threshold 10;
      }
      session-limit {
        by-destination {
          hold-time 0;
          maximum 10;
          packets 200;
          rate 100;
        }
        by-pair {
          hold-time 0;
          maximum 10;
          packets 200;
          rate 100;
        }
        by-source {
          hold-time 5;
          maximum 10;
          packets 200;
          rate 100;
        }
      }
    }
  }
}
```

- [Monitoring Global Stateful Firewall Statistics on page 368](#)

Monitoring Stateful Firewall Conversations

Purpose Use the `show services stateful-firewall conversations` command to show conversations, or collections of related flows.

Action `user@host# show services stateful-firewall conversations`
Interface: sp-0/0/0, Service set: sset
Conversation: ALG protocol: tcp
Number of initiators: 1, Number of responders: 1
Flow State Dir Frm
count
TCP 10.0.0.1:1025 -> 128.0.0.1:80 Forward I 372755
NAT source 10.0.0.1:1025 -> 129.0.0.1:1024
Software 2001:0:0:1::1 -> 1001::1
TCP 128.0.0.1:80 -> 129.0.0.1:1024 Forward O 794083
NAT dest 129.0.0.1:1024 -> 10.0.0.1:1025
Software 2001:0:0:1::1 -> 1001::1

Monitoring CGN, Stateful Firewall, and Software Flows

Purpose Use the following commands to check the creation of the softwires, pre-NAT flows, and post-NAT flows. Output can be filtered using more specific fields such as AFTR or B4 address or both for DS-Lite, and software-concentrator or software-initiator or both for 6rd.

- `show services stateful-firewall flows`
- `show services software flows`

Action user@host# **show services stateful-firewall flows**

Interface: sp-0/1/0, Service set: dslite-svc-set2

Understanding Junos VPN Site Secure

Junos VPN Site Secure is a suite of IPsec features supported on multiservices line cards (MS-DPC, MS-MPC, and MS-MIC), and was referred to as IPsec services in Junos releases earlier than 13.2. In Junos OS Release 13.2 and later, the term IPsec features is used exclusively to refer to the IPsec implementation on Adaptive Services and Encryption Services PICs. This topic provides you an overview of Junos VPN Site Secure, and has the following sections:

- [IPsec on page 371](#)
- [Security Associations on page 372](#)
- [IKE on page 372](#)
- [Comparison of IPsec on ES PICs and Junos VPN Site Secure on Multiservices Line Cards on page 372](#)

IPsec

The IPsec architecture provides a security suite for the IP version 4 (IPv4) and IP version 6 (IPv6) network layers. The suite provides such functionality as authentication of origin, data integrity, confidentiality, replay protection, and nonrepudiation of source. In addition to IPsec, the Junos OS also supports the Internet Key Exchange (IKE), which defines mechanisms for key generation and exchange, and manages security associations (SAs).

IPsec also defines a security association and key management framework that can be used with any network-layer protocol. The SA specifies what protection policy to apply to traffic between two IP-layer entities. IPsec provides secure tunnels between two peers.

Security Associations

To use IPsec security services, you create SAs between hosts. An SA is a simplex connection that enables two hosts to communicate with each other securely by means of IPsec. There are two types of SAs:

- Manual SAs require no negotiation; all values, including the keys, are static and specified in the configuration. Manual SAs statically define the security parameter index (SPI) values, algorithms, and keys to be used, and require matching configurations on both ends of the tunnel. Each peer must have the same configured options for communication to take place.
- Dynamic SAs require additional configuration. With dynamic SAs, you configure IKE first and then the SA. IKE creates dynamic security associations; it negotiates SAs for IPsec. The IKE configuration defines the algorithms and keys used to establish the secure IKE connection with the peer security gateway. This connection is then used to dynamically agree upon keys and other data used by the dynamic IPsec SA. The IKE SA is negotiated first and then used to protect the negotiations that determine the dynamic IPsec SAs.

IKE

IKE is a key management protocol that creates dynamic SAs; it negotiates SAs for IPsec. An IKE configuration defines the algorithms and keys used to establish a secure connection with a peer security gateway.

IKE performs the following tasks:

- Negotiates and manages IKE and IPsec parameters.
- Authenticates secure key exchange.
- Provides mutual peer authentication by means of shared secrets (not passwords) and public keys.
- Provides identity protection (in main mode).

Two versions of the IKE protocol (IKEv1 and IKEv2) are supported now. IKE negotiates security attributes and establishes shared secrets to form the bidirectional IKE SA. In IKE, inbound and outbound IPsec SAs are established and the IKE SA secures the exchanges. Starting with Junos OS Release 11.4, both IKEv1 and IKEv2 are supported by default on all M Series, MX Series, and T Series routers. IKE also generates keying material, provides Perfect Forward Secrecy, and exchanges identities.

Comparison of IPsec on ES PICs and Junos VPN Site Secure on Multiservices Line Cards

[Table 23 on page 373](#) compares the top-level configuration of IPsec features on the ES PIC interfaces, and IPsec on the Adaptive Services PICs and Junos VPN Site Secure on Multiservices Line Cards .

Table 23: Statement Equivalents for ES and AS Interfaces

ES PIC Configuration	AS and MultiServices Line Cards Configuration
[edit security ipsec] proposal {...}	[edit services ipsec-vpn ipsec] proposal {...}
[edit security ipsec] policy {...}	[edit services ipsec-vpn ipsec] policy {...}
[edit security ipsec] security-association sa-dynamic {...}	[edit services ipsec-vpn rule <i>rule-name</i>] term <i>term-name</i> match-conditions {...} then dynamic {...}
[edit security ipsec] security-association sa-manual {...}	[edit services ipsec-vpn rule <i>rule-name</i>] term <i>term-name</i> match-conditions {...} then manual {...}
[edit security ike] proposal {...}	[edit services ipsec-vpn ike] proposal {...}
[edit security ike] policy {...}	[edit services ipsec-vpn ike] policy {...}
Not available	[edit services ipsec-vpn] rule-set {...}
Not available	[edit services ipsec-vpn] service-set {...}
[edit interfaces <i>es-fpc/pic/port</i>] tunnel source <i>address</i>	[edit services ipsec-vpn service-set <i>set-name</i>] ipsec-vpn local-gateway <i>address</i>
[edit interfaces <i>es-fpc/pic/port</i>] tunnel destination <i>address</i>	[edit services ipsec-vpn rule <i>rule-name</i>] remote-gateway <i>address</i>

NOTE: Although many of the same statements and properties are valid on both platforms (MultiServices and ES), the configurations are not interchangeable. You must commit a complete configuration for the PIC type that is installed in your router.

Authentication Algorithms

Authentication is the process of verifying the identity of the sender. Authentication algorithms use a shared key to verify the authenticity of the IPsec devices. The Junos OS uses the following authentication algorithms:

- Message Digest 5 (MD5) uses a one-way hash function to convert a message of arbitrary length to a fixed-length message digest of 128 bits. Because of the conversion process, it is mathematically infeasible to calculate the original message by computing it backwards from the resulting message digest. Likewise, a change to a single character in the message will cause it to generate a very different message digest number.

To verify that the message has not been tampered with, the Junos OS compares the calculated message digest against a message digest that is decrypted with a shared key. The Junos OS uses the MD5 hashed message authentication code (HMAC) variant that provides an additional level of hashing. MD5 can be used with authentication header (AH), Encapsulating Security Payload (ESP), and Internet Key Exchange (IKE).

- Secure Hash Algorithm 1 (SHA-1) uses a stronger algorithm than MD5. SHA-1 takes a message of less than 264 bits in length and produces a 160-bit message digest. The large message digest ensures that the data has not been changed and that it originates from the correct source. The Junos OS uses the SHA-1 HMAC variant that provides an additional level of hashing. SHA-1 can be used with AH, ESP, and IKE.
- SHA-256, SHA-384, and SHA-512 (sometimes grouped under the name SHA-2) are variants of SHA-1 and use longer message digests. The Junos OS supports the SHA-256 version of SHA-2, which can process all versions of Advanced Encryption Standard (AES), Data Encryption Standard (DES), and Triple DES (3DES) encryption.

Encryption Algorithms

Encryption encodes data into a secure format so that it cannot be deciphered by unauthorized users. Like authentication algorithms, a shared key is used with encryption algorithms to verify the authenticity of the IPsec devices. The Junos OS uses the following encryption algorithms:

- Data Encryption Standard cipher-block chaining (DES-CBC) is a symmetric secret-key block algorithm. DES uses a key size of 64 bits, where 8 bits are used for error detection and the remaining 56 bits provide encryption. DES performs a series of simple logical operations on the shared key, including permutations and substitutions. CBC takes the first block of 64 bits of output from DES, combines this block with the second block, feeds this back into the DES algorithm, and repeats this process for all subsequent blocks.
- Triple DES-CBC (3DES-CBC) is an encryption algorithm that is similar to DES-CBC, but provides a much stronger encryption result because it uses three keys for 168-bit

(3 x 56-bit) encryption. 3DES works by using the first key to encrypt the blocks, the second key to decrypt the blocks, and the third key to re-encrypt the blocks.

- Advanced Encryption Standard (AES) is a next-generation encryption method based on the Rijndael algorithm developed by Belgian cryptographers Dr. Joan Daemen and Dr. Vincent Rijmen. It uses a 128-bit block and three different key sizes (128, 192, and 256 bits). Depending on the key size, the algorithm performs a series of computations (10, 12, or 14 rounds) that include byte substitution, column mixing, row shifting, and key addition. The use of AES in conjunction with IPsec is defined in RFC 3602, *The AES-CBC Cipher Algorithm and Its Use with IPsec*.

IPsec Protocols

IPsec protocols determine the type of authentication and encryption applied to packets that are secured by the router. The Junos OS supports the following IPsec protocols:

- **AH**—Defined in RFC 2402, AH provides connectionless integrity and data origin authentication for IPv4 and IPv6 packets. It also provides protection against replays. AH authenticates as much of the IP header as possible, as well as the upper-level protocol data. However, some IP header fields might change in transit. Because the value of these fields might not be predictable by the sender, they cannot be protected by AH. In an IP header, AH can be identified with a value of **51** in the **Protocol** field of an IPv4 packet and the **Next Header** field of an IPv6 packet. An example of the IPsec protection offered by AH is shown in [Figure 19 on page 376](#).

NOTE: AH is not supported on the T Series, M120, and M320 routers.

Figure 19: AH Protocol

Header format

Byte 0	Byte 1	Byte 2	Byte 3
Next header	Payload length	Reserved	
Security Parameters Index (SPI)			
Sequence number			
Authentication data (variable)			

Original IPv4 packet before AH is applied

Original IP header	TCP header	Data
--------------------	------------	------

IPv4 packet after AH transport mode is applied

Original IP header	AH header	TCP header	Data
Authenticating			

IPv4 packet after AH tunnel mode is applied

New IP header	AH header	Original IP header	TCP header	Data
Authenticating				

g015522

- ESP—Defined in RFC 2406, ESP can provide encryption and limited traffic flow confidentiality, or connectionless integrity, data origin authentication, and an anti-replay service. In an IP header, ESP can be identified a value of **50** in the **Protocol** field of an IPv4 packet and the **Next Header** field of an IPv6 packet. An example of the IPsec protection offered by ESP is shown in [Figure 20 on page 377](#).

Figure 20: ESP Protocol

- Bundle—When you compare AH with ESP, there are some benefits and shortcomings in both protocols. ESP provides a decent level of authentication and encryption, but does so only for part of the IP packet. Conversely, although AH does not provide encryption, it does provide authentication for the entire IP packet. Because of this, the Junos OS offers a third form of IPsec protocol called a protocol bundle. The bundle option offers a hybrid combination of AH authentication with ESP encryption.

Supported IPsec and IKE Standards

On routers equipped with one or more Adaptive Services PICs (both standalone and integrated versions) or Multiservices PICs or DPCs, the Canada and U.S. version of Junos OS substantially supports the following RFCs, which define standards for IP Security (IPsec) and Internet Key Exchange (IKE).

- RFC 2085, *HMAC-MD5 IP Authentication with Replay Prevention*
- RFC 2401, *Security Architecture for the Internet Protocol* (obsoleted by RFC 4301)
- RFC 2402, *IP Authentication Header* (obsoleted by RFC 4302)

This RFC is not supported on the ES PIC.

- RFC 2403, *The Use of HMAC-MD5-96 within ESP and AH*
- RFC 2404, *The Use of HMAC-SHA-1-96 within ESP and AH* (obsoleted by RFC 4305)
- RFC 2405, *The ESP DES-CBC Cipher Algorithm With Explicit IV*
- RFC 2406, *IP Encapsulating Security Payload (ESP)* (obsoleted by RFC 4303 and RFC 4305)
- RFC 2407, *The Internet IP Security Domain of Interpretation for ISAKMP* (obsoleted by RFC 4306)
- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)* (obsoleted by RFC 4306)
- RFC 2409, *The Internet Key Exchange (IKE)* (obsoleted by RFC 4306)
- RFC 2410, *The NULL Encryption Algorithm and Its Use With IPsec*
- RFC 2451, *The ESP CBC-Mode Cipher Algorithms*
- RFC 2460, *Internet Protocol, Version 6 (IPv6)*
- RFC 3193, *Securing L2TP using IPsec*
- RFC 3602, *The AES-CBC Cipher Algorithm and Its Use with IPsec*
- RFC 3947, *Negotiation of NAT-Traversal in the IKE*
- RFC 3948, *UDP Encapsulation of IPsec ESP Packets*
- RFC 4301, *Security Architecture for the Internet Protocol*
- RFC 4302, *IP Authentication Header*

This RFC is not supported on the ES PIC.

- RFC 4303, *IP Encapsulating Security Payload (ESP)*
- RFC 4305, *Cryptographic Algorithm Implementation Requirements for Encapsulating Security Payload (ESP) and Authentication Header (AH)*
- RFC 4306, *Internet Key Exchange (IKEv2) Protocol*
- RFC 4307, *Cryptographic Algorithms for Use in the Internet Key Exchange Version 2 (IKEv2)*

- RFC 4308, *Cryptographic Suites for IPsec*

NOTE: Only Suite VPN-A is supported in Junos OS.

- RFC 4835, *Cryptographic Algorithm Implementation Requirements for Encapsulating Security Payload (ESP) and Authentication Header (AH)*
- RFC 5996, *Internet Key Exchange Protocol Version 2 (IKEv2)*

Junos OS partially supports the following RFCs for IPsec and IKE:

- RFC 3526, *More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)*
- RFC 5114, *Additional Diffie-Hellman Groups for Use with IETF Standards*
- RFC 5903, *Elliptic Curve Groups modulo a Prime (ECP Groups) for IKE and IKEv2*

The following RFCs and Internet draft do not define standards, but provide information about IPsec, IKE, and related technologies. The IETF classifies them as “Informational.”

- RFC 2104, *HMAC: Keyed-Hashing for Message Authentication*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- RFC 3706, *A Traffic-Based Method of Detecting Dead Internet Key Exchange (IKE) Peers*
- Internet draft draft-eastlake-sha2-02.txt, *US Secure Hash Algorithms (SHA and HMAC-SHA)* (expires July 2006)

IPsec Terms and Acronyms

A

Adaptive Services PIC	A next-generation Physical Interface Card (PIC) that provides IPSec services and other services, such as Network Address Translation (NAT) and stateful firewall, on M Series and T Series platforms.
Advanced Encryption Standard (AES)	A next-generation encryption method that is based on the Rijndael algorithm and uses a 128-bit block, three different key sizes (128, 192, and 256 bits), and multiple rounds of processing to encrypt data.
authentication header (AH)	A component of the IPSec protocol used to verify that the contents of a packet have not changed (data integrity), and to validate the identity of the sender (data source authentication). For more information about AH, see RFC 2402.

C

- certificate authority (CA)** A trusted third-party organization that generates, enrolls, validates, and revokes digital certificates. The CA guarantees the identity of a user and issues public and private keys for message encryption and decryption.
- certificate revocation list (CRL)** A list of digital certificates that have been invalidated before their expiration date, including the reasons for their revocation and the names of the entities that have issued them. A CRL prevents usage of digital certificates and signatures that have been compromised.
- cipher block chaining (CBC)** A cryptographic method that encrypts blocks of ciphertext by using the encryption result of one block to encrypt the next block. Upon decryption, the validity of each block of ciphertext depends on the validity of all the preceding ciphertext blocks. For more information on how to use CBC with DES and ESP to provide confidentiality, see RFC 2405.

D

- Data Encryption Standard (DES)** An encryption algorithm that encrypts and decrypts packet data by processing the data with a single shared key. DES operates in increments of 64-bit blocks and provides 56-bit encryption.
- digital certificate** Electronic file that uses private and public key technology to verify the identity of a certificate creator and distribute keys to peers.

E

- Encapsulating Security Payload (ESP)** A component of the IPSec protocol used to encrypt data in an IPv4 or IPv6 packet, provide data integrity, and ensure data source authentication. For more information about ESP, see RFC 2406.
- ES PIC** A PIC that provides first-generation encryption services and software support for IPSec on M Series and T Series platforms.

H

- Hashed Message Authentication Code (HMAC)** A mechanism for message authentication using cryptographic hash functions. HMAC can be used with any iterative cryptographic hash function, such as MD5 or SHA-1, in combination with a secret shared key. For more information on HMAC, see RFC 2104.

I

- Internet Key Exchange (IKE)** Establishes shared security parameters for any hosts or routers using IPSec. IKE establishes the SAs for IPSec. For more information about IKE, see RFC 2407.

M

- Message Digest 5 (MD5)** An authentication algorithm that takes a data message of arbitrary length and produces a 128-bit message digest. For more information, see RFC 1321.

P

- Perfect Forward Secrecy (PFS)** Provides additional security by means of a Diffie-Hellman shared secret value. With PFS, if one key is compromised, previous and subsequent keys are secure because they are not derived from previous keys.

public key infrastructure (PKI) A trust hierarchy that enables users of a public network to securely and privately exchange data through the use of public and private cryptographic key pairs that are obtained and shared with peers through a trusted authority.

R

registration authority (RA) A trusted third-party organization that acts on behalf of a CA to guarantee the identity of a user.

Routing Engine A PCI-based architectural portion of a Junos OS-based router that handles the routing protocol process, the interface process, some of the chassis components, system management, and user access.

S

Secure Hash Algorithm 1 (SHA-1) An authentication algorithm that takes a data message of less than 264 bits in length and produces a 160-bit message digest. For more information on SHA-1, see RFC 3174.

Secure Hash Algorithm 2 (SHA-2) A successor to the SHA-1 authentication algorithm that includes a group of SHA-1 variants (SHA-224, SHA-256, SHA-384, and SHA-512). SHA-2 algorithms use larger hash sizes and are designed to work with enhanced encryption algorithms such as AES.

security association (SA) Specifications that must be agreed upon between two network devices before IKE or IPSec are allowed to function. SAs primarily specify protocol, authentication, and encryption options.

Security Association Database (SADB) A database where all SAs are stored, monitored, and processed by IPSec.

Security Parameter Index (SPI) An identifier that is used to uniquely identify an SA at a network host or router.

Security Policy Database (SPD) A database that works with the SADB to ensure maximum packet security. For inbound packets, IPSec checks the SPD to verify if the incoming packet matches the security configured for a particular policy. For outbound packets, IPSec checks the SPD to see if the packet needs to be secured.

Simple Certificate Enrollment Protocol (SCEP) A protocol that supports CA and registration authority (RA) public key distribution, certificate enrollment, certificate revocation, certificate queries, and certificate revocation list (CRL) queries.

T

Triple Data Encryption Standard (3DES) An enhanced DES algorithm that provides 168-bit encryption by processing data three times with three different keys.

Minimum Security Association Configurations

The following sections show the minimum configurations necessary to set up security associations (SAs) for IPsec services:

- [Minimum Manual SA Configuration on page 383](#)
- [Minimum Dynamic SA Configuration on page 384](#)

Minimum Manual SA Configuration

To define a manual SA configuration, you must include at least the following statements at the `[edit services ipsec-vpn rule rule-name term term-name then manual]` hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual]
  direction (inbound | outbound | bidirectional) {
    authentication {
      algorithm (hmac-md5-96 | hmac-sha1-96);
```

```

        key (ascii-text key | hexadecimal key);
    }
    encryption {
        algorithm algorithm;
        key (ascii-text key | hexadecimal key);
    }
    protocol (ah | esp | bundle);
    spi spi-value;
}

```

Minimum Dynamic SA Configuration

To define a dynamic SA configuration, you must include at least the following statements at the `[edit services ipsec-vpn]` hierarchy level:

```

[edit services ipsec-vpn]
ike {
    proposal proposal-name {
        authentication-algorithm (md5 | sha1 | sha-256);
        authentication-method pre-shared-keys;
        dh-group (group1 | group2 | group5 | group14);
        encryption-algorithm algorithm;
    }
    policy policy-name {
        proposals [ ike-proposal-names ];
        pre-shared-key (ascii-text key | hexadecimal key);
        version (1 | 2);
        mode (aggressive | main);
    }
}
ipsec {
    policy policy-name {
        proposals [ ipsec-proposal-names ];
    }
    proposal proposal-name {
        authentication-algorithm (hmac-md5-96 | hmac-sha1-96);
        encryption-algorithm algorithm;
        protocol (ah | esp | bundle);
    }
}

```

NOTE:

- Starting with Junos OS Release 11.4, both IKEv1 and IKEv2 are supported by default on all M Series, MX Series, and T Series routers. The version statement at the `[edit services ipsec-vpn ike policy name]` hierarchy level allows you to configure the specific IKE version to be supported.
- The mode statement at the `[edit services ipsec-vpn ike policy name]` hierarchy level is required only if the version option is set to 1.

You must also include the `ipsec-policy` statement at the `[edit services ipsec-vpn rule rule-name term term-name then dynamic]` hierarchy level.

 - [Configuring IKE Proposals on page 405](#)
 - [Configuring IKE Policies on page 409](#)
 - [Configuring IPsec Proposals on page 415](#)
 - [Configuring IPsec Policies on page 420](#)

Configuring Security Associations

To use IPsec services, you create a security association (SA) between hosts. An SA is a simplex connection that enables two hosts to communicate with each other securely using IPsec.

NOTE: Both OSPFv2 and OSPFv3 support IPsec authentication. However, dynamic or tunnel mode IPsec SAs are not supported for OSPFv3. If you add SAs into OSPFv3 by including the `ipsec-sa` statement at the `[edit protocols ospf3 area area-number interface interface-name]` hierarchy level, your configuration commit fails. For more information about OSPF authentication and other OSPF properties, see the *Junos OS Routing Protocols Library for Routing Devices*.

You can configure two types of SAs:

- **Manual**—Requires no negotiation; all values, including the keys, are static and specified in the configuration. As a result, each peer must have the same configured options for communication to take place.
- **Dynamic**—Specifies proposals to be negotiated with the tunnel peer. The keys are generated as part of the negotiation and therefore do not need to be specified in the configuration. The dynamic SA includes one or more **proposal** statements that prioritizes a list of protocols and algorithms to be negotiated with the peer.

This section includes the following topics:

- [Configuring Manual Security Associations on page 385](#)
- [Configuring Dynamic Security Associations on page 390](#)
- [Clearing Security Associations on page 390](#)

Configuring Manual Security Associations

Manual SAs require no negotiation; all values, including the keys, are static and specified in the configuration. As a result, each peer must have the same configured options for communication to take place. Manual SAs are best suited for small, static networks where the distribution, maintenance, and tracking of keys are not difficult.

To configure a manual IPsec security association, include the following statements at the `[edit services ipsec-vpn rule rule-name term term-name then manual]` hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual]
direction (inbound | outbound | bidirectional) {
  authentication {
    algorithm (hmac-md5-96 | hmac-sha-256-128 | hmac-sha1-96);
    key (ascii-text key | hexadecimal key);
  }
  auxiliary-spi auxiliary-spi-value;
  encryption {
    algorithm (3des-cbc | aes-128-cbc | aes-192-cbc | aes-256-cbc | des-cbc);
    key (ascii-text key | hexadecimal key);
  }
  protocol (ah | esp | bundle);
  spi spi-value;
}
```

To configure manual SA statements, do the following:

- [Configuring the Direction for IPsec Processing on page 386](#)
- [Configuring the Protocol for a Manual IPsec SA on page 387](#)
- [Configuring the Security Parameter Index on page 387](#)
- [Configuring the Auxiliary Security Parameter Index on page 388](#)
- [Configuring Authentication for a Manual IPsec SA on page 388](#)
- [Configuring Encryption for a Manual IPsec SA on page 389](#)

Configuring the Direction for IPsec Processing

The **direction** statement specifies inbound or outbound IPsec processing. If you want to define different algorithms, keys, or security parameter index (SPI) values for each direction, you configure the **inbound** and **outbound** options. If you want the same attributes in both directions, use the **bidirectional** option.

To configure the direction of IPsec processing, include the **direction** statement at the `[edit services ipsec-vpn rule rule-name term term-name then manual]` hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual]
direction (inbound | outbound | bidirectional) {
  ...
}
```

The following two examples illustrate this:

- Example: Using Different Configuration for the Inbound and Outbound Directions

Define different algorithms, keys, and security parameter index values for each direction:

```
[edit services ipsec-vpn rule rule-name term term-name then manual]
direction bidirectional {
  protocol ah;
  spi 20001;
  authentication {
    algorithm hmac-md5-96;
```

```

        key ascii-text 123456789012abcd;
    }
}
direction outbound {
    protocol esp;
    spi 24576;
    encryption {
        algorithm 3des-cbc;
        key ascii-text 12345678901234567890abcd;
    }
}

```

- Example: Using the Same Configuration for the Inbound and Outbound Directions

Define one set of algorithms, keys, and security parameter index values that is valid in both directions:

```

[edit services ipsec-vpn rule rule-name term term-name then manual]
direction bidirectional {
    protocol ah;
    spi 20001;
    authentication {
        algorithm hmac-md5-96;
        key ascii-text 123456789012abcd;
    }
}

```

Configuring the Protocol for a Manual IPsec SA

IPsec uses two protocols to protect IP traffic: Encapsulating Security Payload (ESP) and authentication header (AH). The AH protocol is used for strong authentication. A third option, **bundle**, uses AH authentication and ESP encryption; it does not use ESP authentication because AH provides stronger authentication of IP packets.

To configure the IPsec protocol, include the **protocol** statement and specify the **ah**, **esp**, or **bundle** option at the `[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]` hierarchy level:

```

[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]
protocol (ah | bundle | esp);

```

Configuring the Security Parameter Index

An SPI is an arbitrary value that uniquely identifies which SA to use at the receiving host. The sending host uses the SPI to identify and select which SA to use to secure every packet. The receiving host uses the SPI to identify and select the encryption algorithm and key used to decrypt packets.

NOTE: Each manual SA must have a unique SPI and protocol combination. Use the auxiliary SPI when you configure the protocol statement to use the **bundle** option.

To configure the SPI, include the **spi** statement and specify a value (from 256 through 16,639) at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then manual direction *direction*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]  
spi spi-value;
```

Configuring the Auxiliary Security Parameter Index

Use the auxiliary SPI when you configure the **protocol** statement to use the **bundle** option.

NOTE: Each manual SA must have a unique SPI and protocol combination.

To configure the auxiliary SPI, include the **auxiliary-spi** statement and specify a value (from 256 through 16,639) at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then manual direction *direction*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]  
auxiliary-spi auxiliary-spi-value;
```

Configuring Authentication for a Manual IPsec SA

To configure an authentication algorithm, include the **authentication** statement and specify an authentication algorithm and a key at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then manual direction *direction*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]  
authentication {  
  algorithm (hmac-md5-96 | hmac-sha1-96 | hmac-sha-256-128)  
  key (ascii-text key | hexadecimal key);  
}
```

The algorithm can be one of the following:

- **hmac-md5-96**—Hash algorithm that authenticates packet data. It produces a 128-bit authenticator value and a 96-bit digest.
- **hmac-sha1-96**—Hash algorithm that authenticates packet data. It produces a 160-bit authenticator value and a 96-bit digest.
- **hmac-sha-256-128**—Hash algorithm that authenticates packet data. It produces a 256-bit authenticator value 256-bit digest, truncated to 128 bits.

The key can be one of the following:

- **ascii-text**—ASCII text key. With the **hmac-md5-96** option, the key contains 16 ASCII characters. With the **hmac-sha1-96** option, the key contains 20 ASCII characters.
- **hexadecimal**—Hexadecimal key. With the **hmac-md5-96** option, the key contains 32 hexadecimal characters. With the **hmac-sha1-96** option, the key contains 40 hexadecimal characters.

Configuring Encryption for a Manual IPsec SA

To configure IPsec encryption, include the **encryption** statement and specify an algorithm and key at the **[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then manual direction direction]
  encryption {
    algorithm algorithm;
    key (ascii-text key | hexadecimal key);
  }
```

The algorithm can be one of the following:

- **des-cbc**—Encryption algorithm that has a block size of 8 bytes; its key size is 64 bits long.
- **3des-cbc**—Encryption algorithm that has a block size of 24 bytes; its key size is 192 bits long.
- **aes-128-cbc**—Advanced Encryption Standard (AES) 128-bit encryption algorithm.
- **aes-192-cbc**—Advanced Encryption Standard (AES) 192-bit encryption algorithm.
- **aes-256-cbc**—Advanced Encryption Standard (AES) 256-bit encryption algorithm.

NOTE: For a list of Data Encryption Standard (DES) encryption algorithm weak and semiweak keys, see RFC 2409, *The Internet Key Exchange (IKE)*. The AES encryption algorithms use a software implementation that has much lower throughput, so DES remains the recommended option. For reference information on AES encryption, see RFC 3602, *The AES-CBC Cipher Algorithm and Its Use with IPsec*.

For **3des-cbc**, the first 8 bytes should differ from the second 8 bytes, and the second 8 bytes should be the same as the third 8 bytes.

If you configure an authentication proposal but do not include the encryption statement, the result is NULL encryption. Certain applications expect this result. If you configure no specific authentication or encryption values, the Junos OS uses the default values of **sha1** for the authentication and **3des-cbc** for the encryption.

The key can be one of the following:

- **ascii-text**—ASCII text key. With the **des-cbc** option, the key contains 8 ASCII characters. With the **3des-cbc** option, the key contains 24 ASCII characters.
- **hexadecimal**—Hexadecimal key. With the **des-cbc** option, the key contains 16 hexadecimal characters. With the **3des-cbc** option, the key contains 48 hexadecimal characters.

NOTE: You cannot configure encryption when you use the AH protocol.

Configuring Dynamic Security Associations

You configure dynamic SAs with a set of proposals that are negotiated by the security gateways. The keys are generated as part of the negotiation and therefore do not need to be specified in the configuration. The dynamic SA includes one or more proposals, which allow you to prioritize a list of protocols and algorithms to be negotiated with the peer.

To enable a dynamic SA, follow these steps:

1. Configure Internet Key Exchange (IKE) proposals and IKE policies associated with these proposals.
2. Configure IPsec proposals and an IPsec policy associated with these proposals.
3. Associate an SA with an IPsec policy by configuring the **dynamic** statement.

To configure a dynamic SA, include the **dynamic** statement and specify an IPsec policy name at the `[edit services ipsec-vpn rule rule-name term term-name then]` hierarchy level. The **ike-policy** statement is optional unless you use the preshared key authentication method.

```
[edit services ipsec-vpn rule rule-name term term-name then]
dynamic {
  ike-policy policy-name;
  ipsec-policy policy-name;
}
```

NOTE: If you want to establish a dynamic SA, the attributes in at least one configured IPsec and IKE proposal must match those of its peer.

Clearing Security Associations

You can set up the router software to clear IKE or IPsec SAs automatically when the corresponding services PIC restarts or is taken offline. To configure this property, include the **clear-ike-sas-on-pic-restart** or **clear-ipsec-sas-on-pic-restart** statement at the `[edit services ipsec-vpn]` hierarchy level:

```
[edit services ipsec-vpn]
clear-ike-sas-on-pic-restart;
clear-ipsec-sas-on-pic-restart;
```

After you add this statement to the configuration, all the IKE or IPsec SAs corresponding to the tunnels in the PIC will be cleared when the PIC restarts or goes offline.

Example: Configuring Manual SAs

This example shows how to create an IPsec tunnel by using manual security associations (SAs), and contains the following sections:

- [Requirements on page 391](#)
- [Overview and Topology on page 391](#)
- [Configuration on page 392](#)
- [Verification on page 403](#)

Requirements

This example uses the following hardware and software components:

- Four M Series, MX Series, or T Series routers with multiservices interfaces installed in them.
- Junos OS Release 9.4 and later.

No special configuration beyond device initialization is required before you can configure this feature.

Overview and Topology

A security association (SA) is a simplex connection that enables two hosts to securely communicate with each other by means of IPsec. There are two types of SAs: manual SA and dynamic SA. This example explains a manual SA configuration.

Manual SAs require no negotiation; all values, including the keys, are static and specified in the configuration. Manual SAs use statically defined security parameter index (SPI) values, algorithms, and keys, and require matching configurations on both ends of the tunnel. Each peer must have the same configured options for communication to take place.

Manual SAs are best suited for small, static networks where the distribution, maintenance, and tracking of keys are not difficult.

[Figure 21 on page 392](#) shows an IPsec topology that contains a group of four routers: Routers 1, 2, 3, and 4.

Figure 21: Manual SA Topology

Routers 2 and 3 establish an IPsec tunnel by using a multiservices PIC and manual SA settings. Routers 1 and 4 provide basic connectivity and are used to verify that the IPsec tunnel is operational.

Configuration

This example uses four routers, and involves the following configurations:

- Routers 1 and 4 are configured for basic OSPF connectivity with Routers 2 and 3 respectively.
- Routers 2 and 3 are configured for OSPF connectivity with Routers 1 and 4 respectively. Routers 2 and 3 are also configured to create an IPsec tunnel by using manual SAs between these two routers. To direct traffic to the IPsec tunnel through the multiservices interface, next-hop style service sets are configured on Routers 2 and 3, and the multiservices interfaces that are configured as the IPsec inside interface are added to the OSPF configuration on the respective routers.

NOTE: The interface types shown in this example are for indicative purpose only. For example, you can use `so-` interfaces instead of `ge-` and `sp-` instead of `ms-`.

Configuring Router 1

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 1.

```
set interfaces ge-1/0/1 description "to R2 ge-1/0/1"
set interfaces ge-1/0/1 unit 0 family inet address 10.1.12.2/30
```

```

set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set protocols ospf area 0.0.0.0 interface ge-1/0/1.0
set protocols ospf area 0.0.0.0 interface lo0.0
set routing-options router-id 10.0.0.1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router 1 for OSPF connectivity with Router 2:

1. Configure an Ethernet interface and loopback interface.

```

[edit interfaces]
user@router1# set ge-1/0/1 description "to R2 ge-1/0/1"
user@router1# set ge-1/0/1 unit 0 family inet address 10.1.12.2/30
user@router1# set lo0 unit 0 family inet address 10.0.0.1/32

```
2. Specify the OSPF area and associate the interfaces with the OSPF area.

```

[edit protocols]
user@router1# set ospf area 0.0.0.0 interface ge-1/0/1.0
user@router1# set ospf area 0.0.0.0 interface lo0.0

```
3. Configure the router ID.

```

[edit routing-options]
user@router1# set router-id 10.0.0.1

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```

user@router1# show interfaces
interfaces {
  ...
  ge-1/0/1 {
    description "to R2 ge-1/0/1";
    unit 0 {
      family inet {
        address 10.1.12.2/30;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.0.0.1/32;
      }
    }
  }
  ...
}

user@router1# show protocols ospf
ospf {

```

```

    area 0.0.0.0 {
        interface ge-1/0/1.0;
        interface lo0.0;
    }
}

user@router1# show routing-options
routing-options {
    router-id 10.0.0.1;
}

```

Configuring Router 2

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 2.

Configuring Interfaces and OSPF Connectivity (with Router 1 and Router 3) on Router 2

```

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure OSPF connectivity and IPsec tunnel parameters on Router 2:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), a loopback interface, and a multiservices interface (ms-1/2/0).

```
[edit interfaces]
user@router2# set ge-1/0/0 unit 0 description "to R3 ge-1/0/0"
user@router2# set ge-1/0/0 unit 0 family inet address 10.1.15.1/30
user@router2# set ge-1/0/1 unit 0 description "to R1 ge-1/0/0"
user@router2# set ge-1/0/1 unit 0 family inet address 10.1.12.1/30
user@router2# set ms-1/2/0 unit 0 family inet
user@router2# set ms-1/2/0 unit 1 family inet
user@router2# set ms-1/2/0 unit 1 service-domain inside
user@router2# set ms-1/2/0 unit 2 family inet
user@router2# set ms-1/2/0 unit 2 service-domain outside
user@router2# set lo0 unit 0 family inet address 10.0.0.2/32
```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
[edit protocols]
user@router2# set ospf area 0.0.0.0 interface ge-1/0/1.0
user@router2# set ospf area 0.0.0.0 interface lo0.0
user@router2# set ospf area 0.0.0.0 interface ms-1/2/0.1
```

3. Configure the router ID.

```
[edit routing-options]
user@router2# set router-ID 10.0.0.2
```

4. Configure an IPsec rule. In this step, you configure an IPsec rule and specify manual SA parameters, such as the remote-gateway address, authentication and encryption properties, and so on.

```
[edit services ipsec-vpn]
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  remote-gateway 10.1.15.2
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional protocol esp
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional spi 261
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional authentication algorithm hmac-sha1-96
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional authentication key ascii-text
  demokeyipsecmanualsa
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional encryption algorithm des-cbc
user@router2# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional encryption key ascii-text manualsa
user@router2# set rule demo-rule-r1-manual-sa match-direction input
```

5. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```
[edit services]
user@router2# set service-set demo-ss-manual-sa next-hop-service
    inside-service-interface ms-1/2/0.1
user@router2# set service-set demo-ss-manual-sa next-hop-service
    outside-service-interface ms-1/2/0.2
user@router2# set service-set demo-ss-manual-sa ipsec-vpn-options local-gateway
    10.1.15.1
user@router2# set service-set demo-ss-manual-sa ipsec-vpn-rules
    demo-rule-r1-manual-sa
```

6. Commit the configuration.

```
[edit]
user@router2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router1# show interfaces

Configuring Router 3

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 3.

```
set interfaces ge-1/0/1 unit 0 description "to R4 ge-1/0/1"  
set interfaces ge-1/0/0 unit 0 family inet address 10.1.56.1/30  
set interfaces ge-1/0/0 unit 0 description "to R2 ge-1/0/0"  
set interfaces ge-1/0/0 unit 0 family inet address 10.1.15.2/30  
set interfaces ms-1/2/0 unit 0 family inet  
set interfaces ms-1/2/0 unit 1 family inet  
set interfaces ms-1/2/0 unit 1 service-domain inside  
set interfaces ms-1/2/0 unit 2 family inet  
set interfaces ms-1/2/0 unit 2 service-domain outside  
set interfaces lo0 unit 0 family inet address 10.0.0.3/32  
set protocols ospf area 0.0.0.0 interface ge-1/0/1.0  
set protocols ospf area 0.0.0.0 interface lo0.0  
set protocols ospf area 0.0.0.0 interface ms-1/2/0.1  
set routing-options router-id 10.0.0.3  
set services ipsec-vpn rule demo-rule-r1-manual-sa term demo-term-manual-sa then  
  remote-gateway 10.1.15.1  
set services ipsec-vpn rule demo-rule-r1-manual-sa term demo-term-manual-sa then  
  manual direction bidirectional protocol esp  
set services ipsec-vpn rule demo-rule-r1-manual-sa term demo-term-manual-sa then

set services ipsec-vpn rule demo-rule-r1-manual-sa match-direction input  
set services service-set demo-ss-manual-sa next-hop-service inside-service-interface  
  ms-1/2/0.1  
set services service-set demo-ss-manual-sa next-hop-service outside-service-interface  
  ms-1/2/0.2  
set services service-set demo-ss-manual-sa ipsec-vpn-options local-gateway 10.1.15.2  
set services service-set demo-ss-manual-sa ipsec-vpn-rules demo-rule-r1-manual-sa
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure OSPF connectivity and IPsec tunnel parameters on Router 3:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), a loopback interface, and a multiservices interface (ms-1/2/0).

```
[edit interfaces]
user@router3# set ge-1/0/0 unit 0 description "to R4 ge-1/0/0"
user@router3# set ge-1/0/0 unit 0 family inet address 10.1.56.1/30
user@router3# set ge-1/0/1 unit 0 description "to R2 ge-1/0/1"
user@router3# set ge-1/0/1 unit 0 family inet address 10.1.15.2/30
user@router3# set ms-1/2/0 unit 0 family inet
user@router3# set ms-1/2/0 unit 1 family inet
user@router3# set ms-1/2/0 unit 1 service-domain inside
user@router3# set ms-1/2/0 unit 2 family inet
user@router3# set ms-1/2/0 unit 2 service-domain outside
user@router3# set lo0 unit 0 family inet address 10.0.0.3/32
```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
[edit protocols]
user@router3# set ospf area 0.0.0.0 interface ge-1/0/1.0
user@router3# set ospf area 0.0.0.0 interface lo0.0
user@router3# set ospf area 0.0.0.0 interface ms-1/2/0.1
```

3. Configure a router ID.

```
[edit routing-options]
user@router3# set router-id 10.0.0.3
```

4. Configure an IPsec rule. In this step, you configure an IPsec rule and specify manual SA parameters, such as the remote-gateway address, authentication and encryption properties, and so on.

```
[edit services ipsec-vpn]
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  remote-gateway 10.1.15.1
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional protocol esp
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional spi 261
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional authentication algorithm hmac-sha1-96
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional authentication key ascii-text
  demokeyipsecmanualsa
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional encryption algorithm des-cbc
user@router3# set rule demo-rule-r1-manual-sa term demo-term-manual-sa then
  manual direction bidirectional encryption key ascii-text manualsa
user@router3# set rule demo-rule-r1-manual-sa match-direction input
```

5. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```
[edit services]
user@router3# set service-set demo-ss-manual-sa next-hop-service
    inside-service-interface ms-1/2/0.1
user@router3# set service-set demo-ss-manual-sa next-hop-service
    outside-service-interface ms-1/2/0.2
user@router3# set service-set demo-ss-manual-sa ipsec-vpn-options local-gateway
    10.1.15.2
user@router3# set service-set demo-ss-manual-sa ipsec-vpn-rules
    demo-rule-r1-manual-sa
```

6. Commit the configuration.

```
[edit]
user@router3# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```

Configuring Router 4

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 4.

```
set interfaces ge-1/0/1 description "to R3 ge-1/0/1"  
set interfaces ge-1/0/1 unit 0 family inet address 10.1.56.2/30  
set interfaces lo0 unit 0 family inet address 10.0.0.4/32  
set protocols ospf area 0.0.0.0 interface ge-1/0/1.0  
set protocols ospf area 0.0.0.0 interface lo0.0  
set routing-options router-id 10.0.0.4
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To set up OSPF connectivity with Router 3

1. Configure the interfaces. In this step, you configure an Ethernet interface (ge-1/0/1) and a loopback interface.

```
user@router4# set interfaces ge-1/0/1 description "to R3 ge-1/0/1"  
user@router4# set interfaces ge-1/0/1 unit 0 family inet address 10.1.56.2/30  
user@router4# set interfaces lo0 unit 0 family inet address 10.0.0.4/32
```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
user@router4# set protocols ospf area 0.0.0.0 interface ge-1/0/1.0  
user@router4# set protocols ospf area 0.0.0.0 interface lo0.0
```

3. Configure the router ID.

```
[edit routing-options]  
user@router4# set router-id 10.0.0.4
```

4. Commit the configuration.

```
[edit]  
user@router4# commit
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router4# show interfaces  
interfaces {  
  ge-1/0/1 {  
    description "to R3 ge-1/0/1";  
    unit 0 {  
      family inet {
```

```

        address 10.1.56.2/30;
    }
}
lo0{
    unit 0 {
        family inet {
            address 10.0.0.4/32;
        }
    }
}
}

user@router4# show routing-options
routing-options {
    router-id 10.0.0.4;
}

user@router4# show protocols ospf
protocols {
    ospf {
        area 0.0.0.0 {
            interface lo0.0;
            interface ge-1/0/1.0;
        }
    }
}

```

Verification

To confirm that the manual SA configuration is working properly, perform the following tasks:

- [Verifying Traffic Flow Through the IPsec Tunnel on page 403](#)
- [Verifying the Security Associations on Router 2 on page 404](#)
- [Verifying the Security Associations on Router 3 on page 404](#)

Verifying Traffic Flow Through the IPsec Tunnel

Purpose Verify that the IPsec tunnel carries traffic between Router 1 and Router 4.

Action Issue a **ping** command from Router 1 to **lo0** on Router 4.

```

user@router1> ping 10.0.0.4
PING 10.0.0.4 (10.0.0.4): 56 data bytes
64 bytes from 10.0.0.4: icmp_seq=0 ttl=254 time=1.375 ms
64 bytes from 10.0.0.4: icmp_seq=1 ttl=254 time=18.375 ms
64 bytes from 10.0.0.4: icmp_seq=2 ttl=254 time=1.120 ms
^C
--- 10.0.0.4 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.120/6.957/18.375/8.075 ms

```

Meaning The output shows that Router 1 is able to reach Router 4 over the IPsec tunnel.

Verifying the Security Associations on Router 2

Purpose Verify that the security associations are active on Router 2 and that the traffic is flowing over the IPsec tunnel.

Action • To verify that the security associations are active, Issue **show services ipsec-vpn ipsec security-associations detail** on Router 2.

```
user@router2> show services ipsec-vpn ipsec security-associations detail
Service set: demo-ss-manual-sa
Rule: demo-rule-r1-manual-sa, Term: demo-term-manual-sa,
Tunnel index: 1
Local gateway: 10.1.15.1, Remote gateway: 10.1.15.2
Local identity: ipv4_subnet(any:0,[0..7]=10.0.0.0/8)
Remote identity: ipv4_subnet(any:0,[0..7]=0.0.0.0/0)
Direction: inbound, SPI: 261, AUX-SPI: 0
Mode: tunnel, Type: manual, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: des-cbc
Anti-replay service: Disabled
Direction: outbound, SPI: 261, AUX-SPI: 0
Mode: tunnel, Type: manual, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: des-cbc
Anti-replay service: Disabled
```

• To verify that traffic is traveling over the bidirectional IPsec tunnel, issue **show services ipsec-vpn ipsec statistics** on Router 2.

```
user@router2# show services ipsec-vpn ipsec statistics
PIC: ms-1/2/0, Service set: demo-ss-manual-sa
sESP Statistics:
Encrypted bytes: 1616
Decrypted bytes: 1560
Encrypted packets: 20
Decrypted packets: 19
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0
```

Meaning The **show services ipsec-vpn ipsec security-associations detail** command output shows the SA properties that you configured.

The **show services ipsec-vpn ipsec statistics** command output shows the traffic flow over the IPsec tunnel.

Verifying the Security Associations on Router 3

Purpose Verify the security associations and flow of traffic over the IPsec tunnel.

Action • To verify that the security associations are active, Issue **show services ipsec-vpn ipsec security-associations detail** on Router 3.

```

user@router3> show services ipsec-vpn ipsec security-associations detail
Service set: demo-ss-manual-sa
Rule: demo-rule-r1-manual-sa, Term: demo-term-manual-sa,
Tunnel index: 1
Local gateway: 10.1.15.2, Remote gateway: 10.1.15.1
Local identity: ipv4_subnet(any:0,[0..7]=10.0.0.0/8)
Remote identity: ipv4_subnet(any:0,[0..7]=0.0.0.0/0)
Direction: inbound, SPI: 261, AUX-SPI: 0
Mode: tunnel, Type: manual, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: des-cbc
Anti-replay service: Disabled
Direction: outbound, SPI: 261, AUX-SPI: 0
Mode: tunnel, Type: manual, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: des-cbc
Anti-replay service: Disabled

```

- To verify that traffic is traveling over the bidirectional IPsec tunnel, issue **show services ipsec-vpn ipsec statistics** on Router 3.

```

user@router3# show services ipsec-vpn ipsec statistics
PIC: ms-1/2/0, Service set: demo-ss-manual-sa
ESP Statistics:
Encrypted bytes: 1560
Decrypted bytes: 1616
Encrypted packets: 19
Decrypted packets: 20
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0

```

Meaning The **show services ipsec-vpn ipsec security-associations detail** command output shows the SA properties that you configured.

The **show services ipsec-vpn ipsec statistics** command output shows the traffic flow over the IPsec tunnel.

 - [Example: Configuring IKE Dynamic SAs on page 466](#)

Configuring IKE Proposals

Dynamic security associations (SAs) require IKE configuration. With dynamic SAs, you configure IKE first, and then the SA. IKE creates the dynamic SAs and negotiates them for IPsec. The IKE configuration defines the algorithms and keys used to establish the secure IKE connection with the peer security gateway.

You can configure one or more IKE proposals. Each proposal is a list of IKE attributes to protect the IKE connection between the IKE host and its peer.

To configure an IKE proposal, include the **proposal** statement and specify a name at the **[edit services ipsec-vpn ike]** hierarchy level:

```
[edit services ipsec-vpn ike]
proposal proposal-name {
  authentication-algorithm (md5 | sha1 | sha-256);
  authentication-method (pre-shared-key | rsa-signatures);
  dh-group (group1 | group2 | group5 | group14 | group19 | group20);
  encryption-algorithm algorithm;
  lifetime-seconds seconds;
}
```

This section includes the following topics:

- [Configuring the Authentication Algorithm for an IKE Proposal on page 406](#)
- [Configuring the Authentication Method for an IKE Proposal on page 406](#)
- [Configuring the Diffie-Hellman Group for an IKE Proposal on page 407](#)
- [Configuring the Encryption Algorithm for an IKE Proposal on page 408](#)
- [Configuring the Lifetime for an IKE SA on page 408](#)
- [Example: Configuring an IKE Proposal on page 409](#)

Configuring the Authentication Algorithm for an IKE Proposal

To configure the authentication algorithm for an IKE proposal, include the **authentication-algorithm** statement at the **[edit services ipsec-vpn ike proposal proposal-name]** hierarchy level:

```
[edit services ipsec-vpn ike proposal proposal-name]
authentication-algorithm (md5 | sha1 | sha-256);
```

The authentication algorithm can be one of the following:

- **md5**—Produces a 128-bit digest.
- **sha1**—Produces a 160-bit digest.
- **sha-256**—Produces a 256-bit digest.

NOTE: For reference information on Secure Hash Algorithms (SHAs), see Internet draft [draft-eastlake-sha2-02.txt](#), *Secure Hash Algorithms (SHA and HMAC-SHA)* (expires July 2006).

Configuring the Authentication Method for an IKE Proposal

To configure the authentication method for an IKE proposal, include the **authentication-method** statement at the **[edit services ipsec-vpn ike proposal proposal-name]** hierarchy level:

```
[edit services ipsec-vpn ike proposal proposal-name]
authentication-method (dsa-signatures | pre-shared-keys | rsa-signatures);
```

NOTE: In IKEv1, the authentication method for SAs is negotiated with the remote peer based on the type of authentication method configured in the IKE proposal. In IKEv2, such a negotiation is not performed with the remote peer. Instead, each IKE peer uses the authentication method that is locally configured for them.

For SAs in IKEv2, the authentication method is the default value as IKEv1 if an authentication method is not configured in the IKE proposal. If you are configuring an authentication method for IKEv2, you must have the same authentication method configured for all proposals referenced in the policy.

The authentication method can be one of the following:

- **pre-shared-keys**—A key derived from an out-of-band mechanism; the key authenticates the exchanges
- **rsa-signatures**—Public key algorithm (supports encryption and digital signatures)

Configuring the Diffie-Hellman Group for an IKE Proposal

Diffie-Hellman is a public-key cryptography scheme that allows two parties to establish a shared secret over an insecure communications channel. It is also used within IKE to establish session keys.

To configure the Diffie-Hellman group for an IKE proposal, include the **dh-group** statement at the `[edit services ipsec-vpn ike proposal proposal-name]` hierarchy level:

```
[edit services ipsec-vpn ike proposal proposal-name]
dh-group (group1 | group2 | group5 | group14 | group19 | group20);
```

The group can be one of the following:

- **group1**—Specifies that IKE uses the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group2**—Specifies that IKE uses the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group5**—Specifies that IKE uses the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group14**—Specifies that IKE uses the 2048-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group19**—Specifies that IKE uses the 256-bit random Elliptic Curve Diffie-Hellman Group when performing the new Diffie-Hellman exchange.
- **group20**—Specifies that IKE uses the 384-bit random Elliptic Curve Diffie-Hellman Group when performing the new Diffie-Hellman exchange.

Using a Diffie-Hellman group based on a greater number of bits results a more secure IKE tunnel than using a group based on fewer bits. However, this additional security might require additional processing time.

Configuring the Encryption Algorithm for an IKE Proposal

To configure the encryption algorithm for an IKE proposal, include the **encryption-algorithm** statement at the **[edit services ipsec-vpn ike proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ike proposal proposal-name]  
  encryption-algorithm algorithm;
```

The encryption algorithm can be one of the following:

- **3des-cbc**—Cipher block chaining encryption algorithm with a key size of 24 bytes; its key size is 192 bits long.
- **des-cbc**—Cipher block chaining encryption algorithm with a key size of 8 bytes; its key size is 56 bits long.
- **aes-128-cbc**—Advanced Encryption Standard (AES) 128-bit encryption algorithm.
- **aes-192-cbc**—Advanced Encryption Standard (AES) 192-bit encryption algorithm.
- **aes-256-cbc**—Advanced Encryption Standard (AES) 256-bit encryption algorithm.

NOTE: For a list of Data Encryption Standard (DES) encryption algorithm weak and semiweak keys, see RFC 2409, *The Internet Key Exchange (IKE)*. The AES encryption algorithms use a software implementation that has much lower throughput, so DES remains the recommended option.

For 3des-cbc, the first 8 bytes should differ from the second 8 bytes, and the second 8 bytes should be the same as the third 8 bytes.

If you configure an authentication proposal but do not include the encryption statement, the result is NULL encryption. Certain applications expect this result. If you configure no specific authentication or encryption values, the Junos OS uses the default values of sha1 for the authentication and 3des-cbc for the encryption.

Configuring the Lifetime for an IKE SA

The **lifetime-seconds** statement sets the lifetime of an IKE SA. When the IKE SA expires, it is replaced by a new SA (and SPI) or the IPsec connection is terminated.

To configure the lifetime for an IKE SA, include the **lifetime-seconds** statement at the **[edit services ipsec-vpn ike proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ike proposal proposal-name]  
  lifetime-seconds seconds;
```

By default, the IKE SA lifetime is 3600 seconds. The range is from 180 through 86,400 seconds.

NOTE: In IKEv1, the lifetime for SAs is negotiated with the remote peer based on the type of lifetime configured in the IKE proposal. In IKEv2, such a negotiation is not performed with the remote peer. Instead, each IKE peer uses the lifetime that is locally configured for them.

For SAs in IKEv2, the lifetime is either the default value as IKEv1 (if another lifetime is not configured in the IKE proposal) or all IKEv2 proposals in the IKE policy must be configured with the same lifetime value.

NOTE: For IKE proposals, there is only one SA lifetime value, specified by the Junos OS. IPsec proposals use a different mechanism.

Example: Configuring an IKE Proposal

Configure an IKE proposal:

```
[edit services ipsec-vpn ike]
proposal ike-proposal {
  authentication-method pre-shared-keys;
  dh-group group1;
  authentication-algorithm sha1;
  encryption-algorithm 3des-cbc;
}
```

Related Documentation

- [Configuring IPsec Proposals on page 415](#)
- [Configuring IKE Policies on page 409](#)
- [Configuring IPsec Policies on page 420](#)
- [Configuring Security Associations on page 385](#)

Configuring IKE Policies

An IKE policy defines a combination of security parameters (IKE proposals) to be used during IKE negotiation. It defines a peer address and the proposals needed for that connection. Depending on which authentication method is used, it defines the preshared key for the given peer or the local certificate. During the IKE negotiation, IKE looks for an IKE policy that is the same on both peers. The peer that initiates the negotiation sends all its policies to the remote peer, and the remote peer tries to find a match.

A match is made when both policies from the two peers have a proposal that contains the same configured attributes. If the lifetimes are not identical, the shorter lifetime between the two policies (from the host and peer) is used. The configured preshared key must also match its peer.

Starting with Junos OS Release 11.4, both IKEv1 and IKEv2 are supported by default on all M Series, MX Series, and T Series routers. You can configure the specific IKE phase to be supported for the negotiation. However, if only IKEv1 is supported, the Junos OS rejects

IKEv2 negotiations. Similarly, if only IKEv2 is supported, the Junos OS rejects all IKEv1 negotiations.

The key management process (kmd) daemon determines which version of IKE is used in a negotiation. If kmd is the IKE initiator, it uses IKEv1 by default and retains the configured version for negotiations. If kmd is the IKE responder, it accepts connections from both IKEv1 and IKEv2.

You can create multiple, prioritized proposals at each peer to ensure that at least one proposal matches a remote peer's proposal.

First, you configure one or more IKE proposals; then you associate these proposals with an IKE policy. You can also prioritize a list of proposals used by IKE in the **policy** statement by listing the proposals you want to use, from first to last.

To configure an IKE policy, include the **policy** statement and specify a policy name at the **[edit services ipsec-vpn ike]** hierarchy level:

```
[edit services ipsec-vpn ike]
policy policy-name {
  description description;
  local-certificate identifier;
  local-id (ipv4_addr ipv4-address | ipv6_addr ipv6-address | key-id identifier);
  version (1 | 2);
  mode (aggressive | main);
  pre-shared-key (ascii-text key | hexadecimal key);
  proposals [ proposal-names ];
  remote-id {
    any-remote-id;
    ipv4_addr [ values ];
    ipv6_addr [ values ];
    key_id [ values ];
  }
  respond-bad-spi max-responses;
}
```

This section includes the following topics:

- [Configuring the IKE Phase on page 411](#)
- [Configuring the Mode for an IKE Policy on page 411](#)
- [Configuring the Proposals in an IKE Policy on page 411](#)
- [Configuring the Preshared Key for an IKE Policy on page 411](#)
- [Configuring the Local Certificate for an IKE Policy on page 412](#)
- [Configuring the Description for an IKE Policy on page 413](#)
- [Configuring Local and Remote IDs for IKE Phase 1 Negotiation on page 413](#)
- [Enabling Invalid SPI Recovery on page 414](#)
- [Example: Configuring an IKE Policy on page 414](#)

Configuring the IKE Phase

Starting with Junos OS Release 11.4, both IKEv1 and IKEv2 are supported by default on all M Series, MX Series, and T Series routers. You can configure the specific IKE phase to be supported for the negotiation. However, if only IKEv1 is supported, the Junos OS rejects IKEv2 negotiations. Similarly, if only IKEv2 is supported, the Junos OS rejects all IKEv1 negotiations.

To configure the IKE phase used, include the **version** statement at the **[edit services ipsec-vpn ike policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
  version (1 | 2);
```

Configuring the Mode for an IKE Policy

IKE policy has two modes: aggressive and main. By default, main mode is enabled. Main mode uses six messages, in three exchanges, to establish the IKE SA. (These three steps are IKE SA negotiation, a Diffie-Hellman exchange, and authentication of the peer.) Main mode also allows a peer to hide its identity.

Aggressive mode also establishes an authenticated IKE SA and keys. However, aggressive mode uses half the number of messages, has less negotiation power, and does not provide identity protection. The peer can use the aggressive or main mode to start IKE negotiation; the remote peer accepts the mode sent by the peer.

NOTE: The mode configuration is required only if the **version** option is set to 1.

To configure the mode for an IKE policy, include the **mode** statement and specify **aggressive** or **main** at the **[edit services ipsec-vpn ike policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
  mode (aggressive | main);
```

Configuring the Proposals in an IKE Policy

The IKE policy includes a list of one or more proposals associated with an IKE policy.

To configure the proposals in an IKE policy, include the **proposals** statement and specify one or more proposal names at the **[edit services ipsec-vpn ike policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
  proposals [ proposal-names ];
```

Configuring the Preshared Key for an IKE Policy

When you include the **authentication-method pre-shared-keys** statement at the **[edit services ipsec-vpn ike proposal *proposal-name*]** hierarchy level, IKE policy preshared keys authenticate peers. You must manually configure a preshared key, which must match

that of its peer. The preshared key can be an ASCII text (alphanumeric) key or a hexadecimal key.

To configure the preshared key in an IKE policy, include the **pre-shared-key** statement and a key at the **[edit services ipsec-vpn ike policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
pre-shared-key (ascii-text key | hexadecimal key);
```

The key can be one of the following:

- **ascii-text**—ASCII text key. With the **des-cbc** option, the key contains 8 ASCII characters. With the **3des-cbc** option, the key contains 24 ASCII characters.
- **hexadecimal**—Hexadecimal key. With the **des-cbc** option, the key contains 16 hexadecimal characters. With the **3des-cbc** option, the key contains 48 hexadecimal characters.

Configuring the Local Certificate for an IKE Policy

When you include the **authentication-method rsa-signatures** statement at the **[edit services ipsec-vpn ike proposal *proposal-name*]** hierarchy level, public key infrastructure (PKI) digital certificates authenticate peers. You must identify a local certificate that is sent to the peer during the IKE authentication phase.

To configure the local certificate for an IKE policy, include the **local-certificate** statement at the **[edit services ipsec-vpn ike policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
local-certificate identifier;
```

The **local-certificate** statement specifies the identifier used to obtain the end entity's certificate from the certification authority. Configuring it in an IKE policy allows you the flexibility of using a separate certificate with each remote peer if that is needed. You must also specify the identity of the certification authority by configuring the **ca-profile** statement at the **[edit security pki]** hierarchy level.

You can use the configured profiles to establish a set of trusted certification authorities for use with a particular service set. This enables you to configure separate service sets for individual clients to whom you are providing IP services; the distinct service sets provide logical separation of one set of IKE sessions from another, using different local gateway addresses, or *virtualization*. To configure the set of trusted certification authorities, include the **trusted-ca** statement at the **[edit services service-set *service-set-name* ipsec-vpn-options]** hierarchy level:

```
[edit services service-set service-set-name ipsec-vpn-options]  
trusted-ca ca-profile;
```

See the following to configure a certificate revocation list:

- [Configuring a Certificate Revocation List on page 413](#)

Configuring a Certificate Revocation List

A certificate revocation list (CRL) contains a list of digital certificates that have been cancelled before their expiration date. When a participating peer uses a digital certificate, it checks the certificate signature and validity. It also acquires the most recently issued CRL and checks that the certificate serial number is not on that CRL.

NOTE: By default, certificate revocation list verification is enabled. You can disable CRL verification by including the `disable` statement at the `[edit security pki ca-profile ca-profile-name revocation-check]` hierarchy level.

By default, if the router either cannot access the Lightweight Directory Access Protocol (LDAP) URL or retrieve a valid certificate revocation list, certificate verification fails and the IPsec tunnel is not established. To override this behavior and permit the authentication of the IPsec peer when the CRL is not downloaded, include the `disable on-download-failure` statement at the `[edit security pki ca-profile ca-profile-name revocation-check crl]` hierarchy level.

To use the CA certificate revocation list, you include statements at the `[edit security pki ca-profile ca-profile-name revocation-check]` hierarchy level. For details, see the [Junos OS System Basics Configuration Guide](#).

Configuring the Description for an IKE Policy

To specify an optional text description for an IKE policy, include the `description` statement at the `[edit services ipsec-vpn ike policy policy-name]` hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]
description description;
```

Configuring Local and Remote IDs for IKE Phase 1 Negotiation

You can optionally specify local identifiers for use in IKE phase 1 negotiation. If the `local-id` statement is omitted, the local gateway address is used.

To specify one or more local IDs, include the `local-id` statement at the `[edit services ipsec-vpn ike policy policy-name]` hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]
local-id (ipv4_addr ipv4-address | ipv6_addr ipv6-address | key-id identifier);
```

You can also specify remote gateway identifiers for which the IKE policy is used. The remote gateway address in which this policy is defined is added by default.

To specify one or more remote IDs, include the `remote-id` statement at the `[edit services ipsec-vpn ike policy policy-name]` hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]
remote-id {
  any-remote-id;
  ipv4_addr [ values ];
  ipv6_addr [ values ];
```

```
key_id [ values ];  
}
```

The **any-remote-id** option allows any remote address to connect. This option is supported only in dynamic endpoints configurations and cannot be configured along with specific values.

Enabling Invalid SPI Recovery

When peers in a security association (SA) become unsynchronized, packets with invalid security parameter index (SPI) values can be sent out, and the receiving peer drops these packets. For example, this could occur when one of the peers reboots. You can enable the device to recover when packets with invalid SPIs are received by resynchronizing the SAs.

To enable recovery from invalid SPI values, include the **respond-bad-spi** statement at the **[edit services ipsec-vpn ike policy] *policy-name*** hierarchy level:

```
[edit services ipsec-vpn ike policy policy-name]  
respond-bad-spi max-responses;
```

Example: Configuring an IKE Policy

Define two IKE policies: **policy 10.1.1.2** and **policy 10.1.1.1**. Each policy is associated with **proposal-1** and **proposal-2**. The following configuration uses only IKEv1 for negotiation.

```
[edit services ipsec-vpn]  
ike {  
  proposal proposal-1 {  
    authentication-method pre-shared-keys;  
    dh-group group1;  
    authentication-algorithm sha1;  
    encryption-algorithm 3des-cbc;  
    lifetime-seconds 1000;  
  }  
  proposal proposal-2 {  
    authentication-method pre-shared-keys;  
    dh-group group2;  
    authentication-algorithm md5;  
    encryption-algorithm des-cbc;  
    lifetime-seconds 10000;  
  }  
  proposal proposal-3 {  
    authentication-method rsa-signatures;  
    dh-group group2;

    encryption-algorithm des-cbc;  
    lifetime-seconds 10000;  
  }  
  policy 10.1.1.2 {  
    mode main;  
    proposals [ proposal-1 proposal-2 ];  
    pre-shared-key ascii-text example-pre-shared-key;  
  }  
  policy 10.1.1.1 {
```

```

local-certificate certificate-file-name;
local-key-pair private-public-key-file;
mode aggressive;
proposals [ proposal-2 proposal-3 ]
pre-shared-key hexadecimal 0102030abbcdd;
}

```

NOTE: Updates to the current IKE proposal and policy configuration are not applied to the current IKE SA; updates are applied to new IKE SAs.

If you want the new updates to take immediate effect, you must clear the existing IKE security associations so that they will be reestablished with the changed configuration. For information about how to clear the current IKE security association, see [clear services ipsec-vpn ike security-associations](#).

Configuring IPsec Proposals

An IPsec proposal lists protocols and algorithms (security services) to be negotiated with the remote IPsec peer.

To configure an IPsec proposal, include the **proposal** statement and specify an IPsec proposal name at the **[edit services ipsec-vpn ipsec]** hierarchy level:

```

[edit services ipsec-vpn ipsec]
proposal proposal-name {
  authentication-algorithm (hmac-md5-96 | hmac-sha1-96);
  description description;
  encryption-algorithm algorithm;
  lifetime-seconds seconds;
  protocol (ah | esp | bundle);
}

```

This section discusses the following topics:

- [Configuring the Protocol for a Dynamic SA on page 419](#)

Configuring the Authentication Algorithm for an IPsec Proposal

To configure the authentication algorithm for an IPsec proposal, include the **authentication-algorithm** statement at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec proposal proposal-name]  
authentication-algorithm (hmac-md5-96 | hmac-sha1-96);
```

The authentication algorithm can be one of the following:

- **hmac-md5-96**—Hash algorithm that authenticates packet data. It produces a 128-bit digest. Only 96 bits are used for authentication.
- **hmac-sha1-96**—Hash algorithm that authenticates packet data. It produces a 160-bit digest. Only 96 bits are used for authentication.

NOTE: Keep the following points in mind when you configure the authentication algorithm in an IPsec proposal:

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, an error occurs and the tunnel is not established in this scenario. For example, if one end of the tunnel contains router 1 configured with the authentication algorithm as hmac-sha-256-128 and the other end of the tunnel contains router 2 configured with the authentication algorithm as hmac-md5-96, the VPN tunnel is not established.
- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, and when one end of the tunnel contains two IPsec proposals to check whether a less secure algorithm is selected or not, an error occurs and the tunnel is not established. For example, if you configure two authentication algorithms for an IPsec proposal as hmac-sha-256-128 and hmac-md5-96 on one end of the tunnel, router 1, and if you configure the algorithm for an IPsec proposal as hmac-md5-96 on the other end of the tunnel, router 2, the tunnel is not established and the number of proposals mismatch.
- When you configure two IPsec proposals at both ends of a tunnel, such as the authentication-algorithm hmac-sha-256-128 and authentication-algorithm hmac-md5-96 statements at the [edit services ipsec-vpn ipsec proposal *proposal-name*] hierarchy level on one of the tunnel, router 1 (with the algorithms in two successive statements to specify the order), and the authentication-algorithm hmac-md5-96 and authentication-algorithm hmac-sha-256-128 statements at the [edit services ipsec-vpn ipsec proposal *proposal-name*] hierarchy level on one of the tunnel, router 2 (with the algorithms in two successive statements to specify the order, which is the reverse order of router 1), the tunnel is established in this combination as expected because the number of proposals is the same on both ends and they contain the same set of algorithms. However, the authentication algorithm selected is hmac-md5-96 and not the stronger algorithm of hmac-sha-256-128. This method of selection of the algorithm occurs because the first matching proposal is selected. Also, for a default proposal, regardless of whether the router supports the Advanced Encryption Standard (AES) encryption algorithm, the 3des-cbc algorithm is chosen and not the aes-cfb algorithm, which is because of the first algorithm in the default proposal being selected. In the sample scenario described here, on router 2, if you reverse the order of the algorithm configuration in the proposal so that it is the same order as the one specified on router 1, hmac-sha-256-128 is selected as the authentication method.
- You must be aware of the order of proposals in an IPsec policy at the time of configuration if you want the matching of proposals to happen in a certain order of preference, such as the strongest algorithm to be considered first when a match is made when both policies from the two peers have a proposal.

Configuring the Description for an IPsec Proposal

To specify an optional text description for an IPsec proposal, include the **description** statement at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec proposal proposal-name]  
description description;
```

Configuring the Encryption Algorithm for an IPsec Proposal

To configure encryption algorithm for an IPsec proposal, include the **encryption-algorithm** statement at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec proposal proposal-name]  
encryption-algorithm algorithm;
```

The encryption algorithm can be one of the following:

- **3des-cbc**—Encryption algorithm that has a block size of 24 bytes; its key size is 192 bits long.
- **des-cbc**—Encryption algorithm that has a block size of 8 bytes; its key size is 48 bits long.
- **aes-128-cbc**—Advanced Encryption Standard (AES) 128-bit encryption algorithm.
- **aes-192-cbc**—Advanced Encryption Standard (AES) 192-bit encryption algorithm.
- **aes-256-cbc**—Advanced Encryption Standard (AES) 256-bit encryption algorithm.

NOTE: For a list of Data Encryption Standard (DES) encryption algorithm weak and semiweak keys, see RFC 2409, *The Internet Key Exchange (IKE)*. The AES encryption algorithms use a software implementation that has much lower throughput, so DES remains the recommended option.

For **3des-cbc**, the first 8 bytes should differ from the second 8 bytes, and the second 8 bytes should be the same as the third 8 bytes.

If you do not configure specific authentication or encryption settings, Junos OS uses the default values of **sha1** for the authentication and **3des-cbc** for the encryption. For NULL encryption to be effective, you must always specify the Encapsulating Security Payload (ESP) protocol for the NULL encryption algorithm by including the **protocol esp** statement at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level, regardless of other system configurations.

Configuring the Lifetime for an IPsec SA

When a dynamic IPsec SA is created, two types of lifetimes are used: hard and soft. The hard lifetime specifies the lifetime of the SA. The soft lifetime, which is derived from the hard lifetime, informs the IPsec key management system that the SA is about to expire.

This allows the key management system to negotiate a new SA before the hard lifetime expires.

NOTE: In IKEv1, the lifetime for SAs is negotiated with the remote peer based on the type of lifetime configured in the IPsec proposal. In IKEv2, such a negotiation is not performed with the remote peer. Instead, each IKE peer uses the lifetime that is locally configured for them.

For SAs in IKEv2, the lifetime is either the default value as IKEv1 (if another lifetime is not configured in the IPsec proposal) or all IKEv2 proposals in the IPsec policy must be configured with the same lifetime value.

To configure the hard lifetime value, include the **lifetime-seconds** statement and specify the number of seconds at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec proposal proposal-name]
lifetime-seconds seconds;
```

The default lifetime is 28,800 seconds. The range is from 180 through 86,400 seconds.

The soft lifetime values are as follows:

- Initiator: Soft lifetime = Hard lifetime – 135 seconds.
- Responder: Soft lifetime = Hard lifetime – 90 seconds.

Configuring the Protocol for a Dynamic SA

The **protocol** statement sets the protocol for a dynamic SA. IPsec uses two protocols to protect IP traffic: ESP and AH. The ESP protocol can support authentication, encryption, or both. The AH protocol is used for strong authentication. AH also authenticates the IP packet. The **bundle** option uses AH authentication and ESP encryption; it does not use ESP authentication because AH provides stronger authentication of IP packets.

To configure the protocol for a dynamic SA, include the **protocol** statement and specify the **ah**, **esp**, or **bundle** option at the **[edit services ipsec-vpn ipsec proposal *proposal-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec proposal proposal-name]
protocol (ah | esp | bundle);
```

Configuring IPsec Policies

An IPsec policy defines a combination of security parameters (IPsec proposals) used during IPsec negotiation. It defines Perfect Forward Secrecy (PFS) and the proposals needed for the connection. During the IPsec negotiation, IPsec looks for a proposal that is the same on both peers. The peer that initiates the negotiation sends all its policies to the remote peer, and the remote peer tries to find a match.

A match is made when both policies from the two peers have a proposal that contains the same configured attributes. If the lifetimes are not identical, the shorter lifetime between the two policies (from the host and peer) is used.

You can create multiple, prioritized IPsec proposals at each peer to ensure that at least one proposal matches a remote peer's proposal.

First, you configure one or more IPsec proposals; then you associate these proposals with an IPsec policy. You can prioritize a list of proposals used by IPsec in the **policy** statement by listing the proposals you want to use, from first to last.

To configure an IPsec policy, include the **policy** statement, and specify the policy name and one or more proposals to associate with the policy, at the **[edit services ipsec-vpn ipsec]** hierarchy level:

```
[edit services ipsec-vpn ipsec]
policy policy-name {
  description description;
  perfect-forward-secrecy {
    keys (group1 | group2 | group5 | group14);
  }
  proposals [ proposal-names ];
}
```

This section includes the following topics related to configuring an IPsec policy:

- [Configuring the Description for an IPsec Policy on page 420](#)
- [Configuring Perfect Forward Secrecy on page 421](#)
- [Configuring the Proposals in an IPsec Policy on page 421](#)
- [IPsec Policy for Dynamic Endpoints on page 421](#)
- [Example: Configuring an IPsec Policy on page 422](#)

Configuring the Description for an IPsec Policy

To specify an optional text description for an IPsec policy, include the **description** statement at the **[edit services ipsec-vpn ipsec policy policy-name]** hierarchy level:

```
[edit services ipsec-vpn ipsec policy policy-name]
description description;
```

Configuring Perfect Forward Secrecy

Perfect Forward Secrecy (PFS) provides additional security by means of a Diffie-Hellman shared secret value. With PFS, if one key is compromised, previous and subsequent keys are secure because they are not derived from previous keys. This statement is optional.

To configure PFS, include the **perfect-forward-secrecy** statement and specify a Diffie-Hellman group at the **[edit services ipsec-vpn ipsec policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec policy policy-name]
perfect-forward-secrecy {
  keys (group1 | group2 | group5 | group14);
}
```

The key can be one of the following:

- **group1**—Specifies that IKE use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group2**—Specifies that IKE use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group5**—Specifies that IKE use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
- **group14**—Specifies that IKE use the 2048-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.

The higher numbered groups provide more security than the lowered numbered groups, but require more processing time.

Configuring the Proposals in an IPsec Policy

The IPsec policy includes a list of one or more proposals associated with an IPsec policy.

To configure the proposals in an IPsec policy, include the **proposals** statement and specify one or more proposal names at the **[edit services ipsec-vpn ipsec policy *policy-name*]** hierarchy level:

```
[edit services ipsec-vpn ipsec policy policy-name]
proposals [ proposal-names ];
```

IPsec Policy for Dynamic Endpoints

An IPsec policy for dynamic endpoints defines a combination of security parameters (IPsec proposals) used during IPsec negotiation between dynamic peer security gateways, in which the remote ends of tunnels do not have a statically assigned IP address. During the IPsec negotiation, the IPsec policy looks for an IPsec proposal that is the same on both peers. The peer that initiates the negotiation sends all its policies to the remote peer, and the remote peer tries to find a match. A match is made when the policies from the two peers have a proposal that contains the same configured attributes. If the lifetimes are not identical, the shorter lifetime between the two policies (from the host and peer) is used.

If no policy is set, any policy proposed by the dynamic peer is accepted.

Example: Configuring an IPsec Policy

Define an IPsec policy, **dynamic policy-1**, that is associated with two proposals (**dynamic-1** and **dynamic-2**):

```
[edit services ipsec-vpn ipsec]
proposal dynamic-1 {
  protocol esp;
  authentication-algorithm hmac-md5-96;
  encryption-algorithm 3des-cbc;
  lifetime-seconds 6000;
}
proposal dynamic-2 {
  protocol esp;
  authentication-algorithm hmac-sha1-96;
  encryption-algorithm 3des-cbc;
  lifetime-seconds 6000;
}
policy dynamic-policy-1 {
  perfect-forward-secrecy {
    keys group1;
  }
  proposals [ dynamic-1 dynamic-2 ];
}
```

NOTE: Updates to the current IPsec proposal and policy configuration are not applied to the current IPsec SA; updates are applied to new IPsec SAs.

If you want the new updates to take immediate effect, you must clear the existing IPsec security associations so that they will be reestablished with the changed configuration. For information about how to clear the current IPsec security association, see the [Junos OS System Basics and Services Command Reference](#).

Configuring IPsec Rules

To configure an IPsec rule, include the **rule** statement and specify a rule name at the **[edit services ipsec-vpn]** hierarchy level:

```
[edit services ipsec-vpn]
rule rule-name {
  match-direction (input | output);
}
```

```

term term-name {
  from {
    destination-address address;
    ipsec-inside-interface interface-name;
    source-address address;
  }
  then {
    anti-replay-window-size bits;
    backup-remote-gateway address;
    clear-dont-fragment-bit;
    dynamic {
      ike-policy policy-name;
      ipsec-policy policy-name;
    }
    initiate-dead-peer-detection;
    dead-peer-detection {
      interval seconds;
      threshold number;
    }
    manual {
      direction (inbound | outbound | bidirectional) {
        authentication {
          algorithm (hmac-md5-96 | hmac-sha1-96);
          key (ascii-text key | hexadecimal key);
        }
        auxiliary-spi spi-value;
        encryption {
          algorithm algorithm;
          key (ascii-text key | hexadecimal key);
        }
        protocol (ah | bundle | esp);
        spi spi-value;
      }
    }
    no-anti-replay;
    remote-gateway address;
    syslog;
    tunnel-mtu bytes;
  }
}

```

Each IPsec rule consists of a set of terms, similar to a firewall filter.

A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.

- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

The following sections explain how to configure the components of IPsec rules:

- [Configuring Match Direction for IPsec Rules on page 424](#)
- [Configuring Match Conditions in IPsec Rules on page 424](#)
- [Configuring Actions in IPsec Rules on page 426](#)

Configuring Match Direction for IPsec Rules

Each rule must include a **match-direction** statement that specifies whether the match is applied on the input or output side of the interface. To configure where the match is applied, include the **match-direction (input | output)** statement at the **[edit services ipsec-vpn rule *rule-name*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name]  
match-direction (input | output);
```

The match direction is used with respect to the traffic flow through the AS or Multiservices PIC. When a packet is sent to the PIC, direction information is carried along with it.

With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.

With a next-hop service set, packet direction is determined by the interface used to route the packet to the AS or Multiservices PIC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the PIC, the packet direction is output.

On the AS or Multiservices PIC, a flow lookup is performed. If no flow is found, rule processing is performed. All rules in the service set are considered. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that matches the packet direction are considered.

Configuring Match Conditions in IPsec Rules

To configure the match conditions in an IPsec rule, include the **from** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name]  
from {  
  destination-address address;  
  ipsec-inside-interface interface-name;  
  source-address address;  
}
```

You can use either the source address or the destination address as a match condition, in the same way that you would configure a firewall filter; for more information, see the *Junos OS Routing Protocols Library for Routing Devices*.

IPsec services support both IPv4 and IPv6 address formats. If you do not specifically configure either the source address or destination address, the default value **0.0.0.0/0**

(IPv4 ANY) is used. To use IPv6 ANY (**0::0/128**) as either the source or destination address, you must configure it explicitly.

For next-hop-style service sets only, the **ipsec-inside-interface** statement allows you to assign a logical interface to the tunnels established as a result of this match condition. The **inside-service-interface** statement that you can configure at the **[edit services service-set name next-hop-service]** hierarchy level allows you to specify .1 and .2 as inside and outside interfaces. However, you can configure multiple adaptive services logical interfaces with the **service-domain inside** statement and use one of them to configure the **ipsec-inside-interface** statement.

The Junos OS evaluates the criteria you configure in the **from** statement. If multiple link-type tunnels are configured within the same next-hop-style service set, the **ipsec-inside-interface** value enables the rule lookup module to distinguish a particular tunnel from other tunnels in case the source and destination addresses for all of them are **0.0.0.0/0** (ANY-ANY).

NOTE: When you configure the **ipsec-inside-interface** statement, interface-style service sets are not supported.

A special situation is provided by a term containing an “any-any” match condition (usually because the **from** statement is omitted). If there is an any-any match in a tunnel, a flow is not needed, because all flows within this tunnel use the same security association (SA) and packet selectors do not play a significant role. As a result, these tunnels will use packet-based IPsec. This strategy saves some flow resources on the PIC, which can be used for other tunnels that need a flow-based service.

The following configuration example shows an any-any tunnel configuration with no **from** statement in **term-1**. Missing selectors in the **from** clause result in a packet-based IPsec service.

```
services {
  ipsec-vpn {
    rule rule-1 {
      term term-1 {
        then {
          remote-gateway 10.1.0.1;
          dynamic {
            ike-policy ike_policy;
            ipsec-policy ipsec_policy;
          }
        }
      }
    }
    match-direction input;
  }
  .....
}
```

Flowless IPsec service is provided to link-type tunnels with an any-any matching, as well as to dynamic tunnels with any-any matching in both dedicated and shared mode.

For link-type tunnels, a mixture of flowless and flow-based IPsec is supported within a service set. If a service set includes some terms with any-any matching and some terms with selectors in the **from** clause, packet-based service is provided for the any-any tunnels and flow-based service is provided for the other tunnels with selectors.

For non link-type tunnels, if a service set contains both any-any terms and selector-based terms, flow-based service is provided to all the tunnels.

Configuring Actions in IPsec Rules

To configure actions in an IPsec rule, include the **then** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name*]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name]
then {
  anti-replay-window-size bits;
  backup-remote-gateway address;
  clear-dont-fragment-bit;
  dynamic {
    ike-policy policy-name;
    ipsec-policy policy-name;
  }
  initiate-dead-peer-detection;
  dead-peer-detection {
    interval seconds;
    threshold number;
  }
  manual {
    direction (inbound | outbound | bidirectional) {
      authentication {
        algorithm (hmac-md5-96 | hmac-sha1-96);
        key (ascii-text key | hexadecimal key);
      }
      auxiliary-spi spi-value;
      encryption {
        algorithm algorithm;
        key (ascii-text key | hexadecimal key);
      }
      protocol (ah | bundle | esp);
      spi spi-value;
    }
  }
  no-anti-replay;
  remote-gateway address;
  syslog;
  tunnel-mtu bytes;
}
```

The principal IPsec actions are to configure a dynamic or manual SA:

- You configure a dynamic SA by including the **dynamic** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level and referencing policies you have configured at the **[edit services ipsec-vpn ipsec]** and **[edit services ipsec-vpn ike]** hierarchy levels.

- You configure a manual SA by including the **manual** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level.

You can configure the following additional properties:

- [Enabling IPsec Packet Fragmentation on page 427](#)
- [Configuring Destination Addresses for Dead Peer Detection on page 427](#)
- [Configuring or Disabling IPsec Anti-Replay on page 428](#)
- [Enabling System Log Messages on page 429](#)
- [Specifying the MTU for IPsec Tunnels on page 429](#)

Enabling IPsec Packet Fragmentation

To enable fragmentation of IP version 4 (IPv4) packets in IPsec tunnels, include the **clear-dont-fragment-bit** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
  clear-dont-fragment-bit;
```

Setting the **clear-dont-fragment-bit** statement clears the Don't Fragment (DF) bit in the packet header, regardless of the packet size. If the packet size exceeds the tunnel maximum transmission unit (MTU) value, the packet is fragmented before encapsulation. For IPsec tunnels, the default MTU value is 1500 regardless of the interface MTU setting.

Configuring Destination Addresses for Dead Peer Detection

To specify the remote address to which the IPsec traffic is directed, include the **remote-gateway** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
  remote-gateway address;
```

To specify a backup remote address, include the **backup-remote-gateway** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
  backup-remote-gateway address;
```

These two statements support both IPv4 and IPv6 address formats.

Configuring the **backup-remote-gateway** statement enables the dead peer detection (DPD) protocol, which monitors the tunnel state and remote peer availability. When the primary tunnel defined by the **remote-gateway** statement is active, the backup tunnel is in standby mode. If the DPD protocol determines that the primary remote gateway address is no longer reachable, a new tunnel is established to the backup address.

If there is no incoming traffic from a peer during a defined interval of 10 seconds, the router detects a tunnel as inactive. A global timer polls all tunnels every 10 seconds and the Adaptive Services (AS) or Multiservices Physical Interface Card (PIC) sends a message listing any inactive tunnels. If a tunnel becomes inactive, the router takes the following steps to fail over to the backup address:

1. The adaptive services message triggers the DPD protocol to send a hello message to the peer.
2. If no acknowledgment is received, two retries are sent at 2-second intervals, and then the tunnel is declared dead.
3. Failover takes place if the tunnel is declared dead or there is an IPsec Phase 1 negotiation timeout. The primary tunnel is put in standby mode and the backup becomes active.
4. If the negotiation to the backup tunnel times out, the router switches back to the primary tunnel. If both peers are down, it tries the failover six times. It then stops failing over and reverts to the original configuration, with the primary tunnel active and the backup in standby mode.

You can also enable triggering of DPD hello messages without configuring a backup remote gateway by including the **initiate-dead-peer-detection** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
initiate-dead-peer-detection;
dead-peer-detection {
  interval seconds;
  threshold number;
}
```

In addition, for IKEv1 SAs you can set **interval** and **threshold** options under the **dead-peer-detection** statement when using the **initiate-dead-peer-detection** statement. These options are not applicable to IKEv2 SAs, which will use the default values. The interval is the amount of time that the peer waits for traffic from its destination peer before sending a DPD request packet, and the threshold is the maximum number of unsuccessful DPD requests to be sent before the peer is considered unavailable.

The monitoring behavior is the same as described for the **backup-remote-gateway** statement. This configuration enables the router to initiate DPD hellos when a backup IPsec gateway does not exist, and clean up the IKE and IPsec SAs in case the IKE peer is not reachable.

If the DPD protocol determines that the primary remote gateway address is no longer reachable, a new tunnel is established to the backup address. However, when you configure **initiate-dead-peer-detection** without a backup remote gateway address and the DPD protocol determines that the primary remote gateway address is no longer reachable, the tunnel is declared dead and IKE and IPsec SAs are cleaned up.

For more information on the DPD protocol, see RFC 3706, *A Traffic-Based Method of Detecting Dead Internet Key Exchange (IKE) Peers*.

Configuring or Disabling IPsec Anti-Replay

To configure the size of the IPsec antireplay window, include the **anti-replay-window-size** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
```

`anti-replay-window-size bits;`

anti-replay-window-size can take values in the range from 64 through 4096 bits. The default value is 64 bits for AS PICs and 128 bits for Multiservices PICs and DPCs. AS PICs can support a maximum replay window size of 1024 bits, whereas Multiservices PICs and DPCs can support a maximum replay window size of 4096 bits. When the software is committing an IPsec configuration, the key management process (kmd) is unable to differentiate between the service interface types. As a result, if the maximum antireplay window size exceeds 1024 for AS PICs, the commit succeeds and no error message is produced. However, the software internally sets the antireplay window size for AS PICs to 1024 bits even if the configured value of the **anti-replay-window-size** is larger.

To disable the IPsec antireplay feature, include the **no-anti-replay** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
no-anti-replay;
```

By default, antireplay service is enabled. Occasionally this can cause interoperability issues with other vendors' equipment.

Enabling System Log Messages

To record an alert in the system logging facility, include the **syslog** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
syslog;
```

Specifying the MTU for IPsec Tunnels

To configure a specific maximum transmission unit (MTU) value for IPsec tunnels, include the **tunnel-mtu** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level:

```
[edit services ipsec-vpn rule rule-name term term-name then]
tunnel-mtu bytes;
```

NOTE: The **tunnel-mtu** setting is the only place you need to configure an MTU value for IPsec tunnels. Inclusion of an **mtu** setting at the **[edit interfaces sp-fpc/pic/port unit logical-unit-number family inet]** hierarchy level is not supported.

Related Documentation

- [Configuring IPsec Rule Sets on page 429](#)
- [Configuring Security Associations on page 385](#)

Configuring IPsec Rule Sets

The **rule-set** statement defines a collection of IPsec rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then, you specify the order of the rules by

including the **rule-set** statement at the **[edit services ipsec-vpn]** hierarchy level with a **rule** statement for each rule:

```
[edit services ipsec-vpn]
rule-set rule-set-name {
  rule rule-name;
}
```

The router software processes the rules in the order in which you specify them in the configuration. If a term in a rule matches the packet, the router performs the corresponding action and the rule processing stops. If no term in a rule matches the packet, processing continues to the next rule in the rule set. If none of the rules match the packet, the packet is dropped by default.

Service Sets for IPsec Tunnels

The Adaptive Services PIC supports two types of service sets when you configure IPsec tunnels. Because they are used for different purposes, it is important to know the differences between these service set types.

- **Next-hop service set**—Supports multicast and multicast-style dynamic routing protocols (such as OSPF) over IPsec. Next-hop service sets allow you to use *inside* and *outside* logical interfaces on the Adaptive Services PIC to connect with multiple routing instances. They also allow the use of Network Address Translation (NAT) and stateful firewall capabilities. However, next-hop service sets do not monitor Routing Engine traffic by default and require configuration of multiple service sets to support traffic from multiple interfaces.
- **Interface service set**—Applied to a physical interface and similar to a stateless firewall filter. They are easy to configure, can support traffic from multiple interfaces, and can monitor Routing Engine traffic by default. However, they cannot support dynamic routing protocols or multicast traffic over the IPsec tunnel.

In general, we recommend that you use next-hop service sets because they support routing protocols and multicast over the IPsec tunnel, they are easier to understand, and the routing table makes forwarding decisions without administrative intervention.

- [Understanding Junos VPN Site Secure on page 371](#)
 - [Configuring Junos VPN Site Secure or IPsec VPN on page 507](#)

Configuring IPsec Service Sets

IPsec service sets require additional specifications that you configure at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level:

```
[edit services service-set service-set-name ipsec-vpn-options]
anti-replay-window-size bits;
```

```

clear-dont-fragment-bit;
copy-dont-fragment-bit
set-dont-fragment-bit
ike-access-profile profile-name;
local-gateway address;
no-anti-replay;
passive-mode-tunneling;
trusted-ca [ ca-profile-names ];
tunnel-mtu bytes;

```

Configuration of these statements is described in the following sections:

- [Configuring the Local Gateway Address for IPsec Service Sets on page 431](#)
- [Configuring IKE Access Profiles for IPsec Service Sets on page 432](#)
- [Configuring Certification Authorities for IPsec Service Sets on page 433](#)
- [Configuring or Disabling Antireplay Service on page 433](#)
- [Clearing the Don't-Fragment Bit on page 434](#)
- [Configuring Passive-Mode Tunneling on page 435](#)
- [Configuring the Tunnel MTU Value on page 436](#)

Configuring the Local Gateway Address for IPsec Service Sets

If you configure an IPsec service set, you must also configure a local IPv4 or IPv6 address by including the **local-gateway** statement:

- If the Internet Key Exchange (IKE) gateway IP address is in **inet.0** (the default situation), you configure the following statement:

```
local-gateway address;
```

- If the IKE gateway IP address is in a VPN routing and forwarding (VRF) instance, you configure the following statement:

```
local-gateway address routing-instance instance-name;
```

You can configure all the link-type tunnels that share the same local gateway address in a single next-hop-style service set. The value you specify for the **inside-service-interface** statement at the **[edit services service-set service-set-name]** hierarchy level should match the **ipsec-inside-interface** value, which you configure at the **[edit services ipsec-vpn rule rule-name term term-name from]** hierarchy level. For more information about IPsec configuration, see *Configuring IPsec Rules*.

NOTE: To configure link-type tunnels, you can configure AMS logical interfaces as the IPsec internal interfaces by using the **ipsec-inside-interface interface-name** statement at the **[edit services ipsec-vpn rule rule-name term term-name from]** hierarchy level.

IKE Addresses in VRF Instances

You can configure Internet Key Exchange (IKE) gateway IP addresses that are present in a VPN routing and forwarding (VRF) instance as long as the peer is reachable through the VRF instance.

For next-hop service sets, the key management process (kmd) places the IKE packets in the routing instance that contains the **outside-service-interface** value you specify, as in this example:

```
routing-instances vrf-nxthop {
  instance-type vrf;
  interface sp-1/1/0.2;
  ...
}
services service-set service-set-1 {
  next-hop-service {
    inside-service-interface sp-1/1/0.1;
    outside-service-interface sp-1/1/0.2;
  }
  ...
}
```

For interface service sets, the **service-interface** statement determines the VRF, as in this example:

```
routing-instances vrf-intf {
  instance-type vrf;
  interface sp-1/1/0.3;
  interface ge-1/2/0.1; # interface on which service set is applied
  ...
}
services service-set service-set-2 {
  interface-service {
    service-interface sp-1/1/0.3;
  }
  ...
}
```

Configuring IKE Access Profiles for IPsec Service Sets

For dynamic endpoint tunneling only, you need to reference the IKE access profile configured at the **[edit access]** hierarchy level. To do this, include the **ike-access-profile** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level:

```
[edit services service-set service-set-name ipsec-vpn-options]
ike-access-profile profile-name;
```

The **ike-access-profile** statement must reference the same name as the **profile** statement you configured for IKE access at the **[edit access]** hierarchy level. You can reference only one access profile in each service set. This profile is used to negotiate IKE and IPsec security associations with dynamic peers only.

NOTE: If you configure an IKE access profile in a service set, no other service set can share the same **local-gateway** address.

Also, you must configure a separate service set for each VRF. All interfaces referenced by the **ipsec-inside-interface** statement within a service set must belong to the same VRF.

Configuring Certification Authorities for IPsec Service Sets

You can specify one or more trusted certification authorities by including the **trusted-ca** statement:

```
trusted-ca [ ca-profile-names ];
```

When you configure public key infrastructure (PKI) digital certificates in the IPsec configuration, each service set can have its own set of trusted certification authorities. The names you specify for the **trusted-ca** statement must match profiles configured at the **[edit security pki]** hierarchy level; for more information, see the *Junos OS Administration Library for Routing Devices*. For more information about IPsec digital certificate configuration, see *Configuring IPsec Rules*.

Configuring or Disabling Antireplay Service

You can include the **anti-replay-window-size** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level to specify the size of the antireplay window.

```
anti-replay-window-size bits;
```

This statement is useful for dynamic endpoint tunnels for which you cannot configure the **anti-replay-window-size** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level.

For static IPsec tunnels, this statement sets the antireplay window size for all the static tunnels within this service set. If a particular tunnel needs a specific value for antireplay window size, set the **anti-replay-window-size** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level. If antireplay check has to be disabled for a particular tunnel in this service set, set the **no-anti-replay** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level.

NOTE: The **anti-replay-window-size** and **no-anti-replay** settings at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level override the settings specified at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level.

You can also include the **no-anti-replay** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level to disable IPsec antireplay service. It occasionally causes interoperability issues for security associations.

no-anti-replay;

This statement is useful for dynamic endpoint tunnels for which you cannot configure the **no-anti-replay** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level.

For static IPsec tunnels, this statement disables the antireplay check for all the tunnels within this service set. If antireplay check has to be enabled for a particular tunnel, then set the **anti-replay-window-size** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level.

NOTE: Setting the **anti-replay-window-size** and **no-anti-replay** statements at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level overrides the settings specified at the **[edit services service-set *service-set-name* ipsec-vpn-options]** hierarchy level.

Clearing the Don't-Fragment Bit

You can include the **clear-dont-fragment-bit** statement at the **[edit services service-set *service-set-name* ipsec-vpn-options]** hierarchy level to clear the Don't Fragment (DF) bit on all IP version 4 (IPv4) packets entering the IPsec tunnel. If the encapsulated packet size exceeds the tunnel maximum transmission unit (MTU), the packet is fragmented before encapsulation.

clear-dont-fragment-bit;

This statement is useful for dynamic endpoint tunnels, for which you cannot configure the **clear-dont-fragment-bit** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level.

For static IPsec tunnels, setting this statement clears the DF bit on packets entering all the static tunnels within this service set. If you want to clear the DF bit on packets entering a specific tunnel, set the **clear-dont-fragment-bit** statement at the **[edit services ipsec-vpn rule *rule-name* term *term-name* then]** hierarchy level.

In packets that are transmitted through dynamic endpoint IPsec tunnels, you can enable the value set in the Don't Fragment (DF) bit of the packet entering the tunnel to be copied only to the outer header of the IPsec packet and to not cause any modification to the DF bit in the inner header of the IPsec packet. If the packet size exceeds the tunnel maximum transmission unit (MTU) value, the packet is fragmented before encapsulation. For IPsec tunnels, the default MTU value is 1500 regardless of the interface MTU setting. To copy the DF bit value to only the outer header and not modify the inner header, use the **copy-dont-fragment-bit** statement at the **[edit services service-set *service-set-name* ipsec-vpn-options]** hierarchy level. You can also configure the DF bit to be set only in the outer IPv4 header of the IPsec packet and not be defined in the inner IPv4 header. To configure the DF bit in only the outer header of the IPsec packet and to leave the inner header unmodified, include the **set-dont-fragment-bit** statement at the **[edit services service-set *service-set-name* ipsec-vpn-options]** hierarchy level. These settings apply for dynamic endpoint tunnels and not for static tunnels, for which you need to include the **copy-dont-fragment-bit** and **set-dont-fragment-bit** statements at the **[edit services**

`ipsec-vpn rule rule-name term term-name then`] hierarchy level to clear the DF bit in the IPv4 packets that enter the static tunnel. These functionalities are supported on MX Series routers with MS-MICs and MS-MPCs.

Configuring Passive-Mode Tunneling

You can include the `passive-mode-tunneling` statement at the `[edit services service-set service-set-name ipsec-vpn-options]` hierarchy level to enable the service set to tunnel malformed packets.

```
[edit services service-set service-set-name ipsec-vpn-options]
passive-mode-tunneling;
```

This functionality bypasses the active IP checks, such as version, TTL, protocol, options, address and other land attack checks, and tunnels the packets as is. If this statement is not configured, packets failing the IP checks are dropped in the PIC. In passive mode, the inner packet is not touched; hence, an ICMP error is not generated, if the packet size exceeds the tunnel MTU value.

The IPsec tunnel is not treated as a next hop and TTL is not decremented. Because an ICMP error is not generated if the packet size exceeds the tunnel MTU value, the packet will be tunnelled even if it crosses the tunnel MTU threshold.

NOTE: This functionality is similar to that provided by the `no-ipsec-tunnel-in-traceroute` statement, described in *Disabling IPsec Tunnel Endpoint in Traceroute*. Starting with Junos OS Release 13.3R4 and 14.2R1, passive mode tunneling is supported on MS-MICs and MS-MPCs.

NOTE: The `header-integrity-check` option that is supported on MS-MICs and MS-MPCs to verify the packet header for anomalies in IP, TCP, UDP, and ICMP information and flag such anomalies and errors has a functionality that is opposite to the functionality caused by passive mode tunneling. If you configure both the `header-integrity-check` statement and the `passive-mode-tunneling` statement on MS-MICs and MS-MPCs, and attempt to commit such a configuration, an error is displayed during commit.

The passive mode tunneling functionality (by including the `passive-mode-tunneling` statement at the `[edit services service-set service-set-name ipsec-vpn-options]` hierarchy level) is a superset of the capability to disable IPsec tunnel endpoint in the traceroute output (by including `no-ipsec-tunnel-in-traceroute` statement at the `[edit services ipsec-vpn]` hierarchy level). Passive mode tunneling also bypasses the active IP checks and tunnel MTU check in addition to not treating an IPsec tunnel as a next-hop as configured by the `no-ipsec-tunnel-in-traceroute` statement.

Configuring the Tunnel MTU Value

You can include the **tunnel-mtu** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level to set the maximum transmission unit (MTU) value for IPsec tunnels.

```
tunnel-mtu bytes;
```

This statement is useful for dynamic endpoint tunnels for which you cannot configure the **tunnel-mtu** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level.

For static IPsec tunnels, this statement sets the tunnel MTU value for all the tunnels within this service set. If you need a specific value for a particular tunnel, then set the **tunnel-mtu** statement at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level.

NOTE: The **tunnel-mtu** setting at the **[edit services ipsec-vpn rule rule-name term term-name then]** hierarchy level overrides the value specified at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level.

Tracing Junos VPN Site Secure Operations

NOTE: Junos VPN Site Secure is a suite of IPsec features supported on multiservices line cards (MS-DPC, MS-MPC, and MS-MIC), and was previously referred to as IPsec services.

Trace operations track IPsec events and record them in a log file in the **/var/log** directory. By default, this file is named **/var/log/kmd**.

To trace IPsec operations, include the **traceoptions** statement at the **[edit services ipsec-vpn]** hierarchy level:

```
[edit services ipsec-vpn]
traceoptions {
  file <filename> <files number> <match regular-expression> <size bytes> <world-readable |
    no-world-readable>;
  flag flag;
  level level;
  no-remote-trace;
}
```

You can specify the following IPsec tracing flags:

- **all**—Trace everything.
- **certificates**—Trace certificates events.
- **database**—Trace security associations database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **snmp**—Trace SNMP operations.
- **timer**—Trace internal timer events.

The **level** statement sets the key management process (kmd) tracing level. The following values are supported:

- **all**—Match all levels.
- **error**—Match error conditions.
- **info**—Match informational messages.
- **notice**—Match conditions that should be handled specially.
- **verbose**—Match verbose messages.
- **warning**—Match warning messages.

This section includes the following topics:

- [Disabling IPsec Tunnel Endpoint in Traceroute on page 437](#)
- [Tracing IPsec PKI Operations on page 438](#)

Disabling IPsec Tunnel Endpoint in Traceroute

If you include the **no-ipsec-tunnel-in-traceroute** statement at the **[edit services ipsec-vpn]** hierarchy level, the IPsec tunnel is not treated as a next hop and the time to live (TTL) is not decremented. Also, if the TTL reaches zero, an ICMP time exceeded message is not generated.

```
[edit services ipsec-vpn]
no-ipsec-tunnel-in-traceroute;
```

NOTE: This functionality is also provided by the **passive-mode-tunneling** statement. You can use the **no-ipsec-tunnel-in-traceroute** statement in specific scenarios in which the IPsec tunnel should not be treated as a next hop and passive mode is not desired.

Tracing IPsec PKI Operations

Trace operations track IPsec PKI events and record them in a log file in the `/var/log` directory. By default, this file is named `/var/log/pkid`.

To trace IPsec PKI operations, include the **traceoptions** statement at the **[edit security pki]** hierarchy level:

```
[edit security pki]
traceoptions {
  file filename <files number> <match regular-expression> <size maximum-file-size>
    <world-readable | no-world-readable>;
  flag flag (all | certificate-verification | enrollment | online-crl-check);
}
```

You can specify the following PKI tracing flags:

- **all**—Trace everything.
- **certificates**—Trace certificates events.
- **database**—Trace security associations database events.
- **general**—Trace general events.
- **ike**—Trace IKE module processing.
- **parse**—Trace configuration processing.
- **policy-manager**—Trace policy manager processing.
- **routing-socket**—Trace routing socket messages.
- **snmp**—Trace SNMP operations.
- **timer**—Trace internal timer events.

Multitask Example: Configuring IPsec Services

The following example-based instructions show how to configure IPsec services. The configuration involves defining an IKE policy, an IPsec policy, IPsec rules, trace options, and service sets.

This topic includes the following tasks:

1. [Configuring the IKE Proposal on page 439](#)
2. [Configuring the IKE Policy \(and Referencing the IKE Proposal\) on page 439](#)
3. [Configuring the IPsec Proposal on page 440](#)
4. [Configuring the IPsec Policy \(and Referencing the IPsec Proposal\) on page 441](#)
5. [Configuring the IPsec Rule \(and Referencing the IKE and IPsec Policies\) on page 441](#)

6. [Configuring IPsec Trace Options on page 442](#)
7. [Configuring the Access Profile \(and Referencing the IKE and IPsec Policies\) on page 443](#)
8. [Configuring the Service Set \(and Referencing the IKE Profile and the IPsec Rule\) on page 444](#)

Configuring the IKE Proposal

The IKE proposal configuration defines the algorithms and keys used to establish the secure IKE connection with the peer security gateway. For more information about IKE proposals, see *Configuring IKE Proposals*.

To define the IKE proposal:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```
2. Configure the authentication method, which is **pre-shared keys** in this example:

```
[edit services ipsec-vpn]
user@host# set ike proposal test-IKE-proposal authentication-method pre-shared-keys
```
3. Configure the Diffie-Hellman Group and specify a name—for example, **group1**:

```
[edit services ipsec-vpn]
user@host# set ike proposal test-IKE-proposal dh-group group1
```
4. Configure the authentication algorithm, which is **sha1** in this example:

```
[edit services ipsec-vpn]
user@host# set ike proposal test-IKE-proposal authentication-algorithm sha1
```
5. Configure the encryption algorithm, which is **aes-256-cbc** in this example:

```
[edit services ipsec-vpn]
user@host# set ike proposal test-IKE-proposal encryption-algorithm aes-256-cbc
```

The following sample output shows the configuration of the IKE proposal:

```
[edit services ipsec-vpn]
user@host# show ike
proposal test-IKE-proposal {
    authentication-method pre-shared-keys;
    dh-group group1;
    authentication-algorithm sha1;
    encryption-algorithm aes-256-cbc;
}
```

Configuring the IKE Policy (and Referencing the IKE Proposal)

The IKE policy configuration defines the proposal, mode, addresses, and other security parameters used during IKE negotiation. For more information about IKE policies, see *Configuring IKE Policies*.

To define the IKE policy and reference the IKE proposal:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```

2. Configure the IKE first phase mode—for example, **main**:

```
[edit services ipsec-vpn]
user@host# set ike policy test-IKE-policy mode main
```

3. Configure the proposal, which is **test-IKE-proposal** in this example:

```
[edit services ipsec-vpn]
user@host# set ike policy test-IKE-policy proposals test-IKE-proposal
```

4. Configure the local identification with an IPv4 address—for example, **192.168.255.2**:

```
[edit services ipsec-vpn]
user@host# set ike policy test-IKE-policy local-id ipv4_addr 192.168.255.2
```

5. Configure the preshared key in ASCII text format, which is **TEST** in this example:

```
[edit services ipsec-vpn]
user@host# set ike policy test-IKE-policy pre-shared-key ascii-text TEST
```

The following sample output shows the configuration of the IKE policy:

```
[edit services ipsec-vpn]
user@host# show ike
policy test-IKE-policy {
    mode main;
    proposals test-IKE-proposal;
    local-id ipv4_addr 192.168.255.2;
    pre-shared-key ascii-text TEST;
}
```

Configuring the IPsec Proposal

The IPsec proposal configuration defines the protocols and algorithms (security services) that are required to negotiate with the remote IPsec peer. For more information about IPsec proposals, see *Configuring IPsec Proposals*.

To define the IPsec proposal:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```

2. Configure the IPsec protocol for the proposal—for example, **esp**:

```
[edit services ipsec-vpn]
user@host# set ipsec proposal test-IPsec-proposal protocol esp
```

3. Configure the authentication algorithm for the proposal, which is **hmac-sha1-96** in this example:

```
[edit services ipsec-vpn]
user@host# set ipsec proposal test-IPsec-proposal authentication-algorithm
hmac-sha1-96
```

4. Configure the encryption algorithm for the proposal, which is **aes-256-cbc** in this example:

```
[edit services ipsec-vpn]
```

```
user@host# set ipsec proposal test-IPsec-proposal encryption-algorithm aes-256-cbc
```

The following sample output shows the configuration of the IPsec proposal:

```
[edit services ipsec-vpn]
user@host# show ike
proposal test-IPsec-proposal {
  protocol esp;
  authentication-algorithm hmac-sha1-96;
  encryption-algorithm aes-256-cbc;
}
```

Configuring the IPsec Policy (and Referencing the IPsec Proposal)

The IPsec policy configuration defines a combination of security parameters (IPsec proposals) used during IPsec negotiation. It defines PFS and the proposals needed for the connection. For more information about IPsec policies, see *Configuring IPsec Policies*.

To define the IPsec policy and reference the IPsec proposal:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```

2. Configure the keys for perfect forward secrecy in the IPsec policy—for example, **group1**:

```
[edit services ipsec-vpn]
user@host# set ipsec policy test-IPsec-policy perfect-forward-secrecy keys group1
```

3. Configure a set of IPsec proposals in the IPsec policy—for example, **test-IPsec-proposal**:

```
[edit services ipsec-vpn]
user@host# set ipsec policy test-IPsec-policy proposals test-IPsec-proposal
```

The following sample output shows the configuration of the IPsec policy:

```
[edit services ipsec-vpn]
user@host# show ipsec policy test-IPsec-policy
perfect-forward-secrecy {
  keys group1;
}
proposals test-IPsec-proposal;
```

Configuring the IPsec Rule (and Referencing the IKE and IPsec Policies)

The IPsec rule configuration defines the direction that specifies whether the match is applied on the input or output side of the interface. The configuration also consists of a set of terms that specify the match conditions and applications that are included and excluded and also specify the actions and action modifiers to be performed by the router software. For more information about IPsec rules, see *Configuring IPsec Rules*.

To define the IPsec rule and reference the IKE and IPsec policies:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```

2. Configure the IP destination address for the IPsec term in the IPsec rule—for example, **192.168.255.2/32**:

```
[edit services ipsec-vpn]
user@host# set rule test-IPsec-rule term 10 from destination-address 192.168.255.2/32
```

3. Configure the remote gateway address for the IPsec term in the IPsec rule—for example, **0.0.0.0**:

```
[edit services ipsec-vpn]
user@host# set rule test-IPsec-rule term 10 then remote-gateway 0.0.0.0
```

4. Configure a dynamic security association for IKE policy for the IPsec term in the IPsec rule, which is **test-IKE-policy** in this example:

```
[edit services ipsec-vpn]
user@host# set rule test-IPsec-rule term 10 then dynamic ike-policy test-IKE-policy
```

5. Configure a dynamic security association for IKE proposal for the IPsec term in the IPsec rule, which is **test-IPsec-proposal** in this example:

```
[edit services ipsec-vpn]
user@host# set rule test-IPsec-rule term 10 then dynamic ipsec-policy test-IPsec-policy
```

6. Configure a direction for which the rule match is being applied in the IPsec rule—for example, **input**:

```
[edit services ipsec-vpn]
user@host# set rule test-IPsec-rule match-direction input
```

The following sample output shows the configuration of the IPsec rule:

```
[edit services ipsec-vpn]
user@host# show rule test-IPsec-rule
term 10 {
  from {
    destination-address {
      192.168.255.2/32;
    }
  }
  then {
    remote-gateway 0.0.0.0;
    dynamic {
      ike-policy test-IKE-policy;
      ipsec-policy test-IPsec-policy;
    }
  }
}
match-direction input;
```

Configuring IPsec Trace Options

The IPsec trace options configuration tracks IPsec events and records them in a log file in the **/var/log** directory. By default, this file is named **/var/log/kmd**. For more information about IPsec rules, see *Tracing IPsec Operations*.

To define the IPsec trace options:

1. In configuration mode, go to the following hierarchy level:

```
user@host# edit services ipsec-vpn
```

2. Configure the trace file, which is **ipsec.log** in this example:

```
[edit services ipsec-vpn]
user@host# set traceoptions file ipsec.log
```

3. Configure all the tracing parameters with the option **all** in this example:

```
[edit services ipsec-vpn]
user@host# set traceoptions flag all
```

The following sample output shows the configuration of the IPsec trace options:

```
[edit services ipsec-vpn]
user@host# show traceoptions
file ipsec.log;
flag all;
```

Configuring the Access Profile (and Referencing the IKE and IPsec Policies)

The access profile configuration defines the access profile and references the IKE and IPsec policies. For more information about access profile, see *Configuring an IKE Access Profile*.

To define the access profile and reference the IKE and IPsec policies:

1. In configuration mode, go to the following hierarchy level:

```
user@host# [edit access]
```

2. Configure the list of local and remote proxy identity pairs with the **allowed-proxy-pair** option. In this example, **10.0.0.0/24** is the IP address for local proxy identity and **10.0.1.0/24** is the IP address for remote proxy identity:

```
[edit access]
user@host# set profile IKE-profile-TEST client * ike allowed-proxy-pair local
10.0.0.0/24 remote 10.0.1.0/24
```

3. Configure the IKE policy—for example, **test-IKE-policy**:

```
[edit access]
user@host# set profile IKE-profile-TEST client * ike ike-policy test-IKE-policy
```

4. Configure the IPsec policy—for example, **test-IPsec-policy**:

```
[edit access]
user@host# set profile IKE-profile-TEST client * ike ipsec-policy test-IPsec-policy
```

5. Configure the identity of logical service interface pool, which is **TEST-intf** in this example:

```
[edit access]
user@host# set profile IKE-profile-TEST client * ike interface-id TEST-intf
```

The following sample output shows the configuration of the access profile:

```
[edit access]
user@host# show
profile IKE-profile-TEST {
```

```
client * {  
    ike {  
        allowed-proxy-pair local 10.0.0.0/24 remote 10.0.1.0/24;  
        ike-policy test-IKE-policy;  
        ipsec-policy test-IPsec-policy; # new statement  
        interface-id TEST-intf;  
    }  
}
```

Configuring the Service Set (and Referencing the IKE Profile and the IPsec Rule)

The service set configuration defines IPsec service sets that require additional specifications and references the IKE profile and the IPsec rule. For more information about IPsec service sets, see [“Configuring IPsec Service Sets” on page 430](#).

To define the service set configuration with the next-hop service sets and IPsec VPN options:

1. In configuration mode, go to the following hierarchy level:

```
user@host# [edit services]
```

2. Configure a service set with parameters for next hop service interfaces for the inside network—for example, **sp-1/2/0.1**:

```
[edit services]
```

```
user@host# set service-set TEST next-hop-service inside-service-interface sp-1/2/0.1
```

3. Configure a service set with parameters for next hop service interfaces for the outside network—for example, **sp-1/2/0.2**:

```
[edit services]
```

```
user@host# set service-set TEST next-hop-service outside-service-interface sp-1/2/0.2
```

4. Configure the IPsec VPN options with the address and routing instance for the local gateway—for example, **192.168.255.2**:

```
[edit services]
```

```
user@host# set service-set TEST ipsec-vpn-options local-gateway 192.168.255.2
```

5. Configure the IPsec VPN options with the IKE access profile for dynamic peers, which is **IKE-profile-TEST** in this example:

```
[edit services]
```

```
user@host# set service-set TEST ipsec-vpn-options ike-access-profile IKE-profile-TEST
```

6. Configure a service set with IPsec VPN rules, which is **test-IPsec-rule** in this example:

```
[edit services]
```

```
user@host# set service-set TEST ipsec-vpn-rules test-IPsec-rule
```

The following sample output shows the configuration of the service set configuration referencing the IKE profile and the IPsec rule:

```
[edit services]user@host# show service-set TEST  
next-hop-service {  
    inside-service-interface sp-1/2/0.1;  
    outside-service-interface sp-1/2/0.2;  
}
```

```
ipsec-vpn-options {  
    local-gateway 192.168.255.2;  
    ike-access-profile IKE-profile-TEST;  
}  
ipsec-vpn-rules test-IPsec-rule;
```

CHAPTER 32

Enhancing Security with Static IPsec over VRF

- [Example: Configuring Statically Assigned IPsec Tunnels over a VRF Instance on page 447](#)

Example: Configuring Statically Assigned IPsec Tunnels over a VRF Instance

This example shows how to configure a statically assigned IPsec tunnel over a VRF instance, and contains the following sections:

- [Requirements on page 447](#)
- [Overview on page 447](#)
- [Configuration on page 447](#)
- [Verification on page 453](#)

Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series router that is configured as a provider edge router.
- Junos OS Release 9.4 and later.

No special configuration beyond device initialization is required before you can configure this feature.

Overview

Junos OS enables you to configure statically assigned IPsec tunnels on Virtual Routing and Forwarding (VRF) instances. Ability to configure IPsec tunnels on VRF instances enhances network segmentation and security. You can have multiple customer tunnels configured on the same PE router over VRF instances. Each VRF instance acts as logical router with an exclusive routing table.

Configuration

This example shows the configuration of an IPsec tunnel over a VRF instance on a provider edge router, and provides step-by-step instructions for completing the required configuration.

This section contains:

- [Configuring the Provider Edge Router on page 448](#)
- [Results on page 450](#)

Configuring the Provider Edge Router

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set interfaces ge-0/3/0 unit 0 family inet address 10.6.6.6/32
set interfaces ge-1/1/0 description "teller ge-0/1/0"
set interfaces ge-1/1/0 unit 0 family inet address 10.21.1.1/16

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a statically assigned IPsec tunnel on a VRF instance:

1. Configure the interfaces. In this step, you configure two Ethernet (**ge**) interfaces, one services interface (**ms**-), and also the service-domain properties for the logical interfaces of the services interface. Note that the logical interface that is marked as the inside interface applies the configured service on the traffic, whereas the one that is marked as the outside interface acts as the egress point for the traffic on which the inside interface has applied the service.

```
[edit interfaces]
user@PE1# set ge-0/3/0 unit 0 family inet address 10.6.6/32
user@PE1# set ge-1/1/0 description "teller ge-0/1/0"
user@PE1# set ge-1/1/0 unit 0 family inet address 10.21.1/16
user@PE1# set ms-1/2/0 unit 0 family inet address 10.7.7/32
user@PE1# set ms-1/2/0 unit 1 family inet
user@PE1# set ms-1/2/0 unit 1 service-domain inside
user@PE1# set ms-1/2/0 unit 2 family inet
user@PE1# set ms-1/2/0 unit 2 service-domain outside
```

2. Configure a routing policy to specify route import and export criteria for the VRF instance. The import and export policies defined in this step are referenced from the routing-instance configuration in the next step.

```
[edit policy-options]
user@PE1# set policy-statement vpn-export then community add vpn-community
user@PE1# set policy-statement vpn-export then accept
user@PE1# set policy-statement vpn-import term a from community vpn-community
user@PE1# set policy-statement vpn-import term a then accept
user@PE1# set community vpn-community members target:100:20
```

3. Configure a routing instance and specify the routing-instance type as **vrf**. Apply the import and export policies defined in the previous step to the routing instance, and specify a static route to send the IPsec traffic to the inside interface (**ms-1/2/0.1**) configured in the first step.

```
[edit routing-instance]
user@PE1# set vrf instance-type vrf
user@PE1# set vrf interface ge-0/3/0.0
user@PE1# set vrf interface ms-1/2/0.1
user@PE1# set vrf route-distinguisher 192.168.0.1:1
user@PE1# set vrf vrf-import vpn-import
user@PE1# set vrf vrf-export vpn-export
user@PE1# set vrf routing-options static route 10.0.0.0/0 next-hop ge-0/3/0.0
user@PE1# set vrf routing-options static route 10.11.1/32 next-hop ge-0/3/0.0
user@PE1# set vrf routing-options static route 10.8.8.1/32 next-hop ms-1/2/0.1
```

4. Configure IKE and IPsec proposals and policies, and a rule to apply the IKE policy on the incoming traffic..

NOTE: By default, Junos OS uses IKE policy version 1.0. Junos OS Release 11.4 and later also support IKE policy version 2.0 which you must configure at `[edit services ipsec-vpn ike policy policy-name pre-shared]`.

```
[edit services]
user@PE1# set ipsec-vpn ipsec proposal demo_ipsec_proposal protocol esp
user@PE1# set ipsec-vpn ipsec proposal demo_ipsec_proposal
  authentication-algorithm hmac-sha1-96
user@PE1# set ipsec-vpn ipsec proposal demo_ipsec_proposal encryption-algorithm
  3des-cbc
user@PE1# set ipsec-vpn ipsec policy demo_ipsec_policy perfect-forward-secrecy
  keys group2
user@PE1# set ipsec-vpn ipsec policy demo_ipsec_policy proposals
  demo_ipsec_proposal
user@PE1# set ipsec-vpn ike proposal demo_ike_proposal authentication-method
  pre-shared-keys
user@PE1# set ipsec-vpn ike proposal demo_ike_proposal dh-group group2
user@PE1# set ipsec-vpn ike policy demo_ike_policy proposals demo_ike_proposal
user@PE1# set ipsec-vpn ike policy demo_ike_policy pre-shared-key ascii-text
  juniperkey
user@PE1# set ipsec-vpn rule demo-rule term demo-term then remote-gateway
  10.21.2.1
user@PE1# set ipsec-vpn rule demo-rule term demo-term then dynamic ike-policy
  demo_ike_policy
user@PE1# set ipsec-vpn rule demo-rule match-direction input
```

5. Configure a next-hop style service set. Note that you must configure the inside and outside interfaces that you configured in the first step as the **inside-service-interface** and **outside-service-interface** respectively.

```
[edit services]
user@PE1# set service-set demo-service-set next-hop-service
  inside-service-interface ms-1/2/0.1
user@PE1# set service-set demo-service-set next-hop-service
  outside-service-interface ms-1/2/0.2
user@PE1# set service-set demo-service-set ipsec-vpn-options local-gateway
  10.21.1.1
user@PE1# set service-set demo-service-set ipsec-vpn-rules demo-rule
```

6. Commit the configuration.

```
[edit]
user@PE1# commit
```

Results

From the configuration mode of Router 1, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show routing-instances**, **show services ipsec-vpn**, and **show services service-set** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
...
```

```

- [Example: Configuring IKE Dynamic SAs on page 466](#)
- [Example: IKE Dynamic SA Configuration with Digital Certificates on page 483](#)

Configuring Dynamic Endpoints for IPsec Tunnels

IPsec tunnels can also be established using *dynamic peer* security gateways, in which the remote ends of tunnels do not have a statically assigned IP address. Since the remote address is not known and might be pulled from an address pool each time the remote host reboots, establishment of the tunnel relies on using IKE **main** mode with either preshared global keys or digital certificates that accept any remote identification value. Both policy-based and link-type tunnels are supported:

- Policy-based tunnels used shared mode.
- Link-type or routed tunnels use dedicated mode. Each tunnel allocates a service interface from a pool of interfaces configured for the dynamic peers. Routing protocols can be configured to run on these service interfaces to learn routes over the IPsec tunnel that is used as a link in this scenario.

This section includes the following topics:

- [Authentication Process on page 456](#)
- [Implicit Dynamic Rules on page 456](#)
- [Reverse Route Insertion on page 457](#)
- [Configuring an IKE Access Profile on page 457](#)
- [Referencing the IKE Access Profile in a Service Set on page 459](#)
- [Configuring the Interface Identifier on page 459](#)
- [Default IKE and IPsec Proposals on page 460](#)

Authentication Process

The remote (dynamic peer) initiates the negotiations with the local (Juniper Networks) router. The local router uses the default IKE and IPsec policies to match the proposals sent by the remote peer to negotiate the security association (SA) values. Implicit proposals contain a list of all the supported transforms that the local router expects from all the dynamic peers.

If preshared key authentication is used, the preshared key is global for a service set. When seeking the preshared key for the peer, the local router matches the peer's source address against any explicitly configured preshared keys in that service set. If a match is not found, the local router uses the global preshared key for authentication. This key is the one configured in the IKE access profile referenced by the service set.

Phase 2 of the authentication matches the *proxy identities* of the protected hosts and networks sent by the peer against a list of configured proxy identities. The accepted proxy identity is used to create the dynamic rules for encrypting the traffic. You can configure proxy identities by including the **allowed-proxy-pair** statement in the IKE access profile. If no entry matches, the negotiation is rejected.

If you do not configure the **allowed-proxy-pair** statement, the default value **ANY(0.0.0.0/0)-ANY** is applied, and the local router accepts any proxy identities sent by the peer. Both IPv4 and IPv6 addresses are accepted, but you must configure all IPv6 addresses manually.

Once the phase 2 negotiation completes successfully, the router builds the dynamic rules and inserts the reverse route into the routing table using the accepted proxy identity.

Implicit Dynamic Rules

After successful negotiation with the dynamic peer, the key management process (kmd) creates a dynamic rule for the accepted phase 2 proxy and applies it on the local AS or Multiservices PIC. The source and destination addresses are specified by the accepted proxy. This rule is used to encrypt traffic directed to one of the end hosts in the phase 2 proxy identity.

The dynamic rule includes an **ipsec-inside-interface** value, which is the interface name assigned to the dynamic tunnel. The **source-address** and **destination-address** values are accepted from the proxy ID. The **match-direction** value is **input** for next-hop-style service sets.

NOTE: You do not configure this rule; it is created by the key management process (kmd).

Rule lookup for static tunnels is unaffected by the presence of a dynamic rule; it is performed in the order configured. When a packet is received for a service set, static rules are always matched first.

Dynamic rules are matched after the rule match for static rules has failed.

Response to dead peer detection (DPD) hello messages takes place the same way with dynamic peers as with static peers. Initiating DPD hello messages from dynamic peers is not supported.

Reverse Route Insertion

Static routes are automatically inserted into the route table for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created based on the remote proxy network and mask sent by the peer and is inserted in the relevant route table after successful phase 1 and phase 2 negotiations.

The route preference for each static reverse route is 1. This value is necessary to avoid conflict with similar routes that might be added by the routing protocol process (rpd).

No routes are added if the accepted remote proxy address is the default (0.0.0.0/0). In this case you can run routing protocols over the IPsec tunnel to learn routes and add static routes for the traffic you want to be protected over this tunnel.

For next-hop-style service sets, the reverse routes include next hops pointing to the locations specified by the **inside-service-interface** statement.

The route table in which to insert these routes depends on where the **inside-service-interface** location is listed. If these interfaces are present in a VPN routing and forwarding (VRF) instance, then routes are added to the corresponding VRF table; otherwise, the routes are added to **inet.0**.

NOTE: Reverse route insertion takes place only for tunnels to dynamic peers. These routes are added only for next-hop-style service sets.

Configuring an IKE Access Profile

You can configure only one tunnel profile per service set for all dynamic peers. The configured preshared key in the profile is used for IKE authentication of all dynamic peers terminating in that service set. Alternatively, you can include the **ike-policy** statement to reference an IKE policy you define with either specific identification values or a wildcard (the **any-remote-id** option). You configure the IKE policy at the **[edit services ipsec-vpn ike]** hierarchy level.

The IKE tunnel profile specifies all the information needed to complete the IKE negotiation. Each protocol has its own statement hierarchy within the client statement to configure protocol-specific attribute value pairs, but only one client configuration is allowed for each profile. The following is the configuration at the **[edit access]** hierarchy level; for more information on access profiles, see the *Junos OS Administration Library for Routing Devices*.

```
[edit access]
profile profile-name {
  client * {
    ike {
```

```

    allowed-proxy-pair {
        remote remote-proxy-address local local-proxy-address;
    }
    pre-shared-key (ascii-text key-string | hexadecimal key-string);
    ike-policy policy-name;
    interface-id <string-value>;
    ipsec-policy ipsec-policy;
}
}
}

```

NOTE: For dynamic peers, the Junos OS supports the IKE main mode with either the preshared key method of authentication or an IKE access profile that uses a local digital certificate.

- In preshared key mode, the IP address is used to identify a tunnel peer to get the preshared key information. The client value * (wildcard) means that configuration within this profile is valid for all dynamic peers terminating within the service set accessing this profile.
- In digital certificate mode, the IKE policy defines which remote identification values are allowed.

The following statements make up the IKE profile:

- **allowed-proxy-pair**—During phase 2 IKE negotiation, the remote peer supplies its network address (**remote**) and its peer's network address (**local**). Since multiple dynamic tunnels are authenticated through the same mechanism, this statement must include the list of possible combinations. If the dynamic peer does not present a valid combination, the phase 2 IKE negotiation fails.

By default, **remote 0.0.0.0/0 local 0.0.0.0/0** is used if no values are configured. Both IPv4 and IPv6 address formats are supported in this configuration, but there are no default IPv6 addresses. You must specify even **0::0/0**.

- **pre-shared-key**—Key used to authenticate the dynamic peer during IKE phase 1 negotiation. This key is known to both ends through an out-of-band secure mechanism. You can configure the value either in **hexadecimal** or **ascii-text** format. It is a mandatory value.
- **ike-policy**—Policy that defines the remote identification values corresponding to the allowed dynamic peers; can contain a wildcard value **any-remote-id** for use in dynamic endpoint configurations only.
- **interface-id**—Interface identifier, a mandatory attribute used to derive the logical service interface information for the session.
- **ipsec-policy**—Name of the IPsec policy that defines the IPsec policy information for the session. You define the IPsec policy at the **[edit services ipsec-vpn ipsec policy *policy-name*]** hierarchy level. If no policy is set, any policy proposed by the dynamic peer is accepted.

Referencing the IKE Access Profile in a Service Set

To complete the configuration, you need to reference the IKE access profile configured at the **[edit access]** hierarchy level. To do this, include the **ike-access-profile** statement at the **[edit services service-set name ipsec-vpn-options]** hierarchy level:

```
[edit services service-set name]
ipsec-vpn-options {
  local-gateway address;
  ike-access-profile profile-name;
}
next-hop-service {
  inside-service-interface interface-name;
  outside-service-interface interface-name;
}
```

The **ike-access-profile** statement must reference the same name as the **profile** statement you configured for IKE access at the **[edit access]** hierarchy level. You can reference only one access profile in each service set. This profile is used to negotiate IKE and IPsec security associations with dynamic peers only.

NOTE: If you configure an IKE access profile in a service set, no other service set can share the same local-gateway address.

Also, you must configure a separate service set for each VRF instance. All interfaces referenced by the **ipsec-inside-interface** statement within a service set must belong to the same VRF instance.

Configuring the Interface Identifier

You can configure an interface identifier for a group of dynamic peers, which specifies which adaptive services logical interface(s) take part in the dynamic IPsec negotiation. By assigning the same interface identifier to multiple logical interfaces, you can create a pool of interfaces for this purpose. To configure an interface identifier, include the **ipsec-interface-id** statement and the **dedicated** or **shared** statement at the **[edit interfaces interface-name unit logical-unit-number dial-options]** hierarchy level:

```
[edit interfaces interface-name unit logical-unit-number dial-options]
ipsec-interface-id identifier;
(dedicated | shared);
```

Specifying the interface identifier in the **dial-options** statement makes this logical interface part of the pool identified by the **ipsec-interface-id** statement.

NOTE: Only one interface identifier can be specified at a time. You can include the **ipsec-interface-id** statement or the **l2tp-interface-id** statement, but not both.

If you configure **shared** mode, it enables one logical interface to be shared across multiple tunnels. The **dedicated** statement specifies that the logical interface is used in a dedicated mode, which is necessary when you are configuring an IPsec link-type tunnel. You must include the **dedicated** statement when you specify an **ipsec-interface-id** value.

Default IKE and IPsec Proposals

The software includes implicit default IKE and IPsec proposals to match the proposals sent by the dynamic peers. The values are shown in [Table 24 on page 460](#); if more than one value is shown, the first value is the default.

NOTE: RSA certificates are not supported with dynamic endpoint configuration.

Table 24: Default IKE and IPsec Proposals for Dynamic Negotiations

Statement Name	Values
Implicit IKE Proposal	
authentication-method	pre-shared keys
dh-group	group1, group2, group5, group14
authentication-algorithm	sha1, md5, sha-256
encryption-algorithm	3des-cbc, des-cbc, aes-128, aes-192, aes-256
lifetime-seconds	3600 seconds
Implicit IPsec Proposal	
protocol	esp, ah, bundle
authentication-algorithm	hmac-sha1-96, hmac-md5-96
encryption-algorithm	3des-cbc, des-cbc, aes-128, aes-192, aes-256
lifetime-seconds	28,800 seconds (8 hours)

Example: Configuring Dynamically Assigned Policy Based Tunnels

This example shows how to configure dynamically assigned policy-based tunnels and contains the following sections.

- [Requirements on page 461](#)
- [Overview and Topology on page 461](#)
- [Configuration on page 462](#)
- [Verification on page 466](#)

Requirements

This example uses the following hardware and software components:

- Three M Series, MX Series or T Series routers.
- Junos OS Release 9.4 or later.

Overview and Topology

An IPsec policy for dynamic endpoints defines a combination of security parameters (IPsec proposals) used during IPsec negotiation between dynamic peer security gateways, in which the remote ends of tunnels do not have a statically assigned IP address.

A policy based VPN is a configuration with a specific VPN tunnel referenced in a policy which acts as a Tunnel. You use a Policy-based VPN if the remote VPN device is a non-Juniper device and if you must access only one subnet or one network at the remote site, across the VPN.

This example explains the IPsec dynamic endpoint tunneling topology as shown in [Figure 22 on page 462](#).

Before you configure dynamically assigned tunnels, be sure you have:

- A local network N-1 connected to a security gateway SG-1. The exit points must have a Juniper Networks router to terminate the static and dynamic peer endpoints. The tunnel termination address on SG-1 is 10.1.1.1 and the local network address is 172.16.1.0/24.
- Two remote peer routers that obtain addresses from an ISP pool and run an RFC-compliant IKE. The remote network N-2 has the address 172.16.2.0/24 and is connected to the security gateway SG-2 with the tunnel termination address 10.2.2.2. The remote network N-3 has the address 172.16.3.0/24 and is connected to the security gateway SG-3 with the tunnel termination address 10.3.3.3.

Figure 22: IPsec Dynamic Endpoint Tunneling Topology

Configuration

To configure dynamically assigned policy based tunnels, perform these tasks:

NOTE: The interface types shown in this example are for indicative purpose only. For example, you can use so- interfaces instead of ge- and sp- instead of ms-.

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of SGI router.

Configuring Interfaces

```
set interfaces ms-0/0/0 unit 0 family inet
set interfaces ms-0/0/0 unit 1 family inet
set interfaces ms-0/0/0 unit 1 service-domain inside
set interfaces ms-0/0/0 unit 1 dial-options ipsec-interface-id demo-ipsec-interface-id
set interfaces ms-0/0/0 unit 1 dial-options mode shared
set interfaces ms-0/0/0 unit 2 family inet
set interfaces ms-0/0/0 unit 2 service-domain outside
```

Configuring Access Profile

```
set access profile demo-access-profile client * ike allowed-proxy-pair remote 172.16.2.0/24
local 172.16.1.0/24
set access profile demo-access-profile client * ike allowed-proxy-pair remote 172.16.3.0/24
local 172.16.1.0/24
set access profile demo-access-profile client * ike ascii-text keyfordynamicpeers
set access profile demo-access-profile client * ike interface-id demo-ipsec-interface-id
```

Configuring Service Set

```
set services service-set demo-service-set next-hop-service inside-service-interface
ms-0/0/0.1
set services service-set demo-service-set next-hop-service outside-service-interface
ms-0/0/0.2
```

Configuring IPsec Properties	<pre> set services ipsec-vpn ipsec proposal ipsec_proposal_demo1 protocol esp set services ipsec-vpn ipsec proposal ipsec_proposal_demo1 authentication-algorithm hmac-sha1-96 set services ipsec-vpn ipsec proposal ipsec_proposal_demo1 encryption-algorithm 3des-cbc set services ipsec-vpn ipsec policy demo2 perfect-forward-secrecy keys group2 set services ipsec-vpn ipsec policy demo2 proposals ipsec_proposal_demo1 set services ipsec-vpn ike proposal ike_proposal_demo1 authentication-method pre-shared-keys set services ipsec-vpn ike proposal ike_proposal_demo1 dh-group group2 set services ipsec-vpn ike policy ike_policy_demo1 version 2 set services ipsec-vpn ike policy ike_policy_demo1 proposals ike_proposal_demo1 set services ipsec-vpn ike policy ike_policy_demo1 pre-shared-key ascii-text keyfordemo1 </pre>
Configuring Routing Instances	<pre> set routing-instances demo-vrf instance-type vrf set routing-instances demo-vrf ms-0/0/0.1 set routing-instances demo-vrf ms-0/0/0.2 </pre>

Configuring a Next-Hop SGI Service-Set

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy.

1. Configure the interfaces.

```

[edit interfaces]
user@router1# set interfaces ms-0/0/0 unit 0 family inet
user@router1# set interfaces ms-0/0/0 unit 1 family inet
user@router1# set interfaces ms-0/0/0 unit 1 service-domain inside
user@router1# set interfaces ms-0/0/0 unit 1 dial-options ipsec-interface-id
  demo-ipsec-interface-id
user@router1# set interfaces ms-0/0/0 unit 1 dial-options mode shared
user@router1# set interfaces ms-0/0/0 unit 2 family inet
user@router1# set interfaces ms-0/0/0 unit 2 service-domain outside

```
2. Configure the access profile.

```

[edit access]
user@router1# set profile demo-access-profile client * ike allowed-proxy-pair remote
  172.16.2.0/24 local 172.16.1.0/24
user@router1# set profile demo-access-profile client * ike ascii-text
  keyfordynamicpeers
user@router1# set profile demo-access-profile client * ike interface-id
  demo-ipsec-interface-id

```
3. Configure the services set.

```

[edit services]
user@router1# set service-set demo-service-set next-hop-service
  inside-service-interface ms-0/0/0.1
user@router1# set service-set demo-service-set next-hop-service
  outside-service-interface ms-0/0/0.2

```
4. Configure the IPsec properties.

```

[edit services ipsec-vpn]
user@router1# set ipsec proposal ipsec_proposal_demo1 protocol esp

```

```
user@router1#set ipsec proposal ipsec_proposal_demo1 authentication-algorithm
hmac-sha1-96
user@router1#set ipsec proposal ipsec_proposal_demo1 encryption-algorithm
3des-cbc
user@router1#set ipsec policy demo2 perfect-forward-secrecy keys group2
user@router1#set ipsec policy demo2 proposals ipsec_proposal_demo1
user@router1#set ike proposal ike_proposal_demo1 authentication-method
pre-shared-keys
user@router1#set ike proposal ike_proposal_demo1 dh-group group2
user@router1#set ike policy ike_policy_demo1 version 2
user@router1#set ike policy ike_policy_demo1 proposals ike_proposal_demo1
user@router1#set ike policy ike_policy_demo1 pre-shared-key ascii-text keyfordemo1
```

5. Configure the routing instances.

```
[edit routing-instances]
user@router1# set demo-vrf instance-type vrf
user@router1# set demo-vrf ms-0/0/0.1
user@router1# set demo-vrf ms-0/0/0.2
```

Results

From configuration mode of Router 1, confirm your configuration by entering the **show interfaces**, **show access**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
interfaces {
  ms-0/0/0 {
    unit 0 {
      family inet;
    }
    unit 1 {
      family inet;
      service-domain inside;
      dial-options {
        ipsec-interface-id demo-ipsec-interface-id;
        mode shared;
      }
    }
    unit 2 {
      family inet;
      service-domain outside;
    }
  }
}
access {
  profile demo-access-profile client * {
    ike {
      allowed-proxy-pair {
        remote 172.16.2.0/24 local 172.16.1.0/24; #Set for Network 2 connected to Network
        1
        remote 172.16.3.0/24 local 172.16.1.0/24; #Set for Network 3 connected to Network
        1
      }
      pre-shared-key {
        ascii-text keyfordynamicpeers;
      }
    }
  }
}
```

```

    }
    interface-id demo-ipsec-interface-id;
  }
}
services {
  service-set demo-service-set {
    next-hop-service {
      inside-service-interface ms-0/0/0.1;
      outside-service-interface ms-0/0/0.2;
    }
    ipsec-vpn-options {
      local-gateway 1.1.1.1;
      ike-access-profile demo-access-profile;
    }
  }
}
ipsec-vpn {
  ipsec {
    proposal ipsec_proposal_demo1 {
      protocol esp;
      authentication-algorithm hmac-sha1-96;
      encryption-algorithm 3des-cbc;
    }
    policy demo2 {
      perfect-forward-secrecy {
        keys group2;
      }
      proposals ipsec_proposal_demo1;
    }
  }
  ike {
    proposal ike_proposal_demo1 {
      authentication-method pre-shared-keys;
      dh-group group2;
    }
    policy ike_policy_demo1 {
      version 2;
      proposals ike_proposal_demo1;
      pre-shared-key ascii-text "$9$jokmT69pRhrz3hrev7Nik"; ## SECRET-DATA
    }
  }
}
}
routing-instances {
  demo-vrf {
    instance-type vrf;
    interface ms-0/0/0.1;
    interface ms-0/0/0.2;
  }
}
}

```

Verification

Verifying That the Next-Hop SGI Service Set with Policy-Based Tunnels Is Created

Purpose Verify that the next-hop SGI service set with policy-based tunnels is created.

Action From operational mode, enter the **show route** command.

```
user@router1> show route
demo-vrf.inet.0: .... # Routing instance
172.11.0.0/24 *[Static/1]..
> via ms-0/0/0.1
172.12.0.0/24 *[Static/1]..
> via ms-0/0/0.1
```

From operational mode, enter the **show services ipsec-vpn ipsec security-associations detail**

```
user@router1>show services ipsec-vpn ipsec security-associations detail
rule: junos-dynamic-rule-0
term: term-0
local-gateway-address : 10.1.1.1 #Tunnel termination address on SG-1
remote-gateway-address: 10.2.2.2 #Tunnel termination address on SG-2
source-address : 0.0.0.0/0
destination-address : 0.0.0.0/0
ipsec-inside-interface: ms-0/0/0.1
term: term-1
local-gateway-address : 10.1.1.1 #Tunnel termination address on SG-1
remote-gateway-address: 10.3.3.3 #Tunnel termination address on SG-3
source-address : 0.0.0.0/0
destination-address : 0.0.0.0/0
IPsec Properties
ipsec-inside-interface: ms-0/0/0.1
match-direction: input
```

Meaning The **show services ipsec-vpn ipsec security-associations detail** command output shows the properties that you configured.

Example: Configuring IKE Dynamic SAs

This example shows how to configure IKE dynamic SAs and contains the following sections.

- [Requirements on page 467](#)
- [Overview and Topology on page 467](#)

- [Configuration on page 468](#)
- [Verification on page 479](#)

Requirements

This example uses the following hardware and software components:

- Four M Series, MX Series, or T Series routers with multiservices interfaces installed in them.
- Junos OS Release 9.4 or later.

No special configuration beyond device initiation is required before you can configure this feature.

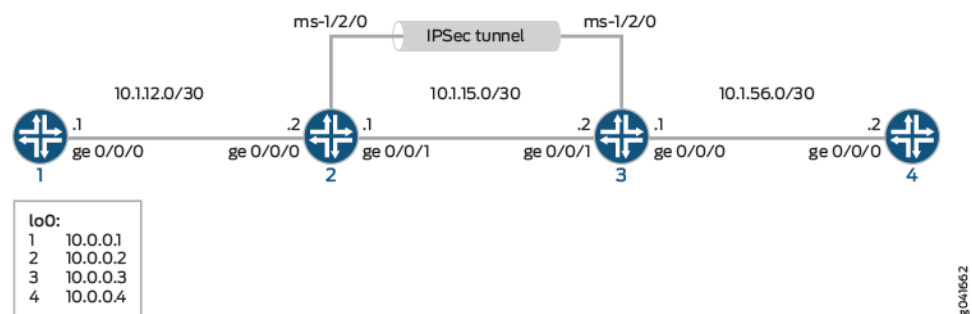

Overview and Topology

A security association (SA) is a simplex connection that enables two hosts to securely communicate with each other by means of IPsec.

Dynamic SAs are best suited for large-scale, geographically distributed networks where manual distribution, maintenance, and tracking of keys are difficult tasks. Dynamic SAs are configured with a set of proposals that are negotiated by the security gateways. The keys are generated as part of the negotiation and do not need to be specified in the configuration. A dynamic SA includes one or more proposals that allow you to prioritize a list of protocols and algorithms to be negotiated with the peer.

[Figure 23 on page 467](#) shows an IPsec topology that contains a group of four routers. This configuration requires Routers 2 and 3 to establish an IPsec tunnel by using an IKE dynamic SA, enhanced authentication, and encryption. Routers 1 and 4 provide basic connectivity and are used to verify that the IPsec tunnel is operational.

Figure 23: IKE Dynamic SAs

NOTE: When you do not specify an IKE proposal, an IPsec proposal, and an IPsec policy on a MultiServices PIC, the Junos OS defaults to the highest level of encryption and authentication. As a result, the default authentication protocol is ESP, the default authentication mode is HMAC-SHA1-96, and the default encryption mode is 3DES-CBC.

Configuration

To configure IKE dynamic SA, perform these tasks:

NOTE: The interface types shown in this example are for indicative purpose only. For example, you can use `so-` interfaces instead of `ge-` and `sp-` instead of `ms-`.

Configuring Router 1

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 1.

```
set interfaces ge-0/0/0 description "to R2 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.12.2/30
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set routing-options router-id 10.0.0.1
set protocols ospf area 0.0.0.0 interface ge-0/0/0
set protocols ospf area 0.0.0.0 interface lo0.0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router 1 for OSPF connectivity with Router 2:

1. Configure an Ethernet interface and a loopback interface.

```
[edit interfaces]
user@router1# set ge-0/0/0 description "to R2 ge-0/0/0"
user@router1# set ge-0/0/0 unit 0 family inet address 10.1.12.2/30
user@router1# set lo0 unit 0 family inet address 10.0.0.1/32
```
2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
[edit interfaces]
user@router1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@router1# set ospf area 0.0.0.0 interface lo0.0
```
3. Configure the router ID.

```
[edit routing-options]
user@router1# set router-id 10.0.0.1
```
4. Commit the configuration.

```
[edit]
user@router1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router1# show interfaces
interfaces {
  ge-0/0/0 {
    description "To R2 ge-0/0/0";
    unit 0 {
      family inet {
        address 10.1.12.2/30;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.0.0.1/32;
      }
    }
  }
}

user@router1# show protocols ospf
protocols {
  ospf {
    area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface lo0.0;
    }
  }
}

user@router1# show routing-options
routing-options {
  router-id 10.0.0.1;
}
```

Configuring Router 2

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 2.

```
set interfaces ge-0/0/0 description "to R1 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.12.1/30

set services service-set demo-service-set ipsec-vpn-options local-gateway 10.1.15.1
set services service-set demo-service-set ipsec-vpn-rules rule-ike

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure OSPF connectivity and IPsec tunnel parameters on Router 2:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), a loopback interface, and a multiservices interface (ms-1/2/0).

```

[edit interfaces]
user@router2# set ge-0/0/0 description "to R1 ge-0/0/0"
user@router2# set ge-0/0/0 unit 0 family inet address 10.1.12.1/30
user@router2# set ge-0/0/1 description "to R3 ge-0/0/1"
user@router2# set ge-0/0/1 unit 0 family inet address 10.1.15.1/30
user@router2# set ms-1/2/0 services-options syslog host local services info
user@router2# set ms-1/2/0 unit 0 family inet
user@router2# set ms-1/2/0 unit 1 family inet
user@router2# set ms-1/2/0 unit 1 service-domain inside
user@router2# set ms-1/2/0 unit 2 family inet
user@router2# set ms-1/2/0 unit 2 service-domain outside

```

```
user@router2# set lo0 unit 0 family inet address 10.0.0.2/32
```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
[edit protocols]
```

```
user@router2# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

```
user@router2# set ospf area 0.0.0.0 interface lo0.0
```

```
user@router2# set ospf area 0.0.0.0 interface ms-1/2/0.1
```

3. Configure the router ID.

```
[edit routing-options]
```

```
user@router2# set router-ID 10.0.0.2
```

4. Configure an IPsec rule. In this step, you configure an IPsec rule, specify manual SA parameters, such as the remote gateway address, authentication and encryption properties, and so on.

NOTE: By default, Junos OS uses IKE policy version 1.0. Junos OS Release 11.4 and later also support IKE policy version 2.0 which you must configure at [edit services ipsec-vpn ike policy *policy-name* pre-shared].

```
[edit services ipsec-vpn]
```

```
user@router2# set rule rule-ike term term-ike then remote-gateway 10.1.15.2
```

```
user@router2# set rule rule-ike term term-ike then dynamic ike-policy  
ike-demo-policy
```

```
user@router2# set rule rule-ike term term-ike then dynamic ipsec-policy  
ipsec-demo-policy
```

```
user@router2# set rule match-direction input
```

```
user@router2# set ike proposal ike-demo-proposal authentication-method  
pre-shared-keys
```

```
user@router2# set ike proposal ike-demo-proposal dh-group group2
```

```
user@router2# set ike policy ike-demo-policy pre-shared proposals demo-proposal
```

```
user@router2# set ike policy ike-demo-policy pre-shared pre-shared-key ascii-text  
keyfordemo
```

```
user@router2# set ipsec proposal ipsec-demo-proposal protocol esp
```

```
user@router2# set ipsec proposal ipsec-demo-proposal authentication-algorithm  
hmac-sha1-96
```

```
user@router2# set ipsec proposal ipsec-demo-proposal encryption-algorithm  
3des-cbc
```

```
user@router2# set ipsec policy ipsec-demo-policy perfect-forward-secrecy keys  
group2
```

```
user@router2# set ipsec proposals ipsec-demo-proposal
```

5. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```
[edit services]
```

```
user@router2# set service-set demo-service-set next-hop-service  
inside-service-interface ms-1/2/0.1
```

```
user@router2# set service-set demo-service-set next-hop-service  
outside-service-interface ms-1/2/0.2
```

```
user@router2# set service-set demo-service-set ipsec-vpn-options local-gateway  
10.1.15.1
```

```
user@router2# set service-set demo-service-set ipsec-vpn-rules rule-ike
```

6. Commit the configuration.

```
[edit]
user@router2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router1# show interfaces

Configuring Router 3

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 3.

```
set interfaces ge-0/0/0 description "to R4 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.56.1/30
set interfaces ge-0/0/1 description "to R2 ge-0/0/1"
set interfaces ge-0/0/1 unit 0 family inet address 10.1.15.2/30
set interfaces ms-1/2/0 services-options syslog host local services info
set interfaces ms-1/2/0 unit 0 family inet
set interfaces ms-1/2/0 unit 1 family inet
set interfaces ms-1/2/0 unit 1 service-domain inside
set interfaces ms-1/2/0 unit 2 family inet
set interfaces ms-1/2/0 unit 2 service-domain outside
set interfaces lo0 unit 0 family inet address 10.0.0.3/32
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ms-1/2/0.1
set routing-options router-id 10.0.0.3
set services ipsec-vpn rule rule-ike term term-ike then remote-gateway 10.1.15.1
set services ipsec-vpn rule rule-ike term term-ike then dynamic ike-policy ike-demo-policy
set services ipsec-vpn rule rule-ike term term-ike then dynamic ipsec-policy
  ipsec-demo-policy
set services ipsec-vpn rule match-direction input
set services ipsec-vpn ike proposal ike-demo-proposal authentication-method
  pre-shared-keys
set services ipsec-vpn ike proposal ike-demo-proposal dh-group group2
set services ipsec-vpn ike policy ike-demo-policy pre-shared proposals demo-proposal
set services ipsec-vpn ike policy ike-demo-policy pre-shared pre-shared-key ascii-text
  keyfordemo
set services ipsec-vpn ipsec proposal ipsec-demo-proposal protocol esp
```

```

set services ipsec-vpn ipsec proposal ipsec-demo-proposal authentication-algorithm
  hmac-sha1-96
set services ipsec-vpn ipsec proposal ipsec-demo-proposal encryption-algorithm 3des-cbc
set services ipsec-vpn ipsec policy ipsec-demo-policy perfect-forward-secrecy keys
  group2
set services ipsec-vpn ipsec proposals ipsec-demo-proposal
set services service-set demo-service-set next-hop-service inside-service-interface
  ms-1/2/0.1
set services service-set demo-service-set next-hop-service outside-service-interface
  ms-1/2/0.2
set services service-set demo-service-set ipsec-vpn-options local-gateway 10.1.15.2
set services service-set demo-service-set ipsec-vpn-rules rule-ike

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure OSPF connectivity and IPsec tunnel parameters on Router 3:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), a loopback interface, and a multiservices interface (ms-1/2/0).

```

[edit interfaces]
user@router3# set ge-0/0/0 description "to R4 ge-0/0/0"
user@router3# set ge-0/0/0 unit 0 family inet address 10.1.56.1/30
user@router3# set ge-0/0/1 description "to R2 ge-0/0/1"
user@router3# set ge-0/0/1 unit 0 family inet address 10.1.15.2/30
user@router3# set ms-1/2/0 services-options syslog host local services info
user@router3# set ms-1/2/0 unit 0 family inet
user@router3# set ms-1/2/0 unit 1 family inet
user@router3# set ms-1/2/0 unit 1 service-domain inside
user@router3# set ms-1/2/0 unit 2 family inet
user@router3# set ms-1/2/0 unit 2 service-domain outside
user@router3# set lo0 unit 0 family inet address 10.0.0.3/32

```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```

[edit protocols]
user@router3# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@router3# set ospf area 0.0.0.0 interface lo0.0
user@router3# set ospf area 0.0.0.0 interface ms-1/2/0.1

```

3. Configure a router ID.

```

[edit routing-options]
user@router3# set router-id 10.0.0.3

```

4. Configure an IPsec rule. In this step, you configure an IPsec rule and specify manual SA parameters, such as the remote gateway address, authentication and encryption properties, and so on.

```

[edit services ipsec-vpn]
user@router3# set rule rule-ike term term-ike then remote-gateway 10.1.15.1
user@router3# set rule rule-ike term term-ike then dynamic ike-policy
  ike-demo-policy

```

```

user@router3# set rule rule-ike term term-ike then dynamic ipsec-policy
ipsec-demo-policy
user@router3# set rule match-direction input
user@router3# set ike proposal ike-demo-proposal authentication-method
pre-shared-keys
user@router3# set ike proposal ike-demo-proposal dh-group group2
user@router3# set ike policy ike-demo-policy pre-shared proposals demo-proposal
user@router3# set ike policy ike-demo-policy pre-shared pre-shared-key ascii-text
keyfordemo
user@router3# set ipsec proposal ipsec-demo-proposal protocol esp
user@router3# set ipsec proposal ipsec-demo-proposal authentication-algorithm
hmac-sha1-96
user@router3# set ipsec proposal ipsec-demo-proposal encryption-algorithm
3des-cbc
user@router3# set ipsec policy ipsec-demo-policy perfect-forward-secrecy keys
group2
user@router3# set ipsec proposals ipsec-demo-proposal

```

5. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```

[edit services]
user@router3# set service-set demo-service-set next-hop-service
inside-service-interface ms-1/2/0.1
user@router3# set service-set demo-service-set next-hop-service
outside-service-interface ms-1/2/0.2
user@router3# set service-set demo-service-set ipsec-vpn-options local-gateway
10.1.15.2
user@router3# set service-set demo-service-set ipsec-vpn-rules rule-ike

```

6. Commit the configuration.

```

[edit]
user@router3# commit

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```

user@router3# show interfaces

        }
        proposals ipsec-demo-proposal;
    }
}
}

```

Configuring Router 4

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 4.

```

set interfaces ge-0/0/0 description "to R3 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.56.2/30
set interfaces lo0 unit 0 family inet address 10.0.0.4/32
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set routing-options router-id 10.0.0.4

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To set up OSPF connectivity with Router 4

1. Configure the interfaces. In this step, you configure an Ethernet interface (ge-1/0/1) and a loopback interface.

```

user@router4# set interfaces ge-0/0/0 description "to R3 ge-0/0/0"

```

```
user@router4# set interfaces ge-0/0/0 unit 0 family inet address 10.1.56.2/30
user@router4# set interfaces lo0 unit 0 family inet address 10.0.0.4/32
```

- Specify the OSPF area and associate the interfaces with the OSPF area.

```
user@router4# set protocols ospf area 0.0.0.0 interface ge-0/0/0
user@router4# set protocols ospf area 0.0.0.0 interface lo0.0
```

- Configure the router ID.

```
[edit routing-options]
user@router4# set router-id 10.0.0.4
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router4# show interfaces
interfaces {
  ge-0/0/0 {
    description "To R3 ge-0/0/0";
    unit 0 {
      family inet {
        address 10.1.56.2/30;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.0.0.4/32;
      }
    }
  }
}

user@router4# show protocols ospf
protocols {
  ospf {
    area 0.0.0.0 {
      interface ge-0/0/0.0;
      interface lo0.0;
    }
  }
}

user@router4# show routing-options
routing-options {
  router-id 10.0.0.4;
}
```

Verification

Verifying Your Work on Router 1

Purpose Verify proper operation of Router 1.

Action From operational mode, enter **ping 10.1.56.2** command to the ge-0/0/0 interface on Router 4 to send traffic across the IPsec tunnel

```
user@router1>ping 10.1.56.2
PING 10.1.56.2 (10.1.56.2): 56 data bytes
64 bytes from 10.1.56.2: icmp_seq=0 ttl=254 time=1.351 ms
64 bytes from 10.1.56.2: icmp_seq=1 ttl=254 time=1.187 ms
64 bytes from 10.1.56.2: icmp_seq=2 ttl=254 time=1.172 ms
64 bytes from 10.1.56.2: icmp_seq=3 ttl=254 time=1.154 ms
64 bytes from 10.1.56.2: icmp_seq=4 ttl=254 time=1.156 ms
^C
--- 10.1.56.2 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.154/1.204/1.351/0.074 ms
```

Meaning The output shows that Router 1 is able to reach Router 4 over the IPsec tunnel.

Verifying Your Work on Router 2

Purpose Verify that the IKE SA negotiation is successful.

Action From operational mode, enter the **show services ipsec-vpn ike security-associations** command.

```
user@router2>show services ipsec-vpn ike security-associations
Remote Address State Initiator cookie Responder cookie Exchange type
10.1.15.2 Matured 03075bd3a0000003 4bff26a5c7000003 Main
```

To verify that the IPsec security association is active, issue the **show services ipsec-vpn ipsec security-associations detail** command. Notice that the SA contains the default settings inherent in the MultiServices PIC, such as ESP for the protocol and HMAC-SHA1-96 for the authentication algorithm.

From operational mode, enter the **show services ipsec-vpn ipsec security-associations detail** command.

```
user@router2> show services ipsec-vpn ipsec security-associations detail
Service set: demo-service-set
Rule: rule-ike, Term: term-ike, Tunnel index: 1
Local gateway: 10.1.15.1, Remote gateway: 10.1.15.2
Local identity: ipv4_subnet(any:0,[0..7]=10.1.12.0/24)
Remote identity: ipv4_subnet(any:0,[0..7]=10.1.56.0/24)
Direction: inbound, SPI: 2666326758, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 26863 seconds
Hard lifetime: Expires in 26998 seconds
Anti-replay service: Enabled, Replay window size: 64
Direction: outbound, SPI: 684772754, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 26863 seconds
Hard lifetime: Expires in 26998 seconds
Anti-replay service: Enabled, Replay window size: 64
```

To verify that traffic is traveling through the bidirectional IPsec tunnel, issue the **show services ipsec-vpn statistics** command:

From operational mode, enter the **show services ipsec-vpn statistics** command.

```
user@router2> show services ipsec-vpn ipsec statistics
PIC: ms-1/2/0, Service set: demo-service-set
ESP Statistics:
Encrypted bytes: 2248
Decrypted bytes: 2120
Encrypted packets: 27
Decrypted packets: 25
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0
```

Meaning The **show services ipsec-vpn ipsec security-associations detail** command output shows the SA properties that you configured.

The **show services ipsec-vpn ipsec statistics** command output shows the traffic flow over the IPsec tunnel.

Verifying Your Work on Router 3

Purpose Verify that the IKE SA negotiation is successful on Router 3.

Action From operational mode, enter the **show services ipsec-vpn ike security-associations** command. To be successful, the SA on Router 3 must contain the same settings you specified on Router 2.

```
user@router3>show services ipsec-vpn ike security-associations
Remote Address State Initiator cookie Responder cookie Exchange type
10.1.15.1 Matured 03075bd3a0000003 4bff26a5c7000003 Main
```

To verify that the IPsec SA is active, issue the **show services ipsec-vpn ipsec security-associations detail** command. To be successful, the SA on Router 3 must contain the same settings you specified on Router 2.

From operational mode, enter the **show services ipsec-vpn ipsec security-associations detail** command.

```
user@router3>show services ipsec-vpn ipsec security-associations detail
Service set: demo-service-set
Rule: rule-ike, Term: term-ike, Tunnel index: 1
Local gateway: 10.1.15.2, Remote gateway: 10.1.15.1
Local identity: ipv4_subnet(any:0,[0..7]=10.1.56.0/24)
Remote identity: ipv4_subnet(any:0,[0..7]=10.1.12.0/24)
Direction: inbound, SPI: 684772754, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 26598 seconds
```

```
Hard lifetime: Expires in 26688 seconds
Anti-replay service: Enabled, Replay window size: 64
Direction: outbound, SPI: 2666326758, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 26598 seconds
Hard lifetime: Expires in 26688 seconds
Anti-replay service: Enabled, Replay window size: 64
```

To verify that traffic is traveling through the bidirectional IPsec tunnel, issue the **show services ipsec-vpn statistics** command:

From operational mode, enter the **show services ipsec-vpn ike security-associations** command.

```
user@router3>show services ipsec-vpn ipsec statistics
PIC: ms-1/2/0, Service set: demo-service-set
ESP Statistics:
Encrypted bytes: 2120
Decrypted bytes: 2248
Encrypted packets: 25
Decrypted packets: 27
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0
```

Meaning The **show services ipsec-vpn ipsec security-associations detail** command output shows the SA properties that you configured.

The **show services ipsec-vpn ipsec statistics** command output shows the traffic flow over the IPsec tunnel.

Verifying Your Work on Router 4

Purpose Verify that the IKE SA negotiation is successful.

Action From operational mode, enter **ping 10.1.12.2** command to the ge-0/0/0 interface on Router 1 to send traffic across the IPsec tunnel.

```
user@router4>ping 10.1.12.2
PING 10.1.12.2 (10.1.12.2): 56 data bytes
64 bytes from 10.1.12.2: icmp_seq=0 ttl=254 time=1.350 ms

^C
--- 10.1.12.2 ping statistics ---
6 packets transmitted, 6 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.116/1.172/1.350/0.081 ms
```

To confirm that traffic travels through the IPsec tunnel, issue the **traceroute** command to the ge-0/0/0 interface on Router 1. Notice that the physical interface between Routers 2 and 3 is not referenced in the path; traffic enters the IPsec tunnel through the adaptive services IPsec inside interface on Router 3, passes through the loopback interface on Router 2, and ends at the ge-0/0/0 interface on Router 1.

From operational mode, enter the **traceroute 10.1.12.2**.

```
user@router4>traceroute 10.1.12.2
traceroute to 10.1.12.2 (10.1.12.2), 30 hops max, 40 byte packets
 1 10.1.15.2 (10.1.15.2) 0.987 ms 0.630 ms 0.563 ms
 2 10.0.0.2 (10.0.0.2) 1.194 ms 1.058 ms 1.033 ms
 3 10.1.12.2 (10.1.12.2) 1.073 ms 0.949 ms 0.932 ms
```

Meaning The **ping 10.1.12.2** output shows that Router 4 is able to reach Router 1 over the IPsec tunnel.

The **traceroute 10.1.12.2** output shows that traffic travels the IPsec tunnel.

Example: IKE Dynamic SA Configuration with Digital Certificates

This example shows how to configure IKE dynamic SA with digital certificates and contains the following sections.

- [Requirements on page 483](#)
- [Overview on page 484](#)
- [Configuration on page 484](#)
- [Verification on page 497](#)

Requirements

This example uses the following hardware and software components:

- Four M Series, MX Series, or T Series routers with multiservices interfaces installed in them.
- Junos OS Release 9.4 or later.

Before you configure this example you must request a CA certificate, create a local certificate, and load these digital certificates into the router. For details, see *Requesting for and Installing a Digital Certificates on Your Router*

Overview

A security association (SA) is a simplex connection that enables two hosts to securely communicate with each other using IPsec. This example explains IKE dynamic SA configuration with digital certificates. The use of digital certificates provides additional security to your IKE tunnel. Using default values in the Services PIC, you do not need to configure an IPsec proposal or IPsec policy. However, you must configure an IKE proposal that specifies the use of digital certificates, reference the IKE proposal and local certificate in an IKE policy, and apply the CA profile to the service set.

Figure 24 on page 484 shows an IPsec topology containing a group of four routers. This configuration requires Routers 2 and 3 to establish an IKE-based IPsec tunnel by using digital certificates in place of preshared keys. Routers 1 and 4 provide basic connectivity and are used to verify that the IPsec tunnel is operational.

Topology

Figure 24: MS PIC IKE Dynamic SA Topology Diagram

Configuration

To configure IKE dynamic SA with digital certificates, perform these tasks:

NOTE: The interface types shown in this example are for indicative purpose only. For example, you can use so- interfaces instead of ge- and sp- instead of ms-.

Configuring Router 1

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 1.

```

set interfaces ge-0/0/0 description "to R2 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.12.2/30
set interfaces lo0 unit 0 family inet address 10.0.0.1/32
set routing-options router-id 10.0.0.1
set protocols ospf area 0.0.0.0 interface ge-0/0/0
set protocols ospf area 0.0.0.0 interface lo0.0

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router 1 for OSPF connectivity with Router 2:

1. Configure an Ethernet interface and the loopback interface.

```

[edit interfaces]
user@router1# set ge-0/0/0 description "to R2 ge-0/0/0"
user@router1# set ge-0/0/0 unit 0 family inet address 10.1.12.2/30
user@router1# set lo0 unit 0 family inet address 10.0.0.1/32

```
2. Specify the OSPF area and associate the interfaces with the OSPF area.

```

[edit protocols]
user@router1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@router1# set ospf area 0.0.0.0 interface lo0.0

```
3. Configure the router ID.

```

[edit routing-options]
user@router1# set router-id 10.0.0.1

```
4. Commit the configuration.

```

[edit]
user@router1# commit

```

Results From the configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@router1# show interfaces
interfaces {
  ge-0/0/0 {
    description "To R2 ge-0/0/0";
    unit 0 {
      family inet {
        address 10.1.12.2/30;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.0.0.1/32;
      }
    }
  }
}

```

```
    }  
  }  
  
user@router1# show protocols ospf  
protocols {  
  ospf {  
    area 0.0.0.0 {  
      interface ge-0/0/0.0;  
      interface lo0.0;  
    }  
  }  
}  
  
user@router1# show routing-options  
routing-options {  
  router-id 10.0.0.1;  
}
```

Configuring Router 2

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 2.

```
set interfaces ge-0/0/0 description "to R1 ge-0/0/0"  
set interfaces ge-0/0/0 unit 0 family inet address 10.1.12.1/30

set services service-set demo-service-set ipsec-vpn-options local-gateway 10.1.15.1
set services service-set demo-service-set ipsec-vpn-rules rule-ike

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure OSPF connectivity and IPsec tunnel parameters on Router 2:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), the loopback interface and a multiservices interface (ms-1/2/0).

```

[edit interfaces]
user@router2# set ge-0/0/0 description "to R1 ge-0/0/0"
user@router2# set ge-0/0/0 unit 0 family inet address 10.1.12.1/30
user@router2# set ge-0/0/1 description "to R3 ge-0/0/1"
user@router2# set ge-0/0/1 unit 0 family inet address 10.1.15.1/30
user@router2# set ms-1/2/0 services-options syslog host local services info
user@router2# set ms-1/2/0 unit 0 family inet
user@router2# set ms-1/2/0 unit 1 family inet
user@router2# set ms-1/2/0 unit 1 service-domain inside
user@router2# set ms-1/2/0 unit 2 family inet
user@router2# set ms-1/2/0 unit 2 service-domain outside
user@router2# set lo0 unit 0 family inet address 10.0.0.2/32

```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```

[edit protocols]
user@router2# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@router2# set ospf area 0.0.0.0 interface lo0.0
user@router2# set ospf area 0.0.0.0 interface ms-1/2/0.1

```

3. Configure the router ID.

```

[edit routing-options]
user@router2# set router-ID 10.0.0.2

```

4. Configure an IKE proposal and policy. To enable an IKE proposal for digital certificates, include the **rsa-signatures** statement at the **[edit services ipsec-vpn ike proposal proposal-name authentication-method]** hierarchy level. To reference the local certificate in the IKE policy, include the **local-certificate** statement at the **[edit services ipsec-vpn ike policy policy-name]** hierarchy level. To identify the CA or RA in the service set, include the **trusted-ca** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level.

NOTE: For information about creating and installing digital certificates, see *Requesting for and Installing a Digital Certificates on Your Router*

```
[edit services ipsec-vpn]
user@router2# set ike proposal ike-demo-proposal authentication-method
rsa-signatures
user@router2# set ike policy ike-digital-certificates proposals ike-demo-proposal
user@router2# set ike policy ike-digital-certificates local-id fqdn router2.juniper.net
user@router2# set ike policy ike-digital-certificates local-certificate local-entrust2
user@router2# set ike policy ike-digital-certificates remote-id fqdn router3.juniper.net
```

5. Configure an IPsec proposal and policy. Also, set the **established-tunnels** knob to **immediately**.

```
[edit services ipsec-vpn]
user@router2# set ipsec proposal ipsec-demo-proposal protocol esp
user@router2# set ipsec proposal ipsec-demo-proposal authentication-algorithm
hmac-sha1-96
user@router2# set ipsec proposal ipsec-demo-proposal encryption-algorithm
3des-cbc
user@router2# set ipsec policy ipsec-demo-policy perfect-forward-secrecy keys
group2
user@router2# set ipsec proposals ipsec-demo-proposal
user@router2# set establish-tunnels immediately
```

6. Configure an IPsec rule.

```
[edit services ipsec-vpn]
user@router2# set rule rule-ike term term-ike then remote-gateway 10.115.2
user@router2# set rule rule-ike term term-ike then dynamic ike-policy
ike-digital-certificates
user@router2# set rule rule-ike term term-ike then dynamic ipsec-policy
ipsec-demo-policy
user@router2# set rule match-direction input
```

7. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```
[edit services]
user@router2# set service-set demo-service-set next-hop-service
inside-service-interface ms-1/2/0.1
user@router2# set service-set demo-service-set next-hop-service
outside-service-interface ms-1/2/0.2
user@router2# set service-set demo-service-set ipsec-vpn-options trusted-ca
entrust
user@router2# set service-set demo-service-set ipsec-vpn-options local-gateway
10.115.1
user@router2# set service-set demo-service-set ipsec-vpn-rules rule-ike
```

8. Commit the configuration.

```
[edit]
user@router2# commit
```

Results From the configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```

user@router2# show interfaces
interfaces {
  ge-0/0/0 {
    description "To R1 ge-0/0/0";
    unit 0 {
      family inet {
        address 10.1.12.1/30;
      }
    }
  }
  ge-0/0/1 {

}

```

Configuring Router 3

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 3.

```

set interfaces ge-0/0/0 description "to R4 ge-0/0/0"
set interfaces ge-0/0/0 unit 0 family inet address 10.1.56.1/30
set interfaces ge-0/0/1 description "to R2 ge-0/0/1"
set interfaces ge-0/0/1 unit 0 family inet address 10.1.15.2/30
set interfaces ms-1/2/0 services-options syslog host local services info
set interfaces ms-1/2/0 unit 0 family inet
set interfaces ms-1/2/0 unit 1 family inet
set interfaces ms-1/2/0 unit 1 service-domain inside
set interfaces ms-1/2/0 unit 2 family inet
set interfaces ms-1/2/0 unit 2 service-domain outside
set interfaces lo0 unit 0 family inet address 10.0.0.3/32
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ms-1/2/0.1
set routing-options router-id 10.0.0.3
set services ipsec-vpn rule rule-ike term term-ike then remote-gateway 10.1.15.1
set services ipsec-vpn rule rule-ike term term-ike then dynamic ike-policy
    ike-digital-certificates
set services ipsec-vpn rule rule-ike term term-ike then dynamic ipsec-policy
    ipsec-demo-policy
set services ipsec-vpn rule match-direction input
set services ipsec-vpn ike proposal ike-demo-proposal authentication-method
    rsa-signatures
set services ipsec-vpn ike policy ike-digital-certificates proposals ike-demo-proposal
set services ipsec-vpn ike policy ike-digital-certificates local-id fqdn router3.juniper.net
set services ipsec-vpn ike policy ike-digital-certificates local-certificate local-entrust3
set services ipsec-vpn ike policy ike-digital-certificates remote-id fqdn router2.juniper.net
set services ipsec-vpn ipsec proposal ipsec-demo-proposal protocol esp
set services ipsec-vpn ipsec proposal ipsec-demo-proposal authentication-algorithm
    hmac-sha1-96
set services ipsec-vpn ipsec proposal ipsec-demo-proposal encryption-algorithm 3des-cbc
set services ipsec-vpn ipsec policy ipsec-demo-policy perfect-forward-secrecy keys
    group2
set services ipsec-vpn ipsec proposals ipsec-demo-proposal
set services ipsec-vpn establish-tunnels immediately
set services service-set demo-service-set next-hop-service inside-service-interface
    ms-1/2/0.1
set services service-set demo-service-set next-hop-service outside-service-interface
    ms-1/2/0.2

```

```

set services service-set demo-service-set ipsec-vpn-options trusted-ca entrust
set services service-set demo-service-set ipsec-vpn-options local-gateway 10.1.15.2
set services service-set demo-service-set ipsec-vpn-rules rule-ike

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

NOTE: If the IPsec peers do not have a symmetrical configuration containing all the necessary components, they cannot establish a peering relationship. You need to request a CA certificate, create a local certificate, load these digital certificates into the router, and reference them in your IPsec configuration. For information about digital certification, see *Requesting for and Installing a Digital Certificates on Your Router*

To configure OSPF connectivity and IPsec tunnel parameters on Router 3:

1. Configure interface properties. In this step, you configure two Ethernet interfaces (ge-1/0/0 and ge-1/0/1), the loopback interface, and a multiservices interface (ms-1/2/0).

```

[edit interfaces]
user@router3# set ge-0/0/0 description "to R4 ge-0/0/0"
user@router3# set ge-0/0/0 unit 0 family inet address 10.1.56.1/30
user@router3# set ge-0/0/1 description "to R2 ge-0/0/1"
user@router3# set ge-0/0/1 unit 0 family inet address 10.1.15.2/30
user@router3# set ms-1/2/0 services-options syslog host local services info
user@router3# set ms-1/2/0 unit 0 family inet
user@router3# set ms-1/2/0 unit 1 family inet
user@router3# set ms-1/2/0 unit 1 service-domain inside
user@router3# set ms-1/2/0 unit 2 family inet
user@router3# set ms-1/2/0 unit 2 service-domain outside
user@router3# set lo0 unit 0 family inet address 10.0.0.3/32

```

2. Specify the OSPF area, associate the interfaces with the OSPF area.

```

[edit protocols]
user@router3# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@router3# set ospf area 0.0.0.0 interface lo0.0
user@router3# set ospf area 0.0.0.0 interface ms-1/2/0.1

```

3. Configure a router ID.

```

[edit routing-options]
user@router3# set router-id 10.0.0.3

```

4. Configure an IKE proposal and policy. To enable an IKE proposal for digital certificates, include the **rsa-signatures** statement at the **[edit services ipsec-vpn ike proposal proposal-name authentication-method]** hierarchy level. To reference the local certificate in the IKE policy, include the **local-certificate** statement at the **[edit services ipsec-vpn ike policy policy-name]** hierarchy level. To identify the CA or RA in the service set, include the **trusted-ca** statement at the **[edit services service-set service-set-name ipsec-vpn-options]** hierarchy level.

NOTE: For information about creating and installing digital certificates, see *Requesting for and Installing a Digital Certificates on Your Router*

```
[edit services ipsec-vpn]
user@router3# set ike proposal ike-demo-proposal authentication-method
rsa-signatures
user@router3# set ike policy ike-digital-certificates proposals ike-demo-proposal
user@router3# set ike policy ike-digital-certificates local-id fqdn router2.juniper.net
user@router3# set ike policy ike-digital-certificates local-certificate local-entrust2
user@router3# set ike policy ike-digital-certificates remote-id fqdn router3.juniper.net
```

5. Configure an IPsec proposal. Also, set the **established-tunnels** knob to **immediately**.

```
[edit services ipsec-vpn]
user@router3# set ipsec proposal ipsec-demo-proposal protocol esp
user@router3# set ipsec proposal ipsec-demo-proposal authentication-algorithm
hmac-sha1-96
user@router3# set ipsec proposal ipsec-demo-proposal encryption-algorithm
3des-cbc
user@router3# set ipsec policy ipsec-demo-policy perfect-forward-secrecy keys
group2
user@router3# set ipsec proposals ipsec-demo-proposal
user@router3# set establish-tunnels immediately
```

6. Configure an IPsec rule.

```
[edit services ipsec-vpn]
user@router3# set rule rule-ike term term-ike then remote-gateway 10.1.15.2
user@router3# set rule rule-ike term term-ike then dynamic ike-policy
ike-digital-certificates
user@router3# set rule rule-ike term term-ike then dynamic ipsec-policy
ipsec-demo-policy
user@router3# set rule match-direction input
```

7. Configure a next-hop style service set, specify the local-gateway address, and associate the IPsec VPN rule with the service set.

```
[edit services]
user@router3# set service-set demo-service-set next-hop-service
inside-service-interface ms-1/2/0.1
user@router3# set service-set demo-service-set next-hop-service
outside-service-interface ms-1/2/0.2
user@router3# set service-set demo-service-set ipsec-vpn-options trusted-ca
entrust
user@router3# set service-set demo-service-set ipsec-vpn-options local-gateway
10.1.15.2
user@router3# set service-set demo-service-set ipsec-vpn-rules rule-ike
```

8. Commit the configuration.

```
[edit]
user@router3# commit
```

Results From the configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, and **show services** commands. If the output

does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router3# show interfaces
interfaces {
  ge-0/0/0 {
    description "To R4 ge-0/0/0";
    unit 0 {
      family inet {
        address 10.1.56.1/30;

```

Configuring Router 4

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI, at the [edit] hierarchy level, of Router 4.

```
set interfaces ge-0/0/0 description "to R3 ge-0/0/0"  
set interfaces ge-0/0/0 unit 0 family inet address 10.1.56.2/30  
set interfaces lo0 unit 0 family inet address 10.0.0.4/32  
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0  
set protocols ospf area 0.0.0.0 interface lo0.0  
set routing-options router-id 10.0.0.4
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To set up OSPF connectivity with Router 4

1. Configure the interfaces. In this step, you configure an Ethernet interface (ge-1/0/1) and the loopback interface.

```
[edit interfaces]  
user@router4# set ge-0/0/0 description "to R3 ge-0/0/0"  
user@router4# set ge-0/0/0 unit 0 family inet address 10.1.56.2/30  
user@router4# set lo0 unit 0 family inet address 10.0.0.4/32
```

2. Specify the OSPF area and associate the interfaces with the OSPF area.

```
[edit protocols]  
user@router4# set ospf area 0.0.0.0 interface ge-0/0/0  
user@router4# set ospf area 0.0.0.0 interface lo0.0
```

3. Configure the router ID.

```
[edit routing-options]  
user@router4# set router-id 10.0.0.4
```

Results From the configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration

```
user@router4# show interfaces  
interfaces {  
  ge-0/0/0 {  
    description "To R3 ge-0/0/0";
```

```

        unit 0 {
            family inet {
                address 10.1.56.2/30;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 10.0.0.4/32;
            }
        }
    }
}

user@router4# show protocols ospf
protocols {
    ospf {
        area 0.0.0.0 {
            interface ge-0/0/0.0;
            interface lo0.0;
        }
    }
}

user@router4# show routing-options
routing-options {
    router-id 10.0.0.4;
}

```

Verification

Verifying Your Work on Router 1

Purpose On Router 1, verify ping command to the so-0/0/0 interface on Router 4 to send traffic across the IPsec tunnel.

Action From operational mode, enter **ping 10.1.56.2**.

```

user@router1>ping 10.1.56.2
PING 10.1.56.2 (10.1.56.2): 56 data bytes
64 bytes from 10.1.56.2: icmp_seq=0 ttl=254 time=1.351 ms
64 bytes from 10.1.56.2: icmp_seq=1 ttl=254 time=1.187 ms
64 bytes from 10.1.56.2: icmp_seq=2 ttl=254 time=1.172 ms
64 bytes from 10.1.56.2: icmp_seq=3 ttl=254 time=1.154 ms
64 bytes from 10.1.56.2: icmp_seq=4 ttl=254 time=1.156 ms
^C
--- 10.1.56.2 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.154/1.204/1.351/0.074 ms

```

If you ping the loopback address of Router 4, the operation succeeds because the address is part of the OSPF network configured on Router 4.

```

user@router1>ping 10.0.0.4
PING 10.0.0.4 (10.0.0.4): 56 data bytes
64 bytes from 10.0.0.4: icmp_seq=0 ttl=62 time=1.318 ms
64 bytes from 10.0.0.4: icmp_seq=1 ttl=62 time=1.084 ms

```

```
64 bytes from 10.0.0.4: icmp_seq=2 ttl=62 time=3.260 ms
^C
--- 10.0.0.4 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.084/1.887/3.260/0.975 ms
```

Verifying Your Work on Router 2

Purpose To verify that matched traffic is being diverted to the bidirectional IPsec tunnel, view the IPsec statistics:

Action From operational mode, enter the **show services ipsec-vpn ipsec statistics**.

```
user@router2>show services ipsec-vpn ipsec statistics
PIC: sp-1/2/0, Service set: service-set-dynamic-demo-service-set
ESP Statistics:
Encrypted bytes: 162056
Decrypted bytes: 161896
Encrypted packets: 2215
Decrypted packets: 2216
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0
```

To verify that the IKE SA negotiation is successful, issue the **show services ipsec-vpn ike security-associations** command:

From operational mode, enter the **show services ipsec-vpn ike security-associations**

```
user@router2> show services ipsec-vpn ike security-associations
Remote Address State Initiator cookie Responder cookie Exchange type
10.1.15.2 Matured d82610c59114fd37 ec4391f76783ef28 Main
```

To verify that the IPsec security association is active, issue the **show services ipsec-vpn ipsec security-associations detail** command. Notice that the SA contains the default settings inherent in the Services PIC, such as ESP for the protocol and HMAC-SHA1-96 for the authentication algorithm.

From operational mode, enter the **show services ipsec-vpn ipsec security-associations detail**

```
user@router2> show services ipsec-vpn ipsec security-associations detail
Service set: service-set-dynamic-demo-service-set
Rule: rule-ike, Term: term-ike, Tunnel index: 1
Local gateway: 10.1.15.1, Remote gateway: 10.1.15.2
IPsec inside interface: sp-1/2/0.1
Local identity: ipv4_subnet(any:0,[0..7]=0.0.0.0/0)
Remote identity: ipv4_subnet(any:0,[0..7]=0.0.0.0/0)
Direction: inbound, SPI: 857451461, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 9052 seconds
Hard lifetime: Expires in 9187 seconds
```

```

Anti-replay service: Enabled, Replay window size: 64
Direction: outbound, SPI: 1272330309, AUX-SPI: 0
Mode: tunnel, Type: dynamic, State: Installed
Protocol: ESP, Authentication: hmac-sha1-96, Encryption: 3des-cbc
Soft lifetime: Expires in 9052 seconds
Hard lifetime: Expires in 9187 seconds
Anti-replay service: Enabled, Replay window size: 64

```

To display the digital certificates that are used to establish the IPsec tunnel, issue the `show services ipsec-vpn certificates` command:

From operational mode, enter the **show services ipsec-vpn certificates**

```

user@router2> show services ipsec-vpn certificates
Service set: service-set-dynamic-demo-service-set, Total entries: 3
Certificate cache entry: 3
Flags: Non-root Trusted
Issued to: router3.juniper.net, Issued by: juniper
Alternate subject: router3.juniper.net
Validity:

Validity:
Not before: 2005 Oct 18th, 23:54:22 GMT
Not after: 2025 Oct 19th, 00:24:22 GMT

```

To display the CA certificate, issue the `show security pki ca-certificate detail` command. Notice that there are three separate certificates: one for certificate signing, one for key encipherment, and one for the CA's digital signature.

From operational mode, enter the **show security pki ca-certificate detail**

```

user@router2> show security pki ca-certificate detail

To display the local certificate request, issue the `show security pki certificate-request` command:

From operational mode, enter the **show security pki certificate-request**

```
user@router2> show security pki certificate-request
Certificate identifier: local-entrust2
Issued to: router2.juniper.net
Public key algorithm: rsaEncryption(1024 bits)
Public key verification status: Passed
```

To display the local certificate, issue the `show security pki local-certificate` command:

From operational mode, enter the **show security pki local-certificate**

```
user@router2> show security pki local-certificate
Certificate identifier: local-entrust2
Issued to: router2.juniper.net, Issued by: juniper
Validity:
Not before: 2005 Nov 21st, 23:28:22 GMT
Not after: 2008 Nov 21st, 23:58:22 GMT
Public key algorithm: rsaEncryption(1024 bits)
Public key verification status: Passed
```

Verifying Your Work on Router 3

Purpose To verify that matched traffic is being diverted to the bidirectional IPsec tunnel, view the IPsec statistics:

Action From operational mode, enter the **show services ipsec-vpn ipsec statistics**.

```
user@router3>show services ipsec-vpn ipsec statistics
PIC: sp-1/2/0, Service set: service-set-dynamic-demo-service-set
ESP Statistics:
Encrypted bytes: 161896
Decrypted bytes: 162056
Encrypted packets: 2216
Decrypted packets: 2215
AH Statistics:
Input bytes: 0
Output bytes: 0
Input packets: 0
Output packets: 0
Errors:
AH authentication failures: 0, Replay errors: 0
ESP authentication failures: 0, ESP decryption failures: 0
Bad headers: 0, Bad trailers: 0
```

To verify that the IKE SA negotiation is successful, issue the `show services ipsec-vpn ike security-associations` command. To be successful, the SA on Router 3 must contain the same settings you specified on Router 2.

From operational mode, enter the **show services ipsec-vpn ike security-associations**.

```
user@router3>show services ipsec-vpn ike security-associations
Remote Address State Initiator cookie Responder cookie Exchange type
10.1.15.1 Matured d82610c59114fd37 ec4391f76783ef28 Main
```

To verify that the IPsec SA is active, issue the `show services ipsec-vpn ipsec security-associations detail` command. To be successful, the SA on Router 3 must contain the same settings you specified on Router 2.

From operational mode, enter the **show services ipsec-vpn ipsec security-associations detail**.

```
user@router3>show services ipsec-vpn ipsec security-associations detail

To display the local certificate request, issue the `show security pki certificate-request` command:

From operational mode, enter the **show security pki certificate-request**.

```
user@router3>show security pki certificate-request
Certificate identifier: local-entrust3
Issued to: router3.juniper.net
Public key algorithm: rsaEncryption(1024 bits)
Public key verification status: Passed
```

To display the local certificate, issue the `show security pki local-certificate` command:

From operational mode, enter the **show security pki local-certificate**.

```
user@router3>show security pki local-certificate
Certificate identifier: local-entrust3
Issued to: router3.juniper.net, Issued by: juniper
Validity:
Not before: 2005 Nov 21st, 23:33:58 GMT
Not after: 2008 Nov 22nd, 00:03:58 GMT
Public key algorithm: rsaEncryption(1024 bits)
Public key verification status: Passed
```

Verifying Your Work on Router 4

Purpose On Router 4, issue a ping command to the so-0/0/0 interface on Router 1 to send traffic across the IPsec tunnel.

Action From operational mode, enter **ping 10.1.12.2**.

```
user@router4>ping 10.1.12.2
PING 10.1.12.2 (10.1.12.2): 56 data bytes
64 bytes from 10.1.12.2: icmp_seq=0 ttl=254 time=1.350 ms
64 bytes from 10.1.12.2: icmp_seq=1 ttl=254 time=1.161 ms
64 bytes from 10.1.12.2: icmp_seq=2 ttl=254 time=1.124 ms
64 bytes from 10.1.12.2: icmp_seq=5 ttl=254 time=1.116 ms
^C
--- 10.1.12.2 ping statistics ---
```

```
4 packets transmitted, 4 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 1.116/1.172/1.350/0.081 ms
```

The final way you can confirm that traffic travels over the IPsec tunnel is by issuing the `traceroute` command to the `so-0/0/0` interface on Router 1. Notice that the physical interface between Routers 2 and 3 is not referenced in the path; traffic enters the IPsec tunnel through the adaptive services IPsec inside interface on Router 3, passes through the loopback interface on Router 2, and ends at the `so-0/0/0` interface on Router 1.

From operational mode, enter the **`traceroute 10.1.12.2`**.

```
user@router4>traceroute 10.1.12.2  
traceroute to 10.1.12.2 (10.1.12.2), 30 hops max, 40 byte packets  
1 10.1.15.2 (10.1.15.2) 0.987 ms 0.630 ms 0.563 ms  
2 10.0.0.2 (10.0.0.2) 1.194 ms 1.058 ms 1.033 ms  
3 10.1.12.2 (10.1.12.2) 1.073 ms 0.949 ms 0.932 ms
```

Configuring Junos VPN Site Secure or IPSec VPN

IPsec VPN is supported on all MX Series routers with MS-MICs, MS-MPCs, or MS-DPCs.

On M Series and T Series routers, IPsec VPN is supported with Multiservices 100 PICs, Multiservices 400 PICs, and Multiservices 500 PICs.

MS-MICs and MS-MPCs are supported from Junos OS Release 13.2 and later. MS-MICs and MS-MPCs support all features that are supported by MS-DPCs and MS-PICs except for authentication header protocol (ah), encapsulating security payload protocol (esp), and bundle (ah and esp protocol) protocol for a dynamic or manual security association and flowless IPsec service.

Class of Service Overview

The CoS configuration available for the AS PIC enables you to configure Differentiated Services (DiffServ) code point (DSCP) marking and forwarding-class assignment for packets transiting the AS PIC. You can configure the CoS service alongside the stateful firewall and NAT services, using a similar rule structure. The component structures are described in detail in the *Class of Service Feature Guide for Routing Devices*.

Standards for Differentiated Services are described in the following documents:

- RFC 2474, *Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers*
- RFC 2475, *An Architecture for Differentiated Services*

NOTE: CoS BA classification is not supported on services interfaces.

Restrictions and Cautions for CoS Configuration on Services Interfaces

The following restrictions and cautions apply to CoS configuration on services interfaces:

- The adaptive services interface does not support scheduling, only DiffServ marking and queue assignment. You must configure scheduling at the **[edit class-of-service]** hierarchy level on the output interface or fabric.
- In the default configuration, queues 1 and 2 receive 0 percent bandwidth. If packets will be assigned to these queues, you must configure a scheduling map.
- You must issue a **commit full** command before using custom forwarding-class names in the configuration.
- Only the Junos standard DiffServ names can be used in the configuration. Custom names are not recognized.
- On M Series routers, you can configure rewrite rules that change packet headers and attach the rules to output interfaces. These rules might overwrite the DSCP marking configured on an AS or MultiServices PIC. It is important to keep this adverse effect in mind and use care when creating system-wide configurations.

For example, knowing that the AS or MultiServices PIC can mark packets with any ToS or DSCP value and the output interface is restricted to only eight DSCP values, rewrite rules on the output interface condense the mapping from 64 to 8 values with overall loss of granularity. In this case, you have the following options:

- Remove the rewrite rules from the output interface.
- Configure the output interface to include the most important mappings.

- [Configuring CoS Rule Sets on page 519](#)
- [Examples: Configuring CoS on Services Interfaces on page 519](#)

Configuring CoS Rules

To configure a CoS rule, include the **rule** *rule-name* statement at the **[edit services cos]** hierarchy level:

```
[edit services cos]
rule rule-name {
  match-direction (input | output | input-output);
  term term-name {
    from {
      application-sets set-name;
      applications [ application-names ];
      destination-address address;
      destination-prefix-list list-name <except>;
      source-address address;
      source-prefix-list list-name <except>;
    }
    then {
      application-profile profile-name;
      dscp (alias | bits);
      forwarding-class class-name;
      syslog;
      (reflexive | reverse) {
        application-profile profile-name;
        dscp (alias | bits);
        forwarding-class class-name;
        syslog;
      }
    }
  }
}
```

Each CoS rule consists of a set of terms, similar to a filter configured at the **[edit firewall]** hierarchy level. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

The following sections explain how to configure the components of CoS rules:

- [Configuring Match Direction for CoS Rules on page 515](#)
- [Configuring Match Conditions In CoS Rules on page 515](#)
- [Configuring Actions in CoS Rules on page 516](#)
- [Example: Configuring CoS Rules on page 518](#)

Configuring Match Direction for CoS Rules

Each rule must include a **match-direction** statement that specifies the direction in which the rule match is applied. To configure where the match is applied, include the **match-direction** statement at the **[edit services cos rule rule-name]** hierarchy level:

```
match-direction (input | output | input-output);
```

If you configure **match-direction input-output**, bidirectional rule creation is allowed.

The match direction is used with respect to the traffic flow through the AS or Multiservices PIC. When a packet is sent to the PIC, direction information is carried along with it.

With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.

With a next-hop service set, packet direction is determined by the interface used to route the packet to the AS or Multiservices PIC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the AS or Multiservices PIC, the packet direction is output. For more information on inside and outside interfaces, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).

On the AS or Multiservices PIC, a flow lookup is performed. If no flow is found, rule processing is performed. All rules in the service set are considered. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that matches the packet direction are considered.

Configuring Match Conditions In CoS Rules

To configure CoS match conditions, include the **from** statement at the **[edit services cos rule rule-name term term-name]** hierarchy level:

```
from {
  application-sets set-name;
  applications [ application-names ];
  destination-address address;
  destination-prefix-list list-name <except>;
  source-address address;
  source-prefix-list list-name <except>;
}
```

The source address and destination address can be either IPv4 or IPv6. You can use either the source address or the destination address as a match condition, in the same way that you would configure a firewall filter; for more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Alternatively, you can specify a list of source or destination prefixes by configuring the **prefix-list** statement at the **[edit policy-options]** hierarchy level and then including either the **destination-prefix-list** or **source-prefix-list** statement in the CoS rule. For an example, see [“Examples: Configuring Stateful Firewall Rules” on page 335](#).

If you omit the **from** term, the router accepts all traffic and the default protocol handlers take effect:

- User Datagram Protocol (UDP), Transmission Control Protocol (TCP), and Internet Control Message Protocol (ICMP) create a bidirectional flow with a predicted reverse flow.
- IP creates a unidirectional flow.

You can also include application protocol definitions you have configured at the **[edit applications]** hierarchy level; for more information, see [“Configuring Application Protocol Properties” on page 303](#).

- To apply one or more specific application protocol definitions, include the **applications** statement at the **[edit services cos rule rule-name term term-name from]** hierarchy level.
- To apply one or more sets of application protocol definitions you have defined, include the **application-sets** statement at the **[edit services cos rule rule-name term term-name from]** hierarchy level.

NOTE: If you include one of the statements that specifies application protocols, the router derives port and protocol information from the corresponding configuration at the **[edit applications]** hierarchy level; you cannot specify these properties as match conditions.

Configuring Actions in CoS Rules

To configure CoS actions, include the **then** statement at the **[edit services cos rule rule-name term term-name]** hierarchy level:

```
[edit services cos rule rule-name term term-name]
then {
  application-profile profile-name;
  dscp (alias | bits);
  forwarding-class class-name;
  syslog;
  (reflexive | reverse) {
    application-profile profile-name;
    dscp (alias | bits);
    forwarding-class class-name;
    syslog;
  }
}
```

The principal CoS actions are as follows:

- **dscp**—Causes the packet to be marked with the specified DiffServ code point (DSCP) value or alias.
- **forwarding-class**—Causes the packet to be assigned to the specified forwarding class.

For detailed information about DSCP values and forwarding classes, see “[Examples: Configuring CoS on Services Interfaces](#)” on page 519 or the *Class of Service Feature Guide for Routing Devices*.

You can optionally set the configuration to record information in the system logging facility by including the **syslog** statement at the **[edit services cos rule rule-name term term-name then]** hierarchy level. This statement overrides any **syslog** setting included in the service set or interface default configuration.

For information about some additional CoS actions, see the following sections:

- [Configuring Application Profiles for Use as CoS Rule Actions on page 517](#)
- [Configuring Reflexive and Reverse CoS Rule Actions on page 518](#)

Configuring Application Profiles for Use as CoS Rule Actions

You can optionally define one or more application profiles for inclusion in CoS actions. To configure application profiles, include the **application-profile** statement at the **[edit services cos]** hierarchy level:

```
[edit services cos]
application-profile profile-name {
  ftp {
    data {
      dscp (alias | bits);
      forwarding-class class-name;
    }
  }
  sip {
    video {
      dscp (alias | bits);
      forwarding-class class-name;
    }
    voice {
      dscp (alias | bits);
      forwarding-class class-name;
    }
  }
}
```

The **application-profile** statement includes two main components and three traffic types: **ftp** with the **data** traffic type and **sip** with the **video** and **voice** traffic types. You can set the appropriate **dscp** and **forwarding-class** values for each component within the application profile.

NOTE: The **ftp** and **sip** statements are not supported on Juniper Network MX Series 3D Universal Edge Routers.

You can apply the application profile to a CoS configuration by including it at the **[edit services cos rule rule-name term term-name then]** hierarchy level.

Configuring Reflexive and Reverse CoS Rule Actions

CoS services are unidirectional. It might be necessary to specify different treatments for flows in opposite directions.

Regardless of whether a packet matches the input, output or input-output direction, flows in both directions are created. A forward, reverse, or forward-and-reverse CoS action is associated with each flow. Bear in mind that the flow in the opposite direction might end up having a CoS action associated with it that you have not specifically configured.

To control the direction in which service is applied, as distinct from the direction in which the rule match is applied, you can configure the (**reflexive** | **reverse**) statement at the **[edit services cos rule *rule-name* term *term-name* then]** hierarchy level:

```
[edit services cos rule rule-name term term-name then]
(reflexive | reverse) {
  application-profile profile-name;
  dscp (alias | bits);
  forwarding-class class-name;
  syslog;
}
```

The two actions are mutually exclusive:

- **reflexive** causes the equivalent opposing CoS action to be applied to flows in the opposite direction.
- **reverse** allows you to define the CoS behavior for flows in the reverse direction.

If you omit the statement, data flows inherit the CoS behavior of the forward control flow.

Example: Configuring CoS Rules

The following example show a CoS configuration containing two rules, one for input matching on a specified application set and the other for output matching on a specified source address:

```
[edit services]
cos {
  rule my-cos-rule {
    match-direction input-output;
    term term1 {
      from {
        source-address 10.1.3.2/32;
        applications sip;
      }
      then {
        dscp ef;
        syslog;
      }
    }
    term term2 {
      from {
```

```

        destination-address 10.2.3.2;
        applications http;
    }
    then {
        dscp af21;
    }
}
}
}

```

- [Restrictions and Cautions for CoS Configuration on Services Interfaces on page 513](#)
- [Configuring CoS Rule Sets on page 519](#)
- [Examples: Configuring CoS on Services Interfaces on page 519](#)

Configuring CoS Rule Sets

The **rule-set** statement defines a collection of CoS rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then you specify the order of the rules by including the **rule-set** statement at the **[edit services cos]** hierarchy level with a **rule** statement for each rule:

```

rule-set rule-set-name {
    rule rule-name;
}

```

The router software processes the rules in the order in which you specify them in the configuration. If a term in a rule matches the packet, the router performs the corresponding action and the rule processing stops. If no term in a rule matches the packet, processing continues to the next rule in the rule set. If none of the rules matches the packet, the packet is dropped by default.

Examples: Configuring CoS on Services Interfaces

To make settings consistent across Juniper Networks routers, you configure many CoS settings at the **[edit class-of-service]** hierarchy level to be used on services interfaces. When you commit this configuration along with what you configure at the **[edit services cos]** hierarchy level, these properties are applied to the AS or MultiServices PIC.

The following configuration examples at the **[edit class-of-service]** hierarchy level can be applied on services interfaces. For more information, see the *Class of Service Feature Guide for Routing Devices*.

NOTE: The first two configurations, mapping forwarding-class name to forwarding-class ID and mapping forwarding-class name to queue number, are mutually exclusive.

Mapping Forwarding-Class Name to Forwarding-Class ID	<p>Map forwarding-class names to forwarding-class IDs:</p> <pre>[edit class-of-service] forwarding-classes { forwarding-class fc0 0; forwarding-class fc1 0; forwarding-class fc2 1; forwarding-class fc3 1; forwarding-class fc4 2; forwarding-class fc5 2; forwarding-class fc6 3; forwarding-class fc7 3; forwarding-class fc8 4; forwarding-class fc9 4; forwarding-class fc10 5; forwarding-class fc11 5; forwarding-class fc12 6; forwarding-class fc13 6; forwarding-class fc14 7; forwarding-class fc15 7; }</pre>
Mapping Forwarding-Class Name to Queue Number	<p>Map forwarding-class names to queue numbers:</p> <pre>[edit class-of-service] forwarding-classes { queue 0 be; queue 1 ef; queue 2 af; queue 3 nc; queue 4 ef1; queue 5 ef2; queue 6 af1; queue 7 nc1; }</pre>
Mapping Diffserv Code Point Aliases to DSCP Bits	<p>Map alias names to DSCP bit values. The aliases then can be used instead of the DSCP bits in adaptive services configurations.</p> <pre>[edit class-of-service] code-point-aliases { (dscp dscp-ipv6 exp ieee-802.1 inet-precedence) { alias bits; } }</pre>

Here is an example:

```
code-point-aliases {  
  dscp {  
    my1 110001;  
    my2 101110;  
    be 000001;  
    cs7 110000;  
  }  
}
```

Configuring CoS Scheduling Queues on Logical LSQ Interfaces

For link services IQ (**lsq-**) interfaces, you can specify a scheduler map for each logical unit. A logical unit represents either an MLPPP bundle or a DLCI configured on a FRF.16 bundle. The scheduler is applied to the traffic sent to an AS or Multiservices PIC running the Layer 2 link services package.

If you configure a scheduler map on a bundle, you must include the **per-unit-scheduler** statement at the **[edit interfaces lsq-fpc/pic/port]** hierarchy level. If you configure a scheduler map on an FRF.16 DLCI, you must include the **per-unit-scheduler** statement at the **[edit interfaces lsq-fpc/pic/port:channel]** hierarchy level. For more information, see the *Class of Service Feature Guide for Routing Devices*.

If you need latency guarantees for multiclass or LFI traffic, you must use channelized IQ PICs for the constituent links. With non-IQ PICs, because queueing is not done at the channelized interface level on the constituent links, latency-sensitive traffic might not receive the type of service that it should. Constituent links from the following PICs support latency guarantees:

- Channelized E1 IQ PIC
- Channelized OC3 IQ PIC
- Channelized OC12 IQ PIC
- Channelized STM1 IQ PIC
- Channelized T3 IQ PIC

For scheduling queues on a logical interface, you can configure the following scheduler map properties at the **[edit class-of-service schedulers]** hierarchy level:

- **buffer-size**—The queue size; for more information, see [“Configuring Scheduler Buffer Size” on page 524](#).
- **priority**—The transmit priority (low, high, strict-high); for more information, see [“Configuring Scheduler Priority” on page 525](#).
- **shaping-rate**—The subscribed transmit rate; for more information, see [“Configuring Scheduler Shaping Rate” on page 525](#).
- **drop-profile-map**—The random early detection (RED) drop profile; for more information, see [“Configuring Drop Profiles” on page 525](#).

When you configure MLPPP and FRF.12 on M Series and T Series routers, you should configure a single scheduler with non-zero percent transmission rates and buffer sizes for queues 0 through 3, and assign this scheduler to the link services IQ interface (**lsq**) and to each constituent link.

When you configure FRF.16 on M Series and T Series routers, you can assign a single scheduler map to the link services IQ interface (**lsq**) and to each link services IQ DLCI, or you can assign different scheduler maps to the various DLCIs of the bundle, as shown in [“Example: Configuring an LSQ Interface as an NxT1 Bundle Using FRF.16” on page 574](#). For the constituent links of an FRF.16 bundle, you do not need to configure a custom scheduler. Because LFI and multiclass are not supported for FRF.16, the traffic from each constituent link is transmitted from queue 0. This means you should allow most of the bandwidth to be used by queue 0. The default scheduler transmission rate and buffer size percentages for queues 0 through 3 are 95, 0, 0, and 5 percent, respectively. This default scheduler sends all user traffic to queue 0 and all network-control traffic to queue 3, and therefore it is well suited to the behavior of FRF.16. You can configure a custom scheduler that explicitly replicates the 95, 0, 0, and 5 percent queuing behaviors, and apply it to the constituent links.

NOTE: On T Series and M320 routers, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent.

For link services IQ interfaces (**lsq**), these scheduling properties work as they do in other PICs, except as noted in the following sections.

NOTE: On T Series and M320 routers, **lsq** interfaces do not support DiffServ code point (DSCP) and DSCP-IPv6 rewrite markers.

Configuring Scheduler Buffer Size

You can configure the scheduler buffer size in three ways: as a temporal value, as a percentage, and as a remainder. On a single logical interface (MLPPP or a FRF.16 DLCI), each queue can have a different buffer size.

If you specify a temporal value, the queuing algorithm starts dropping packets when it queues more than a computed number of bytes. This number is computed by multiplying logical interface speed by the temporal value. For MLPPP bundles, logical interface speed is equal to the bundle bandwidth, which is the sum of constituent link speeds minus link-layer overhead. For MLFR FRF.16 DLCIs, logical interface speed is equal to bundle bandwidth multiplied by the DLCI shaping rate. In all cases, the maximum temporal value is limited to 200 milliseconds.

Buffer size percentages are implicitly converted into temporal values by multiplying the percentage by 200 milliseconds. For example, buffer size specified as **buffer-size percent 20** is the same as a 40-millisecond temporal delay. The link services IQ implementation guarantees 200 milliseconds of buffer delay for all interfaces with T1 and higher speeds. For slower interfaces, it guarantees one second of buffer delay.

The queueing algorithm evenly distributes leftover bandwidth among all queues that are configured with the **buffer-size remainder** statement. The queueing algorithm guarantees enough space in the transmit buffer for two MTU-sized packets.

Configuring Scheduler Priority

The transmit priority of each queue is determined by the scheduler and the forwarding class. Each queue receives a guaranteed amount of bandwidth specified with the scheduler **transmit-rate** statement.

Configuring Scheduler Shaping Rate

You use the shaping rate to set the percentage of total bundle bandwidth that is dedicated to a DLCI. For link services IQ DLCIs, only percentages are accepted, which allows adjustments in response to dynamic changes in bundle bandwidth—for example, when a link goes up or down. This means that absolute shaping rates are not supported on FRF.16 bundles. Absolute shaping rates are allowed for MLPPP and MLFR bundles only.

For scheduling between DLCIs in a MLFR FRF.16 bundle, you can configure a shaping rate for each DLCI. A shaping rate is expressed as a percentage of the aggregate bundle bandwidth. Shaping rate percentages for all DLCIs within a bundle can add up to 100 percent or less. Leftover bandwidth is distributed equally to DLCIs that do not have the **shaping-rate** statement included at the **[edit class-of-service interfaces lsq-fpc/pic/port:channel unit logical-unit-number]** hierarchy level. If none of the DLCIs in an MLFR FRF.16 bundle specify a DLCI scheduler, the total bandwidth is evenly divided across all DLCIs.

NOTE: For FRF.16 bundles on link services IQ interfaces, only shaping rates based on percentage are supported.

Configuring Drop Profiles

You can configure random early detection (RED) on LSQ interfaces as in other CoS scenarios. To configure RED, include one or more drop profiles and attach them to a scheduler for a particular forwarding class. For more information about RED profiles, see the *Class of Service Feature Guide for Routing Devices*.

The LSQ implementation performs tail RED. It supports a maximum of 256 drop profiles per PIC. Drop profiles are configurable on a per-queue, per-loss-priority, and per-TCP-bit basis.

You can attach scheduler maps with configured RED drop profiles to any LSQ logical interface: an MLPPP bundle, an FRF.15 bundle, or an FRF.16 DLCI. Different queues (forwarding classes) on the same logical interface can have different associated drop profiles.

The following example shows how to configure a RED profile on an LSQ interface:

```
[edit]
class-of-service {
  drop-profiles {
    drop-low {
      # Configure suitable drop profile for low loss priority
      ...
    }
    drop-high {
      # Configure suitable drop profile for high loss priority
      ...
    }
  }
  scheduler-maps {
    schedmap {
      # Best-effort queue will use be-scheduler
      # Other queues may use different schedulers
      forwarding-class be scheduler be-scheduler;
      ...
    }
  }
  schedulers {
    be-scheduler {
      # Configure two drop profiles for low and high loss priority
      drop-profile-map loss-priority low protocol any drop-profile drop-low;
      drop-profile-map loss-priority high protocol any drop-profile drop-high;
      # Other scheduler parameters (buffer-size, priority,
      # and transmit-rate) are already supported.
      ...
    }
  }
  interfaces {
    lsq-1/3/0.0 {
      # Attach a scheduler map (that includes RED drop profiles)
      # to a LSQ logical interface.
      scheduler-map schedmap;
    }
  }
}
```

NOTE: The RED profiles should be applied only on the LSQ bundles and not on the egress links that constitute the bundle.

Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces

For link services IQ (**lsq-**) interfaces, you can specify fragmentation properties for specific forwarding classes. Traffic on each forwarding class can be either multilink encapsulated (fragmented and sequenced) or nonencapsulated (hashed with no fragmentation). By default, traffic in all forwarding classes is multilink encapsulated.

When you do not configure fragmentation properties for the queues on MLPPP interfaces, the fragmentation threshold you set at the **[edit interfaces *interface-name* unit *logical-unit-number* fragment-threshold]** hierarchy level is the fragmentation threshold for all forwarding classes within the MLPPP interface. For MLFR FRF.16 interfaces, the fragmentation threshold you set at the **[edit interfaces *interface-name* mlfr-uni-nni-bundle-options fragment-threshold]** hierarchy level is the fragmentation threshold for all forwarding classes within the MLFR FRF.16 interface.

If you do not set a maximum fragment size anywhere in the configuration, packets are still fragmented if they exceed the smallest maximum transmission unit (MTU) or maximum received reconstructed unit (MRRU) of all the links in the bundle. A nonencapsulated flow uses only one link. If the flow exceeds a single link, then the forwarding class must be multilink encapsulated, unless the packet size exceeds the MTU/MRRU.

Even if you do not set a maximum fragment size anywhere in the configuration, you can configure the MRRU by including the **mrru** statement at the **[edit interfaces *lsq-fpc/pic/port* unit *logical-unit-number*]** or **[edit interfaces *interface-name* mlfr-uni-nni-bundle-options]** hierarchy level. The MRRU is similar to the MTU, but is specific to link services interfaces. By default the MRRU size is 1500 bytes, and you can configure it to be from 1500 through 4500 bytes. For more information, see [“Configuring MRRU on Multilink and Link Services Logical Interfaces” on page 734](#).

To configure fragmentation properties on a queue, include the **fragmentation-maps** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
fragmentation-maps {
  map-name {
    forwarding-class class-name {
      (fragment-threshold bytes | no-fragmentation);
      multilink-class number;
    }
  }
}
```

To set a per-forwarding class fragmentation threshold, include the **fragment-threshold** statement in the fragmentation map. This statement sets the maximum size of each multilink fragment.

To set traffic on a queue to be nonencapsulated rather than multilink encapsulated, include the **no-fragmentation** statement in the fragmentation map. This statement specifies that an extra fragmentation header is not prepended to the packets received on this queue and that static link load balancing is used to ensure in-order packet delivery.

For a given forwarding class, you can include either the **fragment-threshold** or **no-fragmentation** statement; they are mutually exclusive.

You use the **multilink-class** statement to map a forwarding class into a multiclass MLPPP (MCML). For a given forwarding class, you can include either the **multilink-class** or **no-fragmentation** statement; they are mutually exclusive. For more information about MCML, see [“Configuring Multiclass MLPPP on LSQ Interfaces” on page 562](#).

To associate a fragmentation map with a multilink PPP interface or MLFR FRF.16 DLCI, include the **fragmentation-map** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level:

```
[edit class-of-service interfaces]
lsq-fpc/pic/port {
  unit logical-unit-number { # Multilink PPP
    fragmentation-map map-name;
  }
lsq-fpc/pic/port:channel { # MLFR FRF.16
  unit logical-unit-number {
    fragmentation-map map-name;
  }
}
```

For configuration examples, see the following topics:

Configuring Link Services and CoS on Services PICs

To configure link services and CoS on an AS or Multiservices PIC, you must perform the following steps:

1. Enable the Layer 2 service package. You enable service packages per PIC, not per port. When you enable the Layer 2 service package, the entire PIC uses the configured package. To enable the Layer 2 service package, include the **service-package** statement at the **[edit chassis fpc slot-number pic pic-number adaptive-services]** hierarchy level, and specify **layer-2**:

```
[edit chassis fpc slot-number pic pic-number adaptive-services]
service-package layer-2;
```

For more information about AS or Multiservices PIC service packages, see [“Enabling Service Packages” on page 11](#) and [“Layer 2 Service Package Capabilities and Interfaces” on page 543](#).

2. Configure a multilink PPP or FRF.16 bundle by combining constituent links into a virtual link, or bundle.

Configuring an MLPPP Bundle

To configure an MLPPP bundle, configure constituent links and bundle properties by including the following statements in the configuration:

```
[edit interfaces interface-name unit logical-unit-number]
encapsulation ppp;
family mlppp {
    bundle lsq-fpc/pic/port.logical-unit-number;
}
[edit interfaces lsq-fpc/pic/port unit logical-unit-number]
drop-timeout milliseconds;
encapsulation multilink-ppp;
fragment-threshold bytes;
link-layer-overhead percent;
minimum-links number;
mrru bytes;
short-sequence;
family inet {
    address address;
}
```

For more information about these statements, see the *Link and Multilink Services Interfaces Feature Guide for Routing Devices*.

Configuring an MLFR FRF.16 Bundle

To configure an MLFR FRF.16 bundle, configure constituent links and bundle properties by including the following statements in the configuration:

```
[edit chassis fpc slot-number pic slot-number]
mlfr-uni-nni-bundles number;
[edit interfaces interface-name ]
encapsulation multilink-frame-relay-uni-nni;
unit logical-unit-number {
    family mlfr-uni-nni {
        bundle lsq-fpc/pic/port:channel;
    }
}
```

For more information about the **mlfr-uni-nni-bundles** statement, see the *Junos OS Administration Library for Routing Devices*. MLFR FRF.16 uses channels as logical units.

For MLFR FRF.16, you must configure one end as data circuit-terminating equipment (DCE) by including the following statements at the **[edit interfaces lsq-fpc/pic/port:channel]** hierarchy level.

```
encapsulation multilink-frame-relay-uni-nni;
dce;
mlfr-uni-nni-options {
    acknowledge-retries number;
    acknowledge-timer milliseconds;
    action-red-differential-delay (disable-tx | remove-link);
    drop-timeout milliseconds;
    fragment-threshold bytes;
    hello-timer milliseconds;
    link-layer-overhead percent;
    lmi-type (ansi | itu);
    minimum-links number;
    mrru bytes;
    n391 number;
    n392 number;
    n393 number;
    red-differential-delay milliseconds;
    t391 number;
    t392 number;
    yellow-differential-delay milliseconds;
}
unit logical-unit-number {
    dlci dlci-identifier;
    family inet {
        address address;
    }
}
```

For more information about MLFR UNI NNI properties, see *Link and Multilink Services Interfaces Feature Guide for Routing Devices*.

3. To configure CoS components for each multilink bundle, enable per-unit scheduling on the interface, configure a scheduler map, apply the scheduler to each queue, configure a fragmentation map, and apply the fragmentation map to each bundle. Include the following statements:

```

[edit interfaces]
lsq-fpc/pic/port {
  per-unit-scheduler; # Enables per-unit scheduling on the bundle
}
[edit class-of-service]
interfaces {
  lsq-fpc/pic/port { # Multilink PPP
    unit logical-unit-number {
      scheduler-map map-name; # Applies scheduler map to each queue
    }
  }
  lsq-fpc/pic/port:channel { # MLFR FRF.16
    unit logical-unit-number {
      # Scheduler map provides scheduling information for
      # the queues within a single DLCI.
      scheduler-map map-name;
      shaping-rate percent percent;
    }
  }
  forwarding-classes {
    queue queue-number class-name priority (high | low);
  }
  scheduler-maps {
    map-name {
      forwarding-class class-name scheduler scheduler-name;
    }
  }
  schedulers {
    scheduler-name {
      buffer-size (percent percentage | remainder | temporal microseconds);
      priority priority-level;
      transmit-rate (percent percentage | rate | remainder) <exact>;
    }
  }
  fragmentation-maps {
    map-name {
      forwarding-class class-name {
        fragment-threshold bytes;
        no-fragmentation;
      }
    }
  }
}

```

Associate a fragmentation map with a multilink PPP interface or MLFR FRF.16 DLCI by including the following statements at the **[edit class-of-service]** hierarchy level:

```

interfaces {
  lsq-fpc/pic/port {
    unit logical-unit-number { # Multilink PPP
      fragmentation-map map-name;
    }
  }
  lsq-fpc/pic/port:channel { # MLFR FRF.16
    unit logical-unit-number {
      fragmentation-map map-name;
    }
  }
}

```

Oversubscribing Interface Bandwidth on LSQ Interfaces

The term *oversubscribing interface bandwidth* means configuring shaping rates (peak information rates [PIRs]) so that their sum exceeds the interface bandwidth.

On Channelized IQ PICs, Gigabit Ethernet IQ PICs, and FRF.16 link services IQ (**lsq-**) interfaces on AS and Multiservices PICs, you can oversubscribe interface bandwidth. The logical interfaces (and DLCIs within an FRF.16 bundle) can be oversubscribed when there is leftover bandwidth. The oversubscription is limited to the configured PIR. Any unused bandwidth is distributed equally among oversubscribed logical interfaces or DLCIs.

For networks that are not likely to experience congestion, oversubscribing interface bandwidth improves network utilization, thereby allowing more customers to be provisioned on a single interface. If the actual data traffic does not exceed the interface bandwidth, oversubscription allows you to sell more bandwidth than the interface can support.

We recommend avoiding oversubscription in networks that are likely to experience congestion. Be careful not to oversubscribe a service by too much, because this can cause degradation in the performance of the router during congestion. When you configure oversubscription, some output queues can be starved if the actual data traffic exceeds the physical interface bandwidth. You can prevent degradation by using statistical multiplexing to ensure that the actual data traffic does not exceed the interface bandwidth.

NOTE: You cannot oversubscribe interface bandwidth when you configure traffic shaping using the method described in *Applying Scheduler Maps and Shaping Rate to DLCIs and VLANs*.

When configuring oversubscription for FRF.16 bundle interfaces, you can assign traffic control profiles that apply on a physical interface basis. When you apply traffic control profiles to FRF.16 bundles at the *logical* interface level, member link interface bandwidth is underutilized when there is a small proportion of traffic or no traffic at all on an individual DLCI. Support for traffic control features on the FRF.16 bundle physical interface level addresses this limitation.

To configure oversubscription of an interface, perform the following steps:

1. Include the **shaping-rate** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]
shaping-rate (percent percentage | rate);
```

NOTE: When configuring oversubscription for FRF.16 bundle interfaces on a physical interface basis, you *must* specify **shaping-rate** as a percentage.

On LSQ interfaces, you can configure the shaping rate as a percentage.

On IQ and IQ2 interfaces, you can configure the shaping rate as an absolute rate from 1000 through 6,400,000,000,000 bits per second.

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the **shaping-rate** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level. However, with this configuration approach, you cannot independently control the delay-buffer rate, as described in Step 2.

NOTE: For channelized and Gigabit Ethernet IQ interfaces, the **shaping-rate** and **guaranteed-rate** statements are mutually exclusive. You cannot configure some logical interfaces to use a shaping rate and others to use a guaranteed rate. This means there are no service guarantees when you configure a PIR. For these interfaces, you can configure either a PIR or a committed information rate (CIR), but not both.

This restriction does not apply to Gigabit Ethernet IQ2 PICs or link services IQ (LSQ) interfaces on AS or Multiservices PICs. For LSQ and Gigabit Ethernet IQ2 interfaces, you can configure both a PIR and a CIR on an interface. For more information about CIRs, see [“Configuring Guaranteed Minimum Rate on LSQ Interfaces” on page 537](#).

2. Optionally, you can base the delay buffer calculation on a delay-buffer rate. To do this, include the **delay-buffer-rate** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

NOTE: When configuring oversubscription for FRF.16 bundle interfaces on a physical interface basis, you *must* specify **delay-buffer-rate** as a percentage.

```
[edit class-of-service traffic-control-profiles profile-name]
delay-buffer-rate (percent percentage | rate);
```

The delay-buffer rate overrides the shaping rate as the basis for the delay-buffer calculation. In other words, the shaping rate or scaled shaping rate is used for delay-buffer calculations only when the delay-buffer rate is not configured.

For LSQ interfaces, if you do not configure a delay-buffer rate, the guaranteed rate (CIR) is used to assign buffers. If you do not configure a guaranteed rate, the shaping rate (PIR) is used in the undersubscribed case, and the scaled shaping rate is used in the oversubscribed case.

On LSQ interfaces, you can configure the delay-buffer rate as a percentage.

On IQ and IQ2 interfaces, you can configure the delay-buffer rate as an absolute rate from 1000 through 6,400,000,000,000 bits per second.

The actual delay buffer is based on the calculations described in the *Class of Service Feature Guide for Routing Devices*. For an example showing how the delay-buffer rates are applied, see [“Examples: Oversubscribing an LSQ Interface” on page 535](#).

Configuring large buffers on relatively low-speed links can cause packet aging. To help prevent this problem, the software requires that the sum of the delay-buffer rates be less than or equal to the port speed.

This restriction does not eliminate the possibility of packet aging, so you should be cautious when using the **delay-buffer-rate** statement. Though some amount of extra buffering might be desirable for burst absorption, delay-buffer rates should not far exceed the service rate of the logical interface.

If you configure delay-buffer rates so that the sum exceeds the port speed, the configured delay-buffer rate is not implemented for the last logical interface that you configure. Instead, that logical interface receives a delay-buffer rate of zero, and a warning message is displayed in the CLI. If bandwidth becomes available (because another logical interface is deleted or deactivated, or the port speed is increased), the configured delay-buffer-rate is reevaluated and implemented if possible.

If you do not configure a delay-buffer rate or a guaranteed rate, the logical interface receives a delay-buffer rate in proportion to the shaping rate and the remaining delay-buffer rate available. In other words, the delay-buffer rate for each logical interface with no configured delay-buffer rate is equal to:

$$(\text{remaining delay-buffer rate} * \text{shaping rate}) / (\text{sum of shaping rates})$$

The remaining delay-buffer rate is equal to:

$$(\text{interface speed}) - (\text{sum of configured delay-buffer rates})$$

3. To assign a scheduler map to the logical interface, include the **scheduler-map** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
scheduler-map map-name;
```

For information about configuring schedulers and scheduler maps, see the *Class of Service Feature Guide for Routing Devices*.

4. Optionally, you can enable large buffer sizes to be configured. To do this, include the **q-pic-large-buffer** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]  
q-pic-large-buffer;
```

If you do not include this statement, the delay-buffer size is more restricted.

We recommend restricted buffers for delay-sensitive traffic, such as voice traffic. For more information, see the *Class of Service Feature Guide for Routing Devices*.

5. To enable scheduling on logical interfaces, include the **per-unit-scheduler** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name ]
  per-unit-scheduler;
```

When you include this statement, the maximum number of VLANs supported is 768 on a single-port Gigabit Ethernet IQ PIC. On a two-port Gigabit Ethernet IQ PIC, the maximum number is 384.

6. To enable scheduling for FRF.16 bundles physical interfaces, include the **no-per-unit-scheduler** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
  no-per-unit-scheduler;
```

7. To apply the traffic-scheduling profile to the logical interface, include the **output-traffic-control-profile** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
  output-traffic-control-profile profile-name;
```

You cannot include the **output-traffic-control-profile** statement in the configuration if any of the following statements are included in the logical interface configuration: **scheduler-map**, **shaping-rate**, **adaptive-shaper**, or **virtual-channel-group**.

For a table that shows how the bandwidth and delay buffer are allocated in various configurations, see the *Class of Service Feature Guide for Routing Devices*.

Examples: Oversubscribing an LSQ Interface

Oversubscribing an LSQ Interface with Scheduling Based on the Logical Interface

Apply a traffic-control profile to a logical interface representing a DLCI on an FRF.16 bundle.

```
interfaces {
  lsq-1/3/0:0 {
    per-unit-scheduler;
    unit 0 {
      dlci 100;
    }
    unit 1 {
      dlci 200;
    }
  }
}
class-of-service {
  traffic-control-profiles {
    tc_0 {
      shaping-rate percent 100;
      guaranteed-rate percent 60;
      delay-buffer-rate percent 80;
    }
  }
}
```

```
tc_1 {
    shaping-rate percent 80;
    guaranteed-rate percent 40;
}
}
interfaces {
    lsq-1/3/0 {
        unit 0 {
            output-traffic-control-profile tc_0;
        }
        unit 1 {
            output-traffic-control-profile tc_1;
        }
    }
}
}
```

**Oversubscribing an
LSQ Interface with
Scheduling Based on
the Physical Interface**

Apply a traffic-control profile to the physical interface representing an FRF.16 bundle:

```
interfaces {
    lsq-0/2/0:0 {
        no-per-unit-scheduler;
        encapsulation multilink-frame-relay-uni-nni;
        unit 0 {
            dlc1 100;
            family inet {
                address 18.18.18.2/24;
            }
        }
    }
}
class-of-service {
    traffic-control-profiles {
        rlsq_tc {
            scheduler-map rlsq;
            shaping-rate percent 60;
            delay-buffer-rate percent 10;
        }
    }
    interfaces {
        lsq-0/2/0:0 {
            output-traffic-control-profile rlsq_tc;
        }
    }
}
scheduler-maps {
    rlsq {
        forwarding-class best-effort scheduler rlsq_scheduler;
        forwarding-class expedited-forwarding scheduler rlsq_scheduler1;
    }
}
schedulers {
    rlsq_scheduler {
        transmit-rate percent 20;
        priority low;
    }
    rlsq_scheduler1 {
```

```

        transmit-rate percent 40;
        priority high;
    }
}

```

Configuring Guaranteed Minimum Rate on LSQ Interfaces

On Gigabit Ethernet IQ PICs, Channelized IQ PICs, and FRF.16 link services IQ (LSQ) interfaces on AS and Multiservices PICs, you can configure guaranteed bandwidth, also known as a committed information rate (CIR). This allows you to specify a guaranteed rate for each logical interface. The guaranteed rate is a minimum. If excess physical interface bandwidth is available for use, the logical interface receives more than the guaranteed rate provisioned for the interface.

You cannot provision the sum of the guaranteed rates to be more than the physical interface bandwidth, or the bundle bandwidth for LSQ interfaces. If the sum of the guaranteed rates exceeds the interface or bundle bandwidth, the commit operation does not fail, but the software automatically decreases the rates so that the sum of the guaranteed rates is equal to the available bundle bandwidth.

To configure a guaranteed minimum rate, perform the following steps:

1. Include the **guaranteed-rate** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```

[edit class-of-service traffic-control-profiles profile-name]
  guaranteed-rate (percent percentage | rate);

```

On LSQ interfaces, you can configure the guaranteed rate as a percentage.

On IQ and IQ2 interfaces, you can configure the guaranteed rate as an absolute rate from 1000 through 160,000,000,000 bits per second.

NOTE: For channelized and Gigabit Ethernet IQ interfaces, the **shaping-rate** and **guaranteed-rate** statements are mutually exclusive. You cannot configure some logical interfaces to use a shaping rate and others to use a guaranteed rate. This means there are no service guarantees when you configure a PIR. For these interfaces, you can configure either a PIR or a committed information rate (CIR), but not both.

This restriction does not apply to Gigabit Ethernet IQ2 PICs or link services IQ (LSQ) interfaces on AS or Multiservices PICs. For LSQ and Gigabit Ethernet IQ2 interfaces, you can configure both a PIR and a CIR on an interface. For more information about CIRs, see the *Class of Service Feature Guide for Routing Devices*.

2. Optionally, you can base the delay buffer calculation on a delay-buffer rate. To do this, include the **delay-buffer-rate** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
delay-buffer-rate (percent percentage | rate);
```

On LSQ interfaces, you can configure the delay-buffer rate as a percentage.

On IQ and IQ2 interfaces, you can configure the delay-buffer rate as an absolute rate from 1000 through 160,000,000,000 bits per second.

The actual delay buffer is based on the calculations described in tables in the *Class of Service Feature Guide for Routing Devices*. For an example showing how the delay-buffer rates are applied, see [“Example: Configuring Guaranteed Minimum Rate” on page 539](#).

If you do not include the **delay-buffer-rate** statement, the delay-buffer calculation is based on the guaranteed rate, the shaping rate if no guaranteed rate is configured, or the scaled shaping rate if the interface is oversubscribed.

If you do not specify a shaping rate or a guaranteed rate, the logical interface receives a minimal delay-buffer rate and minimal bandwidth equal to 4 MTU-sized packets.

You can configure a rate for the delay buffer that is higher than the guaranteed rate. This can be useful when the traffic flow might not require much bandwidth in general, but in some cases can be bursty and therefore needs a large buffer.

Configuring large buffers on relatively low-speed links can cause packet aging. To help prevent this problem, the software requires that the sum of the delay-buffer rates be less than or equal to the port speed. This restriction does not eliminate the possibility of packet aging, so you should be cautious when using the **delay-buffer-rate** statement. Though some amount of extra buffering might be desirable for burst absorption, delay-buffer rates should not far exceed the service rate of the logical interface.

If you configure delay-buffer rates so that the sum exceeds the port speed, the configured delay-buffer rate is not implemented for the last logical interface that you configure. Instead, that logical interface receives a delay-buffer rate of 0, and a warning

message is displayed in the CLI. If bandwidth becomes available (because another logical interface is deleted or deactivated, or the port speed is increased), the configured delay-buffer-rate is reevaluated and implemented if possible.

If the guaranteed rate of a logical interface cannot be implemented, that logical interface receives a delay-buffer rate of 0, even if the configured delay-buffer rate is within the interface speed. If at a later time the guaranteed rate of the logical interface can be met, the configured delay-buffer rate is reevaluated and if the delay-buffer rate is within the remaining bandwidth, it is implemented.

If any logical interface has a configured guaranteed rate, all other logical interfaces on that port that do not have a guaranteed rate configured receive a delay-buffer rate of 0. This is because the absence of a guaranteed rate configuration corresponds to a guaranteed rate of 0 and, consequently, a delay-buffer rate of 0.

3. To assign a scheduler map to the logical interface, include the **scheduler-map** statement at the **[edit class-of-service traffic-control-profiles *profile-name*]** hierarchy level:

```
[edit class-of-service traffic-control-profiles profile-name]  
scheduler-map map-name;
```

For information about configuring schedulers and scheduler maps, see the *Class of Service Feature Guide for Routing Devices*.

4. To enable large buffer sizes to be configured, include the **q-pic-large-buffer** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number]  
q-pic-large-buffer;
```

If you do not include this statement, the delay-buffer size is more restricted. For more information, see the *Class of Service Feature Guide for Routing Devices*.

5. To enable scheduling on logical interfaces, include the **per-unit-scheduler** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name ]  
per-unit-scheduler;
```

When you include this statement, the maximum number of VLANs supported is 767 on a single-port Gigabit Ethernet IQ PIC. On a two-port Gigabit Ethernet IQ PIC, the maximum number is 383.

6. To apply the traffic-scheduling profile to the logical interface, include the **output-traffic-control-profile** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]  
output-traffic-control-profile profile-name;
```

Example: Configuring Guaranteed Minimum Rate

Two logical interface units, 0 and 1, are provisioned with a guaranteed minimum of 750 Kbps and 500 Kbps, respectively. For logical unit 1, the delay buffer is based on the guaranteed rate setting. For logical unit 0, a delay-buffer rate of 500 Kbps is specified.

The actual delay buffers allocated to each logical interface are 2 seconds of 500 Kbps. The 2-second value is based on the following calculation:

$\text{delay-buffer-rate} < [8 \times 64 \text{ Kbps}])$: 2 seconds of delay-buffer-rate

For more information about this calculation, see the *Class of Service Feature Guide for Routing Devices*.

```
chassis {
  fpc 3 {
    pic 0 {
      q-pic-large-buffer;
    }
  }
}
interfaces {
  tl-3/0/1 {
    per-unit-scheduler;
  }
}
class-of-service {
  traffic-control-profiles {
    tc-profile3 {
      guaranteed-rate 750k;
      scheduler-map sched-map3;
      delay-buffer-rate 500k; # 500 Kbps is less than 8 x 64 Kbps
    }
    tc-profile4 {
      guaranteed-rate 500k; # 500 Kbps is less than 8 x 64 Kbps
      scheduler-map sched-map4;
    }
  }
}
interface tl-3/0/1 {
  unit 0 {
    output-traffic-control-profile tc-profile3;
  }
  unit 1 {
    output-traffic-control-profile tc-profile4;
  }
}
```

Layer 2 Service Package Capabilities and Interfaces

As described in [“Enabling Service Packages”](#) on page 11, you can configure the AS or Multiservices PIC and the internal ASM in the M7i platform to use either the Layer 2 or the Layer 3 service package.

When you enable the Layer 2 service package, the AS or Multiservices PIC supports *link services*. On the AS or Multiservices PIC and the ASM, link services include the following:

- Junos CoS components—[“Configuring CoS Scheduling Queues on Logical LSQ Interfaces”](#) on page 523 describes how the Junos CoS components work on link services IQ (**lsq**) interfaces. For detailed information about Junos CoS components, see the *Class of Service Feature Guide for Routing Devices*.
- Data compression using the compressed Real-Time Transport Protocol (CRTTP) for use in voice over IP (VoIP) transmission.

NOTE: On LSQ interfaces, all multilink traffic for a single bundle is sent to a single processor. If CRTTP is enabled on the bundle, it adds overhead to the CPU. Because T3 network interfaces support only one link per bundle, make sure you configure a fragmentation map for compressed traffic on these interfaces and specify the **no-fragmentation** option. For more information, see [“Configuring Delay-Sensitive Packet Interleaving”](#) on page 624 and [“Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces”](#) on page 527.

- Link fragment interleaving (LFI) on Frame Relay links using FRF.12 end-to-end fragmentation—The standard for FRF.12 is defined in the specification FRF.12, *Frame Relay Fragmentation Implementation Agreement*.
- LFI on Multilink Point-to-Point Protocol (MLPPP) links.
- Multilink Frame Relay (MLFR) end-to-end (FRF.15)—The standard for FRF.15 is defined in the specification FRF.15, *End-to-End Multilink Frame Relay Implementation Agreement*.

- Multilink Frame Relay (MLFR) UNI NNI (FRF.16)—The standard for FRF.16 is defined in the specification FRF.16.1, *Multilink Frame Relay UNI/NNI Implementation Agreement*.
- MLPPP—The standard for MLPPP is defined in the specification RFC 1990, *The PPP Multilink Protocol (MP)*.
- Multiclass extension to MLPPP—The standard is defined in the specification RFC 2686, *The Multi-Class Extension to Multi-Link PPP*.

For the LSQ interface on the AS or Multiservices PIC, the configuration syntax is almost the same as for Multilink and Link Services PICs. The primary difference is the use of the interface-type descriptor **lsq** instead of **ml** or **ls**. When you enable the Layer 2 service package on the AS or Multiservices PIC, the following interfaces are automatically created:

```
gr-fpc/pic/port
ip-fpc/pic/port
lsq-fpc/pic/port
lsq-fpc/pic/port:0
...
lsq-fpc/pic/port:N
mt-fpc/pic/port
pd-fpc/pic/port
pe-fpc/pic/port
sp-fpc/pic/port
vt-fpc/pic/port
```

Interface types **gr**, **ip**, **mt**, **pd**, **pe**, and **vt** are standard tunnel interfaces that are available on the AS or Multiservices PIC whether you enable the Layer 2 or the Layer 3 service package. These tunnel interfaces function the same way for both service packages, except that the Layer 2 service package does not support some tunnel functions, as shown in Table 5 on page 24. For more information about tunnel interfaces, see *Tunnel Properties*.

NOTE: Interface type **sp** is created because it is needed by the Junos OS. For the Layer 2 service package, the **sp** interface is not configurable, but you should not disable it.

Interface type **lsq-fpc/pic/port** is the physical link services IQ interface (**lsq**). Interface types **lsq-fpc/pic/port:0** through **lsq-fpc/pic/port:N** represent FRF.16 bundles. These interface types are created when you include the **mlfr-uni-nni-bundles** statement at the **[edit chassis fpc slot-number pic pic-number]** hierarchy level. For more information, see “Configuring CoS Scheduling Queues on Logical LSQ Interfaces” on page 523.

NOTE: On DS0, E1, or T1 interfaces in LSQ bundles, you can configure the **bandwidth** statement, but the router does not use the bandwidth value if the interfaces are included in an MLPPP or MLFR bundle. The bandwidth is calculated internally according to the time slots, framing, and byte-encoding of the interface. For more information about these properties, see the *Junos OS Network Interfaces Library for Routing Devices*.

CHAPTER 39

Configuring Interface Redundancy with SONET APS and Virtual Interfaces

- [Configuring LSQ Interface Redundancy Across Multiple Routers Using SONET APS on page 545](#)
- [Configuring LSQ Interface Redundancy in a Single Router Using SONET APS on page 548](#)
- [Configuring LSQ Interface Redundancy in a Single Router Using Virtual Interfaces on page 548](#)

Configuring LSQ Interface Redundancy Across Multiple Routers Using SONET APS

Link services IQ (**lsq-**) interfaces that are paired with SONET PICs can use the Automatic Protection Switching (APS) configuration already available on SONET networks to provide failure recovery. SONET APS provides stateless failure recovery, if it is configured on SONET interfaces in separate chassis and each SONET PIC is paired with an AS or Multiservices PIC in the same chassis. If one of the following conditions for APS failure is met, the associated SONET PIC triggers recovery to the backup circuit and its associated AS or Multiservices PIC. The failure conditions are:

- Failure of Link Services IQ PIC
- Failure of FPC that hosts the Link Services IQ PIC
- Failure of Packet Forwarding Engine
- Failure of chassis

The guidelines for configuring SONET APS are described in the *Junos OS Network Interfaces Library for Routing Devices*.

The following sections describe how to configure failover properties:

- [Configuring the Association between LSQ and SONET Interfaces on page 546](#)
- [Configuring SONET APS Interoperability with Cisco Systems FRF.16 on page 547](#)
- [Restrictions on APS Redundancy for LSQ Interfaces on page 547](#)

Configuring the Association between LSQ and SONET Interfaces

To configure the association between AS or Multiservices PICs hosting link services IQ interfaces and the SONET interfaces, include the **lsq-failure-options** statement at the **[edit interfaces]** hierarchy level:

```
lsq-fpc/pic/port {
  lsq-failure-options {
    no-termination-request;
    [ trigger-link-failure interface-name ];
  }
}
```

For example, consider the following network scenario:

- Primary router includes interfaces **oc3-0/2/0** and **lsq-1/1/0**.
- Backup router includes interfaces **oc3-2/2/0** and **lsq-3/2/0**.

Configure SONET APS, with **oc3-0/2/0** as the working circuit and **oc3-2/2/0** as the protect circuit. Include the **trigger-link-failure** statement to extend failure to the LSQ PICs:

```
interfaces lsq-1/1/0 {
  lsq-failure-options {
    trigger-link-failure oc3-0/2/0;
  }
}
```

NOTE: You must configure the **lsq-failure-options** statement on the primary router only. The configuration is not supported on the backup router.

To inhibit the router from sending PPP termination-request messages to the remote host if the Link Services IQ PIC fails, include the **no-termination-request** statement at the **[edit interfaces lsq-fpc/pic/port lsq-failure-options]** hierarchy level:

```
[edit interfaces lsq-fpc/pic/port lsq-failure-options]
no-termination-request;
```

This functionality is supported on link PICs as well. To inhibit the router from sending PPP termination-request messages to the remote host if a link PIC fails, include the **no-termination-request** statement at the **[edit interfaces interface-name ppp-options]** hierarchy level.

```
[edit interfaces interface-name ppp-options]
no-termination-request;
```

The **no-termination-request** statement is supported only with MLPPP and SONET APS configurations and works with PPP, PPP over Frame Relay, and MLPPP interfaces only, on the following PICs:

- Channelized OC3 IQ PICs
- Channelized OC12 IQ PICs

- Channelized STM1 IQ PICs
- Channelized STM4 IQ PICs

Configuring SONET APS Interoperability with Cisco Systems FRF.16

Juniper Networks routers configured with APS might not interoperate correctly with Cisco FRF.16. To enable interoperation, include the **cisco-interoperability** statement at the **[edit interfaces lsq-fpc/pic/port mlfr-uni-nni-bundle-options]** hierarchy level:

```
[edit interfaces lsq-fpc/pic/port mlfr-uni-nni-bundle-options]
cisco-interoperability send-lip-remove-link-for-link-reject;
```

The **send-lip-remove-link-for-link-reject** option prompts the router to send a Link Integrity Protocol remove link when it receives an add-link rejection message.

Restrictions on APS Redundancy for LSQ Interfaces

The following restrictions apply to LSQ failure recovery:

- It applies only to Link Services IQ PICs installed in M Series routers, except for M320 routers.
- You must configure the **failure-options** statement on physical LSQ interfaces, not on MLFR channelized units.
- The Link Services IQ PICs must be associated with SONET link PICs. The paired PICs can be installed on different routers or in the same router; in other words, both interchassis and intrachassis recovery are supported
- Failure recovery is stateless; as a result, route flapping and loss of link state is expected in interchassis recovery, requiring PPP renegotiation. In intrachassis recovery, no impact on traffic is anticipated with Routing Engine failover, but PIC failover results in PPP renegotiation.
- The switchover is not revertive: when the original hardware is restored to service, traffic does not automatically revert back to it.
- Normal APS switchover and PIC-triggered APS switchover can be distinguished only by checking the system log messages.

NOTE: When an AS PIC experiences persistent back pressure as a result of high traffic volume for 3 seconds, the condition triggers an automatic core dump and reboot of the PIC to help clear the blockage. A system log message at level LOG_ERR is generated. This mechanism applies to both Layer 2 and Layer 3 service packages.

- [Link Services Configuration for Junos Interfaces](#)

Configuring LSQ Interface Redundancy in a Single Router Using SONET APS

Stateless switchover from one Link Services IQ PIC to another within the same router can be configured by using the SONET APS mechanism described in “[Configuring LSQ Interface Redundancy Across Multiple Routers Using SONET APS](#)” on page 545. Each Link Services IQ PIC must be associated with a specified SONET link PIC within the same router.

NOTE: For complete intrachassis recovery, including recovery from Routing Engine failover, graceful Routing Engine switchover (GRES) must be enabled on the router. For more information, see the *Junos OS Administration Library for Routing Devices*.

Configuring LSQ Interface Redundancy in a Single Router Using Virtual Interfaces

You can configure failure recovery on M Series, MX Series, and T Series routers that have multiple AS or Multiservices PICs and DPCs with **lsq-** interfaces by specifying a virtual LSQ redundancy (**rlsq**) interface in which the primary Link Services IQ PIC is active and a secondary PIC is on standby. If the primary PIC fails, the secondary PIC becomes active, and all LSQ processing is transferred to it. To determine which PIC is currently active, issue the **show interfaces redundancy** command.

NOTE: This configuration does not require the use of SONET APS for failover. Network interfaces that do not support SONET can be used, such as T1 or E1 interfaces.

The following sections provide more information:

- [Configuring Redundant Paired LSQ Interfaces on page 549](#)
- [Restrictions on Redundant LSQ Interfaces on page 550](#)
- [Configuring Link State Replication for Redundant Link PICs on page 551](#)
- [Examples: Configuring Redundant LSQ Interfaces for Failure Recovery on page 553](#)

Configuring Redundant Paired LSQ Interfaces

The physical interface type **rlsq** specifies the pairings between primary and secondary **lsq** interfaces to enable redundancy. To configure a backup **lsq** interface, include the **redundancy-options** statement at the **[edit interfaces rlsqnumber]** hierarchy level:

```
[edit interfaces rlsqnumber]
redundancy-options {
  (hot-standby | warm-standby);
  primary lsq-fpc/pic/port;
  secondary lsq-fpc/pic/port;
}
```

For the **rlsq** interface, **number** can be from 0 through 1023. If the primary **lsq** interface fails, traffic processing switches to the secondary interface. The secondary interface remains active even after the primary interface recovers. If the secondary interface fails and the primary interface is active, processing switches to the primary interface.

The **hot-standby** option is used with one-to-one redundancy configurations, in which one working PIC is supported by one backup PIC. It is supported with MLPPP, CRTTP, FRF.15, and FRF.16 configurations for the LSQ interface to achieve an uninterrupted LSQ service. It sets the requirement for the failure detection and recovery time to be less than 5 seconds. The behavior is revertive, but you can manually switch between the primary and secondary PICs by issuing the **request interfaces (revert | switchover) rlsqnumber** operational mode command. It also provides a switch over time of 5 seconds and less for FRF.15 and a maximum of 10 seconds for FRF.16.

The **warm-standby** option is used with redundancy configurations in which one backup PIC supports multiple working PICs. Recovery times are not guaranteed, because the configuration must be completely restored on the backup PIC after a failure is detected.

Certain combinations of **hot-standby** and **warm-standby** configuration are not permitted and result in a configuration error. The following examples are permitted:

- Interface **rlsq0** configured with **primary lsq-0/0/0** and **warm-standby**, in combination with interface **rlsq0:0** configured with **primary lsq-0/0/0:0**
- Interface **rlsq0:0** configured with **primary lsq-0/0/0:0**, in combination with interface **rlsq0:1** configured with **primary lsq-0/0/0:1**

The following example combinations are not permitted:

- Interface **rlsq0** configured with **primary lsq-0/0/0** and **hot-standby**, in combination with interface **rlsq0:0** configured with **primary lsq-0/0/0:0**
- Interface **rlsq0:0** configured with **primary lsq-0/0/0:0**, in combination with interface **rlsq1:0** configured with **primary lsq-0/0/0:0**
- Interface **rlsq0:0** configured with **primary lsq-0/0/0:1**, in combination with interface **rlsq1:1** configured with **primary lsq-0/0/0:1**
- Interface **rlsq0** configured with **primary lsq-0/0/0**, in combination with interface **rlsq1** configured with **primary lsq-0/0/0**

In addition, the same physical interface cannot be reused as the primary interface for more than one **rlsq** interface, nor can any of the associated logical interfaces. For example, primary interface **lsq-0/0/0** cannot be reused in another **rlsq** interface as **lsq-0/0/0:0**.

Restrictions on Redundant LSQ Interfaces

Link Services IQ PIC failure occurs under the following conditions:

- The primary PIC fails to boot. In this case, the **rlsq** interface does not come up and manual intervention is necessary to reboot or replace the PIC, or to rename the primary PIC to the secondary one in the **rlsq** configuration.
- When configuring an **rlsq** interface, ensure that:
 - The unit number allocated to the **rlsq** interface is less than the number of Multilink Frame Relay user-to-network interface network-to-network interface (UNI-NNI) (FRF.16) bundles allocated on the Link Services PIC.
 - Data-link connection identifier (DLCI) is configured for the **rlsq** interface.

If these conditions are not met, the **rlsq** interface does not boot. When you issue the **show interfaces redundancy** command, the state of the **rlsq** interface is indicated as **Waiting for primary MS PIC**.

- The primary PIC becomes active and then fails. The secondary PIC automatically takes over processing.
- A failover to the secondary PIC takes place. The secondary PIC then fails. If the primary PIC has been restored to active state, processing switches to it.
- The FPC that contains the Link Services IQ PIC fails.

The following constraints apply to redundant LSQ configurations:

- We recommend that primary and secondary PICs be configured in two different FPCs (in chassis other than M10i routers).
- You cannot configure a Link Services IQ PIC with explicit bundle configurations and as a constituent of an **rlsq** interface.
- Redundant LSQ configurations provide full GRES support. (You must configure GRES at the **[edit chassis]** hierarchy level; see the *Junos OS Administration Library for Routing Devices*).
- If you configure the **redundancy-options** statement with the **hot-standby** option, the configuration must include one **primary** interface value and one **secondary** interface value.
- Since the same interface name is used for **hot-standby** and **warm-standby**, if you modify the configuration to change this attribute, it is recommended that you first deactivate the interface, commit the new configuration, and then reactivate the interface.
- You cannot make changes to an active **redundancy-options** configuration. You must deactivate the **rlsqnumber** interface configuration, change it, and reactivate it.

- The **rlsqnumber** configuration becomes active only if the primary interface is active. When the configuration is first activated, the primary interface must be active; if not, the **rlsq** interface waits until the primary interface comes up.
- You cannot modify the configuration of **lsq** interfaces after they have been included in an active **rlsq** interface.
- All the operational mode commands that apply to **rsp** interfaces also apply to **rlsq** interfaces. You can issue **show** commands for the **rlsq** interface or the primary and secondary **lsq** interfaces. However, statistics on the link interfaces are not carried over following a Routing Engine switchover.
- The **rlsq** interfaces also support the **lsq-failure-options** configuration, discussed in [“Configuring LSQ Interface Redundancy Across Multiple Routers Using SONET APS” on page 545](#). If the primary and secondary Link Services IQ PICs fail and the **lsq-failure-options** statement is configured, the configuration triggers a SONET APS switchover.
- Redundant LSQ configurations that require MLPPP Multilink Frame Relay (FRF.15 and FRF.16) are supported only with the **warm-standby** option.
- Redundant LSQ support is extended to ATM network interfaces.
- Channelized interfaces are used with FRF-16 bundles, for example **rlsq0:0**. The **rlsq** number and its constituents, the **primary** and **secondary** interfaces, must match for the configuration to be valid: either all must be channelized, or none. For an example of an FRF.16 configuration, see [“Configuring LSQ Interface Redundancy for an FRF.16 Bundle” on page 556](#).

NOTE: Adaptive Services and Multiservices PICs in layer-2 mode (running Layer 2 services) are not rebooted when a MAC flow-control situation is detected.

Configuring Link State Replication for Redundant Link PICs

Link state replication, also called *interface preservation*, is an addition to the SONET Automatic Protection Switching (APS) functionality that helps promote redundancy of the link PICs used in LSQ configurations.

Link state replication provides the ability to add two sets of links, one from the active (working) SONET PIC and the other from the backup (protect) SONET PIC to the same bundle. If the active SONET PIC fails, links from the standby PIC are used without causing a link renegotiation. All the negotiated state is replicated from the active links to the standby links to prevent link renegotiation. For more information about SONET APS configurations, see the *Junos OS Network Interfaces Library for Routing Devices*.

To configure link state replication, include the **preserve-interface** statement at the **[edit interfaces interface-name sonet-options aps]** hierarchy level on both network interfaces:

```
edit interfaces interface-name sonet-options aps]
  preserve-interface;
```

The following constraints apply to link PIC redundancy:

- APS functionality must be available on the SONET PICs and the interface configurations must be identical on both ends of the link. Any configuration mismatch causes the commit operation to fail.
- This feature is supported only with LSQ and SONET APS-enabled link PICs, including Channelized OC3, Channelized OC12, and Channelized STM1 intelligent queuing (IQ) PICs.
- Link state replication supports MLPPP and PPP over Frame Relay (**frame-relay-ppp**) encapsulation, and fully supports GRES.
- Enabling the interface or protocol traceoptions with a large number of MLPPP links can trigger Link Control Protocol (LCP) renegotiation during the link switchover time.

NOTE: This renegotiation is more likely to take place for configurations with back-to-back Juniper Networks routers than in networks in which a Juniper Networks router is connected to an add/drop multiplexer (ADM).

- In general, networks that connect a Juniper Networks router to an ADM allow faster MLPPP link switchover than those with back-to-back Juniper Networks routers. The MLPPP link switchover time difference may be significant, especially for networks with a large number of MLPPP links.
- An aggressive LCP keepalive timeout configuration can lead to LCP renegotiation during the MLPPP link switchover. By default, the LCP keepalive timer interval is 10 seconds and the consecutive link down count is 3. The MLPPP links start LCP negotiation only after a timeout of 30 seconds. Lowering these configuration values may trigger one or more of the MLPPP links to renegotiate during the switchover time.

NOTE: LCP renegotiation is more likely to take place for configurations with back-to-back Juniper Networks routers than in networks in which a Juniper Networks router is connected to an ADM.

As an example, the following configuration shows the link state replication configuration between the ports **coc3-1/0/0** and **coc3-2/0/0**.

```
interfaces {
  coc3-1/0/0 {
    sonet-options {
      aps {
        preserve-interface;
        working-circuit aps-group-1;
      }
    }
  }
  coc3-2/0/0 {
    sonet-options {
      aps {
        preserve-interface;
      }
    }
  }
}
```

```

        protect-circuit aps-group-1;
    }
}
}

```

Examples: Configuring Redundant LSQ Interfaces for Failure Recovery

Configuring LSQ Interface Redundancy for MLPPP

The following configuration shows that **lsq-1/1/0** and **lsq-1/3/0** work as a pair and the redundancy type is **hot-standby**, which sets the requirement for the failure detection and recovery time to be less than 5 seconds:

```

interfaces rlsq0 {
  redundancy-options {
    primary lsq-1/1/0;
    secondary lsq-1/3/0;
    hot-standby; #either hot-standby or warm-standby is supported
  }
}

```

The following example shows a related MLPPP configuration:

NOTE: MLPPP protocol configuration is required for this configuration.

```

interfaces {
  t1-1/1/2/0 {
    unit 0 {
      family mlppp {
        bundle rlsq0.0;
      }
    }
  }
  rlsq0 {
    unit 0 {
      family inet {
        address 30.1.1.2/24;
      }
    }
  }
}

```

The following example shows a related CoS configuration:

```

class-of-service {
  interfaces {
    rlsq0 {
      unit * {
        fragmentation-maps fr-map1;
      }
    }
  }
}

```

```
}

```

The following example shows a complete link state replication configuration for MLPPP. This example uses two bundles, each with four T1 links. The first four T1 links (**t1-*:1** through **t1-*:4**) form the first bundle and the last four T1 links (**t1-*:5** through **t1-*:8**) form the second bundle. To minimize the duplication in the configuration, this example uses the **[edit groups]** statement; for more information, see the *Junos OS Administration Library for Routing Devices*. This type of configuration is not required; it simplifies the task and minimizes duplication.

```
groups {
  ml-partition-group {
    interfaces {
      <coc3-*> {
        partition 1 oc-slice 1 interface-type coc1;
      }
      <coc1-*> {
        partition 1-8 interface-type t1;
      }
    }
  }
  ml-bundle-group-1 {
    interfaces {
      <t1-*:"[1-4]"> {
        encapsulation ppp;
        unit 0 {
          family mlppp {
            bundle lsq-0/1/0.0;
          }
        }
      }
    }
  }
  ml-bundle-group-2 {
    interfaces {
      <t1-*:"[5-8]"> {
        encapsulation ppp;
        unit 0 {
          family mlppp {
            bundle lsq-0/1/0.1;
          }
        }
      }
    }
  }
}
interfaces {
  lsq-0/1/0 {
    unit 0 {
      encapsulation multilink-ppp;
      family inet {
        address 1.1.1/32 {
          destination 1.1.1.2;
        }
      }
    }
  }
}
```

```
}
unit 1 {
    encapsulation multilink-ppp;
    family inet {
        address 1.1.2.1/32 {
            destination 1.1.2.2;
        }
    }
}
}
coc3-1/0/0 {
    apply-groups ml-partition-group;
    sonet-options {

        apply-groups ml-bundle-group-2;
    }
    t1-2/0/0:1:7 {
        apply-groups ml-bundle-group-2;
    }
    t1-2/0/0:1:8 {
        apply-groups ml-bundle-group-2;
    }
}
```

Configuring LSQ Interface Redundancy for an FRF.15 Bundle

The following example shows a configuration for an FRF.15 bundle:

```
interfaces rlsq0 {
    redundancy-options {
        primary lsq-1/2/0;
        secondary lsq-1/3/0;
        warm-standby; #either hot-standby or warm-standby is supported
    }
    unit 0 {
        encapsulation multilink-frame-relay-end-to-end;
        family inet {
            address 30.1.1.1/24;
        }
    }
}
```

Configuring LSQ Interface Redundancy for an FRF.16 Bundle

The following example shows a configuration for an FRF.16 bundle:

```
interfaces rlsq0:0 {
    dce;
    encapsulation multilink-frame-relay-uni-nni;
```

```
redundancy-options {  
  primary lsq-1/2/0:0;  
  secondary lsq-1/3/0:0;  
  warm-standby; #either hot-standby or warm-standby is supported  
}  
unit 0 {  
  dlc 1000;  
  family inet {  
    address 50.1.1.1/24;  
  }  
}
```

Inline MLPPP for WAN Interfaces Overview

Inline Multilink PPP (MLPPP), Multilink Frame Relay (FRF.16), and Multilink Frame Relay End-to-End (FRF.15) for time-division multiplexing (TDM) WAN interfaces provide bundling services through the Packet Forwarding Engine without requiring a PIC or Dense Port Concentrator (DPC).

Traditionally, bundling services are used to bundle multiple low-speed links to create a higher bandwidth pipe. This combined bandwidth is available to traffic from all links and supports link fragmentation and interleaving (LFI) on the bundle, reducing high priority packet transmission delay.

This support includes multiple links on the same bundle as well as multiclass extension for MLPPP. Through this service you can enable bundling services without additional DPC slots to support Service DPC and free up the slots for other MICs.

NOTE: MLPPP is not supported on MX Series Virtual Chassis.

Configuring inline MLPPP for WAN interfaces benefits the following services:

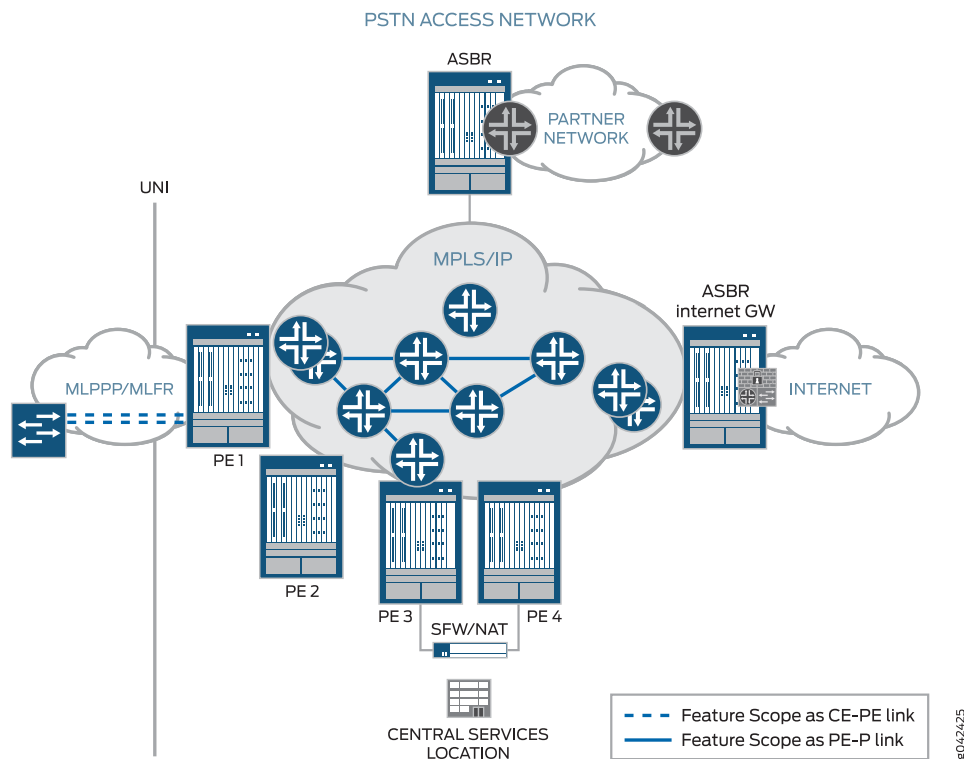

- CE-PE link for Layer 3 VPN and DIA service with public switched telephone networks (PSTN)-based access networks.
- PE-P link when PSTN is used for MPLS networks.

This feature is used by the following service providers:

- Service providers that use PSTN to offer Layer 3 VPN and DIA service with PSTN-based access networks to medium or large business customers.
- Service providers with SONET-based core networks.

The following figure illustrates the scope of this feature:

Figure 25: Inline MLPPP for WAN Interfaces

For connecting many smaller sites in VPNs, bundling the TDM circuits together with MLPPP/MLFR technology is the *only* way to offer higher bandwidth and link redundancy.

MLPPP enables you to bundle multiple PPP links into a single multilink bundle, and MLFR enables you to bundle multiple Frame Relay data-link connection identifiers (DLCIs) into

a single multilink bundle. Multilink bundles provide additional bandwidth, load balancing, and redundancy by aggregating low-speed links, such as T1, E1, and serial links.

MLPPP is a protocol for aggregating multiple constituent links into one larger PPP bundle. MLFR allows you to aggregate multiple Frame Relay links by inverse multiplexing. MLPPP and MLFR provide service options between low-speed T1 and E1 services. In addition to providing additional bandwidth, bundling multiple links can add a level of fault tolerance to your dedicated access service. Because you can implement bundling across multiple interfaces, you can protect users against loss of access when a single interface fails.

To configure inline MLPPP for WAN interfaces, see:

Reserving Bundle Bandwidth for Link-Layer Overhead on LSQ Interfaces

Link-layer overhead can cause packet drops on constituent links because of bit stuffing on serial links. Bit stuffing is used to prevent data from being interpreted as control information.

By default, 4 percent of the total bundle bandwidth is set aside for link-layer overhead. In most network environments, the average link-layer overhead is 1.6 percent. Therefore, we recommend 4 percent as a safeguard. For more information, see RFC 4814, *Hash and Stuffing: Overlooked Factors in Network Device Benchmarking*.

For link services IQ (**lsq-**) interfaces, you can configure the percentage of bundle bandwidth to be set aside for link-layer overhead. To do this, include the **link-layer-overhead** statement:

```
link-layer-overhead percent;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* *mlfr-uni-nni-bundle-options*]**
- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

You can configure the value to be from 0 percent through 50 percent.

Configuring Multiclass MLPPP on LSQ Interfaces

For link services IQ (**lsq**-) interfaces with MLPPP encapsulation, you can configure multiclass MLPPP (MCML). If you do not configure MCML, fragments from different classes cannot be interleaved. All fragments for a single packet must be sent before the fragments from another packet are sent. Nonfragmented packets can be interleaved between fragments of another packet to reduce latency seen by nonfragmented packets. In effect, latency-sensitive traffic is encapsulated as regular PPP traffic, and bulk traffic is encapsulated as multilink traffic. This model works as long as there is a single class of latency-sensitive traffic, and there is no high-priority traffic that takes precedence over latency-sensitive traffic. This approach to LFI, used on the Link Services PIC, supports only two levels of traffic priority, which is not sufficient to carry the four-to-eight forwarding classes that are supported by M Series and T Series routers. For more information about the Link Services PIC support of LFI, see “[Configuring Delay-Sensitive Packet Interleaving on Link Services Logical Interfaces](#)” on page 773.

For link services IQ interfaces only, you can configure MCML, as defined in RFC 2686, *The Multi-Class Extension to Multi-Link PPP*. MCML makes it possible to have multiple classes of latency-sensitive traffic that are carried over a single multilink bundle with bulk traffic. In effect, MCML allows different classes of traffic to have different latency guarantees. With MCML, you can map each forwarding class into a separate multilink class, thus preserving priority and latency guarantees.

NOTE: Configuring both LFI and MCML on the same bundle is not necessary, nor is it supported, because multiclass MLPPP represents a superset of functionality. When you configure multiclass MLPPP, LFI is automatically enabled.

The Junos OS implementation of MCML does not support compression of common header bytes, which is referred to in RFC 2686 as “prefix elision.”

MCML greatly simplifies packet ordering issues that occur when multiple links are used. Without MCML, all voice traffic belonging to a single flow is hashed to a single link to avoid packet ordering issues. With MCML, you can assign voice traffic to a high-priority class, and you can use multiple links. For more information about voice services support on link services IQ interfaces (**lsq**), see “[Configuring Services Interfaces for Voice Services](#)” on page 622.

To configure MCML on a link services IQ interface, you must specify how many multilink classes should be negotiated when a link joins the bundle, and you must specify the mapping of a forwarding class into an MCML class.

To specify how many multilink classes should be negotiated when a link joins the bundle, include the **multilink-max-classes** statement:

```
multilink-max-classes number;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

The number of multilink classes can be 1 through 8. The number of multilink classes for each forwarding class must not exceed the number of multilink classes to be negotiated.

To specify the mapping of a forwarding class into a MCML class, include the **multilink-class** statement at the **[edit class-of-service fragmentation-maps *map-name* forwarding-class *class-name*]** hierarchy level:

```
[edit class-of-service fragmentation-maps map-name forwarding-class class-name]  
multilink-class number;
```

The multilink class index number can be 0 through 7. The **multilink-class** statement and **no-fragmentation** statements are mutually exclusive.

To view the number of multilink classes negotiated, issue the **show interfaces *lsq-fpc/pic/port.logical-unit-number* detail** command.

Enabling Inline LSQ Services

Inline Multilink PPP (MLPPP), Multilink Frame Relay (FRF.16), and Multilink Frame Relay End-to-End (FRF.15) for time-division multiplexing (TDM) WAN interfaces provide bundling services through the Packet Forwarding Engine without requiring a PIC or Dense Port Concentrator (DPC).

Traditionally, bundling services are used to bundle multiple low-speed links to create a higher bandwidth pipe. This combined bandwidth is available to traffic from all links and supports link fragmentation and interleaving (LFI) on the bundle, reducing high priority packet transmission delay.

This support includes multiple links on the same bundle as well as multiclass extension for MLPPP. Through this service you can enable bundling services without additional DPC slots to support Service DPC and free up the slots for other MICs.

The inline LSQ logical interface (referred to as `lsq-`) is a virtual service logical interface that resides on the Packet Forwarding Engine to provide Layer 2 bundling services that do not need a service PIC. The naming convention is `lsq-slot/pic/O`. Currently, only TYPE1 and TYPE2 queuing Modular Point Concentrators (MPCs) support inline LSQ logical interfaces. A Type1 MPC has only one logical unit (LU); therefore only one LSQ logical interface can be created. When configuring a Type1 MPC, use PIC slot 0. Type2 MPC has two LUs; therefore two LSQ logical interfaces can be created. When configuring a Type2 MPC, use PIC slot 0 and slot 2.

Configure each LSQ logical interface with one loopback stream. This stream can be shaped like a regular stream, and is shared with other inline interfaces, such as the inline services (SI) interface.

To support FRF.16 bundles, create logical interfaces with the naming convention `lsq-slot/pic/O:bundle_id`, where *bundle_id* can range from 0 to 254. You can configure logical interfaces created on the main LSQ logical interface as MLPPP or FRF.16.

Because SI and LSQ logical interfaces might share the same stream, and there could be multiple LSQ logical interfaces on that stream, any logical interface-related shaping is configured at the Layer 2 node instead of the Layer 1 node. As a result, when SI is enabled, instead of limiting the stream bandwidth to 1Gb or 10Gb based on the configuration, only the Layer 2 queue allocated for the SI interface is shaped at 1Gb or 10Gb.

For MLPPP and FRF.15, each LSQ logical interface is shaped based on the total bundle bandwidth (sum of member link bandwidths with control packet flow overhead) by configuring one unique Layer 3 node per bundle. Similarly, each FRF.16 logical interface is shaped based on total bundle bandwidth by configuring one unique Layer 2 node per bundle. FRF.16 logical interface data-link connection identifiers (DLCIs) are mapped to Layer 3 nodes.

To enable inline LSQ services and create the `lsq-` logical interface for the specified PIC, specify the `multi-link-layer-2-inline` and `mlfr-uni-nni-bundles-inline` configuration statements.

```
[edit chassis fpc number pic number]
user@host# set multi-link-layer-2-inline
user@host# set mlfr-uni-nni-bundles-inline number
```

For example, to enable inline service for PIC 0 on a Type1 MPC on slot 1:

```
[edit chassis fpc 1 pic 0]
user@host# set multi-link-layer-2-inline
user@host# set mlfr-uni-nni-bundles-inline 1
```

As a result, logical interfaces `lsq-1/0/0`, `lsq-1/0/0:0`, and `lsq-1/0/0:1` are created. The number of inline multilink frame relay user-to-network interface (UNI) and network-to-network interface (NNI) bundles is set to 1.

For example, to enable inline service for both PIC 0 and PIC 2 on Type2 MPC installed in slot 5:

```
[edit chassis fpc 5 pic 0]
user@host# set multi-link-layer-2-inline
user@host# set mlfr-uni-nni-bundles-inline 1
```

```
[edit chassis fpc 5 pic 2]
user@host# set multi-link-layer-2-inline
user@host# set mlfr-uni-nni-bundles-inline 1
```

As a result, logical interfaces lsq-5/0/0, lsq-5/0/0:0, lsq-5/0/0:1, lsq-5/2/0, lsq-5/2/0:0, and lsq-5/2/0:1 are created. The number of inline multilink frame relay user-to-network interface (UNI) and network-to-network interface (NNI) bundles is set to 1.

NOTE: The PIC number here is only used as an anchor to choose the correct LU to bind the inline LSQ interface. The bundling services are operational as long as the Packet Forwarding Engine to which it is bound is operational, even if the logical PIC is offline.

Configuring LSQ Interfaces as NxT1 or NxE1 Bundles Using MLPPP

To configure an NxT1 bundle using MLPPP, you aggregate *N* different T1 links into a bundle. The NxT1 bundle is called a logical interface, because it can represent, for example, a routing adjacency. To aggregate T1 links into a an MLPPP bundle, include the **bundle** statement at the `[edit interfaces t1-fpc/pic/port unit logical-unit-number family mlppp]` hierarchy level:

```
[edit interfaces t1-fpc/pic/port unit logical-unit-number family mlppp]
bundle lsq-fpc/pic/port.logical-unit-number;
```

NOTE: Link services IQ interfaces support both T1 and E1 physical interfaces. These instructions apply to T1 interfaces, but the configuration for E1 interfaces is similar.

To configure the link services IQ interface properties, include the following statements at the `[edit interfaces lsq-fpc/pic/port unit logical-unit-number]` hierarchy level:

```
[edit interfaces lsq-fpc/pic/port unit logical-unit-number]
drop-timeout milliseconds;
```

```

encapsulation multilink-ppp;
fragment-threshold bytes;
link-layer-overhead percent;
minimum-links number;
mrru bytes;
short-sequence;
family inet {
    address address;
}

```

The logical link services IQ interface represents the MLPPP bundle. For the MLPPP bundle, there are four associated queues on M Series routers and eight associated queues on M320 and T Series routers. A scheduler removes packets from the queues according to a scheduling policy. Typically, you designate one queue to have strict priority, and the remaining queues are serviced in proportion to weights you configure.

For MLPPP, assign a single scheduler map to the link services IQ interface (**lsq**) and to each constituent link. The default schedulers for M Series and T Series routers, which assign 95, 0, 0, and 5 percent bandwidth for the transmission rate and buffer size of queues 0, 1, 2, and 3, are not adequate when you configure LFI or multiclass traffic. Therefore, for MLPPP, you should configure a single scheduler with nonzero percent transmission rates and buffer sizes for queues 0 through 3, and assign this scheduler to the link services IQ interface (**lsq**) and to each constituent link, as shown in [“Example: Configuring an LSQ Interface as an NxT1 Bundle Using MLPPP” on page 568](#).

NOTE: For M320 and T Series routers, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent.

If the member link belonging to one MLPP, MLFR, or MFR bundle interface is moved to another bundle interface, or the links are swapped between two bundle interfaces, a commit is required between the delete and add operations to ensure that the configuration is applied correctly.

If the bundle has more than one link, you must include the **per-unit-scheduler** statement at the **[edit interfaces lsq-fpc/pic/port]** hierarchy level:

```

[edit interfaces lsq-fpc/pic/port]
per-unit-scheduler;

```

To configure and apply the scheduling policy, include the following statements at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
interfaces {
    t1-fpc/pic/port unit logical-unit-number {
        scheduler-map map-name;
    }
}
forwarding-classes {
    queue queue-number class-name;
}

```

```

scheduler-maps {
  map-name {
    forwarding-class class-name scheduler scheduler-name;
  }
}
schedulers {
  scheduler-name {
    buffer-size (percent percentage | remainder | temporal microseconds);
    priority priority-level;
    transmit-rate (rate | percent percentage | remainder) <exact>;
  }
}

```

For link services IQ interfaces, a strict-high-priority queue might starve the other three queues because traffic in a strict-high priority queue is transmitted before any other queue is serviced. This implementation is unlike the standard Junos CoS implementation in which a strict-high-priority queue does round-robin with high-priority queues, as described in the *Class of Service Feature Guide for Routing Devices*.

After the scheduler removes a packet from a queue, a certain action is taken. The action depends on whether the packet came from a multilink encapsulated queue (fragmented and sequenced) or a nonencapsulated queue (hashed with no fragmentation). Each queue can be designated as either multilink encapsulated or nonencapsulated, independently of the other. By default, traffic in all forwarding classes is multilink encapsulated. To configure packet fragmentation handling on a queue, include the **fragmentation-maps** statement at the **[edit class-of-service]** hierarchy level:

```

fragmentation-maps {
  map-name {
    forwarding-class class-name {
      fragment-threshold bytes;
      multilink-class number;
      no-fragmentation;
    }
  }
}

```

For NxT1 bundles using MLPPP, the byte-wise load balancing used in multilink-encapsulated queues is superior to the flow-wise load balancing used in nonencapsulated queues. All other considerations are equal. Therefore, we recommend that you configure all queues to be multilink encapsulated. You do this by including the **fragment-threshold** statement in the configuration. If you choose to set traffic on a queue to be nonencapsulated rather than multilink encapsulated, include the **no-fragmentation** statement in the fragmentation map. You use the **multilink-class** statement to map a forwarding class into a multiclass MLPPP (MCML). For more information about MCML, see [“Configuring Multiclass MLPPP on LSQ Interfaces” on page 562](#). For more information about fragmentation maps, see [“Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces” on page 527](#).

When a packet is removed from a multilink-encapsulated queue, the software gives the packet an MLPPP header. The MLPPP header contains a sequence number field, which is filled with the next available sequence number from a counter. The software then

places the packet on one of the N different T1 links. The link is chosen on a packet-by-packet basis to balance the load across the various T1 links.

If the packet exceeds the minimum link MTU, or if a queue has a fragment threshold configured at the **[edit class-of-service fragmentation-maps *map-name* forwarding-class *class-name*]** hierarchy level, the software splits the packet into two or more fragments, which are assigned consecutive multilink sequence numbers. The outgoing link for each fragment is selected independently of all other fragments.

If you do not include the **fragment-threshold** statement in the fragmentation map, the fragmentation threshold you set at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level is the default for all forwarding classes. If you do not set a maximum fragment size anywhere in the configuration, packets are fragmented if they exceed the smallest MTU of all the links in the bundle.

Even if you do not set a maximum fragment size anywhere in the configuration, you can configure the maximum received reconstructed unit (MRRU) by including the **mrru** statement at the **[edit interfaces *lsq-fpc/pic/port* unit *logical-unit-number*]** hierarchy level. The MRRU is similar to the MTU, but is specific to link services interfaces. By default the MRRU size is 1500 bytes, and you can configure it to be from 1500 through 4500 bytes. For more information, see [“Configuring MRRU on Multilink and Link Services Logical Interfaces” on page 734](#).

When a packet is removed from a nonencapsulated queue, it is transmitted with a plain PPP header. Because there is no MLPPP header, there is no sequence number information. Therefore, the software must take special measures to avoid packet reordering. To avoid packet reordering, the software places the packet on one of the N different T1 links. The link is determined by hashing the values in the header. For IP, the software computes the hash based on source address, destination address, and IP protocol. For MPLS, the software computes the hash based on up to five MPLS labels, or four MPLS labels and the IP header.

For UDP and TCP the software computes the hash based on the source and destination ports, as well as source and destination IP addresses. This guarantees that all packets belonging to the same TCP/UDP flow always pass through the same T1 link, and therefore cannot be reordered. However, it does not guarantee that the load on the various T1 links is balanced. If there are many flows, the load is usually balanced.

The N different T1 interfaces link to another router, which can be from Juniper Networks or another vendor. The router at the far end gathers packets from all the T1 links. If a packet has an MLPPP header, the sequence number field is used to put the packet back into sequence number order. If the packet has a plain PPP header, the software accepts the packet in the order in which it arrives and makes no attempt to reassemble or reorder the packet.

Example: Configuring an LSQ Interface as an NxT1 Bundle Using MLPPP

```
[edit chassis]
fpc 1 {
  pic 3 {
    adaptive-services {
      service-package layer-2;
```

```

    }
  }
}
[edit interfaces]
t1-0/0/0 {
  encapsulation ppp;
  unit 0 {
    family mlppp {
      bundle lsq-1/3/0.1; # This adds t1-0/0/0 to the specified bundle.
    }
  }
}
t1-0/0/1 {
  encapsulation ppp;
  unit 0 {
    family mlppp {
      bundle lsq-1/3/0.1;
    }
  }
}
lsq-1/3/0 {
  unit 1 { # This is the virtual link that concatenates multiple T1s.
    encapsulation multilink-ppp;
    drop-timeout 1000;
    fragment-threshold 128;
    link-layer-overhead 0.5;
    minimum-links 2;
    mrru 4500;
    short-sequence;
    family inet {
      address 10.2.3.4/24;
    }
  }
}
[edit interfaces]
lsq-1/3/0 {
  per-unit-scheduler;
}
[edit class-of-service]
interfaces {
  lsq-1/3/0 { # multilink PPP constituent link
    unit 0 {
      scheduler-map sched-map1;
    }
  }
  t1-0/0/0 { # multilink PPP constituent link
    unit 0 {
      scheduler-map sched-map1;
    }
  }
  t1-0/0/1 { # multilink PPP constituent link
    unit 0 {
      scheduler-map sched-map1;
    }
  }
forwarding-classes {
  queue 0 be;
  queue 1 ef;
  queue 2 af;
}

```

```
    queue 3 nc;
}
scheduler-maps {
  sched-map1 {
    forwarding-class af scheduler af-scheduler;
    forwarding-class be scheduler be-scheduler;
    forwarding-class ef scheduler ef-scheduler;
    forwarding-class nc scheduler nc-scheduler;
  }
}
schedulers {
  af-scheduler {
    transmit-rate percent 30;
    buffer-size percent 30;
    priority low;
  }
  be-scheduler {
    transmit-rate percent 25;
    buffer-size percent 25;
    priority low;
  }
  ef-scheduler {
    transmit-rate percent 40;
    buffer-size percent 40;
    priority strict-high; # voice queue
  }
  nc-scheduler {
    transmit-rate percent 5;
    buffer-size percent 5;
    priority high;
  }
}
fragmentation-maps {
  fragmap-1 {
    forwarding-class be {
      fragment-threshold 180;
    }
    forwarding-class ef {
      fragment-threshold 100;
    }
  }
}
[edit interfaces]
lsq-1/3/0 {
  unit 0 {
    fragmentation-map fragmap-1;
  }
}

Configuring LSQ Interfaces as NxT1 or NxE1 Bundles Using FRF.16

To configure an NxT1 bundle using FRF.16, you aggregate *N* different T1 links into a bundle. The NxT1 bundle carries a potentially large number of Frame Relay PVCs, identified by their DLCIs. Each DLCI is called a logical interface, because it can represent, for example, a routing adjacency.

To aggregate T1 links into an FRF.16 bundle, include the **mlfr-uni-nni-bundles** statement at the **[edit chassis fpc slot-number pic slot-number]** hierarchy level and include the **bundle** statement at the **[edit interfaces t1-fpc/pic/port unit logical-unit-number family mlfr-uni-nni]** hierarchy level:

```
[edit chassis fpc slot-number pic slot-number]
mlfr-uni-nni-bundles number;
```

```
[edit interfaces t1-fpc/pic/port unit logical-unit-number family mlfr-uni-nni]
bundle lsq-fpc/pic/port:channel;
```

NOTE: Link services IQ interfaces support both T1 and E1 physical interfaces. These instructions apply to T1 interfaces, but the configuration for E1 interfaces is similar.

To configure the link services IQ interface properties, include the following statements at the **[edit interfaces lsq- fpc/pic/port:channel]** hierarchy level:

```
[edit interfaces lsq- fpc/pic/port:channel]
encapsulation multilink-frame-relay-uni-nni;
dce;
mlfr-uni-nni-options {
  acknowledge-retries number;
  acknowledge-timer milliseconds;
  action-red-differential-delay (disable-tx | remove-link);
  drop-timeout milliseconds;
  fragment-threshold bytes;
  hello-timer milliseconds;
  link-layer-overhead percent;
  lmi-type (ansi | itu);
  minimum-links number;
  mrru bytes;
  n391 number;
  n392 number;
  n393 number;
  red-differential-delay milliseconds;
  t391 number;
  t392 number;
  yellow-differential-delay milliseconds;
}
unit logical-unit-number {
  dlcid dlcid-identifier;
  family inet {
    address address;
```

```
}  
}
```

The link services IQ channel represents the FRF.16 bundle. Four queues are associated with each DLCI. A scheduler removes packets from the queues according to a scheduling policy. On the link services IQ interface, you typically designate one queue to have strict priority. The remaining queues are serviced in proportion to weights you configure.

For link services IQ interfaces, a strict-high-priority queue might starve the other three queues because traffic in a strict-high-priority queue is transmitted before any other queue is serviced. This implementation is unlike the standard Junos CoS implementation in which a strict-high-priority queue does round-robin with high-priority queues, as described in the *Class of Service Feature Guide for Routing Devices*.

If the bundle has more than one link, you must include the **per-unit-scheduler** statement at the **[edit interfaces lsq-fpc/pic/port:channel]** hierarchy level:

```
[edit interfaces lsq-fpc/pic/port:channel]  
  per-unit-scheduler;
```

For FRF.16, you can assign a single scheduler map to the link services IQ interface (**lsq**) and to each link services IQ DLCI, or you can assign different scheduler maps to the various DLCIs of the bundle, as shown in [“Example: Configuring an LSQ Interface as an NxT1 Bundle Using FRF.16” on page 574](#).

For the constituent links of an FRF.16 bundle, you do not need to configure a custom scheduler. Because LFI and multiclass are not supported for FRF.16, the traffic from each constituent link is transmitted from queue 0. This means you should allow most of the bandwidth to be used by queue 0. For M Series and T Series routers, the default schedulers' transmission rate and buffer size percentages for queues 0 through 3 are 95, 0, 0, and 5 percent. These default schedulers send all user traffic to queue 0 and all network-control traffic to queue 3, and therefore are well suited to the behavior of FRF.16. If desired, you can configure a custom scheduler that explicitly replicates the 95, 0, 0, and 5 percent queuing behavior, and apply it to the constituent links.

NOTE: For M320 and T Series routers, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent.

If the member link belonging to one MLPP, MLFR, or MFR bundle interface is moved to another bundle interface, or the links are swapped between two bundle interfaces, a commit is required between the delete and add operations to ensure that the configuration is applied correctly.

To configure and apply the scheduling policy, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]  
  interfaces {  
    lsq-fpc/pic/port:channel {  
      unit logical-unit-number {
```

```

        scheduler-map map-name;
    }
}
forwarding-classes {
    queue queue-number class-name;
}
scheduler-maps {
    map-name {
        forwarding-class class-name scheduler scheduler-name;
    }
}
schedulers {
    scheduler-name {
        buffer-size (percent percentage | remainder | temporal microseconds);
        priority priority-level;
        transmit-rate (rate | percent percentage | remainder) <exact>;
    }
}

```

To configure packet fragmentation handling on a queue, include the **fragmentation-maps** statement at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
fragmentation-maps {
    map-name {
        forwarding-class class-name {
            fragment-threshold bytes;
        }
    }
}

```

For FRF.16 traffic, only multilink encapsulated (fragmented and sequenced) queues are supported. This is the default queuing behavior for all forwarding classes. FRF.16 does not allow for nonencapsulated traffic because the protocol requires that all packets carry the fragmentation header. If a large packet is split into multiple fragments, the fragments must have consecutive sequential numbers. Therefore, you cannot include the **no-fragmentation** statement at the **[edit class-of-service fragmentation-maps *map-name* forwarding-class *class-name*]** hierarchy level for FRF.16 traffic. For FRF.16, if you want to carry voice or any other latency-sensitive traffic, you should not use slow links. At T1 speeds and above, the serialization delay is small enough so that you do not need to use explicit LFI.

When a packet is removed from a multilink-encapsulated queue, the software gives the packet an FRF.16 header. The FRF.16 header contains a sequence number field, which is filled with the next available sequence number from a counter. The software then places the packet on one of the *N* different T1 links. The link is chosen on a packet-by-packet basis to balance the load across the various T1 links.

If the packet exceeds the minimum link MTU, or if a queue has a fragment threshold configured at the **[edit class-of-service fragmentation-maps *map-name* forwarding-class *class-name*]** hierarchy level, the software splits the packet into two or more fragments, which are assigned consecutive multilink sequence numbers. The outgoing link for each fragment is selected independently of all other fragments.

If you do not include the **fragment-threshold** statement in the fragmentation map, the fragmentation threshold you set at the **[edit interfaces *interface-name* unit *logical-unit-number*]** or **[edit interfaces *interface-name* mlfr-uni-nni-bundle-options]** hierarchy level is the default for all forwarding classes. If you do not set a maximum fragment size anywhere in the configuration, packets are fragmented if they exceed the smallest MTU of all the links in the bundle.

Even if you do not set a maximum fragment size anywhere in the configuration, you can configure the maximum received reconstructed unit (MRRU) by including the **mrru** statement at the **[edit interfaces *lsq-fpc/port* unit *logical-unit-number*]** or **[edit interfaces *interface-name* mlfr-uni-nni-bundle-options]** hierarchy level. The MRRU is similar to the MTU but is specific to link services interfaces. By default, the MRRU size is 1500 bytes, and you can configure it to be from 1500 through 4500 bytes. For more information, see [“Configuring MRRU on Multilink and Link Services Logical Interfaces” on page 734](#).

The *N* different T1 interfaces link to another router, which can be from Juniper Networks or another vendor. The router at the far end gathers packets from all the T1 links. Because each packet has an FRF.16 header, the sequence number field is used to put the packet back into sequence number order.

Example: Configuring an LSQ Interface as an NxT1 Bundle Using FRF.16

Configure an NxT1 bundle using FRF.16 with multiple CoS scheduler maps:

```
[edit chassis fpc 1 pic 3]
adaptive-services {
  service-package layer-2;
}
mlfr-uni-nni-bundles 2; # Creates channelized LSQ interfaces/FRF.16 bundles.
[edit interfaces]
t1-0/0/0 {
  encapsulation multilink-frame-relay-uni-nni;
  unit 0 {
    family mlfr-uni-nni {
      bundle lsq-1/3/0:1;
    }
  }
}
t1-0/0/1 {
  encapsulation multilink-frame-relay-uni-nni;
  unit 0 {
    family mlfr-uni-nni {
      bundle lsq-1/3/0:1;
    }
  }
}
lsq-1/3/0:1 { # Bundle link consisting of t1-0/0/0 and t1-0/0/1
  per-unit-scheduler;
  encapsulation multilink-frame-relay-uni-nni;
  dce; # One end needs to be configured as DCE.
  mlfr-uni-nni-bundle-options {
    drop-timeout 180;
    fragment-threshold 64;
  }
}
```

```

hello-timer 180;
minimum-links 2;
mrru 3000;
link-layer-overhead 0.5;
}
unit 0 {
  dlci 26; # Each logical unit maps a single DLCI.
  family inet {
    address 10.2.3.4/24;
  }
}
unit 1 {
  dlci 42;
  family inet {
    address 10.20.30.40/24;
  }
}
unit 2 {
  dlci 69;
  family inet {
    address 10.20.30.40/24;
  }
}
[edit class-of-service]
scheduler-maps {
  sched-map-lsq0 {
    forwarding-class af scheduler af-scheduler-lsq0;
    forwarding-class be scheduler be-scheduler-lsq0;

Configuring LSQ Interfaces as NxT1 or NxEl Bundles Using FRF.15

This example configures an NxT1 bundle using FRF.15 on a link services IQ interface. FRF.15 is similar to FRF.12, as described in [“Configuring LSQ Interfaces for Single Fractional T1 or El Interfaces Using FRF.12” on page 582](#). The difference is that FRF.15 supports multiple physical links in a bundle, whereas FRF.12 supports only one physical link per bundle. For the Junos OS implementation of FRF.15, you can configure one DLCI per physical link.

NOTE: Link services IQ interfaces support both T1 and E1 physical interfaces. This example refers to T1 interfaces, but the configuration for E1 interfaces is similar.

```
[edit interfaces]
lsq-1/3/0 {
  per-unit-scheduler;
  unit 0 {
    encapsulation multilink-frame-relay-end-to-end;
  }
}
unit 1 {
  encapsulation multilink-frame-relay-end-to-end;
}
# First physical link
t1-1/1/0:1 {
  encapsulation frame-relay;
  unit 0 {
    dlci 69;
    family mlfr-end-to-end {
      bundle lsq-1/3/0.0;
    }
  }
}
# Second physical link
t1-1/1/0:2 {
  encapsulation frame-relay;
  unit 0 {
    dlci 13;
    family mlfr-end-to-end {
      bundle lsq-1/3/0.0;
    }
  }
}
```

Configuring LSQ Interfaces for Single Fractional T1 or E1 Interfaces Using MLPPP and LFI

When you configure a single fractional T1 interface, it is called a logical interface, because it can represent, for example, a routing adjacency.

The logical link services IQ interface represents the MLPPP bundle. Four queues are associated with the logical interface. A scheduler removes packets from the queues

according to a scheduling policy. Typically, you designate one queue to have strict priority, and the remaining queues are serviced in proportion to weights you configure.

To configure a single fractional T1 interface using MLPPP and LFI, you associate one DSO (fractional T1) interface with a link services IQ interface. To associate a fractional T1 interface with a link services IQ interface, include the **bundle** statement at the **[edit interfaces ds-fpc/pic/port:channel unit logical-unit-number family mlppp]** hierarchy level:

```
[edit interfaces ds-fpc/pic/port:channel unit logical-unit-number family mlppp]
bundle lsq-fpc/pic/port.logical-unit-number;
```

NOTE: Link services IQ interfaces support both T1 and E1 physical interfaces. These instructions apply to T1 interfaces, but the configuration for E1 interfaces is similar.

To configure the link services IQ interface properties, include the following statements at the **[edit interfaces lsq-fpc/pic/port unit logical-unit-number]** hierarchy level:

```
[edit interfaces lsq-fpc/pic/port unit logical-unit-number]
drop-timeout milliseconds;
encapsulation multilink-ppp;
fragment-threshold bytes;
link-layer-overhead percent;
minimum-links number;
mrru bytes;
short-sequence;
family inet {
    address address;
}
```

For MLPPP, assign a single scheduler map to the link services IQ (**lsq**) interface and to each constituent link. The default schedulers for M Series and T Series routers, which assign 95, 0, 0, and 5 percent bandwidth for the transmission rate and buffer size of queues 0, 1, 2, and 3, are not adequate when you configure LFI or multiclass traffic. Therefore, for MLPPP, you should configure a single scheduler with nonzero percent transmission rates and buffer sizes for queues 0 through 3, and assign this scheduler to the link services IQ (**lsq**) interface and to each constituent link and to each constituent link, as shown in [“Example: Configuring an LSQ Interface for a Fractional T1 Interface Using MLPPP and LFI” on page 580](#).

NOTE: For M320 and T Series routers, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent.

To configure and apply the scheduling policy, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
interfaces {
    ds-fpc/pic/port.channel {
```

```

        scheduler-map map-name;
    }
}
forwarding-classes {
    queue queue-number class-name;
}
scheduler-maps {
    map-name {
        forwarding-class class-name scheduler scheduler-name;
    }
}
schedulers {
    scheduler-name {
        buffer-size (percent percentage | remainder | temporal microseconds);
        priority priority-level;
        transmit-rate (rate | percent percentage | remainder) <exact>;
    }
}

```

For link services IQ interfaces, a strict-high-priority queue might starve all the other queues because traffic in a strict-high priority queue is transmitted before any other queue is serviced. This implementation is unlike the standard Junos CoS implementation in which a strict-high-priority queue receives infinite credits and does round-robin with high-priority queues, as described in the *Class of Service Feature Guide for Routing Devices*.

After the scheduler removes a packet from a queue, a certain action is taken. The action depends on whether the packet came from a multilink encapsulated queue (fragmented and sequenced) or a nonencapsulated queue (hashed with no fragmentation). Each queue can be designated as either multilink encapsulated or nonencapsulated, independently of the other. By default, traffic in all forwarding classes is multilink encapsulated. To configure packet fragmentation handling on a queue, include the **fragmentation-maps** statement at the **[edit class-of-service]** hierarchy level:

```

[edit class-of-service]
fragmentation-maps {
    map-name {
        forwarding-class class-name {
            fragment-threshold bytes;
            no-fragmentation;
        }
    }
}

```

If you require the queue to transmit small packets with low latency, configure the queue to be nonencapsulated by including the **no-fragmentation** statement. If you require the queue to transmit large packets with normal latency, configure the queue to be multilink encapsulated by including the **fragment-threshold** statement. If you require the queue to transmit large packets with low latency, we recommend using a faster link and configuring the queue to be nonencapsulated. For more information about fragmentation maps, see [“Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces” on page 527](#).

When a packet is removed from a multilink-encapsulated queue, it is fragmented. If the packet exceeds the minimum link MTU, or if a queue has a fragment threshold configured

at the **[edit class-of-service fragmentation-maps *map-name* forwarding-class *class-name*]** hierarchy level, the software splits the packet into two or more fragments, which are assigned consecutive multilink sequence numbers.

If you do not include the **fragment-threshold** statement in the fragmentation map, the fragmentation threshold you set at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level is the default for all forwarding classes. If you do not set a maximum fragment size anywhere in the configuration, packets are fragmented if they exceed the smallest MTU of all the links in the bundle.

Even if you do not set a maximum fragment size anywhere in the configuration, you can configure the maximum received reconstructed unit (MRRU) by including the **mrru** statement at the **[edit interfaces *lsq-fpc/pic/port* unit *logical-unit-number*]** hierarchy level. The MRRU is similar to the MTU, but is specific to link services interfaces. By default the MRRU size is 1500 bytes, and you can configure it to be from 1500 through 4500 bytes. For more information, see [“Configuring MRRU on Multilink and Link Services Logical Interfaces” on page 734](#).

When a packet is removed from a multilink-encapsulated queue, the software gives the packet an MLPPP header. The MLPPP header contains a sequence number field, which is filled with the next available sequence number from a counter. The software then places the packet on the fractional T1 link. Traffic from another queue might be interleaved between two fragments of the packet.

When a packet is removed from a nonencapsulated queue, it is transmitted with a plain PPP header. The packet is then placed on the fractional T1 link as soon as possible. If necessary, the packet is placed between the fragments of a packet from another queue.

The fractional T1 interface links to another router, which can be from Juniper Networks or another vendor. The router at the far end gathers packets from the fractional T1 link. If a packet has an MLPPP header, the software assumes the packet is a fragment of a larger packet, and the fragment number field is used to reassemble the larger packet. If the packet has a plain PPP header, the software accepts the packet in the order in which it arrives, and the software makes no attempt to reassemble or reorder the packet.

Example: Configuring an LSQ Interface for a Fractional T1 Interface Using MLPPP and LFI

Configure a single fractional T1 logical interface:

```
[edit interfaces]
lsq-0/2/0 {
  per-unit-scheduler;
  unit 0 {
    encapsulation multilink-ppp;
    link-layer-overhead 0.5;
    family inet {
      address 10.40.1.1/30;
    }
  }
}
ct3-1/0/0 {
  partition 1 interface-type ct1;
}
```

```

ct1-1/0/0:1 {
    partition 1 timeslots 1-2 interface-type ds;
}
ds-1/0/0:1:1 {
    encapsulation ppp;
    unit 0 {
        family mlppp {
            bundle lsq-0/2/0.0;
        }
    }
}
[edit class-of-service]
interfaces {
    ds-1/0/0:1:1 { # multilink PPP constituent link
        unit 0 {
            scheduler-map sched-map1;
        }
    }
}
forwarding-classes {
    queue 0 be;
    queue 1 ef;
    queue 2 af;
    queue 3 nc;
}
scheduler-maps {
    sched-map1 {
        forwarding-class af scheduler af-scheduler;
        forwarding-class be scheduler be-scheduler;
        forwarding-class ef scheduler ef-scheduler;
        forwarding-class nc scheduler nc-scheduler;
    }
}
schedulers {
    af-scheduler {
        transmit-rate percent 20;
        buffer-size percent 20;
        priority low;
    }
    be-scheduler {
        transmit-rate percent 20;
        buffer-size percent 20;
        priority low;
    }
    ef-scheduler {
        transmit-rate percent 50;
        buffer-size percent 50;
        priority strict-high; # voice queue
    }
    nc-scheduler {
        transmit-rate percent 10;
        buffer-size percent 10;
        priority high;
    }
}
fragmentation-maps {
    fragmap-1 {

```

```

        forwarding-class be {
            fragment-threshold 180;
        }
        forwarding-class ef {
            fragment-threshold 100;
        }
    }
}
[edit interfaces]
lsq-0/2/0 {
    unit 0 {
        fragmentation-map fragmap-1;
    }
}

```

Configuring LSQ Interfaces for Single Fractional T1 or E1 Interfaces Using FRF.12

To configure a single fractional T1 interface using FRF.16, you associate a DS0 interface with a link services IQ (lsq) interface. When you configure a single fractional T1, the fractional T1 carries a potentially large number of Frame Relay PVCs identified by their DLCIs. Each DLCI is called a logical interface, because it can represent, for example, a routing adjacency. To associate the DS0 interface with a link services IQ interface, include the **bundle** statement at the **[edit interfaces ds-fpc/pic/port:channel unit logical-unit-number family mlfr-end-to-end]** hierarchy level:

```
[edit interfaces ds-fpc/pic/port:channel unit logical-unit-number family mlfr-end-to-end]
bundle lsq-fpc/pic/port.logical-unit-number;
```

NOTE: Link services IQ interfaces support both T1 and E1 physical interfaces. These instructions apply to T1 interfaces, but the configuration for E1 interfaces is similar.

To configure the link services IQ interface properties, include the following statements at the **[edit interfaces lsq-fpc/pic/port unit logical-unit-number]** hierarchy level:

```
[edit interfaces lsq-fpc/pic/port unit logical-unit-number]
drop-timeout milliseconds;
encapsulation multilink-frame-relay-end-to-end;
fragment-threshold bytes;
link-layer-overhead percent;
minimum-links number;
mrru bytes;
short-sequence;
family inet {
    address address;
```

```
}
```

The logical link services IQ interface represents the FRF.12 bundle. Four queues are associated with each logical interface. A scheduler removes packets from the queues according to a scheduling policy. Typically, you designate one queue to have strict priority, and the remaining queues are serviced in proportion to weights you configure.

For FRF.12, assign a single scheduler map to the link services IQ interface (**lsq**) and to each constituent link. For M Series and T Series routers, the default schedulers, which assign 95, 0, 0, and 5 percent bandwidth for the transmission rate and buffer size of queues 0, 1, 2, and 3, are not adequate when you configure LFI or multiclass traffic. Therefore, for FRF.12, you should configure schedulers with nonzero percent transmission rates and buffer sizes for queues 0 through 3, and assign them to the link services IQ interface (**lsq**) and to each constituent link, as shown in [“Examples: Configuring an LSQ Interface for a Fractional T1 Interface Using FRF.12” on page 585](#).

NOTE: For M320 and T Series routers, the default scheduler transmission rate and buffer size percentages for queues 0 through 7 are 95, 0, 0, 5, 0, 0, 0, and 0 percent.

To configure and apply the scheduling policy, include the following statements at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
interfaces {
  ds-fpc/pic/port.channel {
    scheduler-map map-name;
  }
}
forwarding-classes {
  queue queue-number class-name;
}
scheduler-maps {
  map-name {
    forwarding-class class-name scheduler scheduler-name;
  }
}
schedulers {
  scheduler-name {
    buffer-size (percent percentage | remainder | temporal microseconds);
    priority priority-level;
    transmit-rate (rate | percent percentage | remainder) <exact>;
  }
}
```

For link services IQ interfaces, a strict-high-priority queue might starve the other three queues because traffic in a strict-high-priority queue is transmitted before any other queue is serviced. This implementation is unlike the standard Junos CoS implementation in which a strict-high-priority queue does round-robin with high-priority queues, as described in the *Class of Service Feature Guide for Routing Devices*.

After the scheduler removes a packet from a queue, a certain action is taken. The action depends on whether the packet came from a multilink encapsulated queue (fragmented and sequenced) or a nonencapsulated queue (hashed with no fragmentation). Each queue can be designated as either multilink encapsulated or nonencapsulated, independently of the other. By default, traffic in all forwarding classes is multilink encapsulated. To configure packet fragmentation handling on a queue, include the **fragmentation-maps** statement at the **[edit class-of-service]** hierarchy level:

```
[edit class-of-service]
fragmentation-maps {
  map-name {
    forwarding-class class-name {
      fragment-threshold bytes;
      no-fragmentation;
    }
  }
}
```

If you require the queue to transmit small packets with low latency, configure the queue to be nonencapsulated by including the **no-fragmentation** statement. If you require the queue to transmit large packets with normal latency, configure the queue to be multilink encapsulated by including the **fragment-threshold** statement. If you require the queue to transmit large packets with low latency, we recommend using a faster link and configuring the queue to be nonencapsulated. For more information about fragmentation maps, see [“Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces” on page 527](#).

When a packet is removed from a multilink-encapsulated queue, it is fragmented. If the packet exceeds the minimum link MTU, or if a queue has a fragment threshold configured at the **[edit class-of-service fragmentation-maps map-name forwarding-class class-name]** hierarchy level, the software splits the packet into two or more fragments, which are assigned consecutive multilink sequence numbers.

If you do not include the **fragment-threshold** statement in the fragmentation map, the fragmentation threshold you set at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level is the default for all forwarding classes. If you do not set a maximum fragment size anywhere in the configuration, packets are fragmented if they exceed the smallest MTU of all the links in the bundle.

Even if you do not set a maximum fragment size anywhere in the configuration, you can configure the maximum received reconstructed unit (MRRU) by including the **mrru** statement at the **[edit interfaces lsq-fpc/pic/port unit logical-unit-number]** hierarchy level. The MRRU is similar to the MTU but is specific to link services interfaces. By default, the MRRU size is 1500 bytes, and you can configure it to be from 1500 through 4500 bytes. For more information, see [“Configuring MRRU on Multilink and Link Services Logical Interfaces” on page 734](#).

When a packet is removed from a multilink-encapsulated queue, the software gives the packet an FRF.12 header. The FRF.12 header contains a sequence number field, which is filled with the next available sequence number from a counter. The software then places the packet on the fractional T1 link. Traffic from another queue might be interleaved between two fragments of the packet.

When a packet is removed from a nonencapsulated queue, it is transmitted with a plain Frame Relay header. The packet is then placed on the fractional T1 link as soon as possible. If necessary, the packet is placed between the fragments of a packet from another queue.

The fractional T1 interface links to another router, which can be from Juniper Networks or another vendor. The router at the far end gathers packets from the fractional T1 link. If a packet has an FRF.12 header, the software assumes the packet is a fragment of a larger packet, and the fragment number field is used to reassemble the larger packet. If the packet has a plain Frame Relay header, the software accepts the packet in the order in which it arrives, and the software makes no attempt to reassemble or reorder the packet.

A whole packet from a nonencapsulated queue can be placed between fragments of a multilink-encapsulated queue. However, fragments from one multilink-encapsulated queue cannot be interleaved with fragments from another multilink-encapsulated queue. This is the intent of the specification FRF.12, *Frame Relay Fragmentation Implementation Agreement*. If fragments from two different queues were interleaved, the header fields might not have enough information to separate the fragments.

Examples: Configuring an LSQ Interface for a Fractional T1 Interface Using FRF.12

FRF.12 with Fragmentation and Without LFI

This example shows a 128 KB DS0 interface. There is one traffic stream on **ge-0/0/0**, which is classified into queue 0 (**be**). Packets are fragmented in the link services IQ (**lsq-**) interface according to the threshold configured in the fragmentation map.

- *Link Services Configuration for Junos Interfaces*

Configuring LSQ Interfaces for T3 Links Configured for Compressed RTP over MLPPP

This example bundles a single T3 interface on a link services IQ interface with MLPPP encapsulation. Binding a single T3 interface to a multilink bundle allows you to configure compressed RTP (CRTP) on the T3 interface.

This scenario applies to MLPPP bundles only. The Junos OS does not currently support CRTP over Frame Relay. For more information, see [“Configuring Services Interfaces for Voice Services” on page 622](#).

There is no need to configure LFI at DS3 speeds, because the packet serialization delay is negligible.

```
[edit interfaces]
t3-0/0/0 {
  unit 0 {
    family mlppp {
      bundle lsq-1/3/0.1;
    }
  }
}
lsq-1/3/0.1 {
  encapsulation multilink-ppp;
}
compression {
  rtp {
    # cRTP parameters go here
    #
    port minimum 2000 maximum 64009;
  }
}
```

This configuration uses a default fragmentation map, which results in all forwarding classes (queues) being sent out with a multilink header.

To eliminate multilink headers, you can configure a fragmentation map in which all queues have the **no-fragmentation** statement at the **[edit class-of-service fragmentation-maps map-name forwarding-class class-name]** hierarchy level, and attach the fragmentation map to the **lsq-1/3/0.1** interface, as shown here:

```
[edit class-of-service]
fragmentation-maps {
  fragmap {
    forwarding-class {
      be {
        no-fragmentation;
      }
      af {
        no-fragmentation;
      }
      ef {
        no-fragmentation;
      }
      nc {
        no-fragmentation;
      }
    }
  }
}
interfaces {
  lsq-1/3/0.1 {
```

```

        fragmentation-map fragmap;
    }
}

```

Configuring LSQ Interfaces as T3 or OC3 Bundles Using FRF.12

This example configures a clear-channel T3 or OC3 interface with multiple logical interfaces (DLCIs) on the link. In this scenario, each DLCI represents a customer. DLCIs are shaped at the egress PIC to a particular speed ($N \times \text{DSO}$). This allows you to configure LFI using FRF.12 End-to-End Protocol on Frame Relay DLCIs.

To do this, first configure logical interfaces (DLCIs) on the physical interface. Then bundle the DLCIs, so that there is only one DLCI per bundle.

The physical interface must be capable of per-DLCI scheduling, which allows you to attach shaping rates to each DLCI. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

To prevent fragment drops at the egress PIC, you must assign a shaping rate to the link services IQ logical interfaces and to the egress DLCIs. Shaping rates on DLCIs specify how much bandwidth is available for each DLCI. The shaping rate on link services IQ interfaces should match the shaping rate assigned to the DLCI that is associated with the bundle.

Egress interfaces also must have a scheduler map attached. The queue that carries voice should be strict-high-priority, while all other queues should be low-priority. This makes LFI possible.

This example shows voice traffic in the `ef` queue. The voice traffic is interleaved with bulk data. Alternatively, you can use multiclass MLPPP to carry multiple classes of traffic in different multilink classes, as described in [“Configuring Multiclass MLPPP on LSQ Interfaces” on page 562](#).

```

Configuring LSQ Interfaces for ATM2 IQ Interfaces Using MLPPP

This example configures an ATM2 IQ interface with MLPPP bundled with link services IQ interfaces. This allows you to configure LFI on ATM virtual circuits.

For this type of configuration, the ATM2 IQ interface must have LLC encapsulation.

The following ATM PICs are supported in this scenario:

- 2-port OC-3/STM1 ATM2 IQ
- 4-port DS3 ATM2 IQ

Virtual circuit multiplexed PPP over AAL5 is not supported. Frame Relay is not supported. Bundling of multiple ATM VCs into a single logical interface is not supported.

Unlike DS3 and OC3 interfaces, there is no need to create a separate scheduler map for the ATM PIC. For ATM, you define CoS components at the **[edit interfaces at-fpc/pic/port atm-options]** hierarchy level, as described in the *Junos OS Network Interfaces Library for Routing Devices*.

NOTE: Do not configure RED profiles on ATM logical interfaces that are bundled. Drops do not occur at the ATM interface.

In this example, two ATM VCs are configured and bundled into two link services IQ bundles. A fragmentation map is used to interleave voice traffic with other multilink traffic. Because MLPPP is used, each link services IQ bundle can be configured for CRTP.

```

Aggregated Multiservices Interface

In Junos OS, you can combine multiple services interfaces to create a bundle of interfaces that can function as a single interface. Such a bundle of interfaces is known as an aggregated multiservices interface (AMS), and is denoted as `amsN` in the configuration, where *N* is a unique number that identifies an AMS interface (for example, `ams0`).

AMS configuration provides higher scalability, improved performance, and better failover and load-balancing options.

The current service set configuration model in Junos OS supports only one service PIC per service set. All services provisioned using a service set must be handled by the only one service PIC associated with that service set. AMS configuration enables you to address this limitation by associating an AMS bundle with a service set. An AMS bundle can have up to eight services PICs as member interfaces and can distribute services among the member interfaces. This allows you to have multiple service interfaces to handle services configured in one service set.

Member interfaces are identified as **mams** in the configuration. The **chassisd** process in routers that support AMS configuration creates a **mams** entry for every multiservices interface on the router.

When you configure **services-options** at the **ams** interface level, the options apply to all member interfaces (**mams**) for the **ams** interface.

The options also apply to service sets configured on **ms-** interfaces corresponding to the **ams** interface's member interfaces. All settings are per PIC. For example, session-limit applies per member and not at an aggregate level.

NOTE: You cannot configure **services-options** at both the **ams** (aggregate) and member-interface level. If **services-options** is configured on **ms-x/y/z**, it also applies to service sets on **mams-x/y/z**.

Some different options are available under **services-options** on **ms-** interfaces, so the user should ensure that differences in configuration is meaningful [For example, timeouts should be similar but, say, **syslog-prefix/ip-address** can be different.

NOTE: Per-member drop of traffic and per-member next-hop configuration is required for NAT64. For NAPT-44, this per-member specification allows arbitrary hash-keys and therefore this setting enables better load-balancing options. The main purpose is to allow dynamic NAT operations to be performed. For NAT64, NAPT44, and dynamic NAT44, it is not possible to determine which member allocates the dynamic NAT address. To ensure that reverse flow packets arrive at the same member as the forward flow packets, pool-address-based routes are used to steer reverse flow packets.

NOTE: Until Junos OS Release 13.3, for every media logical interface on which services were configured (interface style services), a logical interface alias was internally created. This interface alias stores the topology chains for features that are performed on the logical interface after an input service was processed to avoid packet loops in the system. With interface aliases, the maximum number of logical interfaces supported with services was reduced to half the supported maximum number because each logical interface consumed two entries, namely, one for the interface itself and the other for the interface alias.

Starting with Junos OS Release 14.1R4, input interface aliases are not created for MS-MPCs and MS-MICs. As a result, the maximum number of logical interfaces that are supported with services PICs is equal to the maximum number supported on the system. After input service processing by MS-MPCs and MS-MICs, the services PIC sends the packet to the Packet Forwarding Engine on the multiservices (ms-) logical interface where the corresponding service is configured. Post-services are not supported on MS-MPCs and MS-MICs in Junos OS Release 13.2 and later.

NOTE: You cannot include MS-DPCs or other multiservices PICs in an AMS configuration that contains MS-MICs or MS-MPCs as member interfaces.

By default, the traffic distribution over the member interfaces of an AMS interface happens in a round-robin fashion. You can also configure the following hash key values to regulate the traffic distribution: **source-ip**, **destination-ip**, **iif** (incoming interface), **oif** (outgoing interface), and **protocol**. For services that require traffic symmetry, you must configure symmetrical hashing. Symmetrical hashing configuration ensures that both forward and reverse traffic are routed through the same member interface.

NOTE:

NOTE: With basic NAT44, load balancing on AMS interfaces of MS-MICs and MS-MPCs does not work properly if the ingress hash key is source IP address and the egress hash key is destination IP address.

If the service set is applied on the Gigabit Ethernet or 10-Gigabit Ethernet interface that functions as the NAT inside interface, then the hash keys used for load balancing might be configured in such a way that the ingress key is set as destination IP address and the egress key is set as source IP address. Because the source IP address undergoes NAT processing, it is not available for hashing the traffic in the reverse direction. Therefore, load-balancing does not happen on the same IP address and forward and reverse traffic do not map to the same PIC. With the hash keys reversed, load balancing occurs correctly.

With next-hop services, for forward traffic, the ingress-key on the inside-interface load-balances traffic, and for reverse traffic, the ingress-key on the outside-interface load-balances traffic or per-member-next-hops steer reverse traffic. With interface-style services, the ingress-key load-balances forward traffic and the egress-key load-balances forward traffic or per-member-next-hops steer reverse traffic. Forward traffic is traffic entering from the inner side of a service-set and reverse traffic is traffic entering from the outer side of a service-set. The forward key is the hash key used for the forward direction of traffic and the reverse key is the hash key used for the reverse direction of traffic (depends on whether it relates to interface-services or next-hop-services style.)

With stateful firewalls, you can configure the following combinations of forward and reverse keys for load balancing. In the following combinations presented for hash keys, FOR-KEY refers to the forward key, REV-KEY denotes the reverse key, SIP signifies source IP address, DIP signifies destination IP address, and PROTO refers to protocol such as IP.

- FOR-KEY: SIP, REV-KEY: DIP
- FOR-KEY: SIP,PROTO REV-KEY: DIP, PROTO
- FOR-KEY: DIP, REV-KEY: SIP
- FOR-KEY: DIP,PROTO REV-KEY: SIP, PROTO
- FOR-KEY: SIP,DIP REV-KEY: SIP, DIP
- FOR-KEY: SIP,DIP,PROTO REV-KEY: SIP, DIP,PROTO

With static NAT configured as basic NAT44 or destination NAT44, and with stateful firewall configured or not, if the forward direction of traffic must undergo NAT processing, configure the hash keys as follows:

- FOR-KEY: DIP, REV-KEY: SIP
- FOR-KEY: DIP,PROTO REV-KEY: SIP, PROTO

If the reverse direction of traffic must undergo NAT processing, configure the hash keys as follows:

- FOR-KEY: SIP, REV-KEY: DIP
- FOR-KEY: SIP,PROTO REV-KEY: DIP, PROTO

With dynamic NAT configured, and with stateful firewall configured or not, only the forward direction traffic can undergo NAT. The forward hash key can be any combination of SIP, DIP, and protocol, and the reverse hash key is ignored.

NOTE:

NOTE: Junos OS AMS configuration supports IPv4 and IPv6 traffic.

IPv6 Traffic on AMS Interfaces Overview

Starting in Junos OS release 14.2R1, you can use AMS interfaces for IPv6 traffic. To configure IPv6 support for an AMS interface, include the **family inet6** statement at the **[edit interfaces *ams-interface-name* unit 1]** hierarchy level. When **family inet** and **family inet6** are set for an AMS interface sub-unit, the **hash-keys** configured at the **[edit services *service-set-name* load-balancing-options]** hierarchy level apply to both the IPv4 and IPv6 flows.

With the support for transmission of IPv6 packets on AMS interfaces, the redistribution action that occurs, when an AMS member interface goes down, has been enhanced. When a member interface of an AMS bundle fails, traffic destined to the failed member is redistributed among the remaining active members. The traffic (flows or sessions) traversing through the existing active members is unaffected. If M members are currently active, the expected result is that only about 1/M fraction of the traffic (flows/sessions) is impacted because that amount of traffic is shifted from the failed member to remain active members. When the failed member interface comes back online, only a fraction of the traffic is redistributed to the new member. If N members are currently active, the expected result is that only about 1/(N+1) fraction of the traffic (flows/sessions) is impacted because that amount of traffic will be moved to the new restored member. The aforementioned values of 1/M and 1/(N+1) assume that the flows are uniformly distributed among members. Because a packet-hash is used to load-balance and because traffic usually contains a typical random combination of IP addresses (or any other fields that are used as load-balancing keys), this assumptions hold good.

Similar to IPv4 traffic, for IPv6 packets, an AMS bundle must contain members of only one service PIC type. You cannot combine MS-DPC(XLR), MS-MIC(XLP) and MS-MPC(XLP) line cards to be of the same AMS bundle. Such service PICs can however be members of separate AMS bundles on the same router (for example, two MS-MICs in *ams0*, and two MS-MPC PICs in *ams1*). The number of flows distributed, in an ideal

environment, can be $1/N$ in a best-case scenario when the N th member goes up or down. However, this assumption considers that the hash-keys load-balance the real or dynamic traffic. For example, consider a real-world deployment where member A is serving only one flow, whereas member B is serving ten flows. If member B goes down, then the number of flows disrupted is 10/11. The NAT pool-split behavior is designed to utilize the benefits of the rehash-minimization feature. The splitting of a NAT pool is performed for dynamic NAT scenarios (dynamic NAT, NAT64, and NATPT44).

If the "original" and "redistributed" flows are defined as follows:

- Member-original-flows—The traffic mapped to a member when all members are up.
- Member-redistributed-flows—The additional traffic mapped to a member, when some other member fails. These traffic flows might need to be rebalanced when member interfaces come up and go down.

With the preceding definitions of the original and redistributed flows for member interfaces, the following observations apply:

- The member-original-flows of a member stay intact as long as that member is up. Such flows are not impacted when other members move between the up and down states.
- The member-redistributed-flows of a member can change when other members go up or down. This change of flows occurs because these additional flows need to be rebalanced among all active members. Therefore, the member-redistributed-flow can vary a lot based on other members going down or up. Although it might seem that when a member goes down, the flows on active-members are preserved, and that when a member goes up, flows on active-members are not preserved in an effective way, this behavior is only because of static or hash-based rebalancing of traffic among active members.

The rehash-minimization feature handles the operational changes in a member interface status only (such as member offline or member OS reset). It does not handle changes in configuration. For example, addition or deletion, or activation and deactivation, of member interfaces at the **[edit interfaces amsN load-balancing-options member-interface mams-a/b/0]** hierarchy level requires the member PICs to be bounced. Twice NAT or hairpinning is not supported, similar to IPv4 support for AMS interfaces.

Member Failure Options and High Availability Settings

Because multiple service interfaces are configured as part of an AMS bundle, AMS configuration also provides for failover and high availability support. You can either configure one of the member interfaces as a backup interface that becomes active when any one of the other member interfaces goes down, or configure the AMS in such a way that when one of the member interfaces goes down, the traffic assigned to that interface is shared across the active interfaces.

The **member-failure-options** configuration statement enables you to configure how to handle traffic when a member interface fails. One option is to redistribute the traffic immediately among the other member interfaces. However, redistribution of traffic

involves recalculating the hash tags, and might cause some disruption in traffic on all the member interfaces.

The other option is to configure the AMS to drop all traffic that is assigned to the failed member interface. With this you can optionally configure an interval, **rejoin-timeout**, for the AMS to wait for the failed interface to come back online after which the AMS can redistribute the traffic among other member interfaces. If the failed member interface comes back online before the configured wait time, traffic continues unaffected on all member interfaces, including the interface that has come back online and resumed the operations.

You can also control the rejoining of the failed interface when it comes back online. If you do not include the **enable-rejoin** statement in the **member-failure-options** configuration, the failed interface is not allowed to rejoin the AMS when it comes back online. In such cases, you can manually rejoin that to the AMS by executing the **request interfaces revert interface-name** operational mode command.

The **rejoin-timeout** and **enable-rejoin** statements enable you to minimize traffic disruptions when member interfaces flap.

NOTE: When **member-failure-options** are not configured, the default behavior is to drop member traffic with a rejoin timeout of 120 seconds.

The **high-availability-options** configuration enables you to designate one of the member interfaces as a backup interface. The backup interface does not participate in routing operations as long as it remains a backup interface. When a member interface fails, the backup interface handles the traffic assigned to the failed interface. When the failed interface comes back online, it becomes the new backup interface.

When both **member-failure-options** and **high-availability-options** are configured for an AMS, the **high-availability-options** configuration takes precedence over the **member-failure-options** configuration. If a second failure occurs before the failed interface comes back online to be the new backup, the **member-failure-options** configuration comes into effect.

- [Example: Configuring Next-Hop Style Services on an Aggregated Multiservices Interface on page 613](#)

Configuring Load Balancing on AMS Infrastructure

Configuring load balancing requires an aggregated Multiservices (AMS) system. AMS involves grouping several Multiservices PICs together. An AMS configuration eliminates the need for separate routers within a system. The primary benefit of having an AMS configuration is the ability to support load balancing of traffic across multiple services PICs.

NOTE: AMS is supported only on Mobility Gateway (MBG) with the MBG MS-DPC. AMS is not supported with JUNOS services like NAT, FW, IPsec, DAA, HCM on the current MS-DPC.

Starting with Junos OS 11.4, high availability (HA) is supported on AMS infrastructure on all MX Series 3D Universal Edge routers. AMS has several benefits:

- Support for configuring behavior if a Multiservices PIC that is part of the AMS configuration fails
- Support for specifying hash keys for each service set in either direction
- Support for adding routes to individual PICs within the AMS system

Configuring AMS Infrastructure

AMS supports load balancing across multiple service sets. All ingress or egress traffic for a service set can be load balanced across different services PICs. To enable load balancing, you have to configure an aggregate interface with existing services interfaces.

To configure failure behavior in AMS, include the **member-failure-options** statement:

```
[edit interfaces ams1]
load-balancing-options {
  member-failure-options {
    drop-member-traffic {
      rejoin-timeout rejoin-timeout;
    }
    redistribute-all-traffic {
      enable-rejoin;
    }
  }
}
```

If a PIC fails, the traffic to the failed PIC can be configured to be redistributed by using the **redistribute-all-traffic** statement at the **[edit interfaces *interface-name* load-balancing-options member-failure-options]** hierarchy level. If the **drop-member-traffic** statement is used, all traffic to the failed PIC is dropped. Both options are mutually exclusive.

NOTE: If **member-failure-options** is not explicitly configured, the default behavior is to drop member traffic with a rejoin timeout of 120 seconds.

Only **mams-** interfaces (services interfaces that are part of AMS) can be aggregated. After an AMS interface has been configured, the constituent **mams-** interfaces cannot be individually configured. A **mams-** interface cannot be used as an **rms** interface. AMS supports IPv4 (family inet) and IPv6 (family inet6). It is not possible to configure addresses on an AMS interface. Network Address Translation (NAT) is the only application that runs on AMS infrastructure at this time.

NOTE: Unit 0 on an AMS interface cannot be configured.

To support multiple applications and different types of translation, AMS infrastructure supports configuring hashing for each service set. The hash keys can be configured separately for ingress and egress. The default configuration uses source IP, destination IP, and the protocol for hashing; incoming-interface for ingress and outgoing-interface for egress are also available.

Configuring High Availability

In an AMS system configured with high availability, a designated Multiservices PIC acts as a backup for other active PICs that are part of the AMS system. Presently, only N:1 backup for high availability is supported; only one PIC is available as backup for all other active PICs. High availability for load balancing is configured by adding the **high-availability-options** statement at the **[edit interfaces *interface-name* load-balancing-options]** hierarchy level.

To configure high availability, include the **high-availability-options** statement:

```
[edit interfaces ams1]
load-balancing-options {
  high-availability-options {
    many-to-one {
      preferred-backup preferred-backup;
    }
  }
}
```

Load Balancing Network Address Translation Flows

Starting with Junos OS Release 11.4, Network Address Translation (NAT) has been programmed as a plug-in and is a function of load balancing and high availability. The plug-in runs on AMS infrastructure. All flows for translation are automatically distributed to different services PICs that are part of the AMS infrastructure. In case of failure of an active Multiservices PIC, the configured backup Multiservices PIC will take over the NAT pool resources of the failed PIC. The hashing method selected depends on the type of NAT. Using NAT on AMS infrastructure has a few limitations:

- NAT flows to failed PICs cannot be restored.
- There is no support for IPv6 flows.
- Twice NAT is not supported for load balancing.

See “[Example: Configuring Static Source Translation on AMS Infrastructure](#)” on page 616 for more details on configuring NAT flows for load balancing.

Hardware and Software Requirements

This example requires MX Series routers that have services interfaces installed in that and Junos OS Release 13.2 running on that.

Overview

The aggregated multiservices (AMS) interface configuration in Junos OS enables you to combine multiple services interfaces to create a bundle of interfaces that can function as a single interface. This example shows you how to configure an AMS interface, load-balancing options, member failure options, high availability settings on an AMS interface, and an interface-style service set configuration that uses the AMS interface.

NOTE: You cannot include MS-DPCs or other multiservices PICs in an AMS configuration that contains MS-MICs or MS-MPCs as member interfaces.

An MS-PIC contains only one interface, whereas the MS-MPC contains four interfaces. To utilize the entire MS-MPC in a single AMS bundle, all the four member interfaces need to be assigned to that AMS bundle.

Keep the following points in mind for every member interface (XLP chip) needs to be part of the AMS interface bundle:

- XLP-based line cards from the same MPC can be part of multiple AMS bundles.
- Multiple XLP chips from several MPCs can also be part of a single bundle (up to eight member interfaces in an AMS bundle, depending on the deployment requirement).
- It is not necessary that all the XLP chips from the same MS-MPC must be part of the same AMS bundle. Some of the XLP chips can be part of an AMS bundle, while other XLP chips can be standalone **ms-** interfaces or need not be configured. However, the same XLP chip cannot be part of two different AMS interfaces at the same time. For example, each XLP chip from the same MS-MPC can be grouped into four different AMS bundles, based on the deployment needs.
- A maximum of up to eight member interfaces can be assigned to an AMS bundle.

For more information about AMS interfaces, see [“Understanding Aggregated Multiservices Interfaces” on page 599](#).

Configuration

CLI Quick Configuration	To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.
Adding Member Interfaces	<pre>set interfaces ams0 load-balancing-options member-interface mams-0/0/0 set interfaces ams0 load-balancing-options member-interface mams-0/1/0 set interfaces ams0 load-balancing-options member-interface mams-1/0/0 set interfaces ams0 load-balancing-options member-interface mams-1/1/0 set interfaces ams0 load-balancing-options member-interface mams-2/0/0 set interfaces ams0 load-balancing-options member-interface mams-2/1/0</pre>
Configuring Logical Units	<pre>set interfaces ams0 unit 1 family inet</pre>
Configuring Member Failure Options	<pre>set interfaces ams0 load-balancing-options member-failure-options drop-member-traffic rejoin-timeout 300 set interfaces ams0 load-balancing-options member-failure-options drop-member-traffic enable-rejoin</pre>
Configuring High Availability Options	<pre>set interfaces ams0 load-balancing-options high-availability-options many-to-one preferred-backup mams-1/0/0</pre>
Configuring Service Set and Interface Services	<pre>set services service-set ams-ssl interface-service service-interface ams0.1 set services service-set ams-ssl interface-service load-balancing-options hash-keys ingress-key source-ip set services service-set ams-ssl interface-service load-balancing-options hash-keys egress-key destination-ip</pre>
Step-by-Step Procedure	<p>The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see <i>Using the CLI Editor in Configuration Mode</i> in the <i>CLI User Guide</i>.</p> <ol style="list-style-type: none"> 1. Create an aggregated multiservices interface and add member interfaces.

NOTE: You cannot configure the same mams to be part of two different AMS interfaces at the same time.

```
[edit]
user@router1# set interfaces ams0 load-balancing-options member-interface
mams-0/0/0
user@router1# set interfaces ams0 load-balancing-options member-interface
mams-0/1/0
user@router1# set interfaces ams0 load-balancing-options member-interface
mams-1/0/0
user@router1# set interfaces ams0 load-balancing-options member-interface
mams-1/1/0
user@router1# set interfaces ams0 load-balancing-options member-interface
mams-2/0/0
```

```
user@router1# set interfaces ams0 load-balancing-options member-interface  
mams-2/1/0
```

2. Configure logical units for the AMS interface.

NOTE: An AMS interface and its member interfaces cannot share the same logical interface units. For example, if one of the member interfaces has logical units 1 and 2 configured on it, you cannot configure logical units 1 and 2 for the AMS. Similarly, if you have configured logical units 3 and 4 on the AMS, you cannot configure those units on any of the member interfaces.

```
[edit interfaces]  
user@router1# set ams0 unit 1 family inet
```

3. Configure member failure options.

```
[edit interfaces ams0]  
user@router1# set load-balancing-options member-failure-options  
drop-member-traffic rejoin-timeout 300  
user@router1# set load-balancing-options member-failure-options  
drop-member-traffic enable-rejoin
```

NOTE: This example shows the `drop-member-traffic` configuration. However, if you would like to redistribute the traffic to other available members when one of the member interfaces goes down, you can include the `redistribute-all-traffic` statement instead of the `drop-member-traffic` statement.

The default behavior, when the `member-failure-options` configuration is not included, is to drop member traffic with a rejoin timeout of 120 seconds.

4. Configure the high-availability options.

```
[edit interfaces ams0]  
user@router1# set load-balancing-options high-availability-options many-to-one  
preferred-backup mams-1/0/0
```

5. Configure interface style services.

```
[edit services]  
user@router1# set service-set ams-ssl interface-service service-interface ams0.1  
user@router1# set service-set ams-ssl interface-service load-balancing-options  
hash-keys ingress-key source-ip  
user@router1# set service-set ams-ssl interface-service load-balancing-options  
hash-keys egress-key destination-ip
```

6. If you are done configuring the device, commit the configuration.

```
[edit]  
user@router1# commit
```

Table 25: Key Configuration Statements Used in this Example

Statement	Description
member-interface	Adds a member interface (mams) to the AMS bundle.
drop-member-traffic	Specifies that all traffic to a member be dropped in case the member interface fails.
rejoin-timeout	Specifies the time interval, in seconds, for the AMS to wait before declaring a member interface down. If the failed member comes back online during this period, it can rejoin the AMS and resume traffic forwarding. The range is 0 through 1000 seconds.
enable-rejoin	Specifies whether a failed interface be allowed to rejoin the AMS when it comes back online. If this statement is not included in the configuration, you must manually add the interface to the AMS when the interface is back online.
preferred-backup	Designates a member interface as the floating backup.
interface-services	Specifies a service interface, an AMS interface in this example, to handle interface services.
hash-keys	Specifies the load-balancing hash keys. You can configure the following hash key values: source-ip , destination-ip , iif (incoming interface), oif (outgoing interface), and protocol . NOTE: For services that require traffic symmetry, you must configure symmetrical hashing. Symmetrical hashing configuration ensures that both forward and reverse traffic are routed through the same member interface.

Results From the configuration mode, confirm your configuration by entering the **show interfaces ams0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@router1# show interfaces ams0
load-balancing-options {
  member-interface mams-0/0/0;
  member-interface mams-0/1/0;
  member-interface mams-1/0/0;
  member-interface mams-1/1/0;
  member-interface mams-2/0/0;
  member-interface mams-2/1/0;
  member-failure-options {
    drop-member-traffic {
      rejoin-timeout 300;
      enable-rejoin;
    }
  }
}

```

```
high-availability-options {
  many-to-one {
    preferred-backup mams-1/0/0;
  }
}
unit 1 {
  family inet;
}

user@router1# show services
service-set ams-ssl {
  interface-service {
    service-interface ams0.1;
    load-balancing-options {
      hash-keys {
        ingress-key source-ip;
        egress-key destination-ip;
      }
    }
  }
}
```

Verification

Confirm that the configuration is working properly.

- [Verifying the AMS Configuration on page 612](#)

Verifying the AMS Configuration

Purpose Verify the AMS configuration and status of member interfaces.

Action From operational mode, enter the **show** command.

```
user@router1> show interfaces load-balancing detail
Load-balancing interfaces detail
Interface      : ams0
State          : Up
Last change    : 00:01:28
Member count   : 6
HA Model       : Many-to-One
Members       :
  Interface    Weight  State
  mams-0/0/0   10      Active
  mams-0/1/0   10      Active
  mams-1/0/0   10      Backup
  mams-1/1/0   10      Active
  mams-2/0/0   10      Active
  mams-2/1/0   10      Active
```

Meaning Shows that **ams0** has six member interfaces with a many-to-one backup configuration. Of the six member interfaces, five are in active state and one, **mams-1/0/0**, is in backup state.

Example: Configuring Next-Hop Style Services on an Aggregated Multiservices Interface

- [Hardware and Software Requirements on page 613](#)
- [Overview on page 613](#)
- [Configuration on page 613](#)

Hardware and Software Requirements

MX Series routers with services interfaces installed and running Junos OS Release 13.2.

Overview

Starting with Release 13.2, Junos OS extends next-hop style services support to aggregated multiservices (AMS) interfaces. In releases earlier than 12.3, only interface style services configurations were supported on AMS interfaces.

The next-hop style services configuration on AMS interfaces is different from the interface style services configuration. For next-hop style services, the load-balancing hash keys are defined as part of the logical unit configuration of the AMS interface. For interface style services, the hash keys configuration falls under the service-set configuration.

This example explains the next-hop style services configuration on an AMS interface, and shows the verification steps to verify that the configuration is working correctly.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

Configuring an aggregated multiservices interface

```
set interfaces ams0 load-balancing-options member-interface mams-1/0/0
set interfaces ams0 load-balancing-options member-interface mams-1/1/0
set interfaces ams0 load-balancing-options member-interface mams-2/0/0
set interfaces ams0 load-balancing-options member-interface mams-2/1/0
set interfaces ams0 unit 1 family inet
set interfaces ams0 unit 1 service-domain inside
set interfaces ams0 unit 2 family inet
set interfaces ams0 unit 2 service-domain outside
```

Configuring Routing Instances that Use AMS interfaces

```
set routing-instances ri-internal instance-type virtual-router
set routing-instances ri-internal interface ge-0/0/2.0
set routing-instances ri-internal interface ams0.1
set routing-instances ri-internal routing-options static route 22.22.22.0/24 next-hop ams0.1
set routing-instances ri-external instance-type virtual-router
set routing-instances ri-external interface ge-2/0/6.0
set routing-instances ri-external interface ams0.2
```

	<code>set routing-instances ri-external routing-options static route 0.0.0.0/0 next-hop ams0.2</code>
Configuring Hash Keys	<code>set interfaces ams0 unit 1 load-balancing-options hash-keys ingress-key source-ip protocol</code> <code>set interfaces ams0 unit 2 load-balancing-options hash-keys ingress-key destination-ip protocol</code>
Configure Next Hop Services	<code>set services service-set ams-test stateful-firewall-rules sfw1</code> <code>set services service-set ams-test next-hop-service inside-service-interface ams0.1</code> <code>set services service-set ams-test next-hop-service outside-service-interface ams0.2</code>

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see “*Using the CLI Editor in Configuration Mode*” in the *CLI User Guide*.

1. Configure an aggregated multiservices interface and the load-balancing options.

```
[edit interfaces ams0]
user@router1# set load-balancing-options member-interface mams-1/0/0
user@router1# set load-balancing-options member-interface mams-1/1/0
user@router1# set load-balancing-options member-interface mams-2/0/0
user@router1# set load-balancing-options member-interface mams-2/1/0
user@router1# set unit 1 family inet
user@router1# set unit 1 service-domain inside
user@router1# set unit 2 family inet
user@router1# set unit 2 service-domain outside
```

2. Configure routing instances that use the aggregated multiservices interfaces configured in the first step.

```
[edit routing-instances]
user@router1# set ri-internal instance-type virtual-router
user@router1# set ri-internal interface ge-0/0/2.0
user@router1# set ri-internal interface ams0.1
user@router1# set ri-internal routing-options static route 22.22.22.0/24 next-hop ams0.1
user@router1# set ri-external instance-type virtual-router
user@router1# set ri-external interface ge-2/0/6.0
user@router1# set ri-external interface ams0.2
user@router1# set ri-external routing-options static route 0.0.0.0/0 next-hop ams0.2
```

3. Configure hash keys for the aggregated multiservices interfaces.

NOTE: Unlike in the interface-style configuration where hash keys are defined in the service-set configuration, for next-hop services, the hash keys are specified in the AMS configuration under the logical units.

```
[edit interfaces ams0]
user@router1# set unit 1 load-balancing-options hash-keys ingress-key source-ip protocol
user@router1# set unit 2 load-balancing-options hash-keys ingress-key destination-ip protocol
```

4. Configure next-hop style services under the service-set configuration.

```
[edit services service-set ams-test]
```

```

user@router1# set stateful-firewall-rules sfw1
user@router1# set next-hop-service inside-service-interface ams0.1
user@router1# set next-hop-service outside-service-interface ams0.2

```

5. Commit the configuration.

```

[edit]
user@router1# commit

```

Results From the configuration mode, confirm your configuration by entering the **show interfaces ams0**, **show routing-instances**, and **show services service-set ams-test** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@router1# show interfaces ams0
load-balancing-options {
  member-interface mams-1/0/0;
  member-interface mams-1/1/0;
  member-interface mams-2/0/0;
  member-interface mams-2/1/0;
  member-failure-options {
    redistribute-all-traffic {
      enable-rejoin;
    }
  }
}
unit 1 {
  family inet;
  service-domain inside;
  load-balancing-options {
    hash-keys {
      ingress-key [ source-ip protocol ];
    }
  }
}
unit 2 {
  family inet;
  service-domain outside;
  load-balancing-options {
    hash-keys {
      ingress-key [ destination-ip protocol ];
    }
  }
}

user@router1# show routing-instances
ri-internal {
  instance-type virtual-router;
  interface ge-0/0/2.0;
  interface ams0.1
  routing-options {
    static {
      route 22.22.22.0/24 next-hop ams0.1;
    }
  }
}

```

```
ri-external {
  instance-type virtual-router;
  interface ge-2/0/6.0;
  interface ams0.2
  routing-options {
    static {
      route 0.0.0.0/0 next-hop ams0.2;
    }
  }
}

user@router1# show services service-set ams
stateful-firewall-rules sfw1;
next-hop-service {
  inside-service-interface ams0.1;
  outside-service-interface ams0.2;
}
```

 - [Understanding Aggregated Multiservices Interfaces on page 599](#)

Example: Configuring Static Source Translation on AMS Infrastructure

This example shows a static source translation configured on an AMS interface. The flows will be load balanced across member interfaces with this example.

Configure the AMS interface **ams0** with load balancing options.

```
[edit interfaces ams0]
load-balancing-options {
  member-interface mams-5/0/0;
  member-interface mams-5/1/0;
}
unit 1 {
  family inet;
}
unit 2 {
  family inet;
}
```

Configure hashing for the service set for both ingress and egress traffic.

```
[edit services service-set ss1]
interface-service {
  service-interface ams0.1;
  load-balancing-options {
    hash-keys {
      ingress-key destination-ip;
      egress-key source-ip;
    }
  }
}
```

NOTE: Hashing is determined based on whether the service set is applied on the ingress or egress interface.

Configure two NAT pools because you have configured two member interfaces for the AMS interface.

```
[edit services]
nat {
  pool p1 {
    address-range low 20.1.1.80 high 20.1.1.80;
  }
  pool p2 {
    address 20.1.1.81/32;
  }
}
```

Configure the NAT rule and translation.

```
[edit services]
nat {
  rule r1 {
    match-direction input;
    term t1 {
      from {
        source-address {
          20.1.1.2/32;
        }
      }
      then {
        translated {
          source-pool p1;
          translation-type {
            basic-nat44;
          }
        }
      }
    }
    term t1 {
      from {
        source-address {
          40.1.1.2/32;
        }
      }
      then {
        translated {
          source-pool p2;
          translation-type {
            basic-nat44;
          }
        }
      }
    }
  }
}
```

NOTE: A similar configuration can be applied for translation types `dynamic-nat44` and `napt-44`. Twice NAT cannot run on AMS infrastructure at this time.

Voice Services Overview

Adaptive services interfaces include a voice services feature that allows you to specify interface type **lsq-fpc/pic/port** to accommodate voice over IP (VoIP) traffic. This interface uses compressed RTP (CRTP), which is defined in RFC 2508, *Compressing IP/UDP/RTP Headers for Low-Speed Serial Links*.

CRTP enables VoIP traffic to use low-speed links more effectively, by compressing the 40-byte IP/UDP/RTP header down to 2 to 4 bytes in most cases.

Voice services on the AS and MultiServices PICs support single-link PPP-encapsulated IPv4 traffic over the following physical interface types: ATM2, DS3, E1, E3, OC3, OC12, STM1, and T1, including the channelized versions of these interfaces.

Voice services do not require a separate service rules configuration.

Voice services also support LFI on Juniper Networks M Series Multiservice Edge routers, except the M320 router. For more information about configuring voice services, see [“Configuring Services Interfaces for Voice Services” on page 622](#).

For link services IQ interfaces (**lsq**) only, you can configure CRTP with multiclass MLPPP (MCML). MCML greatly simplifies packet ordering issues that occur when multiple links are used. Without MCML, all voice traffic belonging to a single flow is hashed to a single link in order to avoid packet ordering issues. With MCML, you can assign voice traffic to a high-priority class, and you can use multiple links. For more information about MCML support on link services IQ interfaces, see [“Configuring Link Services and CoS on Services PICs” on page 529](#).

- [Configuring Network Interfaces for Voice Services on page 626](#)
- [Examples: Configuring Voice Services on page 627](#)

Configuring Services Interfaces for Voice Services

You define voice service properties such as compression by configuring statements and values for a voice services interface, specified by the interface type **lsq**-. You can include the following statements:

```
encapsulation mlppp;
family inet {
    address address;
}
compression {
    rtp {
        f-max-period number;
        maximum-contexts number <force>;
        port {
            minimum port-number;
            maximum port-number;
        }
        queues [ queue-numbers ];
    }
}
fragment-threshold bytes;
```

You can include these statements at the following hierarchy levels:

- [edit interfaces (lsq | ls)-fpc/pic/port unit logical-unit-number]
- [edit logical-systems logical-system-name interfaces (lsq | ls)-fpc/pic/port unit logical-unit-number]

The following sections provide detailed instructions for configuring for voice services on services interfaces:

- [Configuring the Logical Interface Address for the MLPPP Bundle on page 622](#)
- [Configuring Compression of Voice Traffic on page 623](#)
- [Configuring Delay-Sensitive Packet Interleaving on page 624](#)
- [Example: Configuring Compression of Voice Traffic on page 624](#)

Configuring the Logical Interface Address for the MLPPP Bundle

To configure the logical address for the MLPPP bundle, include the **address** statement:

```
address address {
    ...
}
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces (lsq | ls)-fpc/pic/port unit logical-unit-number family inet]

- [edit logical-systems *logical-system-name* interfaces (lsq | ls)-fpc/pic/port unit *logical-unit-number* family inet]

address specifies an IP address for the interface. AS and Multiservices PICs support only IP version 4 (IPv4) addresses, which are therefore configured under the **family inet** statement.

For information on other addressing properties you can configure that are not specific to service interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

Configuring Compression of Voice Traffic

You can specify how a services interface handles voice traffic compression by including the **compression** statement:

```
compression {
  rtp {
    f-max-period number;
    maximum-contexts number <force>;
    port {
      minimum port-number;
      maximum port-number;
    }
    queues [ queue-numbers ];
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces (lsq | ls)-fpc/pic/port unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces (lsq | ls)-fpc/pic/port unit *logical-unit-number*]

The following statements configure the indicated compression properties:

- **f-max-period *number***—Sets the maximum number of compressed packets to insert between the transmission of full headers. If you do not include the statement, the default is 255 packets.
- **maximum-contexts *number* <force>**—Specifies the maximum number of RTP contexts to accept during negotiation. The optional **force** statement requires the PIC to use the value specified for maximum RTP contexts, regardless of the negotiated value. This option enables interoperability with Junos OS Releases that base the RTP context value on link speed.
- **port, minimum *port-number*, and maximum *port-number***—Specify the lower and upper boundaries for a range of UDP destination port values on which RTP compression takes effect. Values for **port-number** can range from 0 through 65,535. RTP compression is applied to traffic transiting the ports within the specified range.
- **queues [*queue-numbers*]**—Specifies one or more of queues **q0**, **q1**, **q2**, and **q3**. RTP compression is applied to the traffic in the specified queues.

NOTE: If you specify both a port range and one or more queues, compression takes place if either condition is met.

Configuring Delay-Sensitive Packet Interleaving

When you configure CRTP, the software automatically enables link fragmentation and interleaving (LFI). LFI reduces excessive delays by fragmenting long packets into smaller packets and interleaving them with real-time frames. This allows real-time and non-real-time data frames to be carried together on lower-speed links without causing excessive delays to the real-time traffic. When the peer interface receives the smaller fragments, it reassembles the fragments into their original packet. For example, short delay-sensitive packets, such as packetized voice, can race ahead of larger delay-insensitive packets, such as common data packets.

By default, LFI is always active when you include the **compression rtp** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level. You control the operation of LFI indirectly by setting the **fragment-threshold** statement on the same logical interface. For example, if you include the **fragment-threshold 256** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level, all IP packets larger than 256 bytes are fragmented.

Example: Configuring Compression of Voice Traffic

Configure compression on a T1 interface with MLPPP encapsulation. Configure fragmentation for all IP packets larger than 128 bytes.

```
[edit interfaces]
t1-1/0/0 {
  unit 0 {
    family mlppp {
      bundle lsq-1/1/0.1;
    }
  }
}
lsq-1/1/0 {
  encapsulation mlppp;
  unit 1 {
    compression {
      rtp {
        port minimum 2000 maximum 64009;
      }
    }
    family inet {
      address 30.1.1.2/24;
    }
    fragment-threshold 128;
  }
}
```

Related Documentation

- [Voice Services Overview on page 621](#)

- [Configuring Encapsulation for Voice Services on page 625](#)
- [Configuring Network Interfaces for Voice Services on page 626](#)
- [Examples: Configuring Voice Services on page 627](#)

Configuring Encapsulation for Voice Services

Voice services interfaces support the following logical interface encapsulation types:

- Multilink Point-to-Point Protocol (MLPPP), which is the default encapsulation
- ATM2 IQ MLPPP over AAL5 LLC
- Frame Relay PPP

For general information on encapsulation, see the *Junos OS Network Interfaces Library for Routing Devices*. You can also configure physical interface encapsulation on voice services interfaces.

To configure voice services encapsulation, include the **encapsulation** statement:

encapsulation *type*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

For voice services interfaces, the valid values for the **type** variable are **atm-mlppp-llc**, **frame-relay-ppp** or **multilink-ppp**.

You must also configure the physical interface with the corresponding encapsulation type, either Frame Relay or PPP. LSQ interfaces are supported by the following physical interface types: ATM2 IQ, DS3, E1, E3, OC3, OC12, STM1, and T1, including the channelized versions of these interfaces. For examples, see “[Examples: Configuring Voice Services](#)” on page 627.

NOTE: The only protocol type supported with **frame-relay-ppp** encapsulation is **family mlppp**.

Related Documentation

- [Voice Services Overview on page 621](#)
- [Configuring Services Interfaces for Voice Services on page 622](#)
- [Configuring Network Interfaces for Voice Services on page 626](#)
- [Examples: Configuring Voice Services on page 627](#)

Configuring Network Interfaces for Voice Services

To complete a voice services interface configuration, you need to configure the physical network interface with either MLPPP encapsulation and a voice services bundle or PPP encapsulation and a compression interface, as described in the following sections:

- [Configuring Voice Services Bundles with MLPPP Encapsulation on page 626](#)
- [Configuring the Compression Interface with PPP Encapsulation on page 626](#)

Configuring Voice Services Bundles with MLPPP Encapsulation

For voice services interfaces, you configure the link bundle as a channel. The physical interface is usually connected to networks capable of supporting MLPPP; the interface types supported for voice traffic are T1, E1, T3, E3, OC3, OC12, and STM1, including channelized versions of these interfaces.

NOTE:

For M Series routers and T Series routers, the following caveats apply:

- Maximum supported throughput on the bundle interfaces is 45 Mbps.
- Bundling of the logical interfaces under a T3 physical interface into the same or different bundles is not supported.

To configure a physical interface link for MLPPP, include the following statement:

```
bundle interface-name;
```

You can configure this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family mlppp]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family mlppp]**

When you configure **family mlppp**, no other protocol configuration is allowed. For more information on link bundles, see [“Configuring the Links in a Multilink or Link Services Bundle” on page 721](#).

Configuring the Compression Interface with PPP Encapsulation

To configure the physical interface for PPP encapsulation, you also need to specify the services interface to be used for voice compression: a Link Services IQ (**lsq-**) interface.

To configure the compression interface, include the **compression-device** statement:

```
compression-device interface-name;
```

You can configure this statement at the following hierarchy levels:

- **[edit interfaces (lsq | ls)-*fpc/pic/port* unit *logical-unit-number*]**

- `[edit logical-systems logical-system-name interfaces (lsq | ls)-fpc/pic/port unit logical-unit-number]`

**Related
Documentation**

- [Voice Services Overview on page 621](#)
- [Configuring Services Interfaces for Voice Services on page 622](#)
- [Configuring Encapsulation for Voice Services on page 625](#)
- [Examples: Configuring Voice Services on page 627](#)

Examples: Configuring Voice Services

Configure voice services using a T1 physical interface and MLPPP bundle encapsulation:

```
[edit interfaces]
t1-0/2/0:1 {
  encapsulation ppp;
  unit 0 {
    family mlppp {
      bundle lsq-1/3/0.1;
    }
  }
}
lsq-1/3/0 {
  unit 1 {
    encapsulation mlppp;
    family inet {
      address 10.5.5.2/30;
    }
    compression {
      rtp {
        f-max-period 100;
        queues [ q1 q2 ];
        port {
          minimum 16384;
          maximum 32767;
        }
      }
    }
  }
  fragment-threshold 128;
}
```

Configure voice services using Frame Relay encapsulation without bundling:

```
[edit interfaces]
t1-1/0/0 {
  encapsulation frame-relay;
  unit 0 {
    dlci 100;
    encapsulation frame-relay-ppp;
    compression-device lsq-2/0/0.0;
  }
}
```

```
lsq-2/0/0 {  
  unit 0 {  
    compression {  
      rtp {  
        f-max-period 100;  
        queues [ q1 q2 ];  
        port {  
          minimum 16000;  
          maximum 32000;  
        }  
      }  
    }  
  }  
  family inet {  
    address 10.1.1.1/32;  
  }  
}
```

Configure voice services using an ATM2 physical interface (the corresponding class-of-service configuration is provided for illustration):

```
[edit interfaces]  
at-1/2/0 {  
  atm-options {  
    vpi 0;  
    pic-type atm2; # only ATM2 PICs are supported  
  }  
  unit 0 {  
    vci 0.69;  
    encapsulation atm-mlppp-llc;  
    family mlppp {  
      bundle lsq-1/3/0.10;  
    }  
  }  
  unit 1 {  
    vci 0.42;  
    encapsulation atm-mlppp-llc;  
    family mlppp {  
      bundle lsq-1/3/0.11;  
    }  
  }  
}  
lsq-1/3/0 {  
  unit 10 {  
    encapsulation multilink-ppp;  
  }  
  # Large packets need to be fragmented.  
  # Fragmentation can also be specified per forwarding class.  
  fragment-threshold 320;  
  compression {  
    rtp {  
      port minimum 2000 maximum 64009;  
    }  
  }  
}  
unit 11 {
```

```

    encapsulation multilink-ppp;
  }
  fragment-threshold 160;
  [edit class-of-service]
  scheduler-maps {
    sched {
      # Scheduling parameters apply to bundles on the AS or Multiservices PIC.
      # Unlike DS3/SONET interfaces, there is no need to create
      # a separate scheduler map for the ATM PIC. ATM defines
      # CoS constructs under the [edit interfaces at-fpc/pic/port] hierarchy.
      ...
    }
  }
  fragmentation-maps {
    fragmap {
      forwarding-class {
        ef {
          # In this example, voice is carried in the ef queue.
          # It is interleaved with bulk data.
          # Alternatively, you could use multiclass MLPPP to
          # carry multiple classes of traffic in different
          # multilink classes.
          no-fragmentation;
        }
      }
    }
  }
  interfaces {
    # Assign fragmentation and scheduling parameters to LSQ interfaces.
    lsq-1/3/0 {
      unit 0 {
        shaping-rate 512k;
        scheduler-map sched;
        fragmentation-map fragmap;
      }
      unit 1 {
        shaping-rate 128k;
        scheduler-map sched;
        fragmentation-map fragmap;
      }
    }
  }
}

```

- [HTTP URL Tracking and Policy Control for Client Requests on page 634](#)
- [Configuring HTTP URL Tracking and Policy Control on page 635](#)

HTTP Content Manager (HCM)

HTTP Content Management (HCM) is an application used for inspecting the HTTP traffic transmitted through port 80 (default) or any other port you use to transmit HTTP traffic. HCM can be installed on an MX-series router that is running the corresponding version of the Junos OS release. HCM inspects HTTP traffic even if the default port 80 is not used for HTTP traffic and is interoperable with ms, rms, and ams interface types. It supports fragmented HTTP request packets and GET, PUT, and POST requests.

Configuring the HTTP-Manager Package on the Router

1. Before you install the HTTP-Manager package on the router, ensure that you have the appropriate version of the HTTP-Manager package for the Junos OS image you are using on the router. When you have confirmed that you have the right package, use the request system software add command to install the HTTP-Manager package. You would need to restart the CLI after the package is installed.

```
user@router> request system software add http-manager-12.2R2-1-A1.2.tgz
```

```
NOTICE: Validating configuration against package-name.
```

```
NOTICE: Use the 'no-validate' option to skip this if desired.
```

```
Checking compatibility with configuration
```

```
Initializing...
```

```
WARNING: cli has been replaced by an updated version:
```

```
CLI release 12.2R2 built by builder on 2012-01-24 02:36:22 UTC
```

```
Restart cli using the new version ? [yes,no] (yes)
```

```
Restarting cli ...
```

2. When the CLI has restarted, use the **show version** command to see whether the HTTP-Manager packages are installed.

```
user@router> show version
```

```
...
```

```
HTTP-Manager Management Component [12.2R2-1-A1.2]
```

HTTP-Manager Dataplane Component [12.2R2-1-A1.2]

user@router>..

3. If you want to upgrade the Junos OS image on a router that has the HTTP-Manager package installed, you should first save and then delete the HTTP-Manager configuration from the router.
 - To view the HTTP-Manager configuration, use the **user@router>extension juniper-http-manager show <section>** command.
 - To delete the HTTP-Manager configuration from the router, use the **user@router>extension juniper-http-manager delete <section>** command.
 - Any remnant HTTP-Manager configuration left on the router will be deleted when the Junos OS image is upgraded. So, ensure that you have saved all necessary HTTP Content Management configurations.
 - To delete the HTTP-Manager package from the router, use the **user@router>>request system software delete <http-manager-package>** command.
 - Reinstall the HTTP-Manager package on the router after you upgrade the Junos OS image on the router.

HTTP URL Tracking and Policy Control for Client Requests

The URL manipulation capability in the service plane allows an administrator to enter all the URLs associated with an action. An administrator can now enter URLs and actions in the service plane and apply them to the traffic associated with an interface and a subscriber by using the existing functions.

NOTE: The URL manipulation capability is supported only when the Junos OS Extension-Provider packages are installed and configured on the device.

In Junos OS releases earlier than 12.3, the extension-provider packages were variously referred to as Junos Services Framework (JSF), MP-SDK, and eJunos.

The HTTP URL manipulation allows routers to:

- Monitor HTTP transactions in the service plane and identify matching incoming HTTP requests with preconfigured URLs. When a matching HTTP request is found, the associated action and preconfigured URL are applied to the transaction.
- Maintain the statistics of HTTP requests that match the preconfigured URLs. Such statistics must be maintained per policy on a per-rule or per-term basis across all service sets.
- Display the current statistics for all visible HTTP-URL matches.
- Scale 50,000 HTTP transactions per second on a single MS-DPC network processing unit.

Guidelines for Configuring HTTP URL Monitoring for Client Requests

HTTP URL manipulation can be configured with service rules containing a sequence of terms. The URL rules are evaluated based on the longest prefix or suffix matches. The rules and terms are configured if:

- Multiple hostnames are specified in a match condition with an OR operator (that is, “any” is a potential match).
- Multiple request-URLs are specified in a match condition with an OR operator (that is, “any” is a potential match).
- The “discard” action causes HTTP requests matched to URLs to be dropped (stateful).
- The “accept” action causes HTTP requests matched to URLs to be allowed (stateful).
- The “log-request” action causes HTTP requests matched to URLs to be logged (fast log, once per transaction).
- The “count” action causes HTTP requests matched to URLs to be counted against the specified rule or term. The total number is the total of all service sets in which the rule or terms exists.
- The “discard” action can be combined only with the “log-request” action.
- The “accept” action can be combined with the “log-request” and “count” actions.
- If any given HTTP request matches more than one rule or term, the action applied is undeterministic and may be any of the matched rules or terms.
- The number of rules, terms, url-lists, and individual clauses in the rules, terms, and url-lists are limited by service-plane memory. No hard limits are imposed.
- If a hostname is not specified, then “*” (any) is assumed. Similarly, if a request-URL is not specified, then “*” (any) is assumed. Matching of hostnames and request-URLs to the HTTP request follows the same process described for url-lists. However, a match happens only when both the hostname and the request-URL match an entry in the same term of a rule.
- Multiple “url” and “url-list” clauses may be entered for the same “from {}” clause.

Configuring HTTP URL Tracking and Policy Control

To configure an HTTP URL Tracking and Policy Control, include the **url-rule *url-rule-name*** statement at the **[edit services hcm]** hierarchy level:

```
services {
  hcm {
    url-rule url-rule-name {
      term term-num {
        from {
          url-list url-list-name;
          url url_identifier {
            host hostname;
            request-url page-name;
          }
        }
      }
    }
  }
}
```

```
    }
    then {
        discard;
        accept;
        count;
        log-request;
    }
}
url-rule-set url-rule-set-name {
    url-rule rule1;
    url-rule rule2;
}
}
```

Each HCM rule consists of a set of terms, similar to a firewall filter. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

- [Examples: Configuring L2TP Services on page 648](#)
- [Tracing L2TP Operations on page 652](#)

Layer 2 Tunneling Protocol Overview

L2TP is defined in RFC 2661, *Layer Two Tunneling Protocol (L2TP)*.

L2TP facilitates the tunneling of PPP packets across an intervening network in a way that is as transparent as possible to both end users and applications. It employs access profiles for group and individual user access, and uses authentication to establish secure connections between the two ends of each tunnel. Multilink PPP functionality is also supported.

The L2TP services are supported on the following routers only:

- M7i routers with AS PICs
- M10i routers with AS and MultiServices 100 PICs
- M120 routers with AS, MultiServices 100, and MultiServices 400 PICs
- On MX Series routers, the L2TP access concentrator (LAC) and L2TP network server (LNS) functions are supported only on MPCs; they are not supported on any services PIC or MS-DPC. For details about MPC support for L2TP, see the [MX Series Interface Module Reference](#)

For more information, see “[L2TP Services Configuration Overview](#)” on page 638.

- Related Documentation**

L2TP Services Configuration Overview

The statements for configuring L2TP services are found at the following hierarchy levels:

- **[edit services l2tp tunnel-group *group-name*]**

The L2TP **tunnel-group** statement identifies an L2TP instance or L2TP server. Associated statements specify the local gateway address on which incoming tunnels and sessions are accepted, the Adaptive Services (AS) Physical Interface Card (PIC) that processes data for the sessions in this tunnel group, references to L2TP and PPP access profiles, and other attributes for configuring window sizes and timer values.

- **[edit interfaces *sp-fpc/pic/port* unit *logical-unit-number* dial-options]**

The **dial-options** statement includes configuration for the **l2tp-interface-id** statement and the **shared/dedicated** flag. The interface identifier associates a user session with a logical interface. Sessions can use either shared or dedicated logical interfaces. To run routing protocols, a session must use a dedicated logical interface.

- **[edit access profile *profile-name* client *name* l2tp]**

Tunnel profiles are defined at the **[edit access]** hierarchy level. Tunnel clients are defined with authentication, multilink negotiation and fragmentation, and other L2TP attributes in these profiles.

- **[edit access profile *profile-name* client *name* ppp]**

User profiles are defined at the **[edit access]** hierarchy level. User clients are defined with authentication and other PPP attributes in these profiles. These client profiles are used when local authentication is specified.

- **[edit access radius-server *address*]**

When you configure **authentication-order radius** at the **[edit access profile *profile-name*]** hierarchy level, you must configure a RADIUS service at the **[edit access radius-server]** hierarchy level.

NOTE: For information about L2TP LAC and LNS configurations on MX Series routers for subscriber access, see *L2TP for Subscriber Access Overview*.

- Related Documentation**
- [Layer 2 Tunneling Protocol Overview on page 637](#)
 - [AS PIC Redundancy for L2TP Services on page 648](#)
 - [L2TP Minimum Configuration on page 639](#)

- [Examples: Configuring L2TP Services on page 648](#)

L2TP Minimum Configuration

To configure L2TP services, you must perform at least the following tasks:

- Define a tunnel group at the **[edit services l2tp]** hierarchy level with the following attributes:
 - **l2tp-access-profile**—Profile name for the L2TP tunnel.
 - **ppp-access-profile**—Profile name for the L2TP user.
 - **local-gateway**—Address for the L2TP tunnel.
 - **service-interface**—AS PIC interface for the L2TP service.
 - Optionally, you can configure **traceoptions** for debugging purposes.

The following example shows a minimum configuration for a tunnel group with trace options:

```
[edit services l2tp]
tunnel-group finance-lns-server {
  l2tp-access-profile westcoast_bldg_1_tunnel;
  ppp-access-profile westcoast_bldg_1;
  local-gateway {
    address 10.21.255.129;
  }
  service-interface sp-1/3/0;
}
traceoptions {
  flag all;
  filter {
    protocol udp;
    protocol l2tp;
    protocol ppp;
    protocol radius;
  }
}
```

- At the **[edit interfaces]** hierarchy level:
 - Identify the physical interface at which L2TP tunnel packets enter the router, for example **ge-0/3/0**.
 - Configure the AS PIC interface with **unit 0 family inet** defined for IP service, and configure another logical interface with **family inet** and the **dial-options** statement.

The following example shows a minimum interfaces configuration for L2TP:

```
[edit interfaces]
ge-0/3/0 {
  unit 0 {
    family inet {
      address 10.58.255.129/28;
    }
  }
}
```

```

    }
  }
}
sp-1/3/0 {
  unit 0 {
    family inet;
  }
  unit 20 {
    dial-options {
      l2tp-interface-id test;
      shared;
    }
    family inet;
  }
}

```

- At the **[edit access]** hierarchy level:
 - Configure a tunnel profile. Each client specifies a unique L2TP Access Concentrator (LAC) name with an **interface-id** value that matches the one configured on the AS PIC interface unit; **shared-secret** is authentication between the LAC and the L2TP Network Server (LNS).
 - Configure a user profile. If RADIUS is used as the authentication method, it needs to be defined.
 - Define the RADIUS server with an IP address, port, and authentication data shared between the router and the RADIUS server.

NOTE: When the L2TP Network Server (LNS) is configured with RADIUS authentication, the default behavior is to accept the preferred RADIUS-assigned IP address. Previously, the default behavior was to accept and install the nonzero peer IP address that came into the IP-Address option of the IPCP Configuration Request packet.

- Optionally, you can define a group profile for common attributes, for example **keepalive 0** to turn off keepalive messages.

The following example shows a minimum profiles configuration for L2TP:

```

[edit access]
group-profile westcoast_users {
  ppp {
    keepalive 0;
  }
}
profile westcoast_bldg_1_tunnel {
  client production {
    l2tp {
      interface-id test;
      shared-secret "$9$n8HX6A01RhVl1R"; # SECRET-DATA
    }
    user-group-profile westcoast_users;
  }
}

```

```

}
profile westcoast_bldg_1 {
  authentication-order radius;
}
radius-server {
  192.168.65.63 {
    port 1812;
    secret "$9$Vyb4ZHkPQ39mf9pORlexNdbgoZUjqP5"; # SECRET-DATA
  }
}

```

- Related Documentation**
- [L2TP Services Configuration Overview on page 638](#)
 - [Configuring L2TP Tunnel Groups on page 641](#)

 - [Tracing L2TP Operations on page 652](#)
 - [Examples: Configuring L2TP Services on page 648](#)

Configuring L2TP Tunnel Groups

To establish L2TP service on a router, you need to identify an L2TP tunnel group and specify a number of values that define which access profiles, interface addresses, and other properties to use in creating a tunnel. To identify the tunnel group, include the **tunnel-group** statement at the **[edit services l2tp]** hierarchy level:

```

tunnel-group group-name {
  hello-interval seconds;
  hide-avps;
  l2tp-access-profile profile-name;
  local-gateway address {
    address address;
    gateway-name gateway-name;
  }
  maximum-send-window packets;
  ppp-access-profile profile-name;
  receive-window packets;
  retransmit-interval seconds;
  service-interface interface-name;
  syslog {
    host hostname {
      services severity-level;
      facility-override facility-name;
      log-prefix prefix-value;
    }
  }
  tunnel-timeout seconds;
}

```

NOTE: If you delete a tunnel group or mark it inactive, all L2TP sessions in that tunnel group are terminated. If you change the value of the `local-gateway` address or the `service-interface` statement, all L2TP sessions using those settings are terminated. If you change or delete other statements at the `[edit services l2tp tunnel-group group-name]` hierarchy level, new tunnels you establish will use the updated values but existing tunnels and sessions are not affected.

The following sections explain how to configure L2TP tunnel groups:

- [Configuring Access Profiles for L2TP Tunnel Groups on page 642](#)
- [Configuring the Local Gateway Address and PIC on page 642](#)
- [Configuring Window Size for L2TP Tunnels on page 643](#)
- [Configuring Timers for L2TP Tunnels on page 643](#)

- [Configuring System Logging of L2TP Tunnel Activity on page 644](#)

Configuring Access Profiles for L2TP Tunnel Groups

To validate L2TP connections and session requests, you set up access profiles by configuring the `profile` statement at the `[edit access]` hierarchy level. You need to configure two types of profiles:

- L2TP tunnel access profile, which validates all L2TP connection requests to the specified local gateway address
- PPP access profile, which validates all PPP session requests through L2TP tunnels established to the local gateway address

For more information on configuring the profiles, see the *Junos OS Administration Library for Routing Devices*. A profile example is included in “[Examples: Configuring L2TP Services](#)” on page 648.

To associate the profiles with a tunnel group, include the `l2tp-access-profile` and `ppp-access-profile` statements at the `[edit services l2tp tunnel-group group-name]` hierarchy level:

```
l2tp-access-profile profile-name;  
ppp-access-profile profile-name;
```

Configuring the Local Gateway Address and PIC

When you configure an L2TP group, you must also define a local address for the L2TP tunnel connections and the AS PIC that processes the requests:

- To configure the local gateway IP address, include the `address` statement at the `[edit services l2tp tunnel-group group-name local-gateway]` hierarchy level:

```
address address;
```

- To configure the AS PIC, include the **service-interface** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
service-interface sp-fpc/pic/port;
```

You can optionally specify the logical unit number along with the service interface. If specified, the unit is used as a logical interface representing PPP sessions negotiated using this profile.

NOTE: If you change the local gateway address or the service interface configuration, all L2TP sessions using those settings are terminated.

Dynamic class-of-service (CoS) functionality is supported on L2TP LNS sessions or L2TP sessions with ATM VCs, as long as the L2TP session is configured to use an IQ2 PIC on the egress interface. For more information, see the *Class of Service Feature Guide for Routing Devices*.

Configuring Window Size for L2TP Tunnels

You can configure the maximum window size for packet processing at each end of the L2TP tunnel:

- The receive window size limits the number of concurrent packets the server processes. By default, the maximum is 16 packets. To change the window size, include the **receive-window** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
receive-window packets;
```

- The maximum-send window size limits the other end's receive window size. The information is transmitted in the receive window size attribute-value pair. By default, the maximum is 32 packets. To change the window size, include the **maximum-send-window** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
maximum-send-window packets;
```

Configuring Timers for L2TP Tunnels

You can configure the following timer values that regulate L2TP tunnel processing:

- Hello interval—If the server does not receive any messages within a specified time interval, the router software sends a hello message to the tunnel's remote peer. By default, the interval length is 60 seconds. If you configure a value of 0, no hello messages are sent. To configure a different value, include the **hello-interval** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
hello-interval seconds;
```

- Retransmit interval—By default, the retransmit interval length is 30 seconds. To configure a different value, include the **retransmit-interval** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
retransmit-interval seconds;
```

- Tunnel timeout—If the server cannot send any data through the tunnel within a specified time interval, it assumes that the connection with the remote peer has been lost and deletes the tunnel. By default, the interval length is 120 seconds. To configure a different value, include the **tunnel-timeout** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
tunnel-timeout seconds;
```

Hiding Attribute-Value Pairs for L2TP Tunnels

Once an L2TP tunnel has been established and the connection authenticated, information is encoded by means of attribute-value pairs. By default, this information is not hidden. To hide the attribute-value pairs once the shared secret is known, include the **hide-avps** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
hide-avps;
```

Configuring System Logging of L2TP Tunnel Activity

You can specify properties that control how system log messages are generated for L2TP services.

To configure interface-wide default system logging values, include the **syslog** statement at the **[edit services l2tp tunnel-group group-name]** hierarchy level:

```
syslog {
  host hostname {
    services severity-level;
    facility-override facility-name;
    log-prefix prefix-value;
  }
}
```

Configure the **host** statement with a hostname or IP address that specifies the system log target server. The hostname **local** directs system log messages to the Routing Engine. For external system log servers, the hostname must be reachable from the same routing instance to which the initial data packet (that triggered session establishment) is delivered. You can specify only one system logging hostname.

Table 26 on page 644 lists the severity levels that you can specify in configuration statements at the **[edit services l2tp tunnel-group group-name syslog host hostname]** hierarchy level. The levels from **emergency** through **info** are in order from highest severity (greatest effect on functioning) to lowest.

Table 26: System Log Message Severity Levels

Severity Level	Description
any	Includes all severity levels
emergency	System panic or other condition that causes the router to stop functioning

Table 26: System Log Message Severity Levels (*continued*)

Severity Level	Description
alert	Conditions that require immediate correction, such as a corrupted system database
critical	Critical conditions, such as hard drive errors
error	Error conditions that generally have less serious consequences than errors in the emergency, alert, and critical levels
warning	Conditions that warrant monitoring
notice	Conditions that are not errors but might warrant special handling
info	Events or nonerror conditions of interest

We recommend setting the system logging severity level to **error** during normal operation. To monitor PIC resource usage, set the level to **warning**. To gather information about an intrusion attack when an intrusion detection system error is detected, set the level to **notice** for a specific service set. To debug a configuration or log Network Address Translation (NAT) events, set the level to **info**.

For more information about system log messages, see the *Junos OS System Log Messages Reference*.

To use one particular facility code for all logging to the specified system log host, include the **facility-override** statement at the **[edit services l2tp tunnel-group group-name syslog host hostname]** hierarchy level:

```
facility-override facility-name;
```

The supported facilities include: **authorization**, **daemon**, **ftp**, **kernel**, **user**, and **local0** through **local7**.

To specify a text prefix for all logging to this system log host, include the **log-prefix** statement at the **[edit services l2tp tunnel-group group-name syslog host hostname]** hierarchy level:

```
log-prefix prefix-text;
```

Related Documentation

- [L2TP Services Configuration Overview on page 638](#)
- [L2TP Minimum Configuration on page 639](#)
- [Configuring the Identifier for Logical Interfaces that Provide L2TP Services on page 646](#)

Configuring the Identifier for Logical Interfaces that Provide L2TP Services

You can configure L2TP services on adaptive services interfaces on M7i, M10i, M120, and MX Series routers only. You must configure the logical interface to be dedicated or shared. If a logical interface is dedicated, it can represent only one session at a time. A shared logical interface can have multiple sessions.

To configure the logical interface, include the **l2tp-interface-id** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* *dial-options*]** hierarchy level:

```
l2tp-interface-id name;  
(dedicated | shared);
```

The **l2tp-interface-id** name configured on the logical interface must be replicated at the **[edit access profile *name*]** hierarchy level:

- For a user-specific identifier, include the **l2tp-interface-id** statement at the **[edit access profile *name* ppp]** hierarchy level.
- For a group identifier, include the **l2tp-interface-id** statement at the **[edit access profile *name* l2tp]** hierarchy level.

You can configure multiple logical interfaces with the same interface identifier, to be used as a pool for several users. For more information on configuring access profiles, see the *Junos OS Administration Library for Routing Devices*.

NOTE: If you delete the **dial-options** statement settings configured on a logical interface, all L2TP sessions running on that interface are terminated.

Example: Configuring Multilink PPP on a Shared Logical Interface

Multilink PPP is supported on either shared or dedicated logical interfaces. The following example can be used to configure many multilink bundles on a single shared interface:

```
interfaces {  
  sp-1/3/0 {  
    traceoptions {  
      flag all;  
    }  
    unit 0 {  
      family inet;  
    }  
    unit 20 {  
      dial-options {  
        l2tp-interface-id test;  
        shared;  
      }  
      family inet;  
    }  
  }  
}
```

```

access {
  profile t {
    client test {
      l2tp {
        interface-id test;
        multilink;
        shared-secret "$9$n8HX6A01RhLvL1R"; # SECRET-DATA
      }
    }
  }
  profile u {
    authentication-order radius;
  }
  radius-server {
    192.168.65.63 {
      port 1812;
      secret "$9$Vyb4ZHkPQ39mf9pORlexNdbgoZUjqP5"; # SECRET-DATA
    }
  }
}
services {
  l2tp {
    tunnel-group 1 {
      l2tp-access-profile t;
      ppp-access-profile u;
      local-gateway {
        address 10.70.1.1;
      }
      service-interface sp-1/3/0;
    }
    traceoptions {
      flag all;
      debug-level packet-dump;
      filter {
        protocol l2tp;
        protocol ppp;
        protocol radius;
      }
    }
  }
}

```

AS PIC Redundancy for L2TP Services

L2TP services support AS PIC redundancy. To configure redundancy, you specify a redundancy services PIC (**rsp**) interface in which the primary AS PIC is active and a secondary AS PIC is on standby. If the primary AS PIC fails, the secondary PIC becomes active, and all service processing is transferred to it. If the primary AS PIC is restored, it remains in standby and does not preempt the secondary AS PIC; you need to manually restore the services to the primary PIC. To determine which PIC is currently active, issue the **show interfaces redundancy** command.

NOTE: On L2TP, the only service option supported is *warm standby*, in which one backup PIC supports multiple working PICs. Recovery times are not guaranteed, because the configuration must be completely restored on the backup PIC after a failure is detected. The tunnels and sessions are torn down upon switchover and need to be restarted by the LAC and PPP client, respectively. However, configuration is preserved and available on the new active PIC, although the protocol state needs to be reestablished.

As with the other AS PIC services that support warm standby, you can issue the **request interfaces (revert | switchover)** command to manually switch between primary and secondary L2TP interfaces.

For more information, see [“Configuring AS or Multiservices PIC Redundancy” on page 41](#). For an example configuration, see [“Examples: Configuring L2TP Services” on page 648](#). For information on operational mode commands, see the [CLI Explorer](#).

Examples: Configuring L2TP Services

Configure L2TP with multiple group and user profiles and a pool of logical interfaces for concurrent tunnel sessions:

```
[edit access]
address-pool customer_a {
  address 10.1.1.1/32;
}
address-pool customer_b {
  address-range low 10.2.2.1 high 10.2.3.2;
}
group-profile sunnyvale_users {
  ppp {
```

```

        framed-pool customer_a;
        idle-timeout 15;
        primary-dns 192.168.65.1;
        secondary-dns 192.168.65.2;
        primary-wins 192.168.65.3;
        secondary-wins 192.168.65.4;
        interface-id west;
    }
}
group-profile eastcoast_users {
    ppp {
        framed-pool customer_b;
        idle-timeout 20;
        primary-dns 192.168.65.5;
        secondary-dns 192.168.65.6;
        primary-wins 192.168.65.7;
        secondary-wins 192.168.65.8;
        interface-id east;
    }
}
group-profile sunnyvale_tunnel {
    l2tp {
        maximum-sessions-per-tunnel 100;
        interface-id west_shared;
    }
}
group-profile east_tunnel {
    l2tp {
        maximum-sessions-per-tunnel 125;
        interface-id east_shared;
    }
}
profile sunnyvale_bldg_1 {
    client white {
        chap-secret "$9$3s2690leK8X7VKM7VwgaJn/Ctu1hclv87Ct87"; # SECRET-DATA
        ppp {
            idle-timeout 22;
            primary-dns 192.168.65.1;
            framed-ip-address 10.12.12.12/32;
            interface-id east;
        }
        group-profile sunnyvale_users;
    }
    client blue {
        chap-secret "$9$eq1KWxbwgZUHNdjmqmTF3uO1Rhr-dsoJDNd"; # SECRET-DATA
        group-profile sunnyvale_users;
    }
    authentication-order password;
}
profile sunnyvale_bldg_1_tunnel {
    client test {
        l2tp {
            shared-secret "$9$r3HKvLg4ZUDkX7JGjif5pOBIRS8LN"; # SECRET-DATA
            maximum-sessions-per-tunnel 75;
            interface-id west_shared;
            ppp-authentication chap;
        }
    }
}

```

```
    }
    group-profile sunnyvale_tunnel;
}
client production {
    l2tp {
        shared-secret
            "$9$R2QErV8X-goGylVwg4jiTz36/t0BEleWFnRhrlXxbs2aJDHqf3nCP5";
        ppp-authentication chap;
    }
    group-profile sunnyvale_tunnel;
}
}
[edit services]
l2tp {
    tunnel-group finance-lns-server {
        l2tp-access-profile sunnyvale_bldg_1_tunnel;
        ppp-access-profile sunnyvale_bldg_1;
        local-gateway {
            address 10.1.117.3;
        }
        service-interface sp-1/3/0;
        receive-window 1500;
        maximum-send-window 1200;
        retransmit-interval 5;
        hello-interval 15;
        tunnel-timeout 55;
    }
    traceoptions {
        flag all;
    }
}
[edit interfaces sp-1/3/0]
unit 0 {
    family inet;
}
unit 10 {
    dial-options {
        l2tp-interface-id foo-user;
        dedicated;
    }
    family inet;
}
unit 11 {
    dial-options {
        l2tp-interface-id east;
        dedicated;
    }
    family inet;
}
unit 12 {
    dial-options {
        l2tp-interface-id east;
        dedicated;
    }
    family inet;
}
```

```

unit 21 {
    dial-options {
        l2tp-interface-id west;
        dedicated;
    }
    family inet;
}
unit 30 {
    dial-options {
        l2tp-interface-id west_shared;
        shared;
    }
    family inet;
}
unit 40 {
    dial-options {
        l2tp-interface-id east_shared;
        shared;
    }
    family inet;
}

```

Configure L2TP redundancy:

```

interfaces {
    rsp0 {
        redundancy-options {
            primary sp-0/0/0;
            secondary sp-1/3/0;
        }
        unit 0 {
            family inet;
        }
        unit 11 {
            dial-options {
                l2tp-interface-id east_shared;
                shared;
            }
            family inet;
        }
    }
}

```

Tracing L2TP Operations

Tracing operations track all AS PIC operations and record them in a log file in the `/var/log` directory. By default, this file is named `/var/log/l2tpd`.

NOTE: This topic refers to tracing L2TP LNS operations on M Series routers. To trace L2TP LAC operations on MX Series routers, see *Tracing L2TP Operations for Subscriber Access*.

To trace L2TP operations, include the **traceoptions** statement at the **[edit services l2tp]** hierarchy level:

```
traceoptions {
  debug-level level;
  file <filename> <files number> <match regular-expression > <size maximum-file-size>
    <world-readable | no-world-readable>;
  filter {
    protocol name;
    user-name username;
  }
  flag flag;
  interfaces interface-name {
    debug-level severity;
    flag flag;
  }
  level (all | error | info | notice | verbose | warning);
  no-remote-trace;
}
```

You can specify the following L2TP tracing flags:

- **all**—Trace everything.
- **configuration**—Trace configuration events.
- **protocol**—Trace routing protocol events.
- **routing-socket**—Trace routing socket events.
- **rpd**—Trace routing protocol process events.

You can specify a trace level for PPP, L2TP, RADIUS, and User Datagram Protocol (UDP) tracing. To configure a trace level, include the **debug-level** statement at the **[edit services l2tp traceoptions]** hierarchy level and specify one of the following values:

- **detail**—Detailed debug information
- **error**—Errors only
- **packet-dump**—Packet decoding information

You can filter by protocol. To configure filters, include the **filter protocol** statement at the **[edit services l2tp traceoptions]** hierarchy level and specify one or more of the following protocol values:

- **ppp**
- **l2tp**
- **radius**
- **udp**

To implement filtering by protocol name, you must also configure either **flag protocol** or **flag all**.

You can also configure traceoptions for L2TP on a specific adaptive services interface. To configure per-interface tracing, include the **interfaces** statement at the **[edit services l2tp traceoptions]** hierarchy level:

```
interfaces interface-name {
  debug-level level;
  flag flag;
}
```

NOTE: Implementing traceoptions consumes CPU resources and affects the packet processing performance.

You can specify the **debug-level** and **flag** statements for the interface, but the options are slightly different from the general L2TP traceoptions. You specify the debug level as **detail**, **error**, or **extensive**, which provides complete PIC debug information. The following flags are available:

- **all**—Trace everything.
- **ipc**—Trace L2TP Inter-Process Communication (IPC) messages between the PIC and the Routing Engine.
- **packet-dump**—Dump each packet's content based on debug level.
- **protocol**—Trace L2TP, PPP, and multilink handling.
- **system**—Trace packet processing on the PIC.

AACL Overview

NOTE: Starting with Junos OS Release 12.1, all interface-style services are supported for dynamic Point-to-Point Protocol over Ethernet (PPPoE) subscribers on all MX Series routers with modular Modular Port Concentrators (MPCs).

The application-aware access list (AACL) service adds support for a new service that uses application names and groups as matching criteria for filtering traffic. AACL is a stateless, rules-based service that must be combined with application identification to enable policies to be applied to flows based on application and application group membership in addition to traditional packet matching rules. It is supported on MX Series routers equipped with Multiservices DPCs and on M120 or M320 routers equipped with Multiservices 400 PICs. Starting with Junos OS Release 11.3, AACL is supported on T320, T640, and T1600 routers also.

AACL is configured in a similar way to other rules-based services such as Network Address Translation (NAT), class of service (CoS), and stateful firewall. To configure AACL, include rule specifications for match criteria and actions at the **[edit services aacl]** hierarchy level. You can chain AACL rules along with other service rules by including them in a service-set definition at the **[edit services service-set]** hierarchy level, as previously documented.

There is one pair of related operational commands, **show/clear application-aware-access-list statistics**.

For more information on the CLI configuration, see the *Application Aware Services Interfaces Feature Guide for Routing Devices*. For more information on the operational command, see the [CLI Explorer](#).

NOTE: Because the Junos OS extension-provider package framework lacks aggressive constraint checks, you should not set the `policy-db-size` statement at the `[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]` hierarchy level to a high value. For Junos Application Aware (previously known as dynamic application awareness) configurations, the recommended values for the extension-provider options at this hierarchy level are as follows:

- `control-cores = 1`
- `data-cores = 7`
- `object-cache-size = 1280` (for Multiservices 400 PIC and Multiservices DPC)
- `policy-db-size = 200`
- Include these package values: `jservices-idp`, `jservices-appid`, `jservices-llpdf`, `jservices-aacl`

For more information about this configuration, see the following topics in the *SDK Applications Configuration Guide and Command Reference*:

- *Configuring Control and Data Cores*
- *Configuring Memory Settings*
- *Configuring Packages on the PIC*

Best-Effort Application Identification of DPI-Serviced Flows

This topic describes the following information:

- [Features that Support Application-Level Filtering on page 659](#)
- [Best-Effort Application Determination on page 659](#)
- [APPID, AACL, and L-PDF Processing in Preconvergence Scenarios on page 659](#)

Features that Support Application-Level Filtering

On MX Series routers equipped with Multiservices DPCs and M120 or M320 routers equipped with Multiservices 400 PICs, Intrusion Detection and Prevention (IDP) is accomplished by Deep Packet Inspection (DPI) of TCP, UDP, and ICMP flows. The application identification (APPID) feature defines applications as members of application groups in TCP/UDP/ICMP traffic. IDP depends on APPID for identification and detection of some Layer 7 applications.

The application-aware access list (AACL) service uses application names and groups as matching criteria for filtering traffic. The service defines the applications and application groups for which statistics are collected for a specific user or interface.

The local policy decision function (L-PDF) enables you to configure properties for statistics output. L-PDF supports a process that regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

Best-Effort Application Determination

Typically, APPID conclusively determines the Layer 7 application associated with a given DPI-serviced flow. In these cases, the application identification is final. Occasionally, APPID is only able to make an initial, inconclusive determination of the Layer 7 application associated with a given flow. This is referred to as a "best-effort" application identification. In such cases, the APPID process continues processing packets on that flow and might subsequently make a conclusive determination of the application associated with that flow. In some cases of best-effort application identification, the flow ends before a final application determination can be made.

APPID, AACL, and L-PDF Processing in Preconvergence Scenarios

The following sections describe APPID, AACL, and L-PDF processing in various stages of application identification for a DPI-serviced flow of TCP/UDP/ICMP traffic.

- [Prior to a Final or Best-Effort Application Identification on page 659](#)
- [Upon Best-Effort Application Identification on page 660](#)
- [While Application Identification Is on a Best-Effort Basis on page 660](#)
- [If a Flow Ends Before an Application Identification Is Made on page 660](#)
- [If a Flow Ends While Application Identification on a Best-Effort Basis on page 660](#)

Prior to a Final or Best-Effort Application Identification

During the time that APPID has not yet made either a final or best-effort determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has not yet made either a final or best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has not yet made either a final or best-effort determination of the associated application.

Upon Best-Effort Application Identification

When a best-effort application determination is made, AACL does not apply any AACL term actions configured for that flow. There are a number of reasons for this, one being that the action itself (such as "discard") could make a final application determination impossible. Instead, AACL or L-PDF tracks the flow and accepts all packets for that flow until a final determination is made, at which time the normal AACL or L-PDFL actions are fully applied to the flow.

While Application Identification Is on a Best-Effort Basis

During the time that APPID identification of the application associated with a given flow is on a best-effort basis, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has only made a best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has only made a best-effort determination of the associated application.

If a Flow Ends Before an Application Identification Is Made

If a flow ends before APPID has made either a final or a best-effort application identification, AACL or L-PDF uses the "unknown" application ID as a final determination and performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** AACL term action is configured for the "application-group-any" application, then the statistics for that flow will be collected and aggregated against the count bucket type, and reported as such.

If a Flow Ends While Application Identification on a Best-Effort Basis

If a flow ends while the application identification is on a best-effort basis, AACL or L-PDF uses that best-effort determination as a final determination. AACL or L-PDF performs

any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** AACL term action is configured for that Layer 7 application, then the statistics for the flow will be collected and aggregated against the AACL or L-PDF statistics. However, in the case of nested applications, AACL and L-PDF will not consider the best-effort determination as final and the nested application will be reported as an unknown application.

- [then on page 1589](#)

Configuring AACL Rules

To configure an AACL rule, include the **rule** *rule-name* statement at the **[edit services aACL]** hierarchy level:

```
rule rule-name {
  match-direction (input | output | input-output);
  term term-name {
    from {
      application-group-any;
      application-groups [ application-group-names ];
      applications [ application-names ];
      destination-address address <any-unicast>;
      destination-address-range low minimum-value high maximum-value;
      destination-prefix-list list-name;
      nested-applications [ nested-application-names ];
      nested-application-unknown;
      source-address address <any-unicast>;
      source-address-range low minimum-value high maximum-value;
      source-prefix-list list-name;
    }
    then {
      (accept | discard);
      count (application | application-group | application-group-any | nested-application
        | none);
      forwarding-class class-name;
      policer policer-name;
    }
  }
}
```

Each AACL rule consists of a set of terms, similar to a filter configured at the **[edit firewall]** hierarchy level. A term consists of the following:

- **from** statement—Specifies the match conditions and applications that are included and excluded.
- **then** statement—Specifies the actions and action modifiers to be performed by the router software.

The following sections explain how to configure the components of ACL rules:

- [Configuring Match Direction for ACL Rules on page 662](#)
- [Configuring Match Conditions in ACL Rules on page 662](#)
- [Configuring Actions in ACL Rules on page 664](#)
- [Logging ACL Flows Based on Application on page 665](#)

Configuring Match Direction for ACL Rules

Each rule must include a **match-direction** statement that specifies the direction in which the rule match is applied. To configure where the match is applied, include the **match-direction** statement at the **[edit services acl rule *rule-name*]** hierarchy level:

```
match-direction (input | output | input-output);
```

If you configure **match-direction input-output**, bidirectional rule creation is allowed.

The match direction is used with respect to the traffic flow through the services PIC or DPC. When a packet is sent to the PIC or DPC, direction information is carried along with it.

With an interface service set, packet direction is determined by whether a packet is entering or leaving the interface on which the service set is applied.

With a next-hop service set, packet direction is determined by the interface used to route the packet to the services PIC or DPC. If the inside interface is used to route the packet, the packet direction is input. If the outside interface is used to direct the packet to the PIC or DPC, the packet direction is output. For more information on inside and outside interfaces, see [“Configuring Service Sets to be Applied to Services Interfaces” on page 31](#).

On the PIC or DPC, a flow lookup is performed. If no flow is found, rule processing is performed. All rules in the service set are considered. During rule processing, the packet direction is compared against rule directions. Only rules with direction information that matches the packet direction are considered.

Configuring Match Conditions in ACL Rules

To configure ACL match conditions, include the **from** statement at the **[edit services acl rule *rule-name* term *term-name*]** hierarchy level:

```
from {  
  application-group-any;  
  application-groups [ application-group-names ];  
  applications [ application-names ];  
  destination-address address <any-unicast>;  
  destination-address-range low minimum-value high maximum-value;  
  destination-prefix-list list-name;
```

```

nested-applications [ nested-application-names ];
nested-application-unknown
source-address address <any-unicast>;
source-address-range low minimum-value high maximum-value;
source-prefix-list list-name;
}

```

IPv4 and IPv6 source and destination addresses are supported. You can use either the source address or the destination address as a match condition, in the same way that you configure a firewall filter; for more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Alternatively, you can specify a list of source or destination prefixes by configuring the **prefix-list** statement at the **[edit policy-options]** hierarchy level and then including either the **destination-prefix-list** or the **source-prefix-list** statement in the ACL rule. For an example, see “[Example: Configuring ACL Rules](#)” on page 666.

If you omit the **from** term, the ACL rule accepts all traffic and the default protocol handlers take effect:

- User Datagram Protocol (UDP), Transmission Control Protocol (TCP), and Internet Control Message Protocol (ICMP) create a bidirectional flow with a predicted reverse flow.
- IP creates a unidirectional flow.

You can also include application and application group definitions you have configured at the **[edit services application-identification]** hierarchy level; for more information, see the topics in *Application Identification*.

- To apply one or more specific application protocol definitions, include the **applications** statement at the **[edit services aacl rule *rule-name* term *term-name* from]** hierarchy level.
- To apply one or more sets of application group definitions you have defined, include the **application-groups** statement at the **[edit services aacl rule *rule-name* term *term-name* from]** hierarchy level.

NOTE: If you include one of the statements that specifies application protocols, the router derives port and protocol information from the corresponding configuration at the **[edit services application-identification]** hierarchy level; you cannot specify these properties as match conditions.

- To consider any application group defined in the database as a match, include the **application-group-any** statement at the **[edit services aacl rule *rule-name* term *term-name* from]** hierarchy level.
- To consider any nested application defined in the database a match, include the **nested-applications** statement at the **[edit services aacl rule *rule-name* term *term-name* from]** hierarchy level. Nested applications are protocols that run on a parent application. For example, if the Facebook application runs on the parent application `junos:http`, the nested application will be `junos:http:facebook`.

Configuring Actions in ACL Rules

To configure ACL actions, include the **then** statement at the **[edit services aac rule rule-name term term-name]** hierarchy level:

```
then {  
  (accept | discard);  
  (count (application | application-group | application-group-any | nested-application |  
    none) | forwarding-class class-name);  
}
```

You must include one of the following actions:

- **accept**—The packet is accepted and sent on to its destination.
- **discard**—The packet is not accepted and is not processed further.

When you select **accept** as the action, you can optionally configure one or both of the following action modifiers. No action modifiers are allowed with the **discard** action.

- **count (application | application-group | application-group-any | nested-application | none)**—For all accepted packets that match the rules, record a packet count using ACL statistics practices. You can specify one of the following options; there is no default setting:
 - **application**—Count the application that matched in the **from** clause.
 - **application-group**—Count the application group that matched in the **from** clause.
 - **application-group-any**—Count all application groups that match **from application-group-any** under the **any** group name.
 - **nested-application**—Count all nested applications that matched in the **from** clause.
 - **none**—Same as not specifying **count** as an action.

NOTE:

- When a session closes before APPID has identified nested applications, the session is treated as a best-effort session and ACL does not get the nested application information. In such cases, nested applications will be reported as unknown applications.
- During the time that the application identification (APPID) feature has not yet made a final determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection. For more information, see [“Best-Effort Application Identification of DPI-Serviced Flows” on page 658](#).

-
- **forwarding-class class-name**—Specify the packets’ forwarding-class name.

You can optionally include a **policer** that has been specified at the **[edit firewall]** hierarchy level. Only the bit-rate and burst-size properties specified for the policer are applied in the ACL rule set. The only action application when a policer is configured is **discard**. For

more information on policer definitions, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Logging AACL Flows Based on Application

You can now log AACL flows based on application. You can select a specific application or request information on unknown applications.

You can now configure AACL rules to match unknown applications. All existing actions that can apply to recognized applications can also apply to unknown applications. You can use the following statements at the **[edit services aacl rule rule-name term term-name from]** hierarchy level:

- application-group-any
- application-groups
- application-unknown
- applications
- nested-application-unknown
- nested-applications

The addition of matching “application unknown” enables the specific logging of the input flows associated with applications that cannot be identified. Because logging is triggered by an input event, you must specify **match-direction** as **input-output** or **input**.

To configure logging of flows for AACL, include the **match-direction input** or **match-direction input-output** statement at the **[edit services aacl rule rule-name]** hierarchy level, include an **applications** or **application-unknown** statement at the **[edit services aacl rule rule-name term term-name from]** hierarchy level, and include only one **log** statement at the **[edit services aacl rule rule-name term term-name then]** hierarchy level. The log statements can include any of the following options:

- session-start
- session-end
- session-start-end-no-stats
- session-start-interim-end
- session-interim-end
- session-end

- [Configuring AACL Rule Sets on page 666](#)
- [Configuring Logging of AACL Flows on page 667](#)
- [Example: Configuring AACL Rules on page 666](#)

Example: Configuring AACL Rules

The following example shows an AACL configuration containing a rule with three terms using a variety of match conditions and actions:

```
[edit services aacl]
rule aacl-test {
  match-direction input;
  term term1 {
    from {
      source-address 10.0.1.1
      application test1;
    }
    then {
      accept;
    }
  }
  term term2 {
    from {
      source-address {
        any-unicast;
      }
      application test1;
    }
    then {
      discard;
    }
  }
  term term3 {
    from {
      source-address {
        any-unicast;
      }
      application test1 test2;
    }
    then {
      accept;
      count application;
    }
  }
}
```

- Related Documentation**
- [AACL Overview on page 657](#)
 - [Configuring AACL Rules on page 661](#)

Configuring AACL Rule Sets

The **rule-set** statement defines a collection of AACL rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then, you specify the order of the rules by

including the **rule-set** statement at the **[edit services aacl]** hierarchy level with a **rule** statement for each rule:

```
rule-set rule-set-name {
  rule rule-name;
}
```

The router software processes the rules in the order in which you specify them in the configuration. If a term in a rule matches the packet, the router performs the corresponding action and the rule processing stops. If no term in a rule matches the packet, processing continues to the next rule in the rule set. If none of the rules matches the packet, the packet is dropped by default.

- [Example: Configuring AACL Rules on page 666](#)

Configuring Logging of AACL Flows

You can configure logging of AACL flows for a given application or for all unknown applications using AACL rules. You must set **match-direction** to **input** or **input-output** for logging to occur.

1. Create a rule and term.

```
user@host# edit services aacl rule rule-name term term-name
```

2. Specify selection of an application.

```
[edit services aacl rule rule-name term term-name]
user@host# set from applications application-name]
```

OR

Specify selection of all unknown applications.

```
[edit services aacl rule <variable>rule-name</variable> term
<variable>term-name</variable>]
set from application-unknown
```

3. In the **then** statement, specify logging of input flow.

```
[edit services aacl rule rule-name term term-name]
user@host# set then log input-flows]
```

Example—Configuration of Logging of Input Flows for Unknown Applications

```
[edit services aacl rule aacL_rule5]
match-direction input-output;
term t0 {
  from {
    application-unknown;
  }
  then {
    count application;
```

```
        log input-flow;
        accept;
    }
}
```

Example—Setup of a Specific Log File

The following example shows how to direct the aacL flow log to a file other than the default syslog file on the Routing Engine file system.

```
[edit system syslog]
file aacL_log {
    external any;
    match aacL-flow-log;
}
```

APPID Overview

NOTE: Starting with Junos OS Release 12.1, all interface-style services are supported for dynamic Point-to-Point Protocol over Ethernet (PPPoE) subscribers on all MX Series routers with modular Modular Port Concentrators (MPCs).

The APPID feature identifies applications as constituents of application groups in TCP/UDP/ICMP traffic. It is supported on MX Series routers equipped with Multiservices DPCs and on M120 or M320 routers equipped with Multiservices 400 PICs and Aggregated Multiservices (AMS) PICs. Aggregated Multiservices PICs (ams- interfaces) enable multiple ms- interfaces to be grouped together in a single bundle and cause the traffic destined for this AMS group to be distributed over the member services PICs of the group.

Junos OS Trio chipsets enable the calculation of a symmetric hash for the forward and reverse flows, and support a microcode map in the forwarding plane. This capability enables load-balancing of traffic across various services PICs in an AMS group. Starting with Junos OS Release 12.1, ams- interfaces enable an N:1 redundancy mechanism to cluster together N number of ms- interfaces in an AMS group that supports load sharing.

NOTE: For ams- interfaces and rms- interfaces, the statistics data in the bulk statistics file is collected using the reports received from the MS PICs. For the ams- interfaces, the retrieval and storage of statistics is not possible because of multiple PICs containing statistics data for the same subscriber. For interfaces in an AMS group, statistics data from different MS PICs in the AMS group are collected and aggregated on the Routing Engine where a timer control is activated and the data is saved in the bulkstats file based on this timer. This method of collection causes the statistics data in the bulkstats file to be displayed with a small delay period.

To configure APPID, include statements at the **[edit services application-identification]** hierarchy level to specify parameter values for defining applications, enable or disable application rules, and gather the applications and rules into groups.

The following are related operational commands:

- **show/clear application-identification application-system-cache**
- **show/clear application-identification counters**

For more information on the CLI configuration, see the *Application Identification*. For more information on the operational commands, see the [CLI Explorer](#).

NOTE: Because the extension-provider package framework lacks aggressive constraint checks, you should not set the `policy-db-size` statement at the `[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]` hierarchy level to a high value. For Junos Application Aware (previously known as Dynamic Application Awareness) configurations, the recommended values for the extension-provider package options at this hierarchy level are as follows:

- `control-cores = 1`
- `data-cores = 7`
- `object-cache-size = 1280` (for Multiservices 400 PIC and Multiservices DPC)
- `policy-db-size = 200`
- Include these package values: `jservices-idp`, `jservices-appid`, `jservices-llpdf`, `jservices-aac1`

For more information about this configuration, see the following topics in the *SDK Applications Configuration Guide and Command Reference*:

- *Configuring Control and Data Cores*
- *Configuring Memory Settings*
- *Configuring Packages on the PIC*

NOTE: In the export version of JUNOS, signature download is not expected to work for AppID and IDP features in Junos Application Aware. In order to make it work, you must additionally install the Crypto Software Suite.

Best-Effort Application Identification of DPI-Serviced Flows

This topic describes the following information:

- [Features that Support Application-Level Filtering on page 672](#)
- [Best-Effort Application Determination on page 672](#)
- [APPID, AACL, and L-PDF Processing in Preconvergence Scenarios on page 672](#)

Features that Support Application-Level Filtering

On MX Series routers equipped with Multiservices DPCs and M120 or M320 routers equipped with Multiservices 400 PICs, Intrusion Detection and Prevention (IDP) is accomplished by Deep Packet Inspection (DPI) of TCP, UDP, and ICMP flows. The application identification (APPID) feature defines applications as members of application groups in TCP/UDP/ICMP traffic. IDP depends on APPID for identification and detection of some Layer 7 applications.

The application-aware access list (AACL) service uses application names and groups as matching criteria for filtering traffic. The service defines the applications and application groups for which statistics are collected for a specific user or interface.

The local policy decision function (L-PDF) enables you to configure properties for statistics output. L-PDF supports a process that regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

Best-Effort Application Determination

Typically, APPID conclusively determines the Layer 7 application associated with a given DPI-serviced flow. In these cases, the application identification is final. Occasionally, APPID is only able to make an initial, inconclusive determination of the Layer 7 application associated with a given flow. This is referred to as a "best-effort" application identification. In such cases, the APPID process continues processing packets on that flow and might subsequently make a conclusive determination of the application associated with that flow. In some cases of best-effort application identification, the flow ends before a final application determination can be made.

APPID, AACL, and L-PDF Processing in Preconvergence Scenarios

The following sections describe APPID, AACL, and L-PDF processing in various stages of application identification for a DPI-serviced flow of TCP/UDP/ICMP traffic.

- [Prior to a Final or Best-Effort Application Identification on page 672](#)
- [Upon Best-Effort Application Identification on page 673](#)
- [While Application Identification Is on a Best-Effort Basis on page 673](#)
- [If a Flow Ends Before an Application Identification Is Made on page 673](#)
- [If a Flow Ends While Application Identification on a Best-Effort Basis on page 673](#)

Prior to a Final or Best-Effort Application Identification

During the time that APPID has not yet made either a final or best-effort determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has not yet made either a final or best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has not yet made either a final or best-effort determination of the associated application.

Upon Best-Effort Application Identification

When a best-effort application determination is made, AACL does not apply any AACL term actions configured for that flow. There are a number of reasons for this, one being that the action itself (such as "discard") could make a final application determination impossible. Instead, AACL or L-PDF tracks the flow and accepts all packets for that flow until a final determination is made, at which time the normal AACL or L-PDFL actions are fully applied to the flow.

While Application Identification Is on a Best-Effort Basis

During the time that APPID identification of the application associated with a given flow is on a best-effort basis, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has only made a best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has only made a best-effort determination of the associated application.

If a Flow Ends Before an Application Identification Is Made

If a flow ends before APPID has made either a final or a best-effort application identification, AACL or L-PDF uses the "unknown" application ID as a final determination and performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** AACL term action is configured for the "application-group-any" application, then the statistics for that flow will be collected and aggregated against the count bucket type, and reported as such.

If a Flow Ends While Application Identification on a Best-Effort Basis

If a flow ends while the application identification is on a best-effort basis, AACL or L-PDF uses that best-effort determination as a final determination. AACL or L-PDF performs

any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** AACL term action is configured for that Layer 7 application, then the statistics for the flow will be collected and aggregated against the AACL or L-PDF statistics. However, in the case of nested applications, AACL and L-PDF will not consider the best-effort determination as final and the nested application will be reported as an unknown application.

Defining an Application Identification

To configure a specific IP address or port-based application identification, include the **application** *application-name* statement at the **[edit services application-identification]** hierarchy level:

```
application application-name {  
  disable;  
  idle-timeout seconds;  
  index number;  
  session-timeout seconds;  
  type type;  
  type-of-service service-type;  
  port-mapping {  
    port-range {  
      tcp [ ports-and-port-ranges ];  
      udp [ ports-and-port-ranges ];  
    }  
    disable;  
  }  
}
```

You can include the following general properties in the configuration:

- **application**—Application name, a required statement; maximum 31 characters. Predefined applications have the prefix **junos-** to avoid conflict with user-defined ones.
- **idle-timeout**—Amount of time that a session remains idle before it is deleted.
- **index**—Application index number in the range from 1 through 65,534, with integers 1 through 1024 reserved for predefined applications.
- **session-timeout**—Lifetime of a session.

- **type**—Well known applications, such as HTTP or FTP.
- **type-of-service**—Type of service, defined by service objective. There is no default value; options are **maximize-reliability**, **maximize-throughput**, **minimize-delay**, and **minimize-monetary-cost**.
- **disable**—Disable this application definition in the APPID service.

NOTE: You can also specify session and idle timeout values globally for a Multiservices interface by including the following statements at the [edit interfaces *interface-name* services-options] hierarchy level:

- **inactivity-non-tcp-timeout**—Inactivity timeout period for non-TCP established sessions.
- **inactivity-tcp-timeout**—Inactivity timeout period for TCP established sessions.
- **session-timeout**—Lifetime of a session.
- **disable-global-timeout-override**—Disallow overriding a global inactivity or session timeout.

You can include the following port-mapping properties at the [edit services application-identification port-mapping] hierarchy level:

- **port-range**—TCP or UDP port number or numeric range, entered as [*minimum-value* – *maximum-value*]. For port-mapping configurations, this entry is required if the parent node exists.
- **disable**—Disable port-mapping properties for this application.

NOTE: For applications with signatures for both client-to-server and server-to-client directions, the APPID for Junos Application Aware (previously known as Dynamic Application Awareness) must accept the data packets in both directions on the same session to complete the identification process.

For a configuration example, see “[Examples: Configuring Application Identification Properties](#)” on page 688.

- [\[edit services application-identification\] Hierarchy Level on page 1295](#)

Configuring APPID Rules

This configuration specifies the properties for identifying an application for which a source or destination IP address and port is used for a known application, without the requirement of an application signature. For example, the Session Initiation Protocol (SIP) server initiates a session from its identified port, 5060. You can therefore specify the SIP server IP address and port 5060 in the port mapping configuration for the SIP application. The advantage of using this method is to provide efficiency and accuracy of application identification for your network.

To configure application rule properties, include the **rule** statement at the [\[edit services application-identification\]](#) hierarchy level:

```
rule rule-name {  
  address address-name {  
    destination {  
      ip address</prefix-length>;  
      port-range {  
        tcp [ ports-and-port-ranges ];  
        udp [ ports-and-port-ranges ];  
      }  
    }  
    source {  
      ip address</prefix-length>;  
      port-range {  
        tcp [ ports-and-port-ranges ];  
        udp [ ports-and-port-ranges ];  
      }  
    }  
    order number;  
  }  
  application application-name;  
  disable;  
}
```

You can include the following application rule properties:

- **address**—Address properties for APPID rule processing. This statement is mandatory; you must specify either destination or source properties.
- **destination**—Destination address and port information. The **ip** statement defines the IP address and netmask (IPv4 only), and the **port-range** statement defines the TCP or UDP port number or numeric range, entered as **[*minimum-value* – *maximum-value*]**.
- **source**—Source address and port information. The **ip** statement defines the IP address and netmask (IPv4 only), and the **port-range** statement defines the TCP or UDP port number or numeric range, entered as **[*minimum-value* – *maximum-value*]**.
- **order**—Application matching priority. For address configurations, the order number resolves the conflict when multiple address entries are matched for a specific session;

the lower the number, the higher the priority. This statement is mandatory and must contain a unique value.

- **application**—Name of the application to be included in the rule.
- **disable**—Disable processing for this application rule.

The **rule-set** statement defines a collection of APPID rules that determine what actions the router software performs on packets in the data stream. You define each rule by specifying a rule name and configuring terms. Then, you specify the order of the rules by including the **rule-set** statement at the **[edit services application-identification]** hierarchy level with a **rule** statement for each rule:

```
rule-set rule-set-name {
  rule application-rule-name;
}
```

Using Stateful Firewall Rules to Identify Data Sessions

The APPID configuration properties enable the Junos OS to detect applications based on signatures, ports, and addresses. For signature-based detection, most of the protocol control sessions are identified, but data sessions are not identified. For example, APPID identifies FTP connections to port 21 (FTP control sessions); however, FTP can open child/data sessions to transfer files and data. These sessions are not identified by signature-based APPID because they do not have well-defined signatures.

Application-level gateways (ALGs) configured using stateful firewall rules can assist APPID in identifying these data sessions. These sessions include file and video transfers that are heavy consumers of bandwidth, so a mechanism for policing and classifying this traffic effectively is a useful tool. In addition to FTP, this mechanism applies to TFTP and RTSP traffic.

To incorporate the stateful firewall rules into Junos Application Aware (previously known as Dynamic Application Awareness for Junos OS) sessions, include the following configurations:

1. Include the stateful firewall package at the **[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]** hierarchy level:

```
package jservices-sfw;
```
2. Define two stateful firewall rules as shown in the following example, one to identify the appropriate ALGs for FTP, TFTP, or RTSP traffic and the other to allow all traffic:

NOTE: Session Initiation Protocol (SIP) is already covered by APPID and the SIP ALG is not supported by stateful firewall, hence a SIP configuration is not needed.

```
[edit services]
stateful-firewall {
  rule rule1 {
    match-direction input-output;
    term term1 {
      from {
        applications [ junos-ftp junos-tftp junos-rtsp ];
      }
      then {
        accept;
      }
    }
  }
  rule rule2 {
    match-direction input-output;
    term term1 {
      then {
        accept;
      }
    }
  }
  rule-set rs1 {
    rule rule1;
    rule rule2;
  }
}
```

NOTE: The existing AACL and L-PDF operational mode commands should report the new applications when they are identified.

3. Attach the stateful firewall rule set to a service set, as shown in the following example:

```
service-set test-chaining {
  application-identification-profile add-based;
  stateful-firewall-rule-sets rs1;
  idp-profile idp1;
  aacl-rules rule1;
  interface-service {
    service-interface ms-2/0/0.0;
  }
}
```

4. Include *no-drop* settings for stateful firewall and TCP, as needed.

Stateful firewall processing drops packets in a number of scenarios:

- TCP sessions do not start with a SYN flag. (This prevents sessions from resuming; otherwise, when the PIC starts for the first time, all existing TCP sessions in flight will be dropped).
- If the TCP tracker detects SYN but no SYN/ACK or only an ACK, then the ACK is dropped. There are a number of similar checks to verify the TCP connection, window checks, and so forth.
- TCP checks for stateful firewall are aggressive when ALGs are run. It is not possible to ignore TCP errors when an ALG is run on a session.
- If an ALG detects malformed packets (for example, if the FTP PORT command is not RFC-compliant), it drops packets. If an ALG is not able to allocate resources, it drops packets.

You can include the settings shown in the following example to assist in controlling these packet drops:

```
[edit interfaces]
ms-1/2/0 {
  services-options {
    ignore-errors {
      tcp;
      alg;
    }
  }
}
```

The **tcp** statement mediates the first two issues listed, with reference to TCP SYN detection. The **alg** statement handles the fourth issue. ALGs require strict TCP processing, which cannot be relaxed.

- [Tracing APPID Operations on page 686](#)

Configuring Application Profiles

You can define an application profile for use in a service set. The profile consists of one or more rule sets, but only one profile can be included per service set.

To specify the application profile constituents, include the **profile** statement at the **[edit services application-identification]** hierarchy level:

```
profile profile-name {
  [ rule-set rule-set-name ];
}
```

You assign a profile name and include one or more predefined rule sets. For more information on rule sets, see [“Configuring APPID Rules” on page 676](#). You can then include the profile in a service-set definition:

```
[edit services]
service-set service-set-name {
  profile profile-name;
}
```

The definitions specific to Junos Application Aware (previously known as Dynamic Application Awareness) include the APPID and IDP profiles and the ACL rule set. For more information on service sets, see *Service Set Properties*.

 - [Configuring Global APPID Properties on page 683](#)

Configuring Application Groups

You can define an application group to process a number of applications or subgroups at the same time. To configure application group properties, include the **application-group** statement at the **[edit services application-identification]** hierarchy level:

```
application-group group-name {
  application-groups {
    application-group-name;
  }
  applications {
    application-name;
  }
  index number;
  disable;
}
```

You can include the following application group properties:

- **applications**—List of applications to include in this application group. The **name** statement is mandatory and must include at least one entry.
- **application-groups**—List of application groups to include in a larger application group. The **name** statement is mandatory and must include at least one entry.
- **index**—Application group index number in the range from 1 through 65,534. This mandatory value must be unique.
- **disable**—Disable processing for this application group.

Application Identification for Nested Applications

The application identification feature is used by intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports. *Nested applications* are protocols running over the parent application. For example, both Facebook and Yahoo Messenger can run over HTTP, but there is a need to identify them as two different applications. To do this, the application layer is split into two layers: Layer 7 applications and Layer 7 protocols.

The predefined application signatures included with Junos OS have been created to detect the Layer 7 nested applications. Predefined application signatures can be used in attack objects.

To configure nested application properties, include the **nested-application** statement at the **[edit services application-identification]** hierarchy level:

```
nested-application name {
  index number;
  protocol protocol;
  signature name {
    chain-order;
    maximum-transactions number;
    member name {
      context (http-header-content-type | http-header-host | http-url-parsed |
        http-url-parsed-param-parsed);
      direction (any | client-to-server | server-to-client);
      pattern dfa-pattern;
    }
    order number;
  }
  type type;
}
```

You can include the following application rule properties:

- **chain-order**—Signatures can contain multiple members. If the chain order feature is on, those members are read in order. The default for this option is no chain order. If a signature contains only one member, this option is ignored.
- **context**—Define a service specific context. The options are **http-header-content-type**, **http-header-host**, **http-url-parsed**, **http-url-parsed-param-parsed**. This statement is mandatory.
- **direction**—The connection direction of the packets to apply pattern matching. The options are **client-to-server**, **server-to-client**, or **any**. This statement is mandatory.
- **index**—A number that is a one-to-one mapping to the application name that is used to ensure that each signature definition is unique. The index range for predefined

applications is 1 through 32767. The index range for custom applications and custom nested applications is 32768 through 65534.

- **maximum transactions**—The maximum number of transactions that should occur before a match is made. This statement is mandatory.
- **member**—Define a member name for a custom nested application signature definition. Custom definitions can contain multiple members that define attributes for an application.
- **order**—Define application matching priority. For address configurations, the order number resolves the conflict when multiple address entries are matched for a specific session. The lower number has higher priority. This statement is mandatory.
- **pattern**—Define an attack pattern to be detected. This statement is mandatory.
- **protocol**—The protocol that will be monitored to identify nested applications. The value **http** is supported. This statement is mandatory.
- **signature**—Name of the custom nested application signature definition. Must be a unique name with a maximum length of 32 characters. This statement is mandatory.
- **type**—Well-known application name for this application definition, such as Facebook or Kazza. This application name must be unique with a maximum length of 32 characters. This statement is mandatory.

Disabling Application Identification for Nested Applications

Sometimes there is a need to identify multiple different applications running on the same Layer 7 protocols. For example, both Facebook and Yahoo Messenger can run over HTTP, but there is a need to identify them as two different applications. To do this, the application layer is split into two layers: Layer 7 applications and Layer 7 protocols. Application identification for nested applications is turned on by default. You can manually turn it off by using the CLI.

To disable nested application identification:

- Set the **no-nested-application** statement.

```
[edit services application-identification nested-application-settings]  
user@host# no-nested-application
```

To verify the configuration, issue the **show services application-identification nested-application-settings** command.

To reenable nested application identification:

- Delete the **no-nested-application** statement.

```
[edit services application-identification nested-application-settings]
user@host# delete services application-identification nested-application-settings
no-nested-application
```

If you are finished configuring the device, commit the configuration.

**Related
Documentation**

- [APPID Overview on page 669](#)
- [Application Identification for Nested Applications on page 681](#)

Configuring Global APPID Properties

You can define additional properties that apply on a global basis to APPID processing and are not part of a specific application, group, rule, or profile definition. To configure these global APPID properties, include the following statements at the **[edit services application-identification]** hierarchy level:

```
application-identification {
  application-system-cache-timeout seconds;
  max-checked-bytes bytes;
  min-checked-bytes bytes;
  nested-application name
  nested-application-settings
  no-application-identification
  no-application-system-cache;
  no-clear-application-system-cache;
  no-protocol-method;
  no-signature-based;
  signature-method-all-ports;
}
```

The global application properties have the following effect:

- **application-system-cache-timeout**—Lifetime for system cache entries, in seconds.
- **max-checked-bytes**—The maximum number of bytes to be inspected in APPID processing, in the range from 0 through 100,000 bytes.
- **min-checked-bytes**—The minimum number of bytes to be inspected in APPID processing, in the range from 0 through 2000 bytes.
- **nested-application**—Configure a custom nested application definition for the desired application name that will be used by the system to identify the nested application as it passes through the device. For more information see [nested-application](#).
- **nested-application-settings**—Configure nested application options for application identification services. For more information see [nested-application-settings](#).
- **no-application-identification**—Disable all application identification methods.
- **no-application-system-cache**—Disable storing application identification results in the application system cache.

- **no-clear-application-system-cache**—Disable clearing the application system cache.
- **no-protocol-method**—Disable the protocol-based application identification method, which is enabled by default.
- **no-signature-based**—Disable the signature-based application identification method.
- **signature-method-all-ports**—Run signature matching on all traffic.

Configuring APPID Support for Heuristics

Heuristics methodology provides a mechanism for identifying encrypted data packets in point-to-point applications. These packets are not normally detected by the existing application signatures.

To enable APPID to employ heuristics in traffic identification:

1. Include the **enable-heuristics** statement:

```
[edit services application-identification]
user@host# enable-heuristics
```

The **show services application-identification counter** operational command includes additional output fields that report the number of encrypted sessions.

NOTE: When you enable heuristics, performance and scaling values might be negatively affected. This mechanism assists the APPID module in identifying encrypted traffic, but only if the identifications are supported by the current signature package.

- [Defining an Application Identification on page 674](#)
- [Application Identification for Nested Applications on page 681](#)
- [Configuring Global APPID Properties on page 683](#)
- [Configuring APPID Support for Unidirectional Traffic on page 685](#)
- [Examples: Configuring Application Identification Properties on page 688](#)

Configuring APPID Support for Unidirectional Traffic

With asymmetrical routing, a networking device sees only one side of the network sessions, either from client to server or from server to client. Additional functionality is required to support application identification with unidirectional traffic. This addition enables a session for a specified service set to support an asymmetrical routing environment, and allows complete application matches using existing application signatures for traffic in the client-to-server direction only.

To enable APPID to support application matching on unidirectional traffic:

1. Include the **support-uni-directional-traffic** statement:

```
[edit services service-set service-set-name service-set-options]
user@host# support-uni-directional-traffic
```

This enables the session belonging to the specified service set to support the asymmetrical routing environment. The APPID module then reports complete matches for the unidirectional traffic.

2. Include the **enable-asymmetric-traffic-processing** statement:

```
[edit services service-set service-set-name service-set-options]
user@host# enable-asymmetric-traffic-processing
```

This enables the framework and plug-in to handle unidirectional traffic at a service-set level.

When you enable these settings, APPID treats unidirectional TCP traffic like a UDP connection. UDP traffic itself does not receive any special treatment because the service PIC cannot determine whether UDP traffic is unidirectional or bidirectional. The settings do not affect processing of sessions created with bidirectional traffic.

If the traffic includes both unidirectional and bidirectional sessions, the APPID module uses heuristics to decide whether to change the reporting logic.

NOTE: This feature does not change the processing for any services except APPID. However, other services, including stateful firewall, AACL, and IDP, can process unidirectional traffic in a limited manner.

Configuring Automatic Download of Application Package Updates

You can set up automatic downloading of application package updates. To configure downloads, include the **download** statement at the **[edit services application-identification]** hierarchy level:

```
download {  
  automatic {  
    interval hour;  
    start-time time;  
  }  
  url url;  
}
```

You can include the following download statements:

- **download**—Define download properties.
- **automatic**—Set **start-time** value and **interval** in hours for automatic downloads. The default **start-time** is **0:00** and the range is from 0:00 through 24:00. The default **interval** is **24** and the range is from 1 through 168.
- **url**—Specify the download URL.

Tracing APPID Operations

Tracing operations track all adaptive services operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

By default, no events are traced. If you include the **traceoptions** statement at the **[edit services application-identification]** hierarchy level, the default tracing behavior is as follows:

- Important events are logged in a file called **serviced** located in the **/var/log** directory.
- When the file **serviced** reaches 128 kilobytes (KB), it is renamed **serviced.0**, then **serviced.1**, and so on, until there are three trace files. Then the oldest trace file (**serviced.2**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)
- Only the user who configures the tracing operation can access the log files.
- To display the end of the log, issue the **show log serviced | last** operational mode command:

```
[edit]  
user@host# run show log serviced | last
```

You cannot change the directory (**/var/log**) in which trace files are located. However, you can customize the other trace file settings by including the following statements:

```
file filename <files number> <match regex> <size size> <(world-readable |
no-world-readable>;
flag {
  all;
}
```

You configure these statements at the **[edit services application-identification traceoptions]** hierarchy level.

These statements are described in the following sections:

- [Configuring the APPID Log Filename on page 687](#)
- [Configuring the Number and Size of APPID Log Files on page 687](#)
- [Configuring Access to the Log File on page 687](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 688](#)
- [Configuring the Tracing Flags on page 688](#)

Configuring the APPID Log Filename

By default, the name of the file that records trace output is **serviced**. You can specify a different name by including the **file** statement at the **[edit services application-identification traceoptions]** hierarchy level:

```
file filename;
```

Configuring the Number and Size of APPID Log Files

By default, when the trace file reaches 128 kilobytes (KB) in size, it is renamed **filename.0**, then **filename.1**, and so on, until there are three trace files. Then the oldest trace file (**filename.2**) is overwritten.

You can configure the limits on the number and size of trace files by including the following statements at the **[edit services application-identification traceoptions]** hierarchy level:

```
file files number size size;
```

For example, set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation (**filename**) reaches 2 MB, **filename** is renamed **filename.0**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0** is renamed **filename.1** and **filename** is renamed **filename.0**. This process repeats until there are 20 trace files. Then the oldest file (**filename.19**) is overwritten by the newest file (**filename.0**).

The number of files can be from 2 through 1000 files. The file size of each file can be from 10 KB through 1 gigabyte (GB).

Configuring Access to the Log File

By default, only the user who configures the tracing operation can access log files.

To specify that any user can read all log files, include the **file world-readable** statement at the **[edit services application-identification traceoptions]** hierarchy level:

```
file world-readable;
```

To explicitly set the default behavior, include the **file no-world-readable** statement at the **[edit services application-identification traceoptions]** hierarchy level:

```
file no-world-readable;
```

Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including the **match** statement at the **[edit services application-identification traceoptions file filename]** hierarchy level and specifying a regular expression (regex) to be matched:

```
file filename match regex;
```

Configuring the Tracing Flags

By default, if the **traceoptions** configuration is present, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit services application-identification traceoptions]** hierarchy level:

```
flag {  
  all;  
}
```

Currently, the only supported flag is **all**, which instructs the router to trace all operations.

Examples: Configuring Application Identification Properties

The following examples show an address-based application identification configuration:

```
[edit services application-identification]  
rule rule1 {  
  application-name test2;  
  address 1 {  
    source {  
      ip 10.110.1.1/16;  
      port-range {  
        tcp 1110-1150;  
      }  
    }  
  }  
  destination {  
    ip 10.11.1.1/16;  
    port-range {  
      tcp 111-1100;  
    }  
  }  
}
```

```
    }  
  }  
  order 1;  
}  
}  
}  
[edit services application-identification]  
rule-set rs1 {  
  rule rule1;  
}  
profile pf1 {  
  rule-set rs1;  
}  
[edit services]  
service-set sset1 {  
  application-identification-profile pf1;  
}
```

The following examples show application group configuration:

```
[edit services application-identification]  
application-group junos:peer-to-peer {  
  index 5;  
  application-groups {  
    junos:chat;  
    junos:file-sharing;  
    junos:voip;  
  }  
}  
[edit services application-identification]  
application-group junos:voip {  
  index 14;  
  applications {  
    junos:h225ras;  
    junos:h225sgn;  
    junos:mgcp;  
    junos:sip;  
  }  
}
```

The following examples show application identification for nested application configuration:

```
nested-application nested1 {  
  type nested1;  
  index 65345;  
  protocol HTTP;  
  signature nestedcust001 {  
    member m01 {  
      context http-url-parsed;  
      pattern .*nested.*;  
      direction any;  
    }  
    maximum-transactions 2;  
    order 3825;  
  }
```

Detecting Suspicious and Anomalous Network Traffic Using IDP

- IDP Overview on page 691
- Best-Effort Application Identification of DPI-Serviced Flows on page 693

IDP Overview

NOTE: Starting with Junos OS Release 12.1, all interface-style services are supported for dynamic Point-to-Point Protocol over Ethernet (PPPoE) subscribers on all MX Series routers with modular Modular Port Concentrators (MPCs).

The Junos Application Aware (previously known as Dynamic Application Awareness for the Junos OS) set of services adds support for the intrusion detection and prevention (IDP) functionality using Deep Packet Inspection (DPI) technology to Juniper Networks MX Series 3D Universal Edge Routers equipped with Multiservices Dense Port Concentrators (MS-DPCs) and M120 or M320 Multiservices Edge Routers equipped with Multiservices 400 PICs.

The IDP functionality is already supported on Juniper Networks SRX Series Services Gateways running Junos OS and is described in the *Junos OS Intrusion Detection and Prevention (IDP) Library for Security Devices*. Starting with Junos OS Release 11.3, support for the IDP functionality is extended to T320, T640, and T1600 routers. In addition, multiple IDP detectors are now supported on the M120, M320, and MX Series routers with Enhanced III Flexible PIC Concentrators (FPCs).

NOTE: In the export version of JUNOS, signature download is not expected to work for AppID and IDP features in Junos Application Aware. In order to make it work, you must additionally install the Crypto Software Suite.

The same CLI statements and commands are used on all platforms with the following caveats:

- **Service sets**—IDP is incorporated as a component of service sets only on the specified Juniper Networks T Series, M Series and MX Series routers. IDP depends on application identification services (APPID) for definition and detection of some Layer 7 applications. Before configuring an IDP policy, you must download the APPID application package. Only one service set can be applied to a single interface when the APPID functionality is used.
- **Multiple IDP detectors**—Except for the maximum number of decoder binary instances (4) that are loaded into the process space, multiple IDP detectors on the M120, M320, and MX Series routers function in a similar way to the existing IDP detector support on SRX Series devices. To view the current policy and the corresponding detector version, use the **show security idp status detail** command.

To configure IDP properties, include statements at the **[edit security idp]** hierarchy level. In general, you configure IDP processes by including the **idp-policy** statement at the **[edit system processes]** hierarchy level. For use in T Series, M Series and MX Series applications, you then reference this configuration by including the **idp-profile** statement at the **[edit services service-set]** hierarchy level. To configure SNMP IDP objects, include the **idp** statement at the **[edit snmp health-monitor]** hierarchy level. The operational commands for monitoring and regulating IDP activity are the **clear security idp**, **request security idp**, and **show security idp** commands.

To configure the source IP address for downloading security packages, use the command **set security idp security-package source-address ip-address** because it is not possible to download security packages if the router uses private addressing on its outgoing interface. The source address should be a valid IP address on the node.

NOTE: On T Series, M Series and MX Series routers, the IDP **ip-action** statement is supported on TCP, UDP, and ICMP flows. When the **ip-action target** is **service**, the **ip-action** flow is applied if the traffic matches the values specified for the source port, destination port, source address, and destination address. However, for ICMP flows, the destination port is 0, so that any ICMP flow matching the source port, source address, and destination address would be blocked. For more information about the **ip-action** statement, see the *Junos OS CLI Reference*.

When the Multiservices PIC configured for a service set is either administratively taken offline or undergoes a failure, all the traffic entering the configured interface with an IDP service set would be dropped without notification. To avoid this traffic loss, include the **bypass-traffic-on-pic-failure** statement at the **[edit services service-set service-set-name service-set-options]** hierarchy level. When this statement is configured, the affected packets are forwarded in the event of a Multiservices PIC failure or offlining, as though interface-style services were not configured.

NOTE: Data channel applications for protocols such as FTP, TFTP, RTSP, and SIP are not in the same application group as their control channel applications. For example, control channel application `junos:ftp` is in the group `junos:file-server` but the corresponding data application `junos:system:ftp-data` is not in any group.

NOTE: Because the extension-provider package framework lacks aggressive constraint checks, you should not set the `policy-db-size` statement at the `[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]` hierarchy level to a high value. For Junos Application Aware configurations, the recommended values for the extension-provider package options at this hierarchy level are as follows:

- `control-cores = 1`
- `data-cores = 7`
- `object-cache-size = 1280` (for Multiservices 400 PIC and Multiservices DPC)
- `policy-db-size = 200`
- Include these package values: `jservices-idp`, `jservices-appid`, `jservices-llpdf`, `jservices-aacl`

For more information about this configuration, see the following topics in the *SDK Applications Configuration Guide and Command Reference*:

- *Configuring Control and Data Cores*
- *Configuring Memory Settings*
- *Configuring Packages on the PIC*

Best-Effort Application Identification of DPI-Serviced Flows

This topic describes the following information:

- [Features that Support Application-Level Filtering on page 693](#)
- [Best-Effort Application Determination on page 694](#)
- [APPID, AAACL, and L-PDF Processing in Preconvergence Scenarios on page 694](#)

Features that Support Application-Level Filtering

On MX Series routers equipped with Multiservices DPCs and M120 or M320 routers equipped with Multiservices 400 PICs, Intrusion Detection and Prevention (IDP) is accomplished by Deep Packet Inspection (DPI) of TCP, UDP, and ICMP flows. The

application identification (APPID) feature defines applications as members of application groups in TCP/UDP/ICMP traffic. IDP depends on APPID for identification and detection of some Layer 7 applications.

The application-aware access list (AACL) service uses application names and groups as matching criteria for filtering traffic. The service defines the applications and application groups for which statistics are collected for a specific user or interface.

The local policy decision function (L-PDF) enables you to configure properties for statistics output. L-PDF supports a process that regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

Best-Effort Application Determination

Typically, APPID conclusively determines the Layer 7 application associated with a given DPI-serviced flow. In these cases, the application identification is final. Occasionally, APPID is only able to make an initial, inconclusive determination of the Layer 7 application associated with a given flow. This is referred to as a "best-effort" application identification. In such cases, the APPID process continues processing packets on that flow and might subsequently make a conclusive determination of the application associated with that flow. In some cases of best-effort application identification, the flow ends before a final application determination can be made.

APPID, AACL, and L-PDF Processing in Preconvergence Scenarios

The following sections describe APPID, AACL, and L-PDF processing in various stages of application identification for a DPI-serviced flow of TCP/UDP/ICMP traffic.

- [Prior to a Final or Best-Effort Application Identification on page 694](#)
- [Upon Best-Effort Application Identification on page 695](#)
- [While Application Identification Is on a Best-Effort Basis on page 695](#)
- [If a Flow Ends Before an Application Identification Is Made on page 695](#)
- [If a Flow Ends While Application Identification on a Best-Effort Basis on page 695](#)

Prior to a Final or Best-Effort Application Identification

During the time that APPID has not yet made either a final or best-effort determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has not yet made either a final or best-effort determination of the associated application:

- **show services local-policy-decision-function flows (interface *interface-name* | subscriber *subscriber-name*)**
- **show services application-aware-access-list flows (interface *interface-name* | subscriber *subscriber-name*)**

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has not yet made either a final or best-effort determination of the associated application.

Upon Best-Effort Application Identification

When a best-effort application determination is made, ACL does not apply any ACL term actions configured for that flow. There are a number of reasons for this, one being that the action itself (such as "discard") could make a final application determination impossible. Instead, ACL or L-PDF tracks the flow and accepts all packets for that flow until a final determination is made, at which time the normal ACL or L-PDF actions are fully applied to the flow.

While Application Identification Is on a Best-Effort Basis

During the time that APPID identification of the application associated with a given flow is on a best-effort basis, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has only made a best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has only made a best-effort determination of the associated application.

If a Flow Ends Before an Application Identification Is Made

If a flow ends before APPID has made either a final or a best-effort application identification, ACL or L-PDF uses the "unknown" application ID as a final determination and performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** ACL term action is configured for the "application-group-any" application, then the statistics for that flow will be collected and aggregated against the count bucket type, and reported as such.

If a Flow Ends While Application Identification on a Best-Effort Basis

If a flow ends while the application identification is on a best-effort basis, ACL or L-PDF uses that best-effort determination as a final determination. ACL or L-PDF performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** ACL term action is configured for that Layer 7 application, then the statistics for the flow will be collected and aggregated against the ACL or L-PDF statistics. However, in the case of nested applications, ACL and L-PDF will not consider the best-effort determination as final and the nested application will be reported as an unknown application.

L-PDF Overview

NOTE: Starting with Junos OS Release 12.1, all interface-style services are supported for dynamic Point-to-Point Protocol over Ethernet (PPPoE) subscribers on all MX Series routers with modular Modular Port Concentrators (MPCs).

Starting with Junos OS Release 12.1, the local policy decision function (L-PDF) plug-in can offload flows to the Packet Forwarding Engine. Offloading is supported only on MX Series routers with Modular Port Concentrators (MPCs) and accomplished using the Juniper Forwarding Mechanism (JFM). JFM allows services flows to be offloaded to the Packet Forwarding Engine. However, 5-tuple flows cannot be offloaded. Apart from the local L-PDF plug-in, offloading is supported on the packet-triggered subscribers and policy control (PTSP) plug-in. The `show services application-aware-access-list flows subscriber subscriber-name` command displays offload status.

Local policy decision functionality for application-related services adds support for a new process that regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces. This functionality is collectively named the local policy decision function (L-PDF). L-PDF is supported on:

- MX Series routers equipped with Multiservices DPCs.
- M120 or M320 routers equipped with Multiservices 400 PICs.

- Aggregated Multiservices (AMS) PICs.

Multiple `ms-` interfaces can be bundled together in an AMS PIC interface, which causes the traffic destined for this AMS group to be distributed over the member services PICs of the group. Junos OS Trio chipsets enable the calculation of a symmetric hash for the forward and reverse flows, and support a microcode map in the forwarding plane. This capability enables load-balancing of traffic across various services PICs in an AMS group. Starting with Junos OS Release 12.1, `ams-` interfaces enable an N:1 redundancy mechanism to cluster together N number of **`ms-` interfaces** in an AMS group that supports load sharing.

Starting with Junos OS Release 11.3, local L-PDF that resides on the services PIC is supported on T320, T640, and T1600 routers. The application identification (APPID) service defines the applications and how they are grouped. The application-aware access list (AACL) service defines the applications and application groups for which statistics are collected for a specific user or interface. The L-PDF configuration defines the way in which the statistics are output.

To configure properties for statistics output, include the **`policy-decision-statistics-profile`** statement at the **`[edit accounting-options]`** hierarchy level. A new **`traceoptions`** configuration is available at the **`[edit system services local-policy-decision-function]`** hierarchy level. To configure a dynamic profile to attach a specified service set to an interface, include the **`service`** statement at the **`[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number family inet]`** hierarchy level. To attach a service set to a static interface, include the **`service-set service-set-name`** statement at the **`[edit interfaces interface-name unit logical-unit-number family inet service (input | output)]`** hierarchy level. For more information on service sets, see *Service Set Properties*.

The following related operational commands are supported:

- **`show services local-policy-decision-function flows`**
- **`show/clear services local-policy-decision-function statistics`**
- **`show/clear services application-aware-access-list statistics`**

For more information on the CLI configuration, see the *Local Policy Decision Function*. For more information on the operational commands, see the [CLI Explorer](#).

NOTE: Because the Junos OS extension-provider package (variously known as JSF, MP-SDK, and eJunos in releases earlier than 12.3) lacks aggressive constraint checks, you should not set the `policy-db-size` statement at the [edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider] hierarchy level to a high value. For Junos Application Aware (previously known as Dynamic Application Awareness) configurations, the recommended values for the extension-provider package options at this hierarchy level are as follows:

- `control-cores = 1`
- `data-cores = 7`
- `object-cache-size = 1280` (for Multiservices 400 PIC and Multiservices DPC)
- `policy-db-size = 200`
- Include these package values: `jservices-idp`, `jservices-appid`, `jservices-llpdf`, `jservices-aacl`

For more information about this configuration, see the following topics in the *SDK Applications Configuration Guide and Command Reference*:

- *Configuring Control and Data Cores*
- *Configuring Memory Settings*
- *Configuring Packages on the PIC*

Best-Effort Application Identification of DPI-Serviced Flows

This topic describes the following information:

- [Features that Support Application-Level Filtering on page 699](#)
- [Best-Effort Application Determination on page 700](#)
- [APPID, AACL, and L-PDF Processing in Preconvergence Scenarios on page 700](#)

Features that Support Application-Level Filtering

On MX Series routers equipped with Multiservices DPCs and M120 or M320 routers equipped with Multiservices 400 PICs, Intrusion Detection and Prevention (IDP) is accomplished by Deep Packet Inspection (DPI) of TCP, UDP, and ICMP flows. The application identification (APPID) feature defines applications as members of application

groups in TCP/UDP/ICMP traffic. IDP depends on APPID for identification and detection of some Layer 7 applications.

The application-aware access list (AACL) service uses application names and groups as matching criteria for filtering traffic. The service defines the applications and application groups for which statistics are collected for a specific user or interface.

The local policy decision function (L-PDF) enables you to configure properties for statistics output. L-PDF supports a process that regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

Best-Effort Application Determination

Typically, APPID conclusively determines the Layer 7 application associated with a given DPI-serviced flow. In these cases, the application identification is final. Occasionally, APPID is only able to make an initial, inconclusive determination of the Layer 7 application associated with a given flow. This is referred to as a "best-effort" application identification. In such cases, the APPID process continues processing packets on that flow and might subsequently make a conclusive determination of the application associated with that flow. In some cases of best-effort application identification, the flow ends before a final application determination can be made.

APPID, AACL, and L-PDF Processing in Preconvergence Scenarios

The following sections describe APPID, AACL, and L-PDF processing in various stages of application identification for a DPI-serviced flow of TCP/UDP/ICMP traffic.

- [Prior to a Final or Best-Effort Application Identification on page 700](#)
- [Upon Best-Effort Application Identification on page 701](#)
- [While Application Identification Is on a Best-Effort Basis on page 701](#)
- [If a Flow Ends Before an Application Identification Is Made on page 701](#)
- [If a Flow Ends While Application Identification on a Best-Effort Basis on page 701](#)

Prior to a Final or Best-Effort Application Identification

During the time that APPID has not yet made either a final or best-effort determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has not yet made either a final or best-effort determination of the associated application:

- **show services local-policy-decision-function flows (interface *interface-name* | subscriber *subscriber-name*)**
- **show services application-aware-access-list flows (interface *interface-name* | subscriber *subscriber-name*)**

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has not yet made either a final or best-effort determination of the associated application.

Upon Best-Effort Application Identification

When a best-effort application determination is made, ACL does not apply any ACL term actions configured for that flow. There are a number of reasons for this, one being that the action itself (such as "discard") could make a final application determination impossible. Instead, ACL or L-PDF tracks the flow and accepts all packets for that flow until a final determination is made, at which time the normal ACL or L-PDF actions are fully applied to the flow.

While Application Identification Is on a Best-Effort Basis

During the time that APPID identification of the application associated with a given flow is on a best-effort basis, the flow does not contribute to any per-subscriber or per-application statistics collection.

The output of the following operational mode commands includes flows for which APPID has only made a best-effort determination of the associated application:

- **show services local-policy-decision-function flows** (interface *interface-name* | subscriber *subscriber-name*)
- **show services application-aware-access-list flows** (interface *interface-name* | subscriber *subscriber-name*)

In the command output, the **Action** field displays "accept" and the **Application** or **Application group** field displays "unknown" for a flow for which APPID has only made a best-effort determination of the associated application.

If a Flow Ends Before an Application Identification Is Made

If a flow ends before APPID has made either a final or a best-effort application identification, ACL or L-PDF uses the "unknown" application ID as a final determination and performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** ACL term action is configured for the "application-group-any" application, then the statistics for that flow will be collected and aggregated against the count bucket type, and reported as such.

If a Flow Ends While Application Identification on a Best-Effort Basis

If a flow ends while the application identification is on a best-effort basis, ACL or L-PDF uses that best-effort determination as a final determination. ACL or L-PDF performs any necessary collection, aggregation, and reporting of statistics based on that Layer 7 application. In particular, if the **count** ACL term action is configured for that Layer 7 application, then the statistics for the flow will be collected and aggregated against the ACL or L-PDF statistics. However, in the case of nested applications, ACL and L-PDF will not consider the best-effort determination as final and the nested application will be reported as an unknown application.

Related Documentation

- [Configuring ACL Rules on page 661](#)

- [acl-fields on page 1539](#)

- [aacl-statistics-profile on page 1540](#)
- [rule on page 1575](#)
- [services on page 1582](#)
- [term on page 1588](#)
- [then on page 1589](#)

Configuring Statistics Profiles

The local policy decision function (L-PDF) enables you to configure properties for statistics output. To do this, you create a statistics profile, which configures the files to which statistics records are exported and the format that is exported. There are two configurations you can use to specify the profile, as described in the following subsections:

- [Configuring an L-PDF Statistics Profile on page 703](#)
- [Configuring an AACL Statistics Profile on page 704](#)

NOTE: You must use the same configuration stanza for specifying the profile and the file selection. If configurations are committed in both hierarchies, the one at the `[edit system services local-policy-decision-function]` hierarchy level takes precedence.

NOTE:

- When a session closes before APPID has identified nested applications, the session is treated as a best-effort session and L-PDF does not get the nested application information. In such cases, nested applications will be reported as unknown applications.
- During the time that the application identification (APPID) feature has not yet made a final determination of the application associated with a given flow, the flow does not contribute to any per-subscriber or per-application statistics collection. For more information, see [“Best-Effort Application Identification of DPI-Serviced Flows” on page 658](#).

NOTE: For rms- interfaces, the statistics received from the active Multiservices PICs in the RMS group are combined with the statistics of the reported ended flows kept on the Routing Engine. The aggregated value is written to the statistics file. In the case of AMS interfaces, all the Multiservices PICs consisting of the AMS group reports statistics independently. These statistics are aggregated on the Routing Engine. The Routing Engine runs an independent timer, which on expiry writes the aggregated entry in the statistics file. This method of collection causes the statistics data in the statistics file to be displayed with a small delay.

Configuring an L-PDF Statistics Profile

You can specify an L-PDF statistics profile by including the following configuration at the **[edit accounting-options]** hierarchy level:

```
[edit accounting-options]
policy-decision-statistics-profile profile-name {
  application-aware-access-list-fields [ field-name ];
  file filename;
  files number;
  size bytes;
}
```

NOTE: This configuration method is not the preferred method for configuring Junos Application Aware (previously known as Dynamic Application Awareness) statistics. It is only maintained for backwards compatibility and may be deprecated in a future software release and does not support the use of IPv6 address and prefix length. The new, preferred configuration is found at the **[edit system services local-policy-decision-function]** hierarchy level, as described in “[Configuring an ACL Statistics Profile](#)” on page 704. We encourage you to migrate to the new configuration method.

You specify a profile name to identify the profile and other properties as needed by including the **policy-decision-statistics-profile** statement. The **acl-fields** statement specifies which statistics to collect in an accounting-data log file. This log file is located on the **/var/log** directory on the router. You specify the log file by including the **file filename** statement. The filename is prefixed by the **acl_statistics_** prefix; for example, if you specify the filename **lpdfd**, the log file will be **/var/log/acl_statistics_lpdfd**.

The **application-aware-access-list-fields** statement supports the following options:

- **address**—IP Address
- **application**—Application name
- **application-group**—Application group name
- **input-bytes**—Number of input bytes
- **input-interface**—Input interface name
- **input-packets**—Number of input packets
- **mask**—Netmask
- **output-bytes**—Number of output bytes
- **output-packets**—Number of output packets
- **subscriber-name**—Subscriber name
- **timestamp**—Timestamp
- **vrf-name**—VPN routing and forwarding (VRF) name

For more information on configuring profiles, see the *Network Management Administration Guide for Routing Devices*.

Configuring an ACL Statistics Profile

You can specify an ACL statistics profile by including the following configuration at the **[edit system services]** hierarchy level:

```
local-policy-decision-function {
  statistics {
    file filename {
      archive-sites [ url ];
      files number;
      size bytes;
      transfer-interval minutes;
    }
    aacl-statistics-profile profile-name {
      aacl-fields [ field-name ];
      file filename;
      report-interval minutes;
      record-mode (interim-active-only | interim-full);
    }
    record-type (delta | interim);
  }
}
```

To specify the file properties, include the **file** statement at the **[edit system services local-policy-decision-function statistics]** hierarchy level with a unique filename:

- The **archive-sites** statement specifies one or more URLs for archiving the files. Archiving can be done by using FTP or SCP.
- The **files** statement specifies the maximum number of files that are maintained at one time.
- The **size** statement specifies the maximum size of each file.
- The **transfer-interval** statement specifies the interval between data transfers in minutes.

You specify a profile name to identify the profile and other properties as needed by including the **aacl-statistics-profile** statement. The **aacl-fields** statement specifies which statistics to collect in an accounting-data log file. This log file is located on the **/var/stats/aacl** directory on the router. You specify the log file by including the **file filename** statement.

The **aacl-fields** statement supports the following options:

- **address**—IP Address
- **all-fields**—All available fields
- **application**—Application name
- **application-group**—Application group name
- **input-bytes**—Number of input bytes
- **input-interface**—Input interface name

- **ipv6-address**—IPv6 address
- **ipv6-prefix-length**—Prefix length associated with the displayed IPv6 address
- **input-packets**—Number of input packets
- **mask**—Netmask
- **output-bytes**—Number of output bytes
- **output-packets**—Number of output packets
- **subscriber-name**—Subscriber name
- **timestamp**—Timestamp
- **vrf-name**—VPN routing and forwarding (VRF) name

The **record-type** statement specifies whether a record is **delta** or **interim**; **delta** is the default setting. The **report-interval** statement specifies the reporting interval in minutes; the default setting is 15 minutes and the range is 5 through 1440 minutes. The **record-mode** statement specifies how the statistics are reported for each reporting interval; the default setting is **interim-full** and reports all available statistics. To report only statistics that have changed for the reporting interval, use the **interim-active-only** setting.

NOTE: The IPv6 fields (**ipv6-address** and **ipv6-prefix-length**) are not supported for **record-type delta**. The IPv6 fields are supported for **record-type interim** only, meaning that the fields are restricted to the S- (Login) record.

For more information on configuring profiles, see the *Network Management Administration Guide for Routing Devices*.

Related Documentation

- [L-PDF Overview on page 697](#)
- [Best-Effort Application Identification of DPI-Serviced Flows on page 658](#)
- [Applying L-PDF Profiles to Service Sets on page 705](#)
- [Tracing L-PDF Operations on page 707](#)

Applying L-PDF Profiles to Service Sets

You can optionally apply policy decision statistics profiles as part of a service-set definition. To do this, you include the **policy-decision-statistics-profile** statement at the **[edit services service-set *service-set-name*]** hierarchy level:

```
policy-decision-statistics-profile profile-name;
```

NOTE: To provide high availability for the policy decision statistics, associate the service-set definition with a redundant services PIC (rsp) interface.

You can include only one profile name in the specification for the **application-aware access-list** statement.

The following example shows a sample configuration for attachment of an L-PDF statistics profile:

```
services {
  service-set test_aacl_sset {
    aacl-rules aacl_rule;
    policy-decision-statistics-profile {
      pdf_stats_prof;
    }
    interface-service {
      service-interface ms-0/3/0.0;
    }
  }
}
```

NOTE: Only one service set can be applied to a single interface when L-PDF functionality is used.

The following example shows a sample configuration for attachment of a service set to a static interface:

```
interfaces {
  fe-0/0/0 {
    vlan-tagging;
    unit 1 {
      vlan-id 1;
      family inet {
        service {
          input {
            service-set test_aacl_sset;
          }
          output {
            service-set test_aacl_sset;
          }
        }
      }
      address 10.1.1.1/24;
    }
  }
}
```

NOTE: The `session-offload` statement at the `[edit chassis fpc slot-number pic number adaptive-services service-package extension-provider]` hierarchy level controls session offload behavior for Multiservices DPCs on MX Series routers. It controls session offload on a per-device basis, where a device is a Multiservices interface (`ms-fpc-pic-port`). Currently, the session offload function is supported for at most one Multiservices interface. When the offload function is enabled, it is strongly recommended that you limit Junos Application Aware (previously known as Dynamic Application Awareness) features to that Multiservices interface.

The default is to not offload any sessions. For more information on chassis configuration, see the *Junos OS Administration Library for Routing Devices*.

Related Documentation

- [L-PDF Overview on page 697](#)
- [Best-Effort Application Identification of DPI-Serviced Flows on page 658](#)
- [Configuring Statistics Profiles on page 702](#)
- [Tracing L-PDF Operations on page 707](#)

Tracing L-PDF Operations

Tracing operations track L-PDF operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

By default, no events are traced. If you include the `traceoptions` statement at the `[edit system services local-policy-decision-function]` hierarchy level, you can customize the trace file settings:

```
traceoptions {
  file filename <files number> <size size>;
  flag flag;
}
```

The flags track the following information:

- **all**—Everything
- **configuration**—Configuration traces
- **database**—Database traces
- **general**—Miscellaneous traces

Link and Multilink Services Overview

Multilink-based protocols enable you to split, recombine, and sequence datagrams across multiple logical data links. The goal of a multilink operation is to coordinate multiple independent links between a fixed pair of systems, providing a virtual link with greater bandwidth than any of the members.

The Juniper Networks Junos operating system (Junos OS) supports several multilink-based protocols (such as MLPPP, FRF.15, and FRF.16) on the services PICs such as the Multilink Services PIC, the Link Services PIC, and the link services intelligent queuing (IQ) and voice services configured on the Adaptive Services (AS) and MultiServices PICs. For more information about link services IQ, see [“Layer 2 Service Package Capabilities and Interfaces” on page 543](#). For more information about voice services, see [“Configuring Services Interfaces for Voice Services” on page 622](#).

Starting with Junos OS Release 12.1, the following channelized MICs on MX240, MX480, and MX960 routers support Multilink Point-to-Point Protocol (MLPPP)-based services:

- 4-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-4CHOC3-2CHOC12)
- 8-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-8CHOC3-4CHOC12)
- 8-port Channelized DS3/E3 MIC (MIC-3D-8CHDS3-E3-B)

For more information about Multilink Point-to-Point Protocol (MLPPP)-based services MICs, see [“Multilink Interfaces on Channelized MICs Overview” on page 715](#).

NOTE: The ml- interface type is used to configure interfaces on the Multilink Services PIC and does not support class-of-service (CoS) features. The ls- interface type is used for limited CoS configurations on the Link Services PIC, and the lsq- interface type is used for full CoS configurations on the Adaptive Services and MultiServices PICs. The bundle interfaces are configured on the Multiservices DPC as link services IQ (lsq) interfaces and virtual LSQ redundancy (rlsq) interfaces.

For link services IQ (lsq) interfaces, Junos OS CoS components are fully supported and are handled normally on M Series and T Series routers, as described in the *Class of Service Feature Guide for Routing Devices*. For more information on link services IQ configuration, see [“Layer 2 Service Package Capabilities and Interfaces” on page 543](#).

The Link Services and Multilink Services PICs support the following encapsulation types:

- Multilink Point-to-Point Protocol (MLPPP)
- Multilink Frame Relay (MLFR)

Starting with Junos OS Release 12.1, support for the following encapsulation types and protocols has been extended to the MX240, MX480, and MX960 routers with Multiservices DPCs:

- Multilink Point-to-Point Protocol (MLPPP)
- Multiclass MLPPP
- Multilink Frame Relay (MLFR) end-to-end (FRF.15)
- Multilink Frame Relay (MLFR) UNI NNI (FRF.16) (also referred to as MFR)
- Compressed Real-Time Transport Protocol (CRTP)

MLPPP enables you to bundle multiple PPP links into a single logical link. MLFR enables you to bundle multiple Frame Relay data-link connection identifiers (DLCIs) into a single logical link. MLPPP and MLFR provide service option granularity between low-speed T1 and E1 services and higher-speed T3 and E3 services. You use MLPPP and MLFR to increase bandwidth in smaller, more cost-effective increments. In addition to providing incremental bandwidth, bundling multiple links can add a level of fault tolerance to your dedicated access service, because you can implement bundling across multiple PICs, protecting against the failure of any single PIC.

NOTE: Even if the PIC can support up to 4xDS3 total throughput, each aggregate can only run a volume of traffic equal to one DS3 in bandwidth. Aggregating DS3 links is not supported.

At the logical unit level, the Multilink Services and Link Services PICs support the MLPPP and MLFR Frame Relay Forum (FRF) 15 encapsulation types. At the physical interface level, the Link Services PIC also supports the MLFR FRF.16 encapsulation type.

MLPPP and MLFR FRF.15 are supported on interface types **ml-fpc/pic/port**, **ls-fpc/pic/port**, and **lsq-fpc/pic/port**. For MLFR FRF.15, multiple permanent virtual circuits (PVCs) are combined into one aggregated virtual circuit (AVC). This provides fragmentation over multiple PVCs on one end and reassembly of the AVC on the other end.

MLFR FRF.16 is supported on a channelized interface, **ls-fpc/pic/port:channel**, which denotes a single MLFR FRF.16 bundle. For MLFR FRF.16, multiple links are combined to form one logical link. Packet fragmentation and reassembly occur on a per-VC basis. Each bundle can support multiple VCs. Link Services PICs can support up to 256 DLCIs per MLFR FRF.16 bundle. The physical connections must be E1, T1, channelized DS3-to-DS1, channelized DS3-to-DS0, channelized E1, channelized STM1, or channelized IQ interfaces. When you bundle channelized interfaces using the link services interface, the channelized interfaces require M Series Enhanced Flexible PIC Concentrators (FPCs).

NOTE: When running MLPPP or MLFR on a non-QPP interface, you cannot mix logical units that are members of an aggregate with logical units configured using other families, such as **inet**. For example, the following configuration is not valid:

```
interface e3-0/0/0 {
  encapsulation frame-relay;
  unit 99 {
    dlci 99;
    family mlfr-end-to-end {
      bundle ls-0/0/0.1;
    }
  }
  unit 100 { ## mixes mlfr with family inet
    dlci 100;
    family inet {
      address 192.168.164.53/30;
    }
  }
}
```

The standards for MLPPP, MLFR FRF.15, and MLFR FRF.16 are defined in the following specifications:

- RFC 1990, *The PPP Multilink Protocol (MP)*
- FRF.15, *End-to-End Multilink Frame Relay Implementation Agreement*
- FRF.16.1, *Multilink Frame Relay UNI/NNI Implementation Agreement*

NOTE: Endpoint Discriminator Class compatibility checking is enabled on MLPPP interfaces. Prior to Junos OS Release 8.0, when a Juniper Networks router received an unsupported Endpoint Discriminator Class message from an MLPPP session peer, it returned an ACK response.

Multilink and Link Services PICs Overview

Each Multilink Services or Link Services PIC can support a number of *bundles*. A bundle can contain up to eight individual *links*.

For Multilink Services PICs, the links can be T1, E1, or DS0 physical interfaces, and each link is associated with a logical unit number that you configure. For Link Services PICs, the links can be E1, T1, channelized DS3-to-DS1, channelized DS3-to-DS0, channelized E1, channelized STM1 interfaces, or channelized IQ interfaces. For MLFR FRF.16 bundles, each link is associated with a channel number that you configure.

You must configure a link before it can join a bundle. Each bundle should consist solely of one type of link; the mixing of physical interfaces of differing speeds within a bundle is not supported.

NOTE: On M Series Multiservice Edge Routers, only one DS3 link is allowed in an MLFR bundle. MLPPP bundles can include two DS3 links.

Three versions of Multilink Services and three versions of Link Services PICs are available, as shown in [Table 27 on page 714](#). The PIC hardware is identical, except for different faceplates that enable you to identify which version you are installing. The software limits the unit numbers and maximum number of physical interfaces you assign to the PIC.

Table 27: Multilink and Link Services PIC Capacities

PIC Capacity	Unit Numbers	Maximum Number of T1/DS0 Interfaces	Maximum Number of E1 Interfaces
4-bundle PIC	0 through 3	32 links	32 links
32-bundle PIC	0 through 31	256 links	219 links
128-bundle PIC	0 through 127	292 links	219 links

A single PIC can support an aggregate bandwidth of 450 megabits per second (Mbps).

You can configure a larger number of links, but the Multilink Services and Link Services PICs can reliably process only 450 Mbps of traffic. A higher rate of traffic might degrade performance.

NOTE: In Junos OS releases 9.0 and above you are not allowed to configure a unit number greater than the maximum unit number available on your link services PIC. Attempting to do so will cause an error message.

Multilink Interfaces on Channelized MICs Overview

Multiservices Modular Interface Cards (MICs) enable you to perform multiple services on the same MIC by configuring a set of services and applications such as voice services and Layer 2 Tunneling Protocol (L2TP) services. On Juniper Networks MX Series 3D Universal Edge Routers, the Multiservices DPC provides essentially the same capabilities as the Multiservices PIC. The interfaces on both platforms are configured in the same way. The Multilink interfaces are hosted on a channelized MIC. The bundle interfaces are configured on Multiservices DPC as virtual LSQ redundancy (rlsq) interfaces.

Starting with Junos OS Release 12.1, the following channelized MICs on MX240, MX480, and MX960 routers support Multilink Point-to-Point Protocol (MLPPP)-based services:

- 4-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-4CHOC3-2CHOC12)
- 8-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-8CHOC3-4CHOC12)
- 8-port Channelized DS3/E3 MIC (MIC-3D-8CHDS3-E3-B)

The following encapsulations, interfaces, protocol, and packet types are supported on the aforementioned MICs:

- Multilink Point-to-Point Protocol (MLPPP)—Supports Priority-based Flow Control (PFC) for data packets and Link Control Protocol (LCP) for control packets. Compressed Real-Time Transport Protocol (CRTP) and Multiclass MLPPP are supported for both data and control packets.
- Multilink Frame Relay (MLFR) end-to-end (FRF.15)—Supports Ethernet Local Management Interface (LMI), Consortium LMI (C-LMI), and Link Integrity Protocol (LIP) for data and control packets.

- Multilink Frame Relay (MFR) UNI NNI (FRF.16)—Supports Ethernet Local Management Interface (LMI), Consortium LMI (C-LMI), and Link Integrity Protocol (LIP) for data and control packets.
- Link fragmentation and interleaving (LFI) non multilink MLPPP and MLFR packets.

Layer 2 services and voice services functionality are implemented on the Multiservices Dense Port Concentrators which supports the following two kinds of traffic that are routed by the Packet Forwarding Engine:

- Customer-end to provider-end (also, known as customer traffic)—Here, the Multilink fragments from the customer end arrive at the Multiservices interfaces configured on the channelized MIC. These fragments are then transmitted to the Multiservices DPC for Layer 2 processing such as CoS and are reassembled by the Multiservices software running on the Multiservices DPC. These reassembled packets are sent to the Packet Forwarding Engine where they go through the regular router lookup process and are finally sent over the Internet to the provider end. The voice packets also go through the same process.
- Provider-end to customer-end (also, known as Internet traffic)—Here, the data packets that are sent from the Internet provider end are received at any generic ingress interface in the Packet Forwarding Engine. These packets are then sent to the Multiservices DPC for Layer 2 processing. The Multiservices software running on Multiservices DPC fragment these data packets and send it to the Packet Forwarding Engine. These Multilink fragments are sent over the channelized MIC interfaces to the customer end. The voice packets also go through the same process.

NOTE: All the features that are supported on Multilink and Link Services PICs are also supported on the Multilink Services or Link Services MICs. For more information about Multilink and Link Services PICs, see [“Multilink and Link Services PICs Overview” on page 714.](#)

Support for the following encapsulations, interfaces, protocol, and packet types are now extended to the aforementioned MICs:

- Multilink Point-to-Point Protocol (MLPPP)—Supports priority-based flow control (PFC) for data packets and Link Control Protocol (LCP) for control packets. Compressed Real-Time Transport Protocol (CRTP) and multiclass MLPPP are supported for both data and control packets.
- Multilink Frame Relay (MLFR) end-to-end (FRF.15)—Supports Ethernet Local Management Interface (LMI) and Consortium LMI (C-LMI) for data and control packets.
- Multilink Frame Relay (MLFR) UNI NNI (FRF.16)—Supports Ethernet Local Management Interface (LMI), Consortium LMI (C-LMI), and Link Integrity Protocol (LIP) for data and control packets.
- Link fragmentation and interleaving (LFI) on multilink MLPPP and MLFR packets—Reduces delay and jitter on links by breaking up large data packets and interleaving delay-sensitive voice packets with the resulting smaller packets.

Multilink and Link Services Logical Interface Configuration Overview

You configure multilink and link services interface properties at the logical unit level. Default settings for multilink and link services logical interface properties are described in [“Default Settings for Multilink and Link Services Logical Interfaces” on page 717](#).

For general information about logical unit properties or **family inet** properties, see the *Junos OS Network Interfaces Library for Routing Devices*. For information about multilink and link services properties you configure at the **family inet** hierarchy level, see [“Configuring the Links in a Multilink or Link Services Bundle” on page 721](#).

NOTE: On DS0, E1, or T1 interfaces in LSQ bundles, you can configure the **bandwidth** statement, but the router does not use the bandwidth value if the interfaces are included in an MLPPP or MLFR bundle. The bandwidth is calculated internally according to the time slots, framing, and byte-encoding of the interface. For more information about logical interface properties, see the *Junos OS Network Interfaces Library for Routing Devices*.

Default Settings for Multilink and Link Services Logical Interfaces

Table 28 on page 717 lists the default settings for multilink and link services statements, together with the other permitted values or value ranges.

Table 28: Multilink and Link Services Logical Interface Statements

Option	Default Value	Possible Values
DLCI	None	16 through 1022
Drop timeout period	500 ms for bundles greater than or equal to the T1 bandwidth value and 1500 ms for other bundles.	0 through 2000 milliseconds
Encapsulation	For multilink interfaces, multilink-ppp . For link services interfaces, multilink-frame-relay-end-to-end .	multilink-frame-relay-end-to-end , multilink-ppp
Fragmentation threshold	0 bytes	128 through 16,320 bytes (N×64)

Table 28: Multilink and Link Services Logical Interface Statements (*continued*)

Option	Default Value	Possible Values
Interleave fragments	disabled	enabled, disabled
Minimum links	1 link	1 through 8 links
Maximum received reconstructed unit (MRRU)	1504 bytes	1500 through 4500 bytes
Sequence ID format for MLPPP	24 bits	12 or 24 bits
Sequence ID format for MLFR FRF.15 and FRF.16	12 bits	12 bits

See “[Default Settings for Link Services Interfaces](#)” on [page 726](#) for statements that apply to link services physical interfaces only.

CHAPTER 50

Achieving Greater Bandwidth, Load Balancing, and Redundancy with Multilink Bundles

- [Understanding MLPPP Bundles and Link Fragmentation and Interleaving \(LFI\) on Serial Links on page 719](#)
- [Configuring the Number of Bundles on Link Services PICs on page 720](#)
- [Configuring the Links in a Multilink or Link Services Bundle on page 721](#)
- [Example: Configuring a Link Services Interface with Two Links on page 722](#)

Understanding MLPPP Bundles and Link Fragmentation and Interleaving (LFI) on Serial Links

MX240, MX480, and MX960 3D Universal Edge Routers support MLPPP and MLFR multilink encapsulations. MLPPP enables you to bundle multiple PPP links into a single multilink bundle, and MLFR enables you to bundle multiple Frame Relay data-link connection identifiers (DLCIs) into a single multilink bundle. Multilink bundles provide additional bandwidth, load balancing, and redundancy by aggregating low-speed links, such as T1, E1, and serial links.

You configure multilink bundles as logical units or channels on the link services interface **lsq-0/0/0**:

- With MLPPP and MLFR FRF.15, multilink bundles are configured as logical units on **lsq-0/0/0**—for example, **lsq-0/0/0.0** and **lsq-0/0/0.1**.
- With MLFR FRF.16, multilink bundles are configured as channels on **lsq-0/0/0**—for example, **lsq-0/0/0:0** and **lsq-0/0/0:1**.

After creating multilink bundles, you add constituent links to the bundle. The constituent links are the low-speed physical links that are to be aggregated. You can create 64 multilink bundles, and on each multilink bundle you can add up to 8 constituent links. The following rules apply when you add constituent links to a multilink bundle:

- On each multilink bundle, add only interfaces of the same type. For example, you can add either T1 or E1, but not both.

- Only interfaces with a PPP encapsulation can be added to an MLPPP bundle, and only interfaces with a Frame Relay encapsulation can be added to an MLFR bundle.
- If an interface is a member of an existing bundle and you add it to a new bundle, the interface is automatically deleted from the existing bundle and added to the new bundle.

Configuring a multilink bundle on the two serial links increases the bandwidth by 70 percent from approximately 1 Mbps to 1.7 Mbps and prepends each packet with a multilink header as specified in the FRF.12 standard. To increase the bandwidth further, you can add up to eight serial links to the bundle. In addition to a higher bandwidth, configuring the multilink bundle provides load balancing and redundancy. If one of the serial links fails, traffic continues to be transmitted on the other links without any interruption. In contrast, independent links require routing policies for load balancing and redundancy. Independent links also require IP addresses for each link as opposed to one IP address for the bundle. In the routing table, the multilink bundle is represented as a single interface.

Starting with Junos OS Release 13.3, if you attempt to delete or deactivate a static inline service (**si**) MLPPP bundle interface that is still referenced by a member link interface, which could be PPPoE (**pp0**) or **si** logical interfaces, and commit the configuration, the commit operation fails. You must reactivate such MLPPP bundle interface before committing the settings. Alternatively, you must ensure that member links do not refer a static MLPPP bundle before you delete or deactivate the bundle. This method of deactivation and reactivation of an MLPPP bundle is not applicable for interfaces other than **si**- interfaces, such as link services IQ (**lsq**-) and virtual LSQ redundancy (**rlsq**-) interfaces.

Configuring the Number of Bundles on Link Services PICs

You can combine MLFR FRF.16, MLPPP, and MLFR FRF.15 bundles on a single Link Services PIC. For a sample configuration, see “[Example: Configuring a Link Services Interface with Two Links](#)” on page 722.

To configure the number of bundles on a Link Services PIC, include the **mlfr-uni-nni-bundles** statement at the **[edit chassis fpc slot-number pic pic-number]** hierarchy level:

```
mlfr-uni-nni-bundles number;
```

Each Link Services PIC can accommodate a maximum of 256 MLFR UNI NNI bundles. For more information, see the *Junos OS Administration Library for Routing Devices*.

A link can associate with one link services bundle only. All Link Services PICs support up to 256 single-link bundles and up to 256 DLCIs. For an example configuration, see the configuration examples.

NOTE: When one or more links in a bundle are put in loopback, reassembly buffering and hence processing are reduced so as to not affect other bundles. This prevents packet loss on other bundles, while reducing the reassembly buffers available for the bundle with looped links.

Configuring the Links in a Multilink or Link Services Bundle

To complete a multilink or link services interface configuration, you need to configure both the physical interface and the multilink or link services bundle. For multilink interfaces, you configure the link bundle on the logical unit. For link services interfaces, you configure the link bundle as a channel (see [Figure 26 on page 721](#)). The physical interface is usually connected to networks capable of supporting MLPPP or MLFR (FRF.15 or FRF.16).

Figure 26: Multilink Interface Configuration

The following sample configuration refers to the topology in [Figure 26 on page 721](#) and configures a multilink or link services bundle over a T1 connection (for which the T1 physical interface is already configured).

1. To configure a physical T1 link for MLPPP, include the following statements at the **[edit interfaces t1-fpc/pic/port]** hierarchy level:

```
unit 0 {
  family mlppp {
    bundle (ml-fpc/pic/port | ls-fpc/pic/port);
  }
}
```

You do not need to configure an IP address on this link.

To configure a physical T1 link for MLFR FRF.16, include the following statements at the `[edit interfaces t1-fpc/pic/port]` hierarchy level:

```
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
  family mlfr-uni-nni {
    bundle ls-fpc/pic/port:channel;
  }
}
```

You do not need to configure an IP address or a DLCI on this link.

2. To configure the logical address for the MLPPP, MLFR FRF.15, or MLFR FRF.16 bundle, include the **address** and **destination** statements:

```
address address {
  destination address;
}
```

You can include these statements at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number family inet]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number family inet]`

When you add statements such as **mrru** to the configuration and commit, the T1 interface becomes part of the multilink bundle.

NOTE: For MLPPP and MLFR (FRF.15 and FRF.16) links, you must specify the subnet address as /32 or /30. Any other subnet designation is treated as a mismatch.

Example: Configuring a Link Services Interface with Two Links

This example uses the MLFR UNI NNI protocol between Router A and Router B and logically connects link services bundles **ls-1/1/0.3** and **ls-0/0/0.10**, as specified in [Table 29 on page 722](#).

Table 29: Link Services Bundle

Router A	Router B
t1-0/1/0 (ls-1/1/0:3)	t1-0/3/0 (ls-0/0/0:10)
t1-0/1/1 (ls-1/1/0:3)	t1-0/3/1 (ls-0/0/0:10)

For LMI to work properly, you must configure one router to be a DCE.

```
Configuration on [edit interfaces]
Router A         ls-1/1/0:3 {
                  dce;
                  encapsulation multilink-frame-relay-uni-nni;
                  unit 0 {
                    dlci 16;
                    family inet {
                      address 10.3.3.1/32 {
                        destination 10.3.3.2;
                      }
                    }
                  }
                }
              }
            t1-0/1/0 {
              encapsulation multilink-frame-relay-uni-nni;
              unit 0 {
                family mlfr-uni-nni {
                  bundle ls-1/1/0:3;
                }
              }
            }
            t1-0/1/1 {
              encapsulation multilink-frame-relay-uni-nni;
              unit 0 {
                family mlfr-uni-nni {
                  bundle ls-1/1/0:3;
                }
              }
            }
          }
```

```
Configuration on [edit interfaces]
Router B         ls-0/0/0:10 {
                  encapsulation multilink-frame-relay-uni-nni;
                  unit 0 {
                    dlci 16;
                    family inet {
                      address 10.3.3.2/32 {
                        destination 10.3.3.1;
                      }
                    }
                  }
                }
              }
            t1-0/3/0 {
              encapsulation multilink-frame-relay-uni-nni;
              unit 0 {
                family mlfr-uni-nni {
                  bundle ls-0/0/0:10;
                }
              }
            }
            t1-0/3/1 {
              encapsulation multilink-frame-relay-uni-nni;
              unit 0 {
                family mlfr-uni-nni {
```

```
        bundle ls-0/0/0:10;  
    }  
}  
}
```

Configuring Link Services Physical Interfaces

You configure link services interface properties at the logical unit and physical interface level. Default settings for link services physical interface properties are described in “Default Settings for Link Services Interfaces” on page 726.

The following sections explain how to configure link services physical interfaces:

- [Default Settings for Link Services Interfaces on page 726](#)
- [Configuring Encapsulation for Link Services Physical Interfaces on page 726](#)
- [Configuring Acknowledgment Timers on Link Services Physical Interfaces on page 727](#)
- [Configuring Differential Delay Alarms on Link Services Physical Interfaces with MLFR FRF.16 on page 727](#)
- [Configuring Keepalives on Link Services Physical Interfaces on page 728](#)

For information about link services physical interface properties that can also be configured at the logical unit level, see “Multilink and Link Services Logical Interface Configuration Overview” on page 717.

Default Settings for Link Services Interfaces

Table 30 on page 726 lists the default settings for link services statements, together with the other permitted values or value ranges.

Table 30: Link Services Physical Interface Statements for MLFR FRF.16

Option	Default Value	Possible Values
Action red differential delay	remove-link	disable-tx, remove-link
Red differential delay	120 ms	1 through 2000 ms
Yellow differential delay	72 ms	1 through 2000 ms
Drop timeout period	0 ms	0 through 2000 ms
Encapsulation	multilink-frame-relay-uni-nni	multilink-frame-relay-uni-nni
Fragmentation threshold	0 bytes	128 through 16,320 bytes (Nx64)
LMI type	itu	ansi, itu
Minimum links	1 link	1 through 8 links
MRRU	1504 bytes	1500 through 4500 bytes
n391 (full status polling counter)	6	1 through 255
n392 (LMI error threshold)	3	1 through 10
n393 (LMI monitored event count)	4	1 through 10
t391 (link integrity verify polling timer)	10	5 through 30
t392 (polling verification timer)	15	5 through 30
Sequence ID format for MLFR	12 bits	12 bits

Configuring Encapsulation for Link Services Physical Interfaces

Link services interfaces support the physical interface encapsulation MLFR UNI NNI. By default, the physical interface encapsulation on link services interfaces is MLFR UNI NNI. Multilink interfaces do not support physical interface encapsulation.

For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

You can also configure logical interface encapsulation on multilink and link services interfaces. For more information, see “[Configuring Encapsulation for Multilink and Link Services Logical Interfaces](#)” on page 729.

To explicitly configure link services physical interface encapsulation, include the **encapsulation** statement at the **[edit interfaces ls-fpc/pic/port:channel]** hierarchy level:

encapsulation *type*;

You must also configure the T1, E1, or DS0 physical and physical interface with the same encapsulation type.

Configuring Acknowledgment Timers on Link Services Physical Interfaces

For link services interfaces configured with MLFR FRF.16, each link end point in a bundle initiates a request for bundle operation with its peer by transmitting an add link message. A hello message notifies the peer end point that the local end point is up. Both ends of a link generate a hello message periodically, or as configured with the hello timer. A remove link message notifies the peer that the local end management is removing the link from bundle operation. End points respond to add link, remove link, and hello messages by sending acknowledgment messages.

You can configure the maximum period to wait for an add link acknowledgment, hello acknowledgment, or remove link acknowledgment by including the **acknowledge-timer** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

acknowledge-timer *milliseconds*;

The acknowledgment timer can be from 1 through 10 milliseconds. The default is 4 milliseconds.

For link services interfaces, you can configure the number of retransmission attempts to be made for consecutive hello or remove link messages after the expiration of the acknowledgment timer by including the **acknowledge-retries** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

acknowledge-retries *number*;

acknowledgment-retries can be a value from 1 through 5. The default is 2.

You can configure the rate at which hello messages are sent by including the **hello-timer** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

hello-timer *milliseconds*;

A hello message is transmitted after the specified period (in milliseconds) has elapsed. The hello timer can be from 1 through 180 milliseconds; the default is 10 milliseconds. When the hello timer expires, a link end point generates an add-link message.

Configuring Differential Delay Alarms on Link Services Physical Interfaces with MLFR FRF.16

For link services interfaces configured with MLFR FRF.16, the differential delay between links in a bundle is measured and warning is given when a link has a substantially greater differential delay than other links in the same bundle. The implementing endpoint can determine if the differential delay is in an acceptable range and decide to remove the link from the bundle, or to stop transmission on the link.

You can configure the yellow differential delay for links in a bundle by including the **yellow-differential-delay** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

```
yellow-differential-delay milliseconds;
```

The yellow differential delay can be from 1 through 2000 milliseconds. The default is 72 milliseconds.

You can configure the red differential delay for links in a bundle to give warning by including the **red-differential-delay** statements at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

```
red-differential-delay milliseconds;
```

The red differential delay can be from 1 through 2000 milliseconds. The default is 120 milliseconds.

You can configure the action to be taken when differential delay exceeds the red limit by including the **action-red-differential-delay red** statements at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

```
action-red-differential-delay (disable-tx | remove-link);
```

The **disable-tx** option disables transmission on the link. The **remove-link** option removes the link from the bundle. The default action is **remove-link**.

You can view these settings in the output of the **show interfaces extensive lsq-fpc/pic/port:channel** command.

Configuring Keepalives on Link Services Physical Interfaces

You can tune the keepalive settings on the physical link-services interface. By default, the Junos OS uses ITU Q.933 Annex A LMIs for FRF.16. To instead use ITU Annex A LMIs (ANSI), include the **lmi-type ansi** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level. LMI type ANSI is used in the following example:

```
lmi-type ansi;
```

To configure Frame Relay keepalive parameters on a link services interface, include the **n391**, **n392**, **n393**, **t391** and **t392** statements at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

```
[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]  
n391 number;  
n392 number;  
n393 number;  
t391 number;  
t392 number;
```

The statements determine the indicated keepalive settings:

- **n391**—Full status polling interval. The data terminal equipment (DTE) sends a status inquiry to the data communication equipment (DCE) at the interval specified by the **t391** statement. This statement sets the frequency at which the DTE requests full status report; for example, the value **10** means that the DTE requests full status report in every tenth inquiry. The intermediate inquiries request a keepalive response only. The range is **1** through **255**, with a default of **6**.
- **n392**—Error threshold, which is the maximum number of errors that can occur during the number of events set by the **n393** statement before the link is marked inoperative. The range is **1** through **10**, with a default of **3**.
- **n393**—Monitored event count. The range is **1** through **10**, with a default of **4**.
- **t391**—The interval at which the DTE requests a keepalive response from the DCE and updates status, depending on the error threshold value. The range is **5** through **30** seconds, with a default of **10** seconds.
- **t392**—The period during which the DCE checks for keepalive responses from the DTE and updates status, depending on the DCE error threshold value. The range is from **5** through **30** seconds, with a default of **15** seconds.

NOTE: For the LMI to work properly, you must configure one side of a link services bundle to be a DCE.

Related Documentation

- [Link and Multilink Services Overview on page 711](#)
- [Example: Configuring a Link Services Interface with Two Links on page 722](#)

Configuring Encapsulation for Multilink and Link Services Logical Interfaces

Multilink and link services interfaces support the following logical interface encapsulation types:

- MLPPP
- MLFR end-to-end

By default, the logical interface encapsulation type on multilink interfaces is MLPPP. The default logical interface encapsulation type on link services interfaces is MLFR end-to-end. For general information on encapsulation, see the *Junos OS Network Interfaces Library for Routing Devices*.

You can also configure physical interface encapsulation on link services interfaces. For more information, see [“Configuring Encapsulation for Link Services Physical Interfaces” on page 726](#).

To configure multilink or link services encapsulation, include the **encapsulation** statement:

encapsulation *type*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You must also configure the T1, E1, or DS0 physical interface with the same encapsulation type.

CAUTION: When you configure the first MLFR encapsulated unit or delete the last MLFR encapsulated unit on a port, it triggers an interface encapsulation change on the port, which causes an interface flap on the other units within the port that are configured with generic Frame Relay.

**Related
Documentation**

- [Limiting Packet Payload Size on Multilink and Link Services Logical Interfaces on page 732](#)
- [Example: Configuring a Link Services Interface with MLPPP on page 753](#)
- [encapsulation \(Logical Interface\) on page 1603](#)

Configuring the Drop Timeout Period on Multilink and Link Services Logical Interfaces

By default, the drop timeout parameter is disabled. You can configure a drop timeout value to provide a recovery mechanism if individual links in the multilink or link services bundle drop one or more packets. Drop timeout is not a differential delay tolerance setting, and does not limit the overall latency. However, you need to make sure the value you set is larger than the expected differential delay across the links, so that the timeout period does not elapse under normal jitter conditions, but only when there is actual packet loss. You can configure differential delay tolerance for link services interfaces only. For more information, see “[Configuring Differential Delay Alarms on Link Services Physical Interfaces with MLFR FRF.16](#)” on page 727.

To configure the drop timeout value, include the **drop-timeout** statement:

drop-timeout *milliseconds*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

For link services interfaces, you also can configure the drop timeout value at the physical interface level by including the **drop-timeout** statement at the **[edit interfaces ls-fpc/pic/port:channel mlfr-uni-nni-bundle-options]** hierarchy level:

drop-timeout *milliseconds*;

By default, the drop timer has a value of 500 ms for bundles greater than or equal to the T1 bandwidth value, and 1500 ms for other bundles. Any CLI-configured value overrides these defaults. Values can range from 1 through 2000 milliseconds. Values less than 5 milliseconds are not recommended, and a configured value of 0 reverts to the default value of 2000 milliseconds.

NOTE: For multilink or link services interfaces, if a packet or fragment encounters an error condition and is destined for a disabled bundle or link, it does not contribute to the dropped packet and frame counts in the per-bundle statistics. The packet is counted under the global error statistics and is not included in the global output bytes and output packet counts. This unusual accounting happens only if the error conditions are generated inside the multilink interface, not if the packet encounters errors on the wire or elsewhere in the network.

If you configure the **drop-timeout** statement with a value of 0, it disables any resequencing by the PIC for the specified class of MLPPP traffic. Packets are forwarded with the assumption that they arrived in sequence, and forwarding of fragmented packets is disabled for all classes. Fragments dropped as a result of this setting will increment the counter at the class level.

Alternatively, you can configure the **drop-timeout** statement at the **[edit class-of-service fragmentation-maps map-name forwarding-class class]** hierarchy level. The behavior and the default and range values are identical, but the setting applies only to the specified forwarding class. Configuration at the bundle level overrides configuration at the class-of-service level.

By default, compression of the inner PPP header in the MLPPP payload is enabled. To disable compression, include the **disable-mlppp-inner-ppp-pfc** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level. For example:

```
interfaces lsq-1/2/0 {
  unit 0 {
    encapsulation multilink-ppp;
    disable-mlppp-inner-ppp-pfc;
    multilink-max-classes 4;
    family inet {
      address 10.50.1.2/30;
    }
  }
}
```

For more information about CoS configuration, see the *Class of Service Feature Guide for Routing Devices*. You can view the configured drop-timeout value and the status of inner

PPP header compression by issuing the **show interfaces *interface-name* extensive** command.

- [Configuring the Minimum Number of Active Links on Multilink and Link Services Logical Interfaces on page 733](#)

Limiting Packet Payload Size on Multilink and Link Services Logical Interfaces

For multilink and link services logical interfaces with MLPPP encapsulation only, you can configure a *fragmentation threshold* to limit the size of packet payloads transmitted across the individual links within the multilink circuit. The software splits any incoming packet that exceeds the fragmentation threshold into smaller units suitable for the circuit size; it reassembles the fragments at the other end, but does not affect the output traffic stream. The threshold value affects the payload only; it does not affect the MLPPP header. By default, the fragmentation threshold parameter is disabled.

NOTE: To ensure proper load balancing:

- For Link Services MLFR (FRF.15 and FRF.16) interfaces, do not include the **fragment-threshold** statement in the configuration.
- For MLPPP interfaces, do not include both the **fragment-threshold** statement and the **short-sequence** statement in the configuration.
- For MLFR (FRF.15 and FRF.16) and MLPPP interfaces, if the MTU of links in a bundle is less than the bundle MTU plus encapsulation overhead, then fragmentation is automatically enabled. You should avoid this situation for MLFR (FRF.15 and FRF.16) interfaces and for MLPPP interfaces on which short-sequencing is enabled.

To configure a fragmentation threshold value, include the **fragment-threshold** statement:

fragment-threshold *bytes*;

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

For link services interfaces, you also can configure a fragmentation threshold value at the physical interface level by including the **fragment-threshold** statement at the **[edit interfaces *ls-fpc/pic/port:channel* mlfr-uni-nni-bundle-options]** hierarchy level:

fragment-threshold *bytes*;

The maximum fragment size can be from 128 through 16,320 bytes. The Junos OS automatically subdivides packet payloads that exceed this value. Any value you set must be a multiple of 64 bytes ($N \times 64$). The default value, 0, results in no fragmentation.

- [fragment-threshold on page 1606](#)

Configuring the Minimum Number of Active Links on Multilink and Link Services Logical Interfaces

You can set the minimum number of links that must be up for the multilink bundle as a whole to be labeled up. By default, only one link must be up for the bundle to be labeled up. A member link is considered up when the PPP Link Control Protocol (LCP) phase transitions to open state.

The **minimum-links** value should be identical on both ends of the bundle.

To set the minimum number, include the **minimum-links** statement:

minimum-links *number*;

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

For link services interfaces, you also can configure the minimum number of links at the physical interface level by including the **minimum-links** statement at the **[edit interfaces *ls-fpc/pic/port:channel* mlfr-uni-nni-bundle-options]** hierarchy level:

minimum-links *number*;

The number can be from 1 through 8. The maximum number of links supported in a bundle is 8. When 8 is specified, all configured links of a bundle must be up.

- [Limiting Packet Payload Size on Multilink and Link Services Logical Interfaces on page 732](#)

- [Configuring MRRU on Multilink and Link Services Logical Interfaces on page 734](#)

Configuring MRRU on Multilink and Link Services Logical Interfaces

The *maximum received reconstructed unit (MRRU)* is similar to a maximum transmission unit (MTU), but applies only to multilink bundles; it is the maximum packet size that the multilink interface can process. By default, the MRRU is set to 1500 bytes; you can configure a different MRRU value if the peer equipment allows this. The MRRU accounts for the original payload, for example the Layer 3 protocol payload, but does not include the 2-byte PPP header or the additional MLPPP or MLFR header applied while the individual multilink packets are traversing separate links in the bundle.

To configure a different MRRU value, include the **mrru** statement:

mrru bytes;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

For link services interfaces, you also can configure a different MRRU at the physical interface level by including the **mrru** statement at the [edit interfaces *ls-fpc/pic/port:channel* mlfr-uni-nni-bundle-options] hierarchy level:

mrru bytes;

The MRRU size can range from 1500 through 4500 bytes.

NOTE: If you set the MRRU on a bundle to a value larger than the MTU of the individual links within it, you must enable a fragmentation threshold for that bundle. Set the threshold to a value no larger than the smallest MTU of any link included in the bundle.

Determine the appropriate MTU size for the bundle by ensuring that the MTU size does not exceed the sum of the encapsulation overhead and the MTU sizes for the links in the bundle.

You can configure separate **family mtu** values on the following protocol families under bundle interfaces: **inet**, **inet6**, **iso**, and **mpls**. If not configured, the default value of 1500 is used on all except for **mpls** configurations, in which the value 1488 is used.

NOTE: The effective family MTU might be different from the MTU value specified for MLPPP configurations, because it is adjusted downward by the remote MRRU's constraints. The remote MRRU configuration is not supported on M120 routers.

 - [Configuring the Minimum Number of Active Links on Multilink and Link Services Logical Interfaces on page 733](#)

Configuring the Sequence Header Format on Multilink and Link Services Logical Interfaces

For MLPPP, the sequence header format is set to 24 bits by default. You can configure an alternative value of 12 bits, but 24 bits is considered the more robust value for most networks.

To configure a different sequence header value, include the **short-sequence** statement:

short-sequence;

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

For MLFR FRF.15, the sequence header format is set to 24 bits by default. This is the only valid option.

Example: Configuring Link Interfaces on Channelized MICs

- [Requirements on page 736](#)
- [Overview on page 736](#)

- [Configuration on 4-port Channelized SONET/SDH OC3/STM1 \(Multi-Rate\) MIC with SFP on page 737](#)
- [Verification on page 744](#)

Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.1 or later for MX240, MX480, and MX960 routers
- One MX240, MX480, or MX960 router

Overview

This example provides information about configuring the link interfaces on the following channelized MICs:

- 4-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-4CHOC3-2CHOC12)
- 8-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP (MIC-3D-8CHOC3-4CHOC12)
- 8-port Channelized DS3/E3 MIC (MIC-3D-8CHDS3-E3-B)

You need to first partition each port on the MICs to configure the link interfaces T1, T3, and DS, and then you configure the link interfaces for bundles. An MLPPP bundle involves "bundling" multiple T1/T3/DS interfaces into a single, logical interface that uses only one IP address. For more information about MLPPP bundles, see ["Understanding MLPPP Bundles and Link Fragmentation and Interleaving \(LFI\) on Serial Links" on page 719](#). Similarly, you can partition the ports to configure the MICs to the E1/E3 interfaces by setting the framing mode to SDH.

For more information about multilink-based protocols on MX240, MX480, and MX960 routers with Multiservices DPC, see ["Multilink Interfaces on Channelized MICs Overview" on page 715](#).

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

.....

NOTE: You can set the values for each parameter according to your requirement. The values given in this example are for illustration purposes only.

.....

Configuration on 4-port Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP

To partition each port on the MIC and configure the link interfaces T1, T3, and DS on it and to configure the link interfaces for bundles, perform the following tasks:

- [Partitioning Ports on the Channelized MICs and Configuring the Link Interfaces T1, T3, and DS on page 738](#)
- [Configuring MLPPP, MLFR FRF.15, and MLFR FRF.16 on Link Interfaces for Bundles on page 740](#)
- [Results on page 741](#)

CLI Quick Configuration

To quickly configure synchronization on the aforementioned routers, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

bundle rlsq0.1
```

Partitioning Ports on the Channelized MICs and Configuring the Link Interfaces T1, T3, and DS

Step-by-Step Procedure

To partition each port on the channelized MICs:

1. Configure the **coc12-5/2/0** interface by setting the **partition** option to 1 with the sublevel interface type set to **coc1**.

```
[edit interfaces]
user@host# set coc12-5/2/0 partition 1 interface-type coc1
```
2. Configure the **coc12-5/2/0** interface with the OC-slice range (OC-slice range specifies the bandwidth size required for the interface type you are configuring) set to 1.

```
[edit interfaces]
user@host# set coc12-5/2/0 partition 1 oc-slice 1
```
3. Configure the **coc12-5/2/0** interface by setting the **partition** option to 2 with the sublevel interface type set to **coc1** and the OC-slice range set to 2.

```
[edit interfaces]
user@host# set coc12-5/2/0 partition 2 oc-slice 2 interface-type coc1
```
4. Configure the **coc12-5/2/0** interface by setting the **partition** option to 3 with the sublevel interface type set to **coc1** and the OC-slice range set to 3.

```
[edit interfaces]
user@host# set coc12-5/2/0 partition 3 oc-slice 3 interface-type coc1
```
5. Configure the **coc1-5/2/0:1** interface as a clear channel by setting the **no-partition** option for the sublevel interface type **t3**. (A clear channel consolidates the entire bandwidth of a channelized interface into a single unpartitioned stream that looks like a standard interface.)

```
[edit interfaces]
user@host# set coc1-5/2/0:1 no-partition interface-type t3
```
6. Configure the **coc1-5/2/0:3** interface as a clear channel by setting the **no-partition** option for the sublevel interface type **t3**.

```
[edit interfaces]
user@host# set coc1-5/2/0:3 no-partition interface-type t3
```

7. Configure the **coc1-5/2/0:2** interface by setting the **partition** option to 1 and 3 with the sublevel interface type set to **ct1**. Configure the **coc1-5/2/0:2** interface by setting the **partition** option to 2 and 4 with the sublevel interface type set to **t1**.

```
[edit interfaces]
user@host# set coc1-5/2/0:2 partition 1 interface-type ct1
user@host# set coc1-5/2/0:2 partition 2 interface-type t1
user@host# set coc1-5/2/0:2 partition 3 interface-type ct1
user@host# set coc1-5/2/0:2 partition 4 interface-type t1
```

8. Configure the **ct1-5/2/0:2:1** interface by setting the **partition** option to 1 and 2 with the sublevel interface type set to **ds**. Configure the time slots for the partitions.

```
[edit interfaces]
user@host# set ct1-5/2/0:2:1 partition 1 timeslots 1 interface-type ds
user@host# set ct1-5/2/0:2:1 partition 2 timeslots 2 interface-type ds
```

9. Configure a clear channel on the channelized interface **ct3-2/0/0** by setting the **no-partition** option to the sublevel interface type **t3** (a clear channel consolidates the entire bandwidth of a channelized interface into a single unpartitioned stream that looks like a standard interface).

```
[edit interfaces]
user@host# set ct3-2/0/0 no-partition interface-type t3
```

10. Configure a clear channel on the channelized interface **ct3-2/0/0** by setting the **partition** option to 1, 2, and 3 with the sublevel interface type **ds**. Configure the **ct3-2/0/0** interface by setting the **partition** option to 4 with the sublevel interface type **ct1**.

```
[edit interfaces]
user@host# set ct3-2/0/0 partition 1 interface-type t1
user@host# set ct3-2/0/0 partition 2 interface-type t1
user@host# set ct3-2/0/0 partition 3 interface-type t1
user@host# set ct3-2/0/0 partition 4 interface-type ct1
```

11. Configure the **ct1-2/0/0:4** interface by setting the **partition** option to 1 and 2 with the sublevel interface type set to **ds**. Configure the time slots for the partitions.

```
[edit interfaces]
user@host# set ct1-5/2/0:2:1 partition 1 timeslots 1 interface-type ds
user@host# set ct1-5/2/0:2:1 partition 2 timeslots 2 interface-type ds
```

Results Display the results of partitioning each port on the MIC and configuring the link interfaces T1, T3, and DS:

Results for CHOC12/3 interfaces

```
user@host# show interfaces
coc12-5/2/0 {
  partition 1 oc-slice 1 interface-type coc1;
  partition 2 oc-slice 2 interface-type coc1;
  partition 3 oc-slice 3 interface-type coc1;
}
coc1-5/2/0:1 {
  no-partition interface-type t3;
}
coc1-5/2/0:3 {
  no-partition interface-type t3;
```

```
}
coc1-5/2/0:2 {
  partition 1 interface-type ct1;
  partition 2 interface-type t1;
  partition 3 interface-type ct1;
  partition 4 interface-type t1;
}
```

**Results for CHDS3 MIC
interfaces**

```
user@host# show interfaces
ct1-5/2/0:2:1 {
  partition 1 timeslots 1 interface-type ds;
  partition 2 timeslots 2 interface-type ds;
}
ct3-2/0/0 {
  no-partition interface-type t3;
  partition 1 interface-type t1;
  partition 2 interface-type t1;
  partition 3 interface-type t1;
  partition 4 interface-type ct1;
}
ct1-2/0/0:4 {
  partition 1 timeslots 1 interface-type ds;
  partition 2 timeslots 2 interface-type ds;
}
```

Configuring MLPPP, MLFR FRF.15, and MLFR FRF.16 on Link Interfaces for Bundles

**Step-by-Step
Procedure**

To configure MLPPP, MLFR FRF.15, and MLFR FRF.16 on the link interfaces T1, T3, and DS for bundles:

1. Configure the MLPPP encapsulation on the T1 link interfaces **t1-5/2/0:2:2** and **t1-5/2/0:2:4**.

```
[edit interfaces]
user@host# set t1-5/2/0:2:2 unit 0 family mlppp bundle rlsq0.1
user@host# set t1-5/2/0:2:4 unit 0 family mlppp bundle rlsq0.1
```
2. Configure the MLPPP encapsulation on the DS link interfaces **ds-5/2/0:2:1:1** and **ds-5/2/0:2:1:2**.

```
[edit interfaces]
user@host# set ds-5/2/0:2:1:1 unit 0 family mlppp bundle rlsq0.0
user@host# set ds-5/2/0:2:1:2 unit 0 family mlppp bundle rlsq0.0
```
3. Configure the MLPPP encapsulation on the T3 link interfaces **t3-5/2/0:3** and **t3-5/2/0:1**.

```
[edit interfaces]
user@host# set t3-5/2/0:3 unit 0 family mlppp bundle rlsq0.2
user@host# set t3-5/2/0:1 unit 0 family mlppp bundle rlsq0.2
```
4. Configure the MLFR FRF.16 encapsulation on the T1 link interfaces **t1-5/2/0:2:2** and **t1-5/2/0:2:4**.

```
[edit interfaces]
user@host# set t1-5/2/0:2:2 encapsulation multilink-frame-relay-uni-nni unit 0
family mlfr-uni-nni bundle rlsq0:0
```

```
user@host# set t1-5/2/0:2:4 encapsulation multilink-frame-relay-uni-nni unit 0
family mlfr-uni-nni bundle rlsq0:0
```

5. Configure the MLFR FRF.16 encapsulation on the DS link interfaces **ds-5/2/0:2:1:1** and **ds-5/2/0:2:1:2**.

```
[edit interfaces]
user@host# set ds-5/2/0:2:1:1 encapsulation multilink-frame-relay-uni-nni unit 0
family mlfr-uni-nni bundle rlsq0:0
user@host# set ds-5/2/0:2:1:2 encapsulation multilink-frame-relay-uni-nni unit 0
family mlfr-uni-nni bundle rlsq0:0
```

6. Configure the MLFR FRF.15 encapsulation on the T1 link interfaces **t1-5/2/0:2:2** and **t1-5/2/0:2:4**.

```
[edit interfaces]
user@host# set t1-5/2/0:2:2 encapsulation frame-relay unit 0 dlci 10 family
mlfr-end-to-end bundle rlsq0:0
user@host# set t1-5/2/0:2:4 encapsulation frame-relay unit 0 dlci 11 family
mlfr-end-to-end bundle rlsq0:0
```

7. Configure the MLFR FRF.15 encapsulation on the DS link interfaces **ds-5/2/0:2:1:1** and **ds-5/2/0:2:1:2**.

```
[edit interfaces]
user@host# set ds-5/2/0:2:1:1 encapsulation frame-relay unit 0 dlci 10 family
mlfr-end-to-end bundle rlsq0:0
user@host# set ds-5/2/0:2:1:2 encapsulation frame-relay unit 0 dlci 11 family
mlfr-end-to-end bundle rlsq0:0
```

8. Configure the MLFR FRF.15 encapsulation on the T3 link interfaces **t3-5/2/0:1** and **t3-5/2/0:3**.

```
[edit interfaces]
user@host# set t3-5/2/0:1 encapsulation frame-relay unit 0 dlci 11 family
mlfr-end-to-end bundle rlsq0:1
user@host# set t3-5/2/0:3 encapsulation frame-relay unit 0 dlci 10 family
mlfr-end-to-end bundle rlsq0:1
```

Results

Display the results of the configuration of link interfaces for bundles:

MLPPP on T1 links

```
user@host# show interfaces
t1-5/2/0:2:2 {
  unit 0 {
    family mlppp {
      bundle rlsq0:1;
    }
  }
}
t1-5/2/0:2:4 {
  unit 0 {
    family mlppp {
      bundle rlsq0:1;
    }
  }
}
```

MLPPP on DS links

```
user@host# show interfaces
ds-5/2/0:2:1:1 {
  unit 0 {
    family mlppp {
      bundle rlsq0.0;
    }
  }
}
ds-5/2/0:2:1:2 {
  unit 0 {
    family mlppp {
      bundle rlsq0.0;
    }
  }
}
```

MLPPP on T3 links

```
user@host# show interfaces
t3-5/2/0:3 {
  unit 0 {
    family mlppp {
      bundle rlsq0.2;
    }
  }
}
t3-5/2/0:1 {
  unit 0 {
    family mlppp {
      bundle rlsq0.2;
    }
  }
}
```

MLFR FRF.15 on T1 links

```
user@host# show interfaces
t1-5/2/0:2:2 {

                      encapsulation multilink-frame-relay-uni-nni;
                      unit 0 {
                        family mlfr-uni-nni {
                          bundle rlsq0:0;
                        }
                      }
                      ds-5/2/0:2:1:2 {
                      encapsulation multilink-frame-relay-uni-nni;
                      unit 0 {
                        family mlfr-uni-nni {
                          bundle rlsq0:0;
                        }
                      }
                      }
```

Verification

Confirm that the configuration is working properly.

- [Verifying the MLPPP Bundle on page 744](#)
- [Verifying the MLFR FRF.15 Configuration on page 744](#)
- [Verifying the MLFR FRF.16 Configuration on page 744](#)

Verifying the MLPPP Bundle

Purpose Verify that the constituent links are added to the bundle correctly.

Action From operational mode, enter the **show interfaces lsq-fpc/pic/port** command.

Meaning The output displays the constituent links that are added to the bundle. For more information about the **show interfaces lsq-fpc/pic/port** operational command, see the [CLI Explorer](#).

Verifying the MLFR FRF.15 Configuration

Purpose Verify the MLFR FRF.15 configuration.

Action From operational mode, enter the **show interfaces lsq-fpc/pic/port** command.

Meaning The output displays the standard status information about the specified link services IQ interface. For more information about the **show interfaces lsq-fpc/pic/port** operational command, see the [CLI Explorer](#).

Verifying the MLFR FRF.16 Configuration

Purpose Verify the MLFR FRF.16 configuration.

Action From operational mode, enter the **show interfaces lsq-fpc/pic/port** command.

Meaning The output displays the standard status information about the specified link services IQ interface. For more information about the **show interfaces lsq-fpc/pic/port** operational command, see the [CLI Explorer](#).

Example: Configuring an MLPPP Bundle

This example shows how to configure an MLPPP bundle to increase traffic bandwidth.

- [Requirements on page 750](#)
- [Overview on page 750](#)
- [Configuration on page 750](#)
- [Verification on page 753](#)

Requirements

Before you begin, you should have two MX Series routers (MX240, MX480, or MX960 routers) configured with at least two serial interfaces that communicate over serial links.

Overview

In this example, you create the MLPPP bundle `lsq-0/0/0.0` at the logical unit level of the link services interface `lsq-0/0/0` on the MX Series routers R0 and R1. You then add the two serial interfaces `se-1/0/0` and `se-1/0/1` as constituent links to the multilink bundle. In [Figure 27 on page 750](#), your company's branch office is connected to its main branch using routers R0 and R1. You transmit data and voice traffic on two low-speed 1-Mbps serial links. To increase bandwidth, you configure MLPPP and join the two serial links `se-1/0/0` and `se-1/0/1` into the multilink bundle `lsq-0/0/0.0`. Then you configure LFI and CoS on R0 and R1 to enable them to transmit voice packets ahead of data packets.

Figure 27: Configuring MLPPP and LFI on Serial Links

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
For device R0
set interfaces lsq-0/0/0 unit 0 family inet address 10.0.0.10/24
set interfaces se-1/0/0 unit 0 family mlppp bundle lsq-0/0/0.0
```

```

set interfaces se-1/0/1 unit 0 family mlppp bundle lsq-0/0/0.0
set interfaces se-1/0/0 serial-options clocking-mode dce clock-rate 2.0mhz
set interfaces se-1/0/1 serial-options clocking-mode dce clock-rate 2.0mhz

```

For device R1

```

set interfaces lsq-0/0/0 unit 0 family inet address 10.0.0.9/24
set interfaces se-1/0/0 unit 0 family mlppp bundle lsq-0/0/0.0
set interfaces se-1/0/1 unit 0 family mlppp bundle lsq-0/0/0.0

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure MLPPP bundle:

1. Create an interface on both the routers.

```

[edit]
user@host# edit interfaces lsq-0/0/0 unit 0

```
2. Configure a family inet and define the IP address on device R0.

```

[edit interfaces lsq-0/0/0 unit 0]
user@host# set family inet address 10.0.0.10/24

```
3. Configure a family inet and define the IP address on device R1.

```

[edit interfaces lsq-0/0/0 unit 0]
user@host# set family inet address 10.0.0.9/24

```
4. Specify the names of the constituent links to be added to the multilink bundle on both the routers.

```

[edit interfaces]
user@host# edit se-1/0/0 unit 0
user@host# set family mlppp bundle lsq-0/0/0.0
[edit interfaces]
user@host# edit se-1/0/1 unit 0
user@host# set family mlppp bundle lsq-0/0/0.0

```
5. Set the serial options to the same values for both interfaces on R0.

NOTE: R0 is set as a DCE device. The serial options are not set for interfaces on R1. You can set the serial options according to your network setup.

```

[edit interfaces]
user@host# set se-1/0/0 serial-options clocking-mode dce clock-rate 2.0mhz
user@host# set se-1/0/1 serial-options clocking-mode dce clock-rate 2.0mhz

```

Results From configuration mode, confirm your configuration by entering the **show interfaces lsq-0/0/0**, **show interfaces se-1/0/0**, and **show interfaces se-1/0/1** commands for R0 and R1. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
For device R0
[edit]
  user@host# show interfaces lsq-0/0/0
family inet {
  address 10.0.0.10/24;
}
[edit]
user@host# show interfaces se-1/0/0
  clocking-mode dce;
  clock-rate 2.0mhz;
}
  unit 0 {
    family mlppp {
      bundle lsq-0/0/0.0;
    }
  }
[edit]
  user@host# show interfaces se-1/0/1
serial-options {
  clocking-mode dce;
  clock-rate 2.0mhz;
}
  unit 0 {
    family mlppp {
      bundle lsq-0/0/0.0;
    }
  }
}

For device R1
[edit]
user@host# show interfaces lsq-0/0/0
  family inet {
    address 10.0.0.9/24;
  }
}
[edit]
  user@host# show interfaces se-1/0/0
  unit 0 {
    family mlppp {
      bundle lsq-0/0/0.0;
    }
  }
}
[edit]
  user@host# show interfaces se-1/0/1
  unit 0 {
    family mlppp {
      bundle lsq-0/0/0.0;
    }
  }
}
```

If you are done configuring the router, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly:

- [Verifying the MLPPP Bundle on page 753](#)

Verifying the MLPPP Bundle

Purpose Verify that the constituent links are added to the bundle correctly.

Action From operational mode, enter the **show interfaces lsq-0/0/0 statistics** command.

Example: Configuring Inline MLPPP and Multilink Frame Relay End-to-End (FRF.15) for WAN Interfaces

Inline Multilink PPP (MLPPP), Multilink Frame Relay (FRF.16), and Multilink Frame Relay End-to-End (FRF.15) for time-division multiplexing (TDM) WAN interfaces provide bundling services through the Packet Forwarding Engine without requiring a PIC or Dense Port Concentrator (DPC).

This example shows how to configure a Multilink PPP (MLPPP) bundle and Multilink Frame Relay End-to-End (FRF.15) for additional bandwidth, load balancing, and redundancy by aggregating low-speed links such as T1 (WAN interfaces).

- [Requirements on page 754](#)
- [Overview on page 754](#)
- [Configuration on page 755](#)
- [Verification on page 760](#)

Requirements

This example uses the following hardware and software components:

- Two MX Series Routers
- Junos OS Release 14.1 or later release

Before you begin, configure two MX Series routers (the MX240, MX480, or MX960) with at least two WAN interfaces that communicate over T1 links.

Overview

Traditionally, bundling services are used to bundle multiple low-speed links to create a higher bandwidth pipe. This combined bandwidth is available to traffic from all links and supports link fragmentation and interleaving (LFI) on the bundle, reducing high-priority packet transmission delay.

This support includes multiple links on the same bundle as well as multiclass extension for MLPPP. Through this service you can enable bundling services without additional DPC slots to support Service DPC and free up the slots for other MICs.

Configuring inline MLPPP for WAN interfaces benefits the following services:

- CE-PE link for Layer 3 VPN and DIA service with public switched telephone networks (PSTN)-based access networks

- PE-P link when PSTN is used for MPLS networks

In this example, to increase bandwidth, you configure MLPPP and join the T1 links into the multilink bundle. You aggregate T1 links to create the MLFR FRF.15 bundle on two MX Series routers, R0 and R1, and set the interface to **lsq-**. You configure logical units on the **lsq-** interface and set the family type to **inet** and an IP address. Then you configure an IP address for the multilink bundle on the unit level of the interface. You define the multilink bundle as an MLFR FRF.15 bundle by specifying the MLFR end-to-end encapsulation type. You specify the names of the constituent links to be added to the multilink bundle and set the encapsulation type to **frame-relay**. You then define Router R0 as a DCE device and Router R1 as a DTE device. You set the DLCI value (range is from 16 through 1022). Finally, you set the multilink bundle to **lsq-**.

Topology

Figure 28: Configuring Inline MLPPP and Multilink Frame Relay End-End (FRF.15) for WAN Interfaces

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R0

```
set chassis fpc 1 pic 0 multi-link-layer-2-inline
set interfaces lsq-1/0/0 unit 0 encapsulation multilink-ppp
set interfaces lsq-1/0/0 unit 0 family inet address 5.1.1.1/24
set interfaces lsq-1/0/0 unit 1 encapsulation multilink-frame-relay-end-to-end
set interfaces lsq-1/0/0 unit 1 family inet address 6.1.1.1/24
set interfaces t1-1/0/0:1 unit 0 family mlppp bundle lsq-1/0/0.0
set interfaces t1-1/0/0:2 unit 0 family mlppp bundle lsq-1/0/0.0
set interfaces t1-1/0/0:3 dce
set interfaces t1-1/0/0:4 dce
set interfaces t1-1/0/0:3 encapsulation frame-relay
set interfaces t1-1/0/0:4 encapsulation frame-relay
set interfaces t1-1/0/0:3 unit 0 dlci 1 family mlfr-end-to-end bundle lsq-1/0/0.1
set interfaces t1-1/0/0:4 unit 0 dlci 2 family mlfr-end-to-end bundle lsq-1/0/0.1
```

Device R1

```
set chassis fpc 2 pic 0 multi-link-layer-2-inline
set interfaces lsq-2/0/0 unit 0 encapsulation multilink-ppp
set interfaces lsq-2/0/0 unit 0 family inet address 5.1.1.2/24
set interfaces lsq-2/0/0 unit 1 encapsulation multilink-frame-relay-end-to-end
set interfaces lsq-2/0/0 unit 1 family inet address 6.1.1.2/24
```

```
set interfaces t1-2/0/0:1 unit 0 family mlppp bundle lsq-2/0/0.0
set interfaces t1-2/0/0:2 unit 0 family mlppp bundle lsq-2/0/0.0
set interfaces t1-2/0/0:3 encapsulation frame-relay
set interfaces t1-2/0/0:4 encapsulation frame-relay
set interfaces t1-2/0/0:3 unit 0 dlci 1 family mlfr-end-to-end bundle lsq-2/0/0.1
set interfaces t1-2/0/0:4 unit 0 dlci 2 family mlfr-end-to-end bundle lsq-2/0/0.1
```

To Configure Router R0

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure inline MLPPP and Multilink Frame Relay End-to-End (FRF.15) for WAN Interfaces:

1. Enable inline Layer 2 bundling services.

```
[edit]
user@R0# set chassis fpc 1 pic 0 multi-link-layer-2-inline
```

2. Create the interface, specify a logical unit on the multilink bundle, and set the family type.

```
[edit]
user@R0# set interfaces lsq-1/0/0 unit 0 family inet address 5.1.1.1/24
```

3. Specify the *encapsulation* type as MLPPP.

```
[edit]
user@R0# set interfaces lsq-1/0/0 unit 0 encapsulation multilink-ppp
```

4. Create the interface, specify another logical unit on the multilink bundle, and set the family type.

```
[edit]
user@R0# set interfaces lsq-1/0/0 unit 1 family inet address 6.1.1.1/24
```

5. Specify another unit and define the multilink bundle as an MLFR FRF.15 bundle.

```
[edit]
user@R0# set interfaces lsq-1/0/0 unit 1 encapsulation
multilink-frame-relay-end-to-end
```

6. Specify the names of the constituent links to be added to the multilink bundle.

```
[edit]
user@R0# set interfaces t1-1/0/0:1 unit 0 family mlppp bundle lsq-1/0/0.0
user@R0# set interfaces t1-1/0/0:2 unit 0 family mlppp bundle lsq-1/0/0.0
```

7. Define the router as a DCE device.

```
[edit]
user@R0# set interfaces t1-1/0/0:3 dce
user@R0# set interfaces t1-1/0/0:4 dce
```

8. Specify the DLCI as well as the multilink bundle to which the interface is to be added.

```
[edit ]
user@R0# set interfaces t1-1/0/0:3 unit 0 dlci 1 family mlfr-end-to-end bundle
lsq-1/0/0.1
```

```
user@R0# set interfaces t1-1/0/0:4 unit 0 dlci 2 family mlfr-end-to-end bundle
lsq-1/0/0.1
```

9. Specify the names of the constituent links to be added to the multilink bundle.

```
[edit]
user@R0# set interfaces t1-1/0/0:3 encapsulation frame-relay
user@R0# set interfaces t1-1/0/0:4 encapsulation frame-relay
```

To Configure Router R1

Step-by-Step Procedure

To configure inline MLPPP and Multilink Frame Relay End-to-End (FRF.15) for WAN Interfaces:

1. Enable inline Layer 2 bundling services.

```
[edit]
user@R1# set chassis fpc 2pic 0 multi-link-layer-2-inline
```

2. Create the interface, specify a logical unit on the multilink bundle and set the family type.

```
[edit]
user@R1# set interfaces lsq-2/0/0 unit 0 family inet address 5.1.1.2/24
```

3. Specify the encapsulation type as MLPPP.

```
[edit]
user@R1# set interfaces lsq-2/0/0 unit 0 encapsulation multilink-ppp
```

4. Create the interface, specify another logical unit on the multilink bundle and set the family type.

```
[edit]
user@R1# set interfaces lsq-2/0/0 unit 1 family inet address 6.1.1.2/24
```

5. Specify another unit and define the multilink bundle as an MLFR FRF.15 bundle.

```
[edit]
user@R1# set interfaces lsq-2/0/0 unit 1 encapsulation
multilink-frame-relay-end-to-end
```

6. Specify the names of the constituent links to be added to the multilink bundle.

```
[edit]
user@R1# set interfaces t1-2/0/0:1 unit 0 family mlppp bundle lsq-2/0/0.0
user@R1# set interfaces t1-2/0/0:2 unit 0 family mlppp bundle lsq-2/0/0.0
```

7. Specify the DLCI as well as the multilink bundle to which the interface is to be added.

```
[edit ]
user@R1# set interfaces t1-2/0/0:3 unit 0 dlci 1 family mlfr-end-to-end bundle
lsq-2/0/0.1
user@R1# set interfaces t1-2/0/0:4 unit 0 dlci 2 family mlfr-end-to-end bundle
lsq-2/0/0.1
```

8. Specify the names of the constituent links to be added to the multilink bundle.

```
[edit]
user@R1# set interfaces t1-2/0/0:3 encapsulation frame-relay
user@R1# set interfaces t1-2/0/0:4 encapsulation frame-relay
```

Results

For Router R0, from configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces lsq-1/0/0**, **show interfaces t1-1/0/0:1**, **show interfaces t1-1/0/0:2**, **show interfaces t1-1/0/0:3**, and **show interfaces t1-1/0/0:4** commands.

For Router R1, from configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces lsq-2/0/0**, **show interfaces t1-2/0/0:1**, **show interfaces t1-2/0/0:2**, **show interfaces t1-2/0/0:3**, and **show interfaces t1-2/0/0:4** commands.

If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

For Router R0:

```
[edit]
user@R0# show chassis
fpc 1 {
  pic 0 {
    multi-link-layer-2-inline;
  }
}

[edit]
user@R0# show interfaces lsq-1/0/0
unit 0 {
  encapsulation multilink-ppp;
  family inet {
    address 5.1.1.1/24;
  }
}
unit 1 {
  encapsulation multilink-frame-relay-end-to-end;
  family inet {
    address 6.1.1.1/24;
  }
}

[edit]
user@R0# show interfaces t1-1/0/0:1
unit 0 {
  family mlppp {
    bundle lsq-1/0/0.0;
  }
}

[edit]
user@R0# show interfaces t1-1/0/0:2
unit 0 {
  family mlppp {
    bundle lsq-1/0/0.0;
  }
}

[edit]
user@R0# show interfaces t1-1/0/0:3
```

```

dce;
encapsulation frame-relay;
unit 0 {
    dlci 1;
    family mlfr-end-to-end {
        bundle lsq-1/0/0.1;
    }
}

[edit]
user@R0# show interfaces t1-1/0/0:4
dce;
encapsulation frame-relay;
unit 0 {
    dlci 2;
    family mlfr-end-to-end {
        bundle lsq-1/0/0.1;
    }
}

```

If you are done configuring the router, enter **commit** from configuration mode.

For Router R1:

```

[edit]
user@R1# show chassis
fpc 2 {
    pic 0 {
        multi-link-layer-2-inline;
    }
}

[edit]
user@R1# show interfaces lsq-2/0/0
unit 0 {
    encapsulation multilink-ppp;
    family inet {
        address 5.1.1.2/24;
    }
}
unit 1 {
    encapsulation multilink-frame-relay-end-to-end;
    family inet {
        address 6.1.1.2/24;
    }
}

[edit]
user@R1# show interfaces t1-2/0/0:1
unit 0 {
    family mlppp {
        bundle lsq-2/0/0.0;
    }
}

[edit]
user@R1# show interfaces t1-2/0/0:2
unit 0 {

```

```
family mlppp {
  bundle lsq-2/0/0.0;
}

[edit]
user@R1# show interfaces t1-2/0/0:3
encapsulation frame-relay;
unit 0 {
  dlci 1;
  family mlfr-end-to-end {
    bundle lsq-2/0/0.1;
  }
}

[edit]
user@R1# show interfaces t1-2/0/0:4
encapsulation frame-relay;
unit 0 {
  dlci 2;
  family mlfr-end-to-end {
    bundle lsq-2/0/0.1;
  }
}
```

If you are done configuring the router, enter **commit** from configuration mode.

Verification

Verifying the MLPPP Bundle and the MLFR FRF.15 Configuration

- Purpose** Verify that the constituent links are added to the bundle correctly.
- Action** From operational mode, run the **show interfaces lsq-1/0/0 extensive** command.

Sample Output

```
user@R0> show interfaces lsq-1/0/0:0 extensive
Physical interface: lsq-1/0/0, Enabled, Physical link is Up

 - [show interfaces \(Link Services IQ\) on page 1885](#)

Enabling MLPPP Link Fragmentation and Interleaving

MLPPP enables you to bundle multiple PPP links into a single multilink bundle. MLPPP bundle support on an inline LSQ interface is identical to a non-inline LSQ interface, because the configuration to enable fragmentation, link fragmentation and interleaving (LFI), and timeout is identical.

Priority scheduling on a multilink bundle determines the order in which an output interface transmits traffic from an output queue. The queues are serviced in a weighted round-robin fashion. But when a queue containing large packets starts using the multilink bundle, small and delay-sensitive packets must wait their turn for transmission. Because of this delay, some slow links, such as T1 and E1, can become useless for delay-sensitive traffic.

Link fragmentation and interleaving (LFI) solves this problem. It reduces delay and jitter on links by fragmenting large packets and interleaving delay-sensitive packets with the resulting smaller packets for simultaneous transmission across multiple links of a multilink bundle.

To configure schedule maps and fragmentation maps for MLPPP LFI:

1. Assign each forwarding class to an internal queue number by including the **forwarding-classes** statement at the **[edit class-of-service]** hierarchy level.

```
[edit class-of-service]
forwarding-classes {
  queue queue-number class-name;
}
```

For example, to set four output transmission queues:

```
[edit class-of-service]
user@host# set forwarding-classes queue 0 be
user@host# set forwarding-classes queue 1 ef
user@host# set forwarding-classes queue 2 af
user@host# set forwarding-classes queue 3 nc
```

2. To set a per-forwarding class fragmentation threshold, include the **fragment-threshold** statement in the **fragmentation-maps**.

```
[edit class-of-service]
fragmentation-maps {
  map-name{
    forwarding-class class-name {
      fragment-threshold bytes;
    }
  }
}
```

For example, to create two fragmentation maps and set a per-forwarding class fragmentation threshold:

```
[edit class-of-service]
user@host# set fragmentation-maps fragmap-1 forwarding-class af
  fragment-threshold 320
user@host# set fragmentation-maps fragmap-1 forwarding-class be
  fragment-threshold 256
user@host# set fragmentation-maps fragmap-1 forwarding-class ef
  fragment-threshold no-fragmentation
user@host# set fragmentation-maps fragmap-2 forwarding-class af
  fragment-threshold 192
user@host# set fragmentation-maps fragmap-2 forwarding-class be
  fragment-threshold 320
user@host# set fragmentation-maps fragmap-2 forwarding-class ef
  fragment-threshold 192
user@host# set fragmentation-maps fragmap-2 forwarding-class nc
  fragment-threshold no-fragmentation
```

The **fragment-threshold** statement in the LSQ bundle logical interface configuration applies to all forwarding classes. The **fragment-threshold** statement in **fragmentation-maps** for a particular **forwarding class**, if present, overrides the statement

configured in the LSQ bundle logical interface for that class. If **fragment-threshold** is not configured anywhere in the configuration, packets are still fragmented if **fragment-threshold** exceeds the smallest maximum transmission unit (MTU) or maximum received reconstructed unit (MRRU) of all links in the bundle.

3. Configure transmission scheduling parameters.

```
[edit class-of-service scheduler scheduler-name]
schedulers {
  scheduler-name {
    priority priority-level;
    transmit-rate (percent percentage | rate | remainder) <exact | rate-limit>;
  }
}
```

For example, to set the transmit-rate percentage and the priority-level:

```
[edit class-of-service scheduler af-scheduler]
user@host# set transmit-rate percent 30
user@host# set priority low

[edit class-of-service scheduler be-scheduler]
user@host# set transmit-rate percent 20
user@host# set priority low

[edit class-of-service scheduler ef-scheduler]
user@host# set transmit-rate percent 35
user@host# set priority strict-high

[edit class-of-service scheduler nc-scheduler]
user@host# set transmit-rate percent 15
user@host# set priority high
```

4. After defining a scheduler, associate it with a specified forwarding class by including it in a *scheduler-map*.

```
[edit class-of-service]
scheduler-maps {
  map-name {
    forwarding-class class-name scheduler scheduler-name;
  }
}
```

For example, to associate the af-scheduler, be-scheduler, ef-scheduler, and nc-scheduler schedulers, with the af, be, ef, and nc forwarding-classes:

```
[edit class-of-service]
user@host# set scheduler-maps sched-map1 forwarding-class af scheduler
af-scheduler
user@host# set scheduler-maps sched-map1 forwarding-class be scheduler
be-scheduler
user@host# set scheduler-maps sched-map1 forwarding-class ef scheduler
ef-scheduler
user@host# set scheduler-maps sched-map1 forwarding-class nc scheduler
nc-scheduler
```

5. Configure traffic shaping and scheduling profiles.

```
[edit class-of-service]
traffic-control-profiles {
```

```
profile-name {  
    guaranteed-rate (percent percentage | rate) <burst-size bytes>;  
    scheduler-map map-name;  
    shaping-rate (percent percentage | rate) <burst-size bytes>;  
}  
}
```

For example, to set the traffic-control policies:

```
[edit class-of-service traffic-control-policies m1-tcp1]  
user@host# set guaranteed-rate 1m  
user@host# set scheduler-map sched-map1  
user@host# set shaping-rate 1m
```

6. Configure interface-specific CoS properties for incoming packets.

```
[edit class-of-service]  
interfaces {  
    interface-name {  
        unit logical-unit-number {  
            fragmentation-map map-name;  
            output-traffic-control-profile profile-name;  
        }  
    }  
}
```

For example, to apply the specified CoS traffic control profile (traffic scheduling and shaping configuration objects) to the output traffic at the logical interface:

```
[edit class-of-service]  
user@host# set interfaces lsq-0/1/0 unit 100 fragmentation-map fragmap-1  
output-traffic-control-profile m1-tcp1
```

The following partial configuration shows when the fragment threshold for low priority queues inherits from the fragment threshold configured in the bundle IFL and will have the value of 640.

```
[edit class-of-service]  
forwarding-classes {  
    queue 0 be;  
    queue 1 ef;  
    queue 2 af;  
    queue 3 nc;  
}  
fragmentation-maps {  
    fragmap-3 {  
        forwarding-class ef {  
            no-fragmentation;  
        }  
    }  
}  
schedulers {  
    af-scheduler {  
        transmit-rate percent 30;  
        priority low;  
    }  
    be-scheduler {  
        transmit-rate percent 20;
```

```
        priority low;
    }
    ef-scheduler {
        transmit-rate percent 35 rate-limit;
        priority strict-high;
    }
    nc-scheduler {
        transmit-rate percent 15;
        priority high;
    }
}
}
....
```

Configuring Delay-Sensitive Packet Interleaving on Link Services Logical Interfaces

For link services FRF.15 and MLPPP interfaces only, you can configure link fragment interleaving (LFI). LFI reduces excessive delays of Frame Relay packets by fragmenting long packets into smaller packets and interleaving them with real-time frames. This allows real-time and non-real-time data frames to be carried together on lower-speed links without causing excessive delays to the real-time traffic. When the peer interface receives the smaller fragments, it reassembles the fragments into their original packet. For example, short delay-sensitive packets, such as packetized voice, can race ahead of larger delay-insensitive packets, such as common data packets.

NOTE: All Link Services PICs (4-multilink bundle, 32-multilink bundle, and 128-multilink bundle) support up to 256 link services interfaces with LFI enabled, if those link services interfaces contain only one constituent link each. For the Link Services PIC, multiple-link LFI bundles are simply multilink bundles, and are limited based on the type of PIC (4-multilink bundle, 32-multilink bundle, and 128-multilink bundle).

In addition, the multilink bundles you configure subtract from the total of 256 possible LFI-enabled link services interfaces. For example, if a 32-multilink bundle Link Services PIC has 24 multilink bundles configured and active, then you can configure $256 - 24 = 232$ LFI-enabled link services interfaces, each with a single constituent link.

For link services IQ interfaces (**lsq**), the **interleave-fragments** statement is not valid. Instead, you can enable LFI by configuring fragmentation maps. For more information, see [“Configuring CoS Fragmentation by Forwarding Class on LSQ Interfaces” on page 527](#).

You can configure multiple links in a bundle and configure packet interleaving. However, if you use packet interleaving, high-priority, nonmultilink-encapsulated packets use a hash-based algorithm to choose a single link.

For detailed information about link services CoS, see [“Configuring CoS on Link Services Interfaces” on page 801](#).

Per-bundle CoS queuing is supported on link services IQ interfaces (**lsq**). For more information about link services IQ interfaces, see [“Layer 2 Service Package Capabilities and Interfaces” on page 543](#).

The Junos OS supports end-to-end fragmentation in compliance with the FRF.12 *Frame Relay Fragmentation Implementation Agreement* standard. Unlike user-to-network interface (UNI) and network-to-network (NNI) fragmentation, end-to-end supports fragmentation only at the endpoints.

By default, packet interleaving is disabled. To enable packet interleaving, include the **interleave-fragments** statement:

interleave-fragments;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

Configuring LFI with DLCI Scheduling

For Link Services and Channelized DS3 IQ PICs, you can configure LFI and DLCI scheduling. For channelized DS3 interfaces, LFI is supported with FRF.15 only, and on M10i and M20 platforms only.

Configuring LFI with DLCI scheduling enables packets entering the Link Services PIC to be fragmented before being transmitted to the Channelized DS3 IQ PIC. Once the fragmented packets enter the Channelized DS3 IQ PIC, they are scheduled at the DLCI level, to allow priority transmission for real-time applications.

For more information about associating a scheduler with a DLCI, see the *Class of Service Feature Guide for Routing Devices*.

Example: Configuring LFI with DLCI Scheduling

Configure packets entering the Link Services PIC to be fragmented before being transmitted to the Channelized DS3 IQ PIC. Once the fragmented packets enter the Channelized DS3 IQ PIC, they are scheduled at the DLCI level, to allow priority transmission for real-time applications.

```

Configuring DLCIs on Link Services Logical Interfaces

For link services interfaces only, you can configure multiple DLCIs for MLFR FRF.16 or MLPPP bundles.

DLCIs are not supported on multilink interfaces.

Configuring Point-to-Point DLCIs for MLFR FRF.16 and MLPPP Bundles

For link services interfaces only, you can configure multiple point-to-point DLCIs for each MLFR FRF.16 or MLPPP bundle. A channelized interface, such as **ls-1/1/1:0**, denotes a single MLFR FRF.16 bundle. To configure a DLCI, include the **dlsi** statement:

dlsi *dlsi-identifier*;

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

The DLCI identifier is a value from 16 through 1022. Numbers 1 through 15 are reserved for future use.

When you configure point-to-point connections, the maximum transmission unit (MTU) sizes on both sides of the connection must be the same.

Configuring Multicast-Capable DLCIs for MLFR FRF.16 Bundles

For link services interfaces only, you can configure multiple multicast-capable DLCIs for each MLFR FRF.16 bundle. A channelized interface, such as **ls-1/1/1:0**, denotes a single MLFR FRF.16 bundle. By default, Frame Relay connections assume unicast traffic. If your Frame Relay switch performs multicast replication, you can configure the link services connection to support multicast traffic by including the **multicast-dlci** statement:

multicast-dlci *dlci-identifier*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

The DLCI identifier is a value from 16 through 1022 that defines the Frame Relay DLCI over which the switch expects to receive multicast packets for replication.

You can configure multicast support only on point-to-multipoint link services connections. Multicast-capable DLCIs are not supported on multilink interfaces.

If keepalives are enabled, causing the interface to send Local Management Interface (LMI) messages during idle times, the number of possible DLCI configurations is limited by the MTU selected for the interface. For more information, see [“Configuring Keepalives on Link Services Physical Interfaces” on page 728](#).

Example: Configuring a Multilink Interface with MLFR FRF.15

```
[edit interfaces]
ml-1/0/0 {
  unit 1 {
    encapsulation multilink-frame-relay-end-to-end;
    family inet {
      address 192.168.5.2/32 {
        destination 192.168.5.3;
      }
    }
  }
  unit 10 {
```

```

        encapsulation multilink-frame-relay-end-to-end;
        family inet {
            address 10.1.1.3/32 {
                destination 10.1.1.2;
            }
        }
    }
}
t1-5/1/0 {
    unit 0 {
        dlci 16;
        encapsulation multilink-frame-relay-end-to-end;
        family mlfr-end-to-end {
            bundle ml-1/0/0.1;
        }
    }
}
t1-5/1/1 {
    unit 0 {
        dlci 17;
        encapsulation multilink-frame-relay-end-to-end;
        family mlfr-end-to-end {
            bundle ml-1/0/0.10;
        }
    }
}
t1-5/1/2 {
    unit 0 {
        dlci 26;
        encapsulation multilink-frame-relay-end-to-end;
        family mlfr-end-to-end {
            bundle ml-1/0/0.10;
        }
    }
}
}

Example: Configuring Multilink Frame Relay FRF.16

This example shows how to configure MLFR FRF.16 for additional bandwidth, load balancing, and redundancy.

- [Requirements on page 780](#)
- [Overview on page 780](#)
- [Configuration on page 780](#)
- [Verification on page 783](#)

Requirements

Before you begin, you should have two MX Series 3D Universal Edge Routers configured with at least two serial interfaces that communicate over serial links.

Overview

In this example, you aggregate two T1 interfaces to create an MLFR FRF.16 bundle on two MX Series, R0 and R1. You configure the chassis interface and specify the number of MLFR FRF.16 bundles to be created on the interface. You then specify the channel to be configured as a multilink bundle and create interface lsq-0/0/0:0. You set the multilink bundle as an MLFR FRF.16 bundle by specifying the MLFR UNI NNI encapsulation type.

Then you define R0 as a DCE device and R1 as a DTE device. You configure a logical unit on the multilink bundle lsq-0/0/0:0, and set the family type to inet. You then assign a DLCI of 400 and an IP address of 10.0.0.10/24 to the multilink bundle. You create the T1 interfaces, t1-2/0/0 and t1-2/0/1, that are to be added as constituent links to the multilink bundle and define the Frame Relay encapsulation type. Finally, you set the multilink bundle to lsq-0/0/0:0.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
For device R0
set chassis fpc 0 pic 0 mlfr-uni-nni-bundles 1
set interfaces lsq-0/0/0:0 encapsulation multilink-frame-relay-uni-nni
set interfaces lsq-0/0/0 dce
set interfaces lsq-0/0/0 unit 0 dlci 400 family inet address 10.0.0.10/24
set interfaces t1-2/0/0 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/1 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/0 unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0
set interfaces t1-2/0/1 unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0
For device R1
set chassis fpc 0 pic 0 mlfr-uni-nni-bundles 1
set interfaces lsq-0/0/0:0 encapsulation multilink-frame-relay-uni-nni
set interfaces lsq-0/0/0 unit 0 dlci 400 family inet address 10.0.0.9/24
set interfaces t1-2/0/0 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/1 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/0 unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0
set interfaces t1-2/0/1 unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an MLFR FRF.16 bundle:

1. Configure a chassis interface.

[edit]

- ```

user@host# edit chassis

```
2. Specify the number of MLFR bundles.
 

```

[edit chassis]
user@host# set fpc 0 pic 0 mlfr-uni-nni-bundles 1

```
  3. Create an interface.
 

```

[edit]
user@host# edit interfaces lsq-0/0/0:0

```
  4. Specify the MLFR encapsulation type.
 

```

[edit interfaces lsq-0/0/0:0]
user@host# set encapsulation multilink-frame-relay-uni-nni

```
  5. Set the router R0 as a DCE device.
 

```

[edit]
user@host# edit interfaces lsq-0/0/0
user@host# set dce

```
  6. Specify a logical unit on the multilink bundle and set the family type.
 

```

[edit interfaces lsq-0/0/0]
user@host# set unit 0 dlci 400 family inet address 10.0.0.10/24

```
  7. Create the T1 interfaces and set the Frame Relay encapsulation.
 

```

[edit interfaces]
user@host# set t1-2/0/0 encapsulation multilink-frame-relay-uni-nni
user@host# set t1-2/0/1 encapsulation multilink-frame-relay-uni-nni

```
  8. Specify the multilink bundle to which the interface is to be added as a constituent link on device R0.
 

```

[edit interfaces t1-2/0/0]
user@host# set unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0

```
  9. Specify the multilink bundle to which the interface is to be added as a constituent link on device R1.
 

```

[edit interfaces t1-2/0/1]
user@host# set unit 0 family mlfr-uni-nni bundle lsq-0/0/0:0

```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces lsq-0/0/0**, **show interfaces lsq-0/0/0:0**, **show interfaces t1-2/0/0**, and **show interfaces t1-2/0/1** commands for the routers R0 and R1. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

For device R0
[edit]
user@host# show chassis
fpc 0 {
pic 0 {
mlfr-uni-nni-bundles 1;
}
}
[edit]

```

```
user@host# show interfaces lsq-0/0/0
dce;
unit 0 {
dlci 400;
family inet {
address 10.0.0.10/24;
}
}
[edit]
user@host# show interfaces lsq-0/0/0:0
encapsulation multilink-frame-relay-uni-nni;
[edit]
user@host# show interfaces t1-2/0/0
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
family mlfr-uni-nni {
bundle lsq-0/0/0:0;
}
}
[edit]
user@host# show interfaces t1-2/0/1
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
family mlfr-uni-nni {
bundle lsq-0/0/0:0;
}
}

For device R1
[edit]
user@host# show chassis
unit 0 {
dlci 400;
family inet {
address 10.0.0.9/24;
}
}
[edit]
user@host# show interfaces lsq-0/0/0:0
encapsulation multilink-frame-relay-uni-nni;
[edit]
user@host# show interfaces t1-2/0/0
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
family mlfr-uni-nni {
bundle lsq-0/0/0:0;
}
}
[edit]
user@host# show interfaces t1-2/0/1
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
family mlfr-uni-nni {
bundle lsq-0/0/0:0;
}
}
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly:

- [Verifying the MLFR FRF.16 Configuration on page 783](#)

---

### Verifying the MLFR FRF.16 Configuration

**Purpose** Verify the MLFR FRF.16 configuration.

**Action** From operational mode, enter the **show interfaces** command.

## Example: Configuring Multilink Frame Relay FRF.15

This example shows how to configure MLFR FRF.15 for additional bandwidth, load balancing, and redundancy by aggregating low-speed links such as T1, E1, and serial links.

- [Requirements on page 783](#)
- [Overview on page 783](#)
- [Configuration on page 784](#)
- [Verification on page 786](#)

## Requirements

Before you begin, you should have two MX Series 3D Universal Edge Routers (MX240, MX480, or MX960 routers) configured with at least two serial interfaces that communicate over serial links.

## Overview

In this example, you aggregate two T1 links to create the MLFR FRF.15 bundle on two MX Series routers, R0 and R1, and set the interface to `lsq-0/0/0`. You configure a logical unit on the `lsq-0/0/0` interface and set the family type to **inet** with address `10.0.0.4/24`. Then you configure an IP address for the multilink bundle on the unit level of the interface.

You define the multilink bundle as an MLFR FRF.15 bundle by specifying the MLFR end-to-end encapsulation type. You specify the names of the constituent links to be

added to the multilink bundle as t1-2/0/0 and t1-2/0/1 and set the encapsulation type to **frame-relay**. You then define R0 as a DCE device and R1 as a DTE device. You set the DLCI value to 100 (range is from 16 through 1022). Finally, you set the multilink bundle to lsq-0/0/0.0.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
For device R0
set interfaces lsq-0/0/0 unit 0 family inet address 10.0.0.4/24
set interfaces lsq-0/0/0 unit 0 encapsulation multilink-frame-relay-end-to-end
set interfaces t1-2/0/0 encapsulation frame-relay
set interfaces t1-2/0/1 encapsulation frame-relay
set interfaces lsq-0/0/0 dce
set interfaces lsq-0/0/0 unit 0 dlci 100 family mlfr-end-to-end bundle lsq-0/0/0.0
```

```
For device R1
set interfaces lsq-0/0/0 unit 0 family inet address 10.0.0.5/24
set interfaces lsq-0/0/0 unit 0 encapsulation multilink-frame-relay-end-to-end
set interfaces t1-2/0/0 encapsulation frame-relay
set interfaces t1-2/0/1 encapsulation frame-relay
set interfaces lsq-0/0/0 unit 0 dlci 100 family mlfr-end-to-end bundle lsq-0/0/0.0
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the MLFR FRF.15 bundle:

1. Create an interface on both the routers.  

```
[edit]
user@host# edit interfaces lsq-0/0/0 unit 0
```
2. Set a logical unit on the interface and define the family type for the routers R0 and R1.  

```
[edit interfaces lsq-0/0/0 unit 0]
user@host# set family inet address 10.0.0.4/24
user@host# set family inet address 10.0.0.5/24
```
3. Define the multilink bundle as an MLFR FRF.15 bundle.  

```
[edit interfaces lsq-0/0/0 unit 0]
user@host# set encapsulation multilink-frame-relay-end-to-end
```
4. Specify the names of the constituent links to be added to the multilink bundle.  

```
[edit interfaces]
user@host# set t1-2/0/0 encapsulation frame-relay
user@host# set t1-2/0/1 encapsulation frame-relay
```
5. Define the router R0 as a DCE device.  

```
[edit interfaces]
```

```
user@host# edit lsq-0/0/0
user@host# set dce
```

6. Specify the DLCI as well as the multilink bundle to which the interface is to be added.

```
[edit interfaces lsq-0/0/0]
user@host# set unit 0 dlci 100 family mlfr-end-to-end bundle lsq-0/0/0.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces lsq-0/0/0**, **show interfaces t1-2/0/0**, and **show interfaces t1-2/0/1** commands for R0 and R1. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

For device R0

```
[edit]
user@host# show interfaces lsq-0/0/0
dce;
unit 0 {
 encapsulation multilink-frame-relay-end-to-end;
 dlci 100;
 family inet {
 address 10.0.0.4/24;
 }
 family mlfr-end-to-end {
 bundle lsq-0/0/0.0;
 }
}
[edit]
user@host# show interfaces t1-2/0/0
encapsulation frame-relay;
[edit]
user@host# show interfaces t1-2/0/1
encapsulation frame-relay;
```

For device R1

```
[edit]
user@host# show interfaces lsq-0/0/0
unit 0 {
 encapsulation multilink-frame-relay-end-to-end;
 dlci 100;
 family inet {
 address 10.0.0.5/24;
 }
 family mlfr-end-to-end {
 bundle lsq-0/0/0.0;
 }
}
[edit]
user@host# show interfaces t1-2/0/0
encapsulation frame-relay;
[edit]
user@host# show interfaces t1-2/0/1
encapsulation frame-relay;
```

If you are done configuring the router, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly:

- [Verifying the MLFR FRF.15 Configuration on page 786](#)

---

### Verifying the MLFR FRF.15 Configuration

---

**Purpose** Verify the MLFR FRF.15 configuration.

**Action** From operational mode, enter the **show interfaces** command.

## Example: Configuring Inline Multilink Frame Relay (FRF.16) for WAN Interfaces

---

Inline Multilink PPP (MLPPP), Multilink Frame Relay (FRF.16), and Multilink Frame Relay End-to-End (FRF.15) for time-division multiplexing (TDM) WAN interfaces provide bundling services through the Packet Forwarding Engine without requiring a PIC or Dense Port Concentrator (DPC).

Traditionally, bundling services are used to bundle multiple low-speed links to create a higher bandwidth pipe. This combined bandwidth is available to traffic from all links and supports link fragmentation and interleaving (LFI) on the bundle, reducing high priority packet transmission delay.

This support includes multiple links on the same bundle as well as multiclass extension for MLPPP. Through this service you can enable bundling services without additional DPC slots to support Service DPC and free up the slots for other MICs.

This example shows how to configure Multilink Frame Relay (FRF.16) for additional bandwidth, load balancing, and redundancy by aggregating low-speed links such as T1 (WAN interfaces).

- [Requirements on page 788](#)
- [Overview on page 788](#)
- [Configuration on page 789](#)
- [Verification on page 793](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series Routers
- Junos OS Release 14.1 or later release

Before you begin, configure two MX Series routers (the MX240, MX480, or MX960) with at least two WAN interfaces that communicate over T1 links.

### Overview

In this example, you aggregate T1 interfaces to create an MFR FRF.16 bundle on two MX Series routers, R0 and R1. You configure the chassis interface and specify the number of MFR FRF.16 bundles to be created on the interface. You then specify the channel to be configured as a multilink bundle and create interface **lsq-**. You set the multilink bundle as an MFR FRF.16 bundle by specifying the **multilink-frame-relay-uni-nni** encapsulation type. Then you define Router R0 as a DCE device and Router R1 as a DTE device. You configure a logical unit on the multilink bundle **lsq-**, and set the family type to **inet**. You create the T1 interfaces, that are to be added as constituent links to the multilink bundle and define the Frame Relay encapsulation type. Finally, you set the multilink bundle to **lsq-**.

## Topology

Figure 29: Configuring Inline Multilink Frame Relay (FRF.16) for WAN Interfaces

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device R0

```
set chassis fpc 1 pic 0 mlfr-uni-nni-bundles-inline 1
set interfaces lsq-1/0/0:0 dce
set interfaces lsq-1/0/0:0 encapsulation multilink-frame-relay-uni-nni
set interfaces lsq-1/0/0:0 unit 0 dlci 10
set interfaces lsq-1/0/0:0 unit 1 dlci 20
set interfaces lsq-1/0/0:0 unit 0 family inet address 10.1.1.1/24
set interfaces lsq-1/0/0:0 unit 1 family inet address 11.1.1.1/24
set interfaces t1-1/0/0:5 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-1/0/0:6 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-1/0/0:5 unit 0 family mlfr-uni-nni bundle lsq-1/0/0:0
set interfaces t1-1/0/0:6 unit 0 family mlfr-uni-nni bundle lsq-1/0/0:0
```

Device R1

```
set chassis fpc 2 pic 0 mlfr-uni-nni-bundles-inline 1
set interfaces lsq-2/0/0:0 encapsulation multilink-frame-relay-uni-nni
set interfaces lsq-2/0/0:0 unit 0 dlci 10
set interfaces lsq-2/0/0:0 unit 1 dlci 20
set interfaces lsq-2/0/0:0 unit 0 family inet address 10.1.1.2/24
set interfaces lsq-2/0/0:0 unit 1 family inet address 11.1.1.2/24
set interfaces t1-2/0/0:5 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/0:6 encapsulation multilink-frame-relay-uni-nni
set interfaces t1-2/0/0:5 unit 0 family mlfr-uni-nni bundle lsq-2/0/0:0
set interfaces t1-2/0/0:6 unit 0 family mlfr-uni-nni bundle lsq-2/0/0:0
```

### To Configure Router R0

---

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure inline Multilink Frame Relay (FRF.16) for WAN Interfaces:

1. Configure a chassis interface and specify the number of MFR bundles.  

```
[edit]
user@R0# set chassis fpc 1 pic 0 mlfr-uni-nni-bundles-inline 1
```
2. Create the interface and specify the MFR encapsulation type.  

```
[edit]
user@R0# set interfaces lsq-1/0/0:0 encapsulation multilink-frame-relay-uni-nni
```
3. Set Router R0 as a DCE device.  

```
[edit]
user@R0# set interfaces lsq-1/0/0:0 dce
```
4. Specify the DLCI value.  

```
[edit]
user@R0# set interfaces lsq-1/0/0:0 unit 0 dlci 10
user@R0# set interfaces lsq-1/0/0:0 unit 1 dlci 20
```
5. Specify a logical unit on the multilink bundle and set the family type.  

```
[edit]
user@R0# set interfaces lsq-1/0/0:0 unit 0 family inet address 10.1.1.1/24
user@R0# set interfaces lsq-1/0/0:0 unit 1 family inet address 11.1.1.1/24
```
6. Create the T1 interfaces and set the Frame Relay encapsulation.  

```
[edit]
user@R0# set interfaces t1-1/0/0:5 encapsulation multilink-frame-relay-uni-nni
user@R0# set interfaces t1-1/0/0:6 encapsulation multilink-frame-relay-uni-nni
```
7. Specify the multilink bundle to which the interface is to be added as a constituent link on Router R0.  

```
[edit]
user@R0# set interfaces t1-1/0/0:5 unit 0 family mlfr-uni-nni bundle lsq-1/0/0:0
user@R0# set interfaces t1-1/0/0:6 unit 0 family mlfr-uni-nni bundle lsq-1/0/0:0
```

### To Configure Router R1

---

**Step-by-Step Procedure** To configure inline Multilink Frame Relay (FRF.16) for WAN Interfaces:

1. Configure a chassis interface and specify the number of MFR bundles.  

```
[edit]
user@R1# set chassis fpc 2 pic 0 mlfr-uni-nni-bundles-inline 1
```
2. Create the interface and specify the MFR encapsulation type.  

```
[edit]
```

```
user@R1# set interfaces lsq-2/0/0:0 encapsulation multilink-frame-relay-uni-nni
```

3. Specify the DLCI value.

```
[edit]
user@R0# set interfaces lsq-2/0/0:0 unit 0 dlci 10
user@R0# set interfaces lsq-2/0/0:0 unit 1 dlci 20
```

4. Specify a logical unit on the multilink bundle and set the family type.

```
[edit]
user@R0# set interfaces lsq-2/0/0:0 unit 0 family inet address 10.1.1.2/24
user@R0# set interfaces lsq-2/0/0:0 unit 1 family inet address 11.1.1.2/24
```

5. Create the T1 interfaces and set the Frame Relay encapsulation.

```
[edit]
user@R1# set interfaces t1-2/0/0:5 encapsulation multilink-frame-relay-uni-nni
user@R1# set interfaces t1-2/0/0:6 encapsulation multilink-frame-relay-uni-nni
```

6. Specify the multilink bundle to which the interface is to be added as a constituent link on Router R1.

```
[edit]
user@R1# set interfaces t1-2/0/0:5 unit 0 family mlfr-uni-nni bundle lsq-2/0/0:0
user@R1# set interfaces t1-2/0/0:6 unit 0 family mlfr-uni-nni bundle lsq-2/0/0:0
```

## Results

For Router R0, from configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces lsq-1/0/0:0**, **show interfaces t1-1/0/0:5**, and **show interfaces t1-1/0/0:6** commands.

For Router R1, from configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces lsq-2/0/0:0**, **show interfaces t1-2/0/0:5**, and **show interfaces t1-2/0/0:6** commands.

If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

For Router R0:

```
[edit]
user@R0# show chassis
fpc 1 {
 pic 0 {
 mlfr-uni-nni-bundles-inline 1;
 }
}

[edit]
user@R0# show interfaces lsq-1/0/0:0
dce;
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
 dlci 10;
 family inet {
 address 10.1.1.1/24;
```

```
 }
 }
 unit 1 {
 dlci 20;
 family inet {
 address 11.1.1.1/24;
 }
 }
}

[edit]
user@R0# show interfaces t1-1/0/0:5
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
 family mlfr-uni-nni {
 bundle lsq-1/0/0:0;
 }
}

[edit]
user@R0# show interfaces t1-1/0/0:6
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
 family mlfr-uni-nni {
 bundle lsq-1/0/0:0;
 }
}
```

If you are done configuring the router, enter **commit** from configuration mode.

For Router R1:

```
[edit]
user@R1# show chassis
fpc 2 {
 pic 0 {
 mlfr-uni-nni-bundles-inline 1;
 }
}

[edit]
user@R1# show interfaces lsq-2/0/0:0
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
 dlci 10;
 family inet {
 address 10.1.1.2/24;
 }
}
unit 1 {
 dlci 20;
 family inet {
 address 11.1.1.2/24;
 }
}

[edit]
user@R1# show interfaces t1-2/0/0:5
encapsulation multilink-frame-relay-uni-nni;
```

```

unit 0 {
 family mlfr-uni-nni {
 bundle lsq-2/0/0:0;
 }
}

[edit]
user@R1# show interfaces t1-2/0/0:6
encapsulation multilink-frame-relay-uni-nni;
unit 0 {
 family mlfr-uni-nni {
 bundle lsq-2/0/0:0;
 }
}

```

If you are done configuring the router, enter **commit** from configuration mode.

## Verification

### Verifying the MFR FRF.16 Configuration

**Purpose** Verify the MFR FRF.16 configuration.

**Action** From operational mode, run the **show interfaces lsq-1/0/0:0 extensive** command.

## Sample Output

# Configuring Additional Services on Link Services Interfaces

- [Configuring CoS on Link Services Interfaces on page 801](#)
- [Example: Configuring Link and Voice Services Interfaces with a Combination of Bundle Types on page 806](#)

## Configuring CoS on Link Services Interfaces

For link services IQ (**lsq-**) interfaces, Junos class of service (CoS) is fully supported and functions as described in the *Class of Service Feature Guide for Routing Devices*. For more information and detailed configuration examples, see [“Layer 2 Service Package Capabilities and Interfaces” on page 543](#).

On SRX Series devices, the **lsq-** interface is an internal interface, which is not associated with a physical interface. For information about link services on SRX Series devices, see the *Junos OS Interfaces Configuration Guide for Security Devices*.

For information about CoS functions and link services on M Series or T Series routers, see the following sections:

- [CoS for Link Services Interfaces on M Series and T Series Routers on page 801](#)
- [Example: Configuring CoS on Link Services Interfaces on page 803](#)

## CoS for Link Services Interfaces on M Series and T Series Routers

For Link Services PIC interfaces (**ls**) on M Series and T Series routers, queue 0 is the only queue that you should configure to receive fragmented packets. Configure all other queues to be higher-priority queues.

[Table 31 on page 801](#) summarizes how CoS queues work on link services (**ls**) interfaces.

Table 31: Link Services CoS Queues

| Supported Bundling Type   | Queue 0 | Higher-Priority Queues |
|---------------------------|---------|------------------------|
| Hash-based load balancing | No      | Yes                    |
| MLFR FRF.15               | Yes     | No                     |

Table 31: Link Services CoS Queues (*continued*)

| Supported Bundling Type | Queue 0 | Higher-Priority Queues |
|-------------------------|---------|------------------------|
| MLFR FRF.16             | Yes     | No                     |
| MLPPP                   | Yes     | No                     |

For M Series and T Series routers, CoS on link services (**ls**) interfaces works as follows:

- On all platforms, the Link Services PIC currently supports up to four queues: 0, 1, 2, and 3.
- Queue 0 uses MLFR FRF.15, MLFR FRF.16, or MLPPP to bundle packets.
- Higher-priority queues (1, 2, and 3) use hash-based load balancing to bundle packets. IP and MPLS header information is included in the hash.
- MLPPP packets traversing link services interfaces using queue 0 are fragmented and distributed across the constituent links. Queue 0 packets are sent on the least utilized link, proportional to its bandwidth. The queue 0 load balancer attempts to maintain even distribution of all traffic across all constituent links. In situations with a small number of high-priority traffic flows (queues 1, 2, and 3), queue 0 traffic might be unevenly distributed.
- For the MLFR FRF.16 protocol, only queue 0 works. If you configure a bundled interface to use MLFR FRF.16 with queue 0, then you must ensure the classifier does not send any traffic to queues 1, 2, and 3 on that interface.
- To carry high-priority traffic correctly on MLFR FRF.16 interfaces, you must configure an output firewall filter that forces all traffic into queue 0 on the **ls-fpc/pic/port.channel** interface.
- MLFR FRF.15 and MLPPP interfaces support CoS through packet interleaving. The MLFR FRF.16 standard does not support packet interleaving, so all packets destined for an FRF.16 PVC interface must egress from the same queue.
- For constituent link interfaces of Link Services PICs, you can configure standard scheduler maps.
- For input packets and fragments received from constituent links, you can use regular input firewall filters and standard CoS classifiers on the link services interface.
- For packets that pass through a link services interface and are destined for a constituent link interface, all traffic using queue 0 is fragmented. Traffic using higher-priority queues (1, 2, and 3) is not fragmented.
- For MLFR FRF.15 and MLPPP, routing protocol packets smaller than 128 bytes are sent to queue 3; routing protocol packets that exceed 128 bytes are sent to queue 0 and fragmented accordingly. For MLFR FRF.16, queue 0 is used for all packet sizes.
- You must configure output firewall classification for egress traffic on the link services interface, not directly on the constituent link interface directly.
- Inverse multiplexing for ATM (IMA) is not supported on link services interfaces.

For more information, see [“Configuring Delay-Sensitive Packet Interleaving on Link Services Logical Interfaces” on page 773](#) and the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

## Example: Configuring CoS on Link Services Interfaces

Configure CoS on a link services interface and its constituent link interfaces.

**NOTE:** This example applies to M Series and T Series routers. For examples that apply to SRX Series devices, see the *Junos OS Interfaces Configuration Guide for Security Devices*.

Packets that do not match the firewall filters are sent to a queue that performs load balancing by sending fragments to all constituent links.

Packets that match the firewall filters are sent to a queue that does not support packet fragmentation and reassembly; instead, this traffic is load-balanced by sending each packet flow to a different constituent link. Each packet that matches a firewall filter is subjected to a hash on the IP source address and the IP destination address to determine the packet flow to which each packet belongs.

When you configure the MLPPP encapsulation type or the multilink FRF.15 Frame Relay end-to-end encapsulation type, routing protocol packets smaller than 128 bytes are sent to the network-control queue on the constituent link interface. This keeps routing protocols operating normally, even when low-speed links are congested by regular packets.

## Active Flow Monitoring Overview

---

Using a Juniper Networks M Series Multiservice Edge or T Series Core Router or EX9200 switch, a selection of PICs (including the Monitoring Services PIC, Adaptive Services [AS] PIC, Multiservices PIC, or Multiservices DPC) and other networking hardware, you can monitor traffic flow and export the monitored traffic. Monitoring traffic allows you to do the following:

- Gather and export detailed information about IP version 4 (IPv4) traffic flows between source and destination nodes in your network.
- Sample all incoming IPv4 traffic on the monitoring interface and present the data in cflowd record format.
- Perform discard accounting on an incoming traffic flow.
- Encrypt or tunnel outgoing cflowd records, intercepted IPv4 traffic, or both.
- Direct filtered traffic to different packet analyzers and present the data in its original format (port mirror).

**NOTE:** Monitoring Services PICs, AS PICs, and Multiservices PICs must be mounted on an Enhanced Flexible PIC Concentrator (FPC) in an M Series or T Series router.

Multiservices DPCs installed in Juniper Networks MX Series 3D Universal Edge Routers support the same functionality, with the exception of the passive monitoring and flow-tap features.

Although the Monitoring Services PIC was designed initially for use as an offline passive flow monitoring tool, it can also be used in an active flow monitoring topology. In contrast, the AS or Multiservices PIC is designed exclusively for active flow monitoring. To use either the Monitoring Services PIC, AS PIC, or Multiservices PIC for active flow monitoring, you must install the PIC in an M Series or T Series router. The router participates in both the monitoring application and in the normal routing functionality of the network.

Starting with Junos OS Release 11.4, support for active monitoring is extended to logical systems running on T Series and MX Series routers. A logical system is a partition created from a physical router that performs independent routing tasks. Several logical systems in a single router with their own interfaces, policies, instances, and routing tables can perform functions handled by several different routers. A shared services PIC handles flows from all the logical systems. Only version 9 flows, IPv4, and MPLS templates are supported. See [“Example: Configuring Active Monitoring on Logical Systems” on page 823](#) for a sample configuration that enables active monitoring on a logical system.

Specified packets can be filtered and sent to the monitoring interface. For the Monitoring Services PIC, the interface name contains the **mo-** prefix. For the AS or Multiservices PIC, the interface name contains the **sp-** prefix.

**NOTE:** If you upgrade from the Monitoring Services PIC to the Adaptive Services or Multiservices PIC for active flow monitoring, you must change the name of your monitoring interface from **mo-fpc/pic/port** to **sp-fpc/pic/port**.

The major active flow monitoring actions you can configure at the **[edit forwarding-options]** hierarchy level are as follows:

- Sampling, with the **[edit forwarding-options sampling]** hierarchy. This option sends a copy of the traffic stream to an AS or Monitoring Services PIC, which extracts limited information (such as the source and destination IP address) from some of the packets in a flow. The original packets are forwarded to the intended destination as usual.
- Discard accounting, with the **[edit forwarding-options accounting]** hierarchy. This option quarantines unwanted packets, creates cflowd records that describe the packets, and discards the packets instead of forwarding them.
- Port mirroring, with the **[edit forwarding-options port-mirroring]** hierarchy. This option makes one full copy of all packets in a flow and delivers the copy to a single destination. The original packets are forwarded to the intended destination.
- Multiple port mirroring, with the **[edit forwarding-options next-hop-group]** hierarchy. This option allows multiple copies of selected traffic to be delivered to multiple destinations. (Multiple port mirroring requires a Tunnel Services PIC.)

Unlike passive flow monitoring, you do not need to configure a monitoring group. Instead, you can send filtered packets to a monitoring services or adaptive services interface (**mo-** or **sp-**) by using sampling or discard accounting. Optionally, you can configure port mirroring or multiple port mirroring to direct packets to additional interfaces.

These active flow monitoring options provide a wide variety of actions that can be performed on network traffic flows. However, the following restrictions apply:

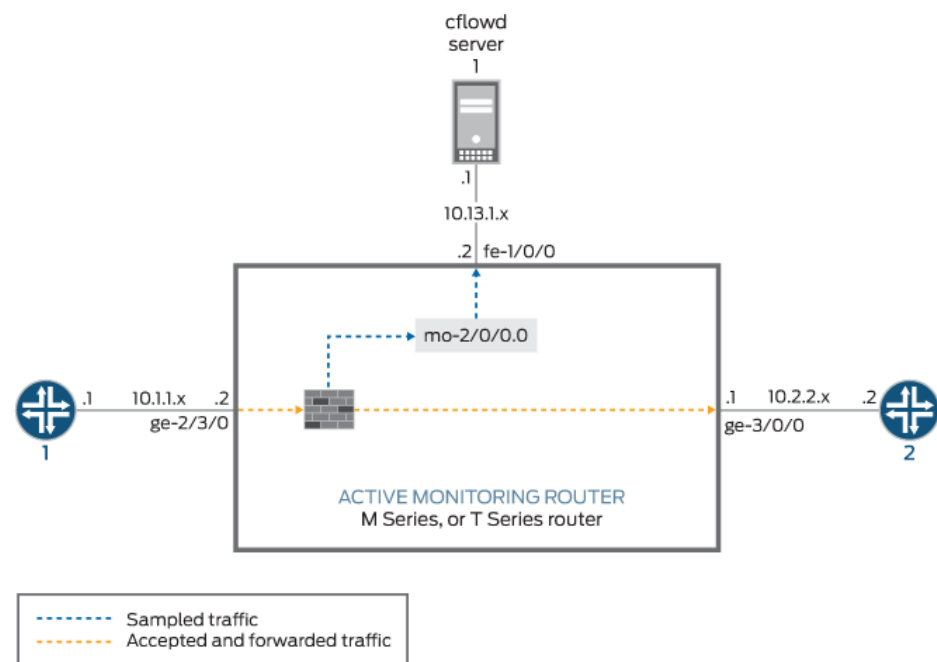

- The router or switch can perform sampling *or* port mirroring at any one time.
- The router or switch can perform forwarding *or* discard accounting at any one time.

Because the Monitoring Services, AS, and Multiservices PICs allow only one action to be performed at any one time, the following configuration options are available:

- Sampling and forwarding
- Sampling and discard accounting
- Port mirroring and forwarding
- Port mirroring and discard accounting
- Sampling and port mirroring on different sets of traffic

Figure 30 on page 817 shows a sample topology.

Figure 30: Active Monitoring Configuration Topology

8043214

In [Unresolved xref], traffic from Router 1 arrives on the monitoring router's Gigabit Ethernet **ge-2/3/0** interface. The exit interface on the monitoring router leading to destination Router 2 is **ge-3/0/0**, but this could be any interface type (such as SONET, Gigabit Ethernet, and so on). The export interface leading to the cflowd server is **fe-1/0/0**.

To enable active monitoring, configure a firewall filter on the interface **ge-2/3/0** with the following match conditions:

- Traffic matching certain firewall conditions is sent to the Monitoring Services PIC using filter-based forwarding. This traffic is quarantined and not forwarded to other routers.
- All other traffic is port-mirrored to the Monitoring Services PIC. Port mirroring copies each packet and sends the copies to the port-mirroring next hop (in this case, a Monitoring Services PIC). The original packets are forwarded out of the router as usual.

## Configuring Flow Monitoring

The flow-monitoring application performs traffic flow monitoring and enables lawful interception of traffic between two routers or switches. Traffic flows can either be passively monitored by an offline router or switch or actively monitored by a router participating in the network.

To configure flow monitoring you need to do the following:

- [Configuring Flow-Monitoring Interfaces on page 818](#)
- [Configuring Flow-Monitoring Properties on page 820](#)
- [Example: Configuring Flow Monitoring on page 822](#)

### Configuring Flow-Monitoring Interfaces

To enable flow monitoring on the Monitoring Services PIC, include the **mo-fpc/pic/port** statement at the **[edit interfaces]** hierarchy level:

```
mo-fpc/pic/port {
 unit logical-unit-number {
 family inet {
 address address {
 destination address;
 }
 filter {
 group filter-group-number;
 input filter-name;
 output filter-name;
 }
 sampling {
 [input output];
 }
 }
 }
 multiservice-options {
 (core-dump | no-core-dump);
 (syslog | no-syslog);
 flow-control-options {
```

```

 down-on-flow-control;
 dump-on-flow-control;
 reset-on-flow-control;
 }
}

```

Specify the physical and logical location of the flow-monitoring interface. You cannot use **unit 0**, because it is already used by internal processes. Specify the source and destination addresses. The **filter** statement allows you to associate an input or output filter or a filter group that you have already configured for this purpose. The **sampling** statement specifies the traffic direction: **input**, **output**, or both.

The **multiservice-options** statement allows you to configure properties related to flow-monitoring interfaces:

- Include the **core-dump** statement to enable storage of core files in **/var/tmp**.
- Include the **syslog** statement to enable storage of system logging information in **/var/log**.

**NOTE:** Boot images for monitoring services interfaces are specified at the [edit chassis images pic] hierarchy level. You must include the following configuration to make the flow monitoring feature operable:

```

[edit system]
ntp {
 boot-server ntp.juniper.net;
 server 172.17.28.5;
}
processes {
 ntp enable;
}

```

For more information, see the *Junos OS Administration Library for Routing Devices*.

- Include the **flow-control-options** statement to configure flow control.

**NOTE:** Starting with Junos OS Release 15.1, instead of an eJunos kernel core file, the multiservices PIC management daemon core file is generated when a prolonged flow control failure occurs and when you configure the setting to generate a core dump during prolonged flow control (by using the **dump-on-flow-control** option with the **flow-control-options** statement). The watchdog functionality continues to generate a kernel core file in such scenarios.

## Configuring Flow-Monitoring Properties

To configure flow-monitoring properties, include the **monitoring** statement at the **[edit forwarding-options]** hierarchy level:

```
monitoring name {
 family inet {
 output {
 cflowd hostname port port-number;
 export-format format;
 flow-active-timeout seconds;
 flow-export-destination {
 collector-pic;
 }
 flow-inactive-timeout seconds;
 interface interface-name {
 engine-id number;
 engine-type number;
 input-interface-index number;
 output-interface-index number;
 source-address address;
 }
 }
 }
}
```

A monitoring instance is a named entity that specifies collector information under the **monitoring name** statement. The following sections describe the properties you can configure:

- [Directing Traffic to Flow-Monitoring Interfaces on page 820](#)
- [Exporting Flows on page 821](#)
- [Configuring Time Periods when Flow Monitoring is Active and Inactive on page 821](#)

---

### Directing Traffic to Flow-Monitoring Interfaces

To direct traffic to a flow-monitoring interface, include the **interface** statement at the **[edit forwarding-options monitoring name output]** hierarchy level. By default, the Junos OS automatically assigns values for the **engine-id** and **engine-type** statements:

- **engine-id**—Monitoring interface location.
- **engine-type**—Platform-specific monitoring interface type.

The **source-address** statement specifies the traffic source for transmission of cflowd information; you must configure it manually. If you provide a different **source-address** statement for each monitoring services output interface, you can track which interface processes a particular cflowd record.

By default, the **input-interface-index** value is the SNMP index of the input interface. You can override the default by including a specific value. The **input-interface-index** and **output-interface-index** values are exported in fields present in the cflowd version 5 flow format.

## Exporting Flows

To direct traffic to a flow collection interface, include the **flow-export-destination** statement. For more information about flow collection, see *Flow Collection*.

To configure the cflowd version number, include the **export-format** statement at the **[edit forwarding-options monitoring name output]** hierarchy level. By default, version 5 is used. Version 8 enables the router software to aggregate the flow information using broader criteria and reduce cflowd traffic. Version 8 aggregation is performed periodically (every few seconds) on active flows and when flows are allowed to expire. Because the aggregation is performed periodically, active timeout events are ignored.

For more information on cflowd properties, see “Enabling Flow Aggregation” on page 898.

## Configuring Time Periods when Flow Monitoring is Active and Inactive

To configure time periods for active flow monitoring and intervals of inactivity, include the **flow-active-timeout** and **flow-inactive-timeout** statements at the **[edit forwarding-options monitoring name output]** hierarchy level:

- The **flow-active-timeout** statement specifies the time interval between flow exports for active flows. If the interval between the time the last packet was received and the time the flow was last exported exceeds the configured value, the flow is exported.

This timer is needed to provide periodic updates when a flow has a long duration. The active timeout setting enables the router to retain the start time for the flow as a constant and send out periodic cflowd reports. This in turn allows the collector to register the start time and determine that a flow has survived for a duration longer than the configured active timeout.

**NOTE:** In active flow monitoring, the cflowd records are exported after a time period that is a multiple of 60 seconds and greater than or equal to the configured active timeout value. For example, if the active timeout value is 90 seconds, the cflowd records are exported at 120-second intervals. If the active timeout value is 150 seconds, the cflowd records are exported at 180-second intervals, and so forth.

- The **flow-inactive-timeout** statement specifies the interval of inactivity for a flow that triggers the flow export. If the interval between the current time and the time that the last packet for this flow was received exceeds the configured inactive timeout value, the flow is allowed to expire.

If the flow stops transmitting for longer than the configured inactive timeout value, the router or switch purges it from the flow table and exports the cflowd record. As a result, the flow is forgotten as far as the PIC is concerned and if the same 5-tuple appears again, it is assigned a new start time and considered a new flow.

Both timers are necessary. The active timeout setting is needed to provide information for flows that constantly transmit packets for a long duration. The inactive timeout setting

enables the router or switch to purge flows that have become inactive and would waste tracking resources.

**NOTE:** The router must contain an Adaptive Services, Multiservices, or Monitoring Services PIC for the `flow-active-timeout` and `flow-inactive-timeout` statements to take effect.

---

## Example: Configuring Flow Monitoring

The following is an example of flow-monitoring properties configured to support input SONET/SDH interfaces, output monitoring services interfaces, and export to cflowd for flow analysis. To complete the configuration, you also need to configure the interfaces and set up a virtual private network (VPN) routing and forwarding (VRF) instance. For a complete example, see the *Junos OS, Release 14.2*. For information on cflowd, see [“Enabling Flow Aggregation” on page 898](#).

```
[edit forwarding-options]
monitoring group1 {
 family inet {
 output {
 cflowd 192.168.245.2 port 2055;
 export-format cflowd-version-5;
 flow-active-timeout 60;
 flow-inactive-timeout 30;
 interface mo-4/0/0.1 {
 engine-id 1;
 engine-type 1;
 input-interface-index 44;
 output-interface-index 54;
 source-address 192.168.245.1;
 }
 interface mo-4/1/0.1 {
 engine-id 2;
 engine-type 1;
 input-interface-index 45;
 output-interface-index 55;
 source-address 192.168.245.1;
 }
 interface mo-4/2/0.1 {
 engine-id 3;
 engine-type 1;
 input-interface-index 46;
 output-interface-index 56;
 source-address 192.168.245.1;
 }
 interface mo-4/3/0.1 {
 engine-id 4;
 engine-type 1;
 input-interface-index 47;
 output-interface-index 57;
 source-address 192.168.245.1;
 }
 }
 }
}
```

```

 }
 }
}

```

## Example: Configuring Active Monitoring on Logical Systems

This example shows a sample configuration that allows you to configure active monitoring on a logical system. The following section shows the configuration on the master router:

```

[edit forwarding-options]
sampling {
 instance inst1 {
 input {
 rate 1;
 }
 family inet;
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version9 {
 template {
 ipv4;
 }
 }
 }
 }
 }
 interface sp-0/1/0 {
 source-address 10.11.12.13;
 }
}
family mpls;
output {
 flow-server 2.2.2.2 {
 port 2055;
 version9 {
 template {
 mpls;
 }
 }
 }
 interface sp-0/1/0 {
 source-address 10.11.12.13;
 }
}
}

```

```
services {
 flow-monitoring {
 version9 {
 template ipv4 {
 flow-active-timeout 60;
 flow-inactive-timeout 60;
 ipv4-template;
 template-refresh-rate {
 packets 1000;
 seconds 10;
 }
 option-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 }
 template mpls {
 mpls-template;
 }
 }
}
```

The configuration for the logical router uses the input parameters and the output interface for sampling from the master router. Each logical router should have separate template definitions for the flow-server configuration. The following section shows the configuration on the logical router:

```
logical-systems {
 ls-1 {
 firewall {
 family inet {
 filter test-sample {
 term term-1 {
 then {
 sample;
 accept;
 }
 }
 }
 }
 }
 interfaces {
 ge-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input test-sample;
 output test-sample;
 }
 }
 }
 }
 }
 forwarding-options {
 sampling {
```

```

instance sample-inst1 {
 family inet;
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version9 {
 template {
 ipv4-ls1;
 }
 }
 }
 }
}
family mpls;
output {
 flow-server 2.2.2.2 {
 port 2055;
 version9 {
 template {
 mpls-ls1;
 }
 }
 }
}
}
services {
 flow-monitoring {
 version9 {
 template ipv4-ls1 {
 flow-active-timeout 60;
 flow-inactive-timeout 60;
 ipv4-template;
 template-refresh-rate {
 packets 1000;
 seconds 10;
 }
 option-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 template mpls-ls1 {
 mpls-template;
 }
 }
 }
}
}

```

- [Configuring Services Interface Redundancy with Flow Monitoring on page 826](#)

## Configuring Services Interface Redundancy with Flow Monitoring

Active monitoring services configurations on AS, Multiservices PICs, and Multiservices DPCs support redundancy. To configure redundancy, you specify a redundancy services PIC (**rsp**) interface in which the primary AS or Multiservices PIC is active and a secondary PIC is on standby. If the primary PIC fails, the secondary PIC becomes active, and all service processing is transferred to it. If the primary PIC is restored, it remains on standby and does not preempt the secondary PIC; you need to manually restore the services to the primary PIC. To determine which PIC is currently active, issue the **show interfaces redundancy** command.

**NOTE:** On flow-monitoring configurations, the only service option supported is *warm standby*, in which one backup PIC supports multiple working PICs. Recovery times are not guaranteed, because the configuration must be completely restored on the backup PIC after a failure is detected. However, configuration is preserved and available on the new active PIC.

As with the other services that support warm standby, you can issue the **request interfaces (revert | switchover)** command to switch manually between the primary and secondary flow monitoring interfaces.

For more information, see “[Configuring AS or Multiservices PIC Redundancy](#)” on page 41. For information on operational mode commands, see the [CLI Explorer](#).

A sample configuration follows.

```
interface {
 rsp0 {
 redundancy-options {
 primary sp-0/0/0;
 secondary sp-1/3/0;
 }
 unit 0 {
 family inet;
 }
 }
}
interface {
 ge-0/2/0 {
 unit 0 {
 family inet {
 filter {
 input as_sample;
 }
 }
 }
 address 10.58.255.49/28;
```

```

 }
 }
}
forwarding-options {
 sampling {
 instance instance1 { # named instances of sampling parameters
 input {
 rate 1;
 run-length 0;
 max-packets-per-second 65535;
 }
 family inet {
 output {
 flow-server 10.10.10.2 {
 port 5000;
 version 5;
 }
 flow-active-timeout 60;
 interface rsp0 {
 source-address 10.10.10.1;
 }
 }
 }
 }
 }
}
}
firewall {
 filter as_sample {
 term t1 {
 then {
 sample;
 accept;
 }
 }
 }
}
}

```

## Flow Offloading

The Junos OS enables you to configure flow offloading for PICS on MX Series routers using Modular Port Concentrator (MPCs) with Modular Interface Cards (MICs). Flows are offloaded to Fast Update Filters (FUFs) on the Packet Forwarding Engine. Offloading produces the greatest benefits when applied to long-lasting or high-bandwidth flows.

The maximum number of active offloads is 200,000 per PIC. When offloaded flows are deleted, more flows can be offloaded.

To configure flow offloading:

- At the **[edit interfaces *interface-name* services-options]** hierarchy level, enter the **trio-flow-offload minimum-bytes *minimum-bytes*** statement.

```
user@host# edit services interface-name
[edit services interface-name services-options]
user@host# set trio-flow-offload minimum-bytes minimum-bytes
```

In the following example, flows are offloaded when they consist of no less than 1024 bytes:

```
user@host# edit services ms-0/1/0
[edit services ms-0/1/0 services-options]
user@host# set trio-flow-offload minimum-bytes 1024
```

# Monitoring Traffic Using Passive Flow Monitoring

- [Passive Flow Monitoring Overview on page 829](#)
- [Enabling Passive Flow Monitoring on page 830](#)

## Passive Flow Monitoring Overview

---

Using a Juniper Networks M Series Multiservice Edge or T Series Core Router, a selection of PICs (including the Monitoring Services PIC, Adaptive Services [AS] PIC, Multiservices PIC, or Multiservices DPC) and other networking hardware, you can monitor traffic flow and export the monitored traffic. Monitoring traffic allows you to do the following:

- Gather and export detailed information about IP version 4 (IPv4) traffic flows between source and destination nodes in your network.
- Sample all incoming IPv4 traffic on the monitoring interface and present the data in cflowd record format.
- Perform discard accounting on an incoming traffic flow.
- Encrypt or tunnel outgoing cflowd records, intercepted IPv4 traffic, or both.
- Direct filtered traffic to different packet analyzers and present the data in its original format (port mirror).

**NOTE:** Monitoring Services PICs, AS PICs, and Multiservices PICs must be mounted on an Enhanced Flexible PIC Concentrator (FPC) in an M Series or T Series router.

Multiservices DPCs installed in Juniper Networks MX Series 3D Universal Edge Routers support the same functionality, with the exception of the passive monitoring and flow-tap features.

The router used for passive monitoring does not route packets from the monitored interface, nor does it run any routing protocols related to those interfaces; it only receives traffic flows, collects intercepted traffic, and exports it to cflowd servers and packet analyzers. [Figure 31 on page 830](#) shows a typical topology for the passive flow-monitoring application.

Figure 31: Passive Monitoring Application Topology

Traffic travels normally between Router 1 and Router 2. To redirect IPv4 traffic, you insert an optical splitter on the interface between these two routers. The optical splitter copies and redirects the traffic to the monitoring station, which is an M40e, M160, M320, or T Series router. The optical cable connects only the receive port on the monitoring station, never the transmit port. This configuration allows the monitoring station to receive traffic from the router being monitored but never to transmit it back.

If you are monitoring traffic flow, the Internet Processor II application-specific integrated circuit (ASIC) in the router forwards a copy of the traffic to the Monitoring Services, Adaptive Services, or Multiservices PIC in the monitoring station. If more than one monitoring PIC is installed, the monitoring station distributes the load of the incoming traffic across the multiple PICs. The monitoring PICs generate flow records in cflowd version 5 format, and the records are then exported to the cflowd collector.

If you are performing lawful interception of traffic between the two routers, the Internet Processor II ASIC filters the incoming traffic and forwards it to the Tunnel Services PIC. Filter-based forwarding is then applied to direct the traffic to the packet analyzers.

Optionally, the intercepted traffic or the cflowd records can be encrypted by the ES PIC or IP Security (IPsec) services and then sent to a cflowd server or packet analyzer.

**Related Documentation**

- [Enabling Passive Flow Monitoring on page 830](#)

## Enabling Passive Flow Monitoring

You can monitor IPv4 traffic from another router if you have the following components installed in an M Series, MX Series, or T Series router:

- Monitoring Services, Adaptive Services, or Multiservices PICs to perform the service processing
- SONET/SDH, Fast Ethernet, or Gigabit Ethernet PICs as transit interface

On SONET/SDH interfaces, you enable passive flow monitoring by including the **passive-monitor-mode** statement at the **[edit interfaces so-fpc/pic/port unit logical-unit-number]** hierarchy level:

```
[edit interfaces so-fpc/pic/port unit logical-unit-number]
passive-monitor-mode;
```

On Asynchronous Transfer Mode (ATM), Fast Ethernet, or Gigabit Ethernet interfaces, you enable passive flow monitoring by including the **passive-monitor-mode** statement at the **[edit interfaces interface-name]** hierarchy level:

```
[edit interfaces interface-name]
passive-monitor-mode;
```

IPv6 passive monitoring is not supported on Monitoring Services PICs. You must configure port mirroring to forward the packets from the passive monitored ports to other interfaces. Interfaces configured on the following FPCs and PIC support IPv6 passive monitoring on the T640 and T1600 routers:

- Enhanced Scaling FPC2
- Enhanced Scaling FPC3
- Enhanced II FPC1
- Enhanced II FPC2
- Enhanced II FPC3
- Enhanced Scaling FPC4
- Enhanced Scaling FPC4.1
- 4-port 10-Gigabit Ethernet LAN/WAN PIC with XFP (supported on both WAN-PHY and LAN-PHY mode for both IPv4 and IPv6 addresses)
- Gigabit Ethernet PIC with SFP
- 10-Gigabit Ethernet PIC with XENPAK (T1600 router)
- SONET/SDH OC192/STM64 PIC (T1600 router)
- SONET/SDH OC192/STM64 PICs with XFP (T1600 router)
- SONET/SDH OC48c/STM16 PIC with SFP (T1600 router)
- SONET/SDH OC48/STM16 (Multi-Rate)
- SONET/SDH OC12/STM4 (Multi-Rate) PIC with SFP
- Type 1 SONET/SDH OC3/STM1 (Multi-Rate) PIC with SFP

To configure port mirroring, include the **port-mirroring** statement at the **[edit forwarding-options]** hierarchy level.

When you configure an interface in passive monitoring mode, the Packet Forwarding Engine silently drops packets coming from that interface and destined to the router itself. Passive monitoring mode also stops the Routing Engine from transmitting any packet from that interface. Packets received from the monitored interface can be forwarded to monitoring interfaces. If you include the **passive-monitor-mode** statement in the configuration:

- The ATM interface is always up, and the interface does not receive or transmit incoming control packets, such as Operation, Administration, and Maintenance (OAM) and Interim Local Management Interface (ILMI) cells.
- The SONET/SDH interface does not send keepalives or alarms and does not participate actively on the network.
- Gigabit and Fast Ethernet interfaces can support both per-port passive monitoring and per-VLAN passive monitoring. The destination MAC filter on the receive port of the Ethernet interfaces is disabled.
- Ethernet encapsulation options are not allowed.
- Ethernet interfaces do not support the **stacked-vlan-tagging** statement for both IPv4 and IPv6 packets in passive monitoring mode.

On monitoring services interfaces, you enable passive flow monitoring by including the **family** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level, specifying the **inet** option:

```
[edit interfaces interface-name unit logical-unit-number]
family inet;
```

For the monitoring services interface, you can configure multiservice physical interface properties. For more information, see [“Configuring Flow-Monitoring Interfaces” on page 818](#).

For conformity with the cflowd record structure, you must include the **receive-options-packets** and **receive-ttl-exceeded** statements at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet]** hierarchy level:

```
[edit interfaces interface-name unit logical-unit-number family inet]
receive-options-packets;
receive-ttl-exceeded;
```

For more information, see the following sections:

- [Passive Flow Monitoring for MPLS Encapsulated Packets on page 832](#)
- [Example: Enabling IPv4 Passive Flow Monitoring on page 834](#)
- [Example: Enabling IPv6 Passive Flow Monitoring on page 836](#)

## Passive Flow Monitoring for MPLS Encapsulated Packets

On monitoring services interfaces, you can process MPLS packets that have not been assigned label values and have no corresponding entry in the **mpls.0** routing table. This allows you to assign a default route to unlabeled MPLS packets.

To configure a default label value for MPLS packets, include the **default-route** statement at the **[edit protocols mpls interface *interface-name* label-map]** hierarchy level:

```
[edit protocols mpls interface interface-name label-map]
default-route {
 (next-hop (address | interface-name | address/interface-name)) | (reject | discard);
 (pop | (swap <out-label>));
 class-of-service value;
 preference preference;
 type type;
}
```

For more information about static labels, see the *MPLS Applications Feature Guide for Routing Devices*.

### Removing MPLS Labels from Incoming Packets

The Junos OS can forward only IPv4 packets to a Monitoring Services, Adaptive Services, or Multiservices PIC. IPv4 and IPv6 packets with MPLS labels cannot be forwarded to a monitoring PIC. By default, if packets with MPLS labels are forwarded to the monitoring PIC, they are discarded. To monitor IPv4 and IPv6 packets with MPLS labels, you must remove the MPLS labels as the packets arrive on the interface.

You can remove up to two MPLS labels from an incoming packet by including the **pop-all-labels** statement at the [edit interfaces *interface-name* (atm-options | fastether-options | gigether-options | sonet-options) mpls] hierarchy level:

```
[edit interfaces interface-name (atm-options | fastether-options | gigether-options |
sonet-options) mpls]
pop-all-labels {
 required-depth [numbers];
}
```

By default, the **pop-all-labels** statement takes effect for incoming packets with one or two labels. You can specify the number of MPLS labels that an incoming packet must have for the **pop-all-labels** statement to take effect by including the **required-depth** statement at the [edit interfaces *interface-name* (atm-options | fastether-options | gigether-options | sonet-options) mpls pop-all-labels] hierarchy level:

```
[edit interfaces interface-name (atm-options | fastether-options | gigether-options |
sonet-options) mpls pop-all-labels]
required-depth [numbers];
```

The required depth can be 1, 2, or [ 1 2 ]. If you include the **required-depth 1** statement, the **pop-all-labels** statement takes effect for incoming packets with one label only. If you include the **required-depth 2** statement, the **pop-all-labels** statement takes effect for incoming packets with two labels only. If you include the **required-depth [ 1 2 ]** statement, the **pop-all-labels** statement takes effect for incoming packets with one or two labels. A required depth of [ 1 2 ] is equivalent to the default behavior of the **pop-all-labels** statement.

When you remove MPLS labels from incoming packets, note the following:

- The **pop-all-labels** statement has no effect on IP packets with three or more MPLS labels.
- When you enable MPLS label removal, you must configure all ports on a PIC with the same label popping mode and required depth.

- You use the **pop-all-labels** statement to enable passive monitoring applications, not active monitoring applications.
- You cannot apply MPLS filters or accounting to the MPLS labels because the labels are removed as soon as the packet arrives on the interface.
- On ATM2 interfaces, you must use a label value greater than 4095 because the lower range of MPLS labels is reserved for label-switched interface (LSI) and virtual private LAN service (VPLS) support. For more information, see the *Junos OS VPNs Library for Routing Devices*.
- The following ATM encapsulation types are not supported on interfaces with MPLS label removal:
  - **atm-ccc-cell-relay**
  - **atm-ccc-vc-mux**
  - **atm-mlppp-llc**
  - **atm-tcc-snap**
  - **atm-tcc-vc-mux**
  - **ether-over-atm-llc**
  - **ether-vpls-over-atm-llc**

### Example: Enabling IPv4 Passive Flow Monitoring

The following example shows a complete configuration for enabling passive flow monitoring on an Ethernet interface.

In this example, the Gigabit Ethernet interface can accept all Ethernet packets. It strips VLAN tags (if there are any) and up to two MPLS labels blindly, and passes IPv4 packets to the monitoring interface. With this configuration, it can monitor IPv4, VLAN+IPv4, VLAN+MPLS+IPv4, and VLAN+MPLS+MPLS+IPv4 labeled packets.

The Fast Ethernet interface can accept only packets with VLAN ID 100. All other packets are dropped. With this configuration, it can monitor VLAN (ID=100)+IPv4, VLAN (ID=100)+MPLS+IPv4, and VLAN (ID=100)+MPLS+MPLS+IPv4 labeled packets.

```
[edit firewall]
family inet {
 filter input-monitoring-filter {
 term def {
 then {
 count counter;
 accept;
 }
 }
 }
}
[edit interfaces]
ge-0/0/0 {
 passive-monitor-mode;
 gigether-options {
```

```

 mpls {
 pop-all-labels;
 }
 }
 unit 0 {
 family inet {
 filter {
 input input-monitoring-filter;
 }
 }
 }
}
fe-0/1/0 {
 passive-monitor-mode;

 fastether-options {
 mpls {
 pop-all-labels required-depth [1 2];
 }
 }
 unit 0 {
 vlan-id 100;
 family inet {
 filter {
 input input-monitoring-filter;
 }
 }
 }
}
mo-1/0/0 {
 unit 0 {
 family inet {
 receive-options-packets;
 receive-ttl-exceeded;
 }
 }
 unit 1 {
 family inet;
 }
}
[edit forwarding-options]
monitoring mon1 {
 family inet {
 output {
 export-format cflowd-version-5;
 cflowd 50.0.0.2 port 2055;
 interface mo-1/0/0.0 {
 source-address 50.0.0.1;
 }
 }
 }
}
[edit routing-instances]
monitoring-vrf {
 instance-type vrf;
 interface ge-0/0/0.0;
}

```

```
interface fe-0/1/0.0;
interface mo-1/0/0.1;
route-distinguisher 68:1;
vrf-import monitoring-vrf-import;
vrf-export monitoring-vrf-export;
routing-options {
 static {
 route 0.0.0.0/0 next-hop mo-1/0/0.1;
 }
}
[edit policy-options]
policy-statement monitoring-vrf-import {
 then {
 reject;
 }
}
policy-statement monitoring-vrf-export {
 then {
 reject;
 }
}
```

### Example: Enabling IPv6 Passive Flow Monitoring

The following example shows a complete configuration for enabling IPv6 passive flow monitoring on an Ethernet interface.

In this example, the Gigabit Ethernet interface can accept all Ethernet packets. It strips VLAN tags (if there are any) and up to two MPLS labels blindly, and passes IPv6 packets to the monitoring interface. With this configuration, the Gigabit Ethernet interface can monitor IPv6, VLAN+IPv6, VLAN+MPLS+IPv6, and VLAN+MPLS+MPLS+IPv6 labeled packets.

The vlan-tagged Gigabit Ethernet interface can accept only packets with VLAN ID 100. All other packets are dropped. With this configuration, it can monitor VLAN (ID=100)+IPv6, VLAN (ID=100)+MPLS+IPv6, and VLAN (ID=100)+MPLS+MPLS+IPv6 labeled packets.

```
[edit interfaces]
xe-0/1/0 {
 passive-monitor-mode;
 unit 0 {
 family inet6 {
 filter {
 input port-mirror6;
 }
 address 2001::1/128;
 }
 }
}
xe-0/1/2 {
 passive-monitor-mode;
 vlan-tagging;
 unit 0 {
 vlan-id 100;
 }
}
```

```

 family inet6 {
 filter {
 input port-mirror6;
 }
 }
 }
}
xe-0/1/1 {
 unit 0 {
 family inet6 {
 address 2000::1/128;
 }
 }
}
[edit firewall]
family inet6 {
 filter port-mirror6 {
 term term2 {
 then {
 count count_pm;
 port-mirror;
 accept;
 }
 }
 }
}
[edit forwarding options]
port-mirroring {
 input {
 rate 1;
 }
 family inet6 {
 output {
 interface xe-0/1/1.0 {
 next-hop 2000::3;
 }
 no-filter-check;
 }
 }
}
}

```

# Processing and Exporting Multiple Records Using Flow Collection

- [Flow Collection Overview on page 839](#)
- [Configuring Flow Collection on page 840](#)
- [Sending cflowd Records to Flow Collector Interfaces on page 843](#)
- [Configuring Flow Collection Mode and Interfaces on Services PICs on page 844](#)

## Flow Collection Overview

---

You can process and export multiple cflowd records with a flow collector interface. You create a flow collector interface on a Monitoring Services II or Multiservices 400 PIC. The flow collector interface combines multiple cflowd records into a compressed ASCII data file and exports the file to an FTP server. To convert a services PIC into a flow collector interface, include the **flow-collector** statement at the **[edit chassis fpc fpc-slot pic pic-slot monitoring-services application]** hierarchy level.

You can use the services PIC for either flow collection or monitoring, but not for both types of service simultaneously. When converting the PIC between service types, you must configure the **flow-collector** statement, take the PIC offline, and then bring the PIC back online. Restarting the router does not enable the new service type.

A flow collector interface, designated by the **cp-fpc/pic/port** interface name, requires three logical interfaces for correct operation. Units 0 and 1 are used to send the compressed ASCII data files to an FTP server, while Unit 2 is used to receive cflowd records from a monitoring services interface.

**NOTE:** Unlike conventional interfaces, the **address** statement at the **[edit interfaces cp-fpc/pic/port unit unit-number family inet]** hierarchy level corresponds to the IP address of the Routing Engine. Likewise, the **destination** statement at the **[edit interfaces cp-fpc/pic/port unit unit-number family inet address ip-address]** hierarchy level corresponds to the IP address of the flow collector interface. As a result, you must configure the **destination** statement for Unit 0 and 1 with *local* addresses that can reach the FTP server. Similarly, configure the **destination** statement for Unit 2 with a *local* IP address so it can reach the monitoring services interface that sends cflowd records.

To activate flow collector services after the services PIC is converted into a flow collector, include the **flow-collector** statement at the **[edit services]** hierarchy level.

After you activate the flow collector, you need to configure the following components:

- Destination of the FTP server
- File specifications
- Input interface-to-flow collector interface mappings
- Transfer log settings

**Related  
Documentation**

- [Configuring Flow Collection on page 840](#)
- [Sending cflowd Records to Flow Collector Interfaces on page 843](#)
- [Configuring Flow Collection Mode and Interfaces on Services PICs on page 844](#)

---

## Configuring Flow Collection

This section describes the following tasks for configuring flow collection:

- [Configuring Destination FTP Servers for Flow Records on page 840](#)
- [Configuring a Packet Analyzer on page 841](#)
- [Configuring File Formats on page 841](#)
- [Configuring Interface Mappings on page 842](#)
- [Configuring Transfer Logs on page 842](#)
- [Configuring Retry Attempts on page 843](#)

### Configuring Destination FTP Servers for Flow Records

Flow collection destinations are where the compressed ASCII data files are sent after the cflowd records are collected and processed. To specify the destination FTP server, include the **destinations** statement at the **[edit services flow-collector]** hierarchy level. You can specify up to two FTP server destinations and include the password for each configured server. If two FTP servers are configured, the first server in the configuration is the primary server and the second is a backup server.

To configure a destination for flow collection files, include the **destinations** statement at the **[edit services flow-collector]** hierarchy level:

```
[edit services flow-collector]
destinations {
 ftp:url {
 password "password";
 }
}
```

To specify the destination FTP server, include the **ftp:url** statement. The value **url** is the FTP server address for the primary flow collection destination and can include macros.

When you include macros in the **ftp:url** statement, a directory can be created only for a single level. For example, the path **ftp://10.2.2.2/%m/%Y** expands to **ftp://10.2.2.2/01/2005**, and the software attempts to create the directory **01/2005** on the destination FTP server. If the **01/** directory already exists on the destination FTP server, the software creates the **/2005/ directory** one level down. If the **01/** directory does not exist on the destination FTP server, the software cannot create the **/2005/ directory**, and the FTP server destination will fail. For more information about macros, see [ftp](#).

To specify the FTP server password, include the **password "password"** statement. The password must be enclosed in quotation marks. You can specify up to two destination FTP servers. The first destination specified is considered the primary destination.

## Configuring a Packet Analyzer

You can specify values for the IP address and identifier of a packet analyzer to which the flow collector interface sends traffic for analysis. The values you specify here override any default values configured elsewhere.

To configure an IP address and identifier for the packet analyzer, include the **analyzer-address** and **analyzer-id** statements at the **[edit services flow-collector]** hierarchy level:

```
[edit services flow-collector]
analyzer-address address;
analyzer-id name;
```

## Configuring File Formats

You configure data file formats, name formats, and transfer characteristics for the flow collection files. File records are sent to the destination FTP server when the timer expires or when a preset number of records are received, whichever comes first.

To configure the flow collection file format, include the **file-specification** statement at the **[edit services flow-collector]** hierarchy level:

```
[edit services flow-collector]
file-specification {
 variant variant-number {
 data-format format;
 name-format format;
 transfer {
 record-level number;
 timeout seconds;
 }
 }
}
```

To set the data file format, include the **data-format** statement. To set the file name format, include the **name-format** statement. To set the export timer and file size thresholds, include the **transfer** statement and specify values for the **timeout** and **record-level** options.

For example, you can specify the name format as follows:

```
[edit services flow-collector file-specification variant variant-number]
name-format "cFlowd-py69Ni69-0-%D_%T-%I_%N.bcp.bi.gz";
```

In this example, **cFlowd-py69Ni69-0** is the static portion used verbatim, **%D** is the date in YYYYMMDD format, **%T** is the time in HHMMSS format, **%I** is the value of **ifAlias**, **%N** is the generation number, and **bcp.bi.gz** is a user-configured string. A number of macros are supported for expressing the date and time information in different ways; for a complete list, see the summary section for [name-format](#).

## Configuring Interface Mappings

You can match an input interface with a flow collector interface and apply the preset file specifications to the input interface.

To configure an interface mapping, include the **interface-map** statement at the **[edit services flow-collector]** hierarchy level:

```
[edit services flow-collector]
interface-map {
 collector interface-name;
 file-specification variant-number;
 interface-name {
 collector interface-name;
 file-specification variant-number;
 }
}
```

To configure the default flow collector and file specifications for all input interfaces, include the **file-specification** and **collector** statements at the **[edit services flow-collector interface-map]** hierarchy level. To override the default settings and apply flow collector and file specifications to a specific input interface, include the **file-specification** and **collector** statements at the **[edit services flow-collector interface-map *interface-name*]** hierarchy level.

## Configuring Transfer Logs

You can configure the filename, export interval, maximum size, and destination FTP server for log files containing the transfer activity history for a flow collector interface.

To configure a transfer log, include the **transfer-log-archive** statement at the **[edit services flow-collector]** hierarchy level:

```
[edit services flow-collector]
transfer-log-archive {
 archive-sites {
 ftp:url {
 password "password";
 username username;
 }
 }
 filename-prefix prefix;
 maximum-age minutes;
}
```

To configure the destination for archiving files, include the **archive-sites** statement. Specify the filename as follows:

```
[edit services flow-collector transfer-log]
filename "cFlowd-py69Ni69-0-%D_%T";
```

where **cFlowd-py69Ni69-0** is the static portion used verbatim, **%D** is the date in YYYYMMDD format, and **%T** is the time in HHMMSS format.

You can optionally include the following statements:

- **filename-prefix**—Sets a standard prefix for all the logged files.
- **maximum-age**—Specifies the duration a file remains on the server. The range is 1 through 360 minutes.

## Configuring Retry Attempts

You can specify values for situations in which the flow collector interface needs more than one attempt to transfer log files to the FTP server:

- Maximum number of retry attempts
- Amount of time the flow collector interface waits between successive retries

To configure retry settings, include the **retry** and **retry-delay** statements at the **[edit services flow-collector]** hierarchy level:

```
retry number;
retry-delay seconds;
```

The **retry** value can be from 0 through 10. The **retry-delay** value can be from 0 through 60 seconds.

### Related Documentation

- *Example: Configuring Flow Collection*

---

## Sending cflowd Records to Flow Collector Interfaces

To specify a flow collector interface as the destination for cflowd records coming from a services PIC, include the **collector-pic** statement at the **[edit forwarding-options monitoring group-name family inet output flow-export-destination]** hierarchy level:

```
[edit forwarding-options monitoring group-name family inet output flow-export-destination]
collector-pic;
```

You can select either the flow collector interface or a cflowd server as the destination for cflowd records, but not both at the same time.

- Related Documentation**
- [Flow Collection Overview on page 839](#)
  - [Configuring Flow Collection on page 840](#)

  - *Example: Configuring Flow Collection*

---

## Configuring Flow Collection Mode and Interfaces on Services PICs

---

You can select the services PIC to run in either flow collection mode or monitoring mode, but not both.

To set the services PIC to run in flow collection mode, include the **flow-collector** statement at the **[edit chassis fpc slot-number pic pic-number monitoring-services application]** hierarchy level:

```
[edit chassis fpc slot-number pic pic-number monitoring-services application]
flow-collector;
```

For further information on configuring chassis properties, see the *Junos OS Administration Library for Routing Devices*.

To specify flow collection interfaces, you configure the **cp** interface at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
cp-fpc/pic/port {
 ...
}
```

- [Example: Configuring Junos Capture Vision on page 855](#)

## Understanding Junos Capture Vision

---

Junos Capture Vision (known as dynamic flow capture in Junos OS Releases earlier than 13.2) enables you to capture packet flows on the basis of dynamic filtering criteria. Specifically, you can use this feature to forward passively monitored packet flows that match a particular filter list to one or more destinations using an on-demand control protocol.

This topic contains the following sections:

- [Junos Capture Vision Architecture on page 847](#)
- [Liberal Sequence Windowing on page 848](#)
- [Intercepting IPv6 Flows on page 849](#)

## Junos Capture Vision Architecture

The architecture consists of one or more *control sources* that send requests to a Juniper Networks router to monitor incoming data, and then forward any packets that match specific filter criteria to a set of one or more *content destinations*. The architectural components are defined as follows:

- **Control source**—A client that monitors electronic data or voice transfer over the network. The control source sends filter requests to the Juniper Networks router using the Dynamic Task Control Protocol (DTCP), specified in draft-cavuto-dtcp-03.txt at <http://www.ietf.org/internet-drafts>. The control source is identified by a unique identifier and an optional list of IP addresses.
- **Monitoring platform**—A T Series or M320 router containing one or more Dynamic Flow Capture (DFC) PICs, which support dynamic flow capture processing. The monitoring platform processes the requests from the control sources, creates the filters, monitors

incoming data flows, and sends the matched packets to the appropriate content destinations.

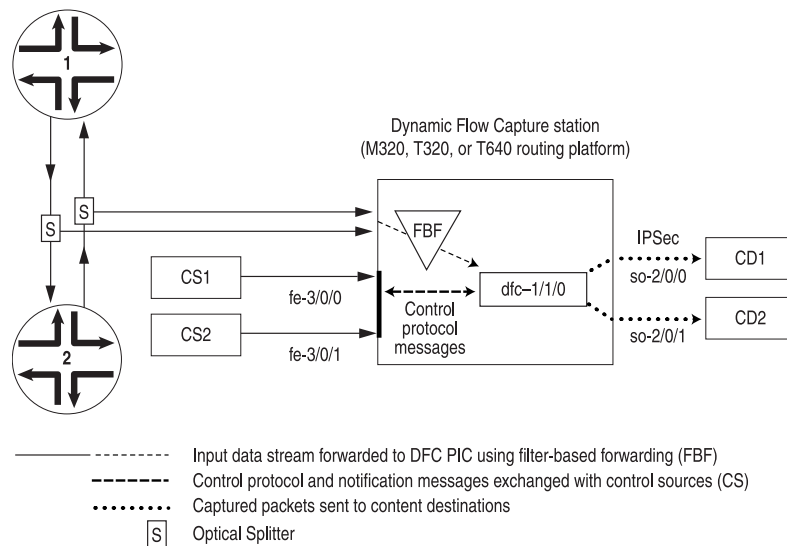

- Content destination—Recipient of the matched packets from the monitoring platform. Typically the matched packets are sent using an IP Security (IPsec) tunnel from the monitoring platform to another router connected to the content destination. The content destination and the control source can be physically located on the same host. For more information on IPsec tunnels, see *Junos VPN Site Secure*.

**NOTE:** The Junos Capture Vision PIC (either a Monitoring Services III PIC or Multiservices 400 PIC) forwards the entire packet content to the content destination, rather than to a content record as is done with cflowd or flow aggregation version 9 templates.

Figure 32 on page 848 shows a sample topology. The number of control sources and content destinations is arbitrary.

**Figure 32: Junos Capture Vision Topology**

g017075

## Liberal Sequence Windowing

Each DTCP packet (add, delete, list, and refresh packets) contains a 64-bit sequence number to identify the order of the packets. Because the network is connectionless, the DTCP packets can arrive out of order to the router running the Junos Capture Vision application.

The *liberal sequence window* feature implements a negative window for the sequence numbers received in the DTCP packets. It enables the Junos Capture Vision application to accept not only DTCP packets with sequence numbers greater than those previously received, but also DTCP packets with lesser sequence numbers, up to a certain limit. This limit is the negative window size; the positive and negative window sizes are +256 and -256 respectively, relative to the current maximum sequence number received. No

configuration is required to activate this feature; the window sizes are hard-coded and nonconfigurable.

## Intercepting IPv6 Flows

Starting with Junos OS Release 11.4, Junos Capture Vision also supports intercepting IPv6 flows in M320, T320, T640, and T1600 routers with a Multiservices 400 or Multiservices 500 PIC. Junos Capture Vision can intercept passively monitored IPv6 traffic only. All support for IPv4 interception remains the same. The interception of IPv6 traffic happens in the same way the filters capture IPv4 flows. With the introduction of IPv6 interception, both IPv4 and IPv6 filters can coexist. The mediation device, however, cannot be located in an IPv6 network.

Junos Capture Vision does not support interception of VPLS and MPLS traffic. The application cannot intercept Address Resolution Protocol (ARP) or other Layer 2 exception packets. The interception filter can be configured to timeout based on factors like total time (seconds), idle time (seconds), total packets or total data transmitted (bytes).

## Configuring Junos Capture Vision

This section describes the following tasks for configuring Junos Capture Vision:

- [Configuring the Capture Group on page 849](#)
- [Configuring the Content Destination on page 850](#)
- [Configuring the Control Source on page 851](#)
- [Configuring the DFC PIC Interface on page 852](#)
- [Configuring the Firewall Filter on page 853](#)
- [Configuring System Logging on page 853](#)
- [Configuring Tracing Options for Junos Capture Vision Events on page 854](#)
- [Configuring Thresholds on page 854](#)
- [Limiting the Number of Duplicates of a Packet on page 855](#)

### Configuring the Capture Group

A capture group defines a profile of Junos Capture Vision configuration information. The static configuration includes information about control sources, content destinations, and notification destinations. Dynamic configuration is added through interaction with control sources using a control protocol.

To configure a capture group, include the **capture-group** statement at the **[edit services dynamic-flow-capture]** hierarchy level:

```
capture-group client-name {
 content-destination identifier {
 address address;
 }
}
```

```

 hard-limit bandwidth;
 hard-limit-target bandwidth;
 soft-limit bandwidth;
 soft-limit-clear bandwidth;
 ttl hops;
}
control-source identifier {
 allowed-destinations [destinations];
 minimum-priority value;
 no-syslog;
 notification-targets address port port-number;
 service-port port-number;
 shared-key value;
 source-addresses [addresses];
}
duplicates-dropped-periodicity seconds;
input-packet-rate-threshold rate;
interfaces interface-name;
max-duplicates number;
pic-memory-threshold percentage percentage;
}

```

To specify the **capture-group**, assign it a unique **client-name** that associates the information with the requesting control sources.

## Configuring the Content Destination

You must specify a destination for the packets that match DFC PIC filter criteria. To configure the content destination, include the **content-destination** statement at the [edit **services dynamic-flow-capture capture-group client-name**] hierarchy level:

```

content-destination identifier {
 address address;
 hard-limit bandwidth;
 hard-limit-target bandwidth;
 soft-limit bandwidth;
 soft-limit-clear bandwidth;
 ttl hops;
}

```

Assign the **content-destination** a unique **identifier**. You must also specify its IP address and you can optionally include additional settings:

- **address**—The DFC PIC interface appends an IP header with this destination address on the matched packet (with its own IP header and contents intact) and sends it out to the content destination.
- **ttl**—The time-to-live (TTL) value for the IP-IP header. By default, the TTL value is 255. Its range is 0 through 255.
- **Congestion thresholds**—You can specify per-content destination bandwidth limits that control the amount of traffic produced by the DFC PIC during periods of congestion. The thresholds are arranged in two pairs: **hard-limit** and **hard-limit-target**, and **soft-limit** and **soft-limit-clear**. You can optionally include one or both of these paired settings. All four settings are 10-second average bandwidth values in bits per second. Typically

**soft-limit-clear** < **soft-limit** < **hard-limit-target** < **hard-limit**. When the content bandwidth exceeds the **soft-limit** setting:

1. A congestion notification message is sent to each control source of the criteria that point to this content destination
2. If the control source is configured for **syslog**, a system log message is generated.
3. A latch is set, indicating that the control sources have been notified. No additional notification messages are sent until the latch is cleared, when the bandwidth falls below the **soft-limit-clear** value.

When the bandwidth exceeds the **hard-limit** value:

1. Junos Capture Vision begins deleting criteria until the bandwidth falls below the **hard-limit-target** value.
2. For each criterion deleted, a CongestionDelete notification is sent to the control source for that criterion.
3. If the control source is configured for **syslog**, a log message is generated.

The application evaluates criteria for deletion using the following data:

- **Priority**—Lower priority criteria are purged first, after adjusting for control source minimum priority.
- **Bandwidth**—Higher bandwidth criteria are purged first.
- **Timestamp**—The more recent criteria are purged first.

## Configuring the Control Source

You configure information about the control source, including allowed source addresses and destinations and authentication key values. To configure the control source information, include the **control-source** statement at the **[edit services dynamic-flow-capture capture-group *client-name*]** hierarchy level:

```
control-source identifier {
 allowed-destinations [destination-identifiers];
 minimum-priority value;
 no-syslog;
 notification-targets address port port-number;
 service-port port-number;
 shared-key value;
 source-addresses [addresses];
}
```

Assign the **control-source** statement a unique ***identifier***. You can also include values for the following statements:

- **allowed-destinations**—One or more content destination identifiers to which this control source can request that matched data be sent in its control protocol requests. If you do not specify any content destinations, all available destinations are allowed.
- **minimum-priority**—Value assigned to the control source that is added to the priority of the criteria in the DTCP ADD request to determine the total priority for the criteria. The

lower the value, the higher the priority. By default, **minimum-priority** has a value of 0 and the allowed range is 0 through 254.

- **notification-targets**—One or more destinations to which the DFC PIC interface can log information about control protocol-related events and other events such as PIC bootup messages. You configure each **notification-target** entry with an IP **address** value and a User Datagram Protocol (UDP) **port** number.
- **service-port**—UDP port number to which the control protocol requests are directed. Control protocol requests that are not directed to this port are discarded by DFC PIC interfaces.
- **shared-key**—20-byte authentication key value shared between the control source and the DFC PIC monitoring platform.
- **source-addresses**—One or more allowed IP addresses from which the control source can send control protocol requests to the DFC PIC monitoring platform. These are /32 addresses.

## Configuring the DFC PIC Interface

You specify the interface that interacts with the control sources configured in the same capture group. A Monitoring Services III PIC can belong to only one capture group, and you can configure only one PIC for each group.

To configure a DFC PIC interface, include the **interfaces** statement at the **[edit services dynamic-flow-capture capture-group client-name]** hierarchy level:

```
interfaces interface-name;
```

You specify DFC interfaces using the **dfc-** identifier at the **[edit interfaces]** hierarchy level. You must specify three logical units on each DFC PIC interface, numbered 0, 1, and 2. You cannot configure any other logical interfaces.

- **unit 0** processes control protocol requests and responses.
- **unit 1** receives monitored data.
- **unit 2** transmits the matched packets to the destination address.

The following example shows the configuration necessary to set up a DFC PIC interface and intercept both IPv4 and IPv6 traffic:

```
[edit interfaces dfc-0/0/0]
unit 0 {
 family inet {
 filter {
 output high; #Firewall filter to route control packets
 # through 'network-control' forwarding class. Control packets
 # are loss sensitive.
 }
 }
 address 10.1.0.0/32 { # DFC PIC address
 destination 10.36.100.1; # DFC PIC address used by
 # the control source to correspond with the
 # monitoring platform
 }
}
```

```

 }
 }
 unit 1 { # receive data packets on this logical interface
 family inet; # receive IPv4 traffic for interception
 family inet6; # receive IPv6 traffic for interception
 }
 unit 2 { # send out copies of matched packets on this logical interface
 family inet;
 }
}

```

In addition, you must configure Junos Capture Vision to run on the DFC PIC in the correct chassis location. The following example shows this configuration at the **[edit chassis]** hierarchy level:

```

fpc 0 {
 pic 0 {
 monitoring-services application dynamic-flow-capture;
 }
}

```

For more information on configuring chassis properties, see the *Junos OS Administration Library for Routing Devices*.

## Configuring the Firewall Filter

You can specify the firewall filter to route control packets through the network control forwarding class. The control packets are loss sensitive. To configure the firewall filter, include the following statements at the **[edit]** hierarchy level:

```

firewall {
 family inet {
 filter high {
 term all {
 then forwarding-class network-control;
 }
 }
 }
}

```

## Configuring System Logging

By default, control protocol activity is logged as a separate system log facility, **dfc**. To modify the filename or level at which control protocol activity is recorded, include the following statements at the **[edit syslog]** hierarchy level:

```

file dfc.log {
 dfc any;
}

```

To cancel logging, include the **no-syslog** statement at the **[edit services dynamic-flow-capture capture-group *client-name* control-source *identifier*]** hierarchy level:

```

no-syslog;

```

**NOTE:** Junos Capture Vision (dfc-) interface supports up to 10,000 filter criteria. When more than 10,000 filters are added to the interface, the filters are accepted, but system log messages are generated indicating that the filter is full.

---

## Configuring Tracing Options for Junos Capture Vision Events

You can enable tracing options for Junos Capture Vision events by including the **traceoptions** statement at the **[edit services dynamic-flow-capture]** hierarchy level.

When you include the **traceoptions** configuration, you can also specify the trace file name, maximum number of trace files, the maximum size of trace files, and whether the trace file can be read by all users or not.

To enable tracing options for Junos Capture Vision events, include the following configuration at the **[edit services dynamic-flow-capture]** hierarchy level:

```
traceoptions{
 file filename <files number> <size size> <world-readable | non-world-readable>;
}
```

To disable tracing for Junos Capture Vision events, delete the **traceoptions** configuration from the **[edit services dynamic-flow-capture]** hierarchy level.

**NOTE:** In Junos OS releases earlier than 9.2R1, tracing of Junos Capture Vision was enabled by default, and the logs were saved to the `/var/log/dfcd` directory.

---

## Configuring Thresholds

You can optionally specify threshold values for the following situations in which warning messages will be recorded in the system log:

- Input packet rate to the DFC PIC interfaces
- Memory usage on the DFC PIC interfaces

To configure threshold values, include the **input-packet-rate-threshold** or **pic-memory-threshold** statements at the **[edit services dynamic-flow-capture capture-group *client-name*]** hierarchy level:

```
input-packet-rate-threshold rate;
pic-memory-threshold percentage percentage;
```

If these statements are not configured, no threshold messages are logged. The threshold settings are configured for the capture group as a whole.

The range of configurable values for the **input-packet-rate-threshold** statement is 0 through 1 Mpps. The PIC calibrates the value accordingly; the Monitoring Services III PIC caps the threshold value at 300 Kpps and the Multiservices 400 PIC uses the full

configured value. The range of values for the **pic-memory-threshold** statement is 0 to 100 percent.

## Limiting the Number of Duplicates of a Packet

You can optionally specify the maximum number of duplicate packets the DFC PIC is allowed to generate from a single input packet. This limitation is intended to reduce the load on the PIC when packets are sent to multiple destinations. When the maximum number is reached, the duplicates are sent to the destinations with the highest criteria class priority. Within classes of equal priority, criteria having earlier timestamps are selected first.

To configure this limitation, include the **max-duplicates** statement at the **[edit services dynamic-flow-capture capture-group *client-name*]** hierarchy level:

```
max-duplicates number;
```

You can also apply the limitation on a global basis for the DFC PIC by including the **g-max-duplicates** statement at the **[edit services dynamic-flow-capture]** hierarchy level:

```
g-max-duplicates number;
```

By default, the maximum number of duplicates is set to 3. The range of allowed values is 1 through 64. A setting for **max-duplicates** for an individual capture-group overrides the global setting.

In addition, you can specify the frequency with which the application sends notifications to the affected control sources that duplicates are being dropped because the threshold has been reached. You configure this setting at the same levels as the maximum duplicates settings, by including the **duplicates-dropped-periodicity** statement at the **[edit services dynamic-flow-capture capture-group *client-name*]** hierarchy level or the **g-duplicates-dropped-periodicity** statement at the **[edit services dynamic-flow-capture]** hierarchy level:

```
duplicates-dropped-periodicity seconds;
g-duplicates-dropped-periodicity seconds;
```

As with the **g-max-duplicates** statement, the **g-duplicates-dropped-periodicity** statement applies the setting globally for the application and is overridden by a setting applied at the capture-group level. By default, the frequency for sending notifications is 30 seconds.

---

## Example: Configuring Junos Capture Vision

The following example includes all parts of a complete Junos Capture Vision configuration.

Configure the Junos Capture Vision PIC interface:

```
[edit interfaces dfc-0/0/0]
unit 0 {
 family inet {
```

```
filter {
 output high; #Firewall filter to route control packets
 # through 'network-control' forwarding class. Control packets
 # are loss sensitive.
}
address 10.1.0.0/32 { # DFC PIC address
 destination 10.36.100.1; # DFC PIC address used by
 # the control source to correspond with the
 # monitoring platform
}
}
unit 1 { # receive data packets on this logical interface
 family inet;
 family inet6;
}
unit 2 { # send out copies of matched packets on this logical interface
 family inet;
}
```

Configure the capture group:

```
services dynamic-flow-capture {
 capture-group g1 {
 interfaces dfc-0/0/0;
 input-packet-rate-threshold 90k;
 pic-memory-threshold percentage 80;
 control-source cs1 {
 source-addresses 10.36.41.1;
 service-port 2400;
 notification-targets {
 10.36.41.1 port 2100;
 }
 shared-key "9ASxdsYoX7wg4aHk";
 allowed-destinations cd1;
 }
 content-destination cd1 {
 address 10.36.70.2;
 ttl 244;
 }
 }
}
```

Configure filter-based forwarding (FBF) to the Junos Capture Vision PIC interface, logical unit 1.

For more information about configuring passive monitoring interfaces, see [“Enabling Passive Flow Monitoring” on page 830](#).

```
interfaces so-1/2/0 {
 encapsulation ppp;
 unit 0 {
 passive-monitor-mode;
 family inet {
 filter {
 input catch;
 }
 }
 }
}
```

```

 }
 }
}

```

Configure the firewall filter:

```

firewall {
 filter catch {
 interface-specific;
 term def {
 then {
 count counter;
 routing-instance fbf_inst;
 }
 }
 }
 family inet {
 filter high {
 term all {
 then forwarding-class network-control;
 }
 }
 }
}

```

Configure a forwarding routing instance. The next hop points specifically to the logical interface corresponding to **unit 1**, because only this particular logical unit is expected to relay monitored data to the Junos Capture Vision PIC.

```

routing-instances fbf_inst {
 instance-type forwarding;
 routing-options {
 static {
 route 0.0.0.0/0 next-hop dfc-0/0/0.1;
 }
 }
}

```

Configure routing table groups:

```

[edit]
routing-options {
 interface-routes {
 rib-group inet common;
 }
 rib-groups {
 common {
 import-rib [inet.0 fbf_inst.inet.0];
 }
 }
 forwarding-table {
 export pplb;
 }
}

```

Configure interfaces to the control source and content destination:

```

interfaces fe-4/1/2 {
 description "to cs1 from dfc";
}

```

```
unit 0 {
 family inet {
 address 10.36.41.2/30;
 }
}
}
interfaces ge-7/0/0 {
 description "to cd1 from dfc";
 unit 0 {
 family inet {
 address 10.36.70.1/30;
 }
 }
}
```

## Understanding Junos Packet Vision

---

Junos Capture Vision (previously known as dynamic flow capture) enables you to capture packet flows on the basis of dynamic filtering criteria, using Dynamic Tasking Control Protocol (DTCP) requests. Junos Packet Vision is a Junos OS application that performs lawful intercept of packet flows, using Dynamic Tasking Control Protocol (DTCP). The application extends the use of DTCP to intercept IPv4 and IPv6 packets in an active monitoring router and send a copy of packets that match filter criteria to one or more content destinations. Junos Packet Vision was previously known as flow-tap application.

Junos Packet Vision data can be used in the following applications:

- Flexible trend analysis for detection of new security threats
- Lawful intercept

Junos Packet Vision is supported on M Series and T Series routers, except M160 and TX Matrix routers. Junos Packet Vision filters are applied on all IPv4 traffic and do not add any perceptible delay in the forwarding path. Junos Packet Vision filters can also be applied on IPv6 traffic. For security, filters installed by one client are not visible to others and the CLI configuration does not reveal the identity of the monitored target. A lighter version of the application is supported on MX Series routers only.

### Related Documentation

- [Junos Packet Vision Architecture on page 860](#)
- [Configuring Junos Packet Vision on page 861](#)
- [Configuring FlowTapLite on page 864](#)
- [Examples: Configuring Junos Packet Vision on page 865](#)

## Junos Packet Vision Architecture

---

The Junos Packet Vision (previously known as Flow-Tap) architecture consists of one or more *mediation devices* that send requests to a Juniper Networks router to monitor incoming data and forward any packets that match specific filter criteria to a set of one or more *content destinations*:

- **Mediation device**—A client that monitors electronic data or voice transfer over the network. The mediation device sends filter requests to the Juniper Networks router using the DTCP. The clients are not identified for security reasons, but have permissions defined by a set of special login classes. Each system can support up to 16 different mediation devices for each user, up to a maximum of 64 mediation devices for the whole system.
- **Monitoring platform**—An M Series or T Series router containing one or more Adaptive Services (AS) or Multiservices PICs, which are configured to support the Junos Packet Vision application. The monitoring platform processes the requests from the mediation devices, applies the dynamic filters, monitors incoming data flows, and sends the matched packets to the appropriate content destinations.
- **Content destination**—Recipient of the matched packets from the monitoring platform. Typically the matched packets are sent using an IP Security (IPsec) tunnel from the monitoring platform to another router connected to the content destination. The content destination and the mediation device can be physically located on the same host. For more information about IPsec tunnels, see *Junos VPN Site Secure*.
- **Dynamic filters**—Firewall filters automatically generated by the Packet Forwarding Engine and applied to all routing instances. Each term in the filter includes a **flow-tap** action that is similar to the existing **sample** or **port-mirroring** actions. As long as one of the filter terms matches an incoming packet, the router copies the packet and forwards it to the Adaptive Services or Multiservices PIC that is configured for Junos Packet Vision service. The Adaptive Services or Multiservices PIC runs the packet through the client filters and sends a copy to each matching content destination.

Following is a sample filter configuration; note that it is dynamically generated by the router (no user configuration is required):

```
filter combined_LEA_filter {
 term LEA1_filter {
 from {
 source-address 1.2.3.4;
 destination-address 3.4.5.6;
 }
 then {
 flow-tap;
 }
 }
 term LEA2_filter {
 from {
 source-address 10.1.1.1;
 source-port 23;
 }
 }
}
```

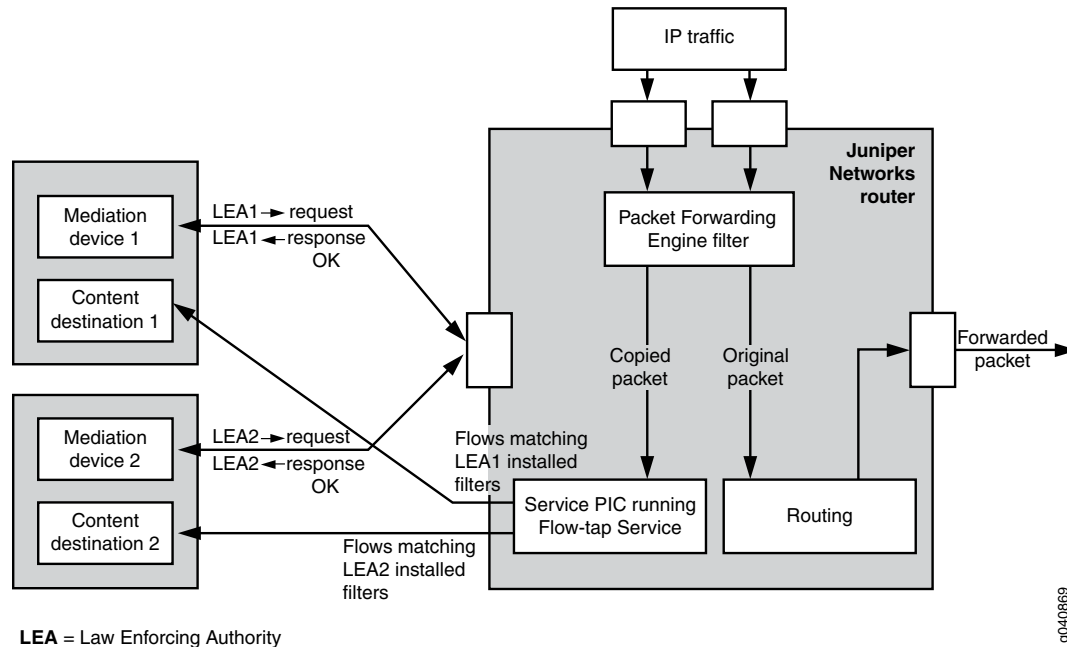

```

 then {
 flow-tap;
 }
 }
}

```

Figure 33 on page 861 shows a sample topology that uses two mediation devices and two content destinations.

Figure 33: Junos Packet Vision Topology

#### Related Documentation

- [Understanding Junos Packet Vision on page 859](#)
- [\[edit services flow-tap\] Hierarchy Level on page 1631](#)
- [Configuring Junos Packet Vision on page 861](#)
- [Examples: Configuring Junos Packet Vision on page 865](#)

## Configuring Junos Packet Vision

This topic explains Junos Packet Vision (previously known as Flow-Tap) configuration, and contains the following sections:

- [Configuring the Junos Packet Vision Interface on page 861](#)
- [Strengthening Junos Packet Vision Security on page 862](#)
- [Restrictions on Junos Packet Vision Services on page 863](#)

### Configuring the Junos Packet Vision Interface

To configure an adaptive services interface for flow-tap service, include the **interface** statement at the **[edit services flow-tap]** hierarchy level:

```
interface sp-fpc/pic/port.unit-number;
```

You can assign any Adaptive Services or Multiservices PIC in the active monitoring router for Junos Packet Vision, and use any logical unit on the PIC.

You can specify the type of traffic for which you want to apply the Junos Packet Vision service by including the **family inet | inet6** statement. If the **family** statement is not included, the Junos Packet Vision service is, by default, applied to the IPv4 traffic. To apply Junos Packet Vision service to IPv6 traffic, you must include the **family inet6** statement in the configuration. To enable the Junos Packet Vision service for IPv4 and IPv6 traffic, you must explicitly configure the **family** statement for both **inet** and **inet6** families.

**NOTE:** You cannot configure Junos Capture Vision (previously known as dynamic flow capture) and Junos Packet Vision services on the same router simultaneously.

You must also configure the logical interface at the **[edit interfaces]** hierarchy level:

```
interface sp-fpc/pic/port {
 unit logical-unit-number {
 family inet;
 family inet6;
 }
}
```

**NOTE:** If you do not include the **family inet6** statement in the configuration, IPv6 flows will not be intercepted.

## Strengthening Junos Packet Vision Security

You can add an extra level of security to Dynamic Tasking Control Protocol (DTCP) transactions between the mediation device and the router by enabling DTCP sessions on top of the SSH layer. To configure SSH settings, include the **flow-tap-dtcp** statement at the **[edit system services]** hierarchy level:

```
flow-tap-dtcp {
 ssh {
 connection-limit value;
 rate-limit value;
 }
}
```

To configure client permissions for viewing and modifying Junos Packet Vision configurations and for receiving tapped traffic, include the **permissions** statement at the **[edit system login class class-name]** hierarchy level:

```
permissions [permissions];
```

The permissions needed to use Junos Packet Vision features are as follows:

- **flow-tap**—Can view Junos Packet Vision configuration

- **flow-tap-control**—Can modify Junos Packet Vision configuration
- **flow-tap-operation**—Can tap flows

You can also specify user permissions on a RADIUS server, for example:

```
Bob Auth-Type := Local, User-Password = = "abc123"
Juniper-User-Permissions = "flow-tap-operation"
```

For details on **[edit system]** and RADIUS configuration, see the *Junos OS Administration Library for Routing Devices*.

## Restrictions on Junos Packet Vision Services

The following restrictions apply to Junos Packet Vision services:

- You cannot configure Junos Capture Vision and Junos Packet Vision features on the same router simultaneously.
- On routers that support LMNR-based FPCs, you cannot configure the Junos Packet Vision for IPv6 along with port mirroring or sampling of IPv6 traffic. This restriction applies even if the router does not have any LMNR-based FPC installed in it. However, there is no restriction on configuring Junos Packet Vision on routers that are configured for port mirroring or sampling of IPv4 traffic.
- Junos Packet Vision does not support interception of MPLS and virtual private LAN service (VPLS).
- Junos Packet Vision cannot intercept Address Resolution Protocol (ARP) and other Layer 2 exceptions.
- IPv4 and IPv6 intercept filters can coexist on a system, subject to a combined maximum of 100 filters.
- When Junos Capture Vision process or the Adaptive Services or Multiservices PIC configured for Junos Packet Vision restarts, all filters are deleted and the mediation devices are disconnected.
- Only the first fragment of an IPv4 fragmented packet stream is sent to the content destination.
- Port mirroring might not work in conjunction with Junos Packet Vision.
- Running the Junos Packet Vision over an IPsec tunnel on the same router can cause packet loops and is not supported.
- M10i routers do not support the standard Junos Packet Vision, but do support FlowTapLite (see [“Configuring FlowTapLite” on page 864](#)). Junos Packet Vision and FlowTapLite cannot be configured simultaneously on the same chassis.
- PIC-based flow-tap is not supported on M7i and M10i routers equipped with an Enhanced Compact Forwarding Engine Board (CFEB-E).
- You cannot configure Junos Packet Vision on channelized interfaces.

### Related Documentation

- [Configuring FlowTapLite on page 864](#)

## Configuring FlowTapLite

A lighter version of the flow-tap application is available on MX Series routers and also on M320 routers with Enhanced III Flexible PIC Concentrators (FPCs). All of the functionality resides in the Packet Forwarding Engine rather than a service PIC or Dense Port Concentrator (DPC).

**NOTE:** On M320 routers only, if the replacement of FPCs results in a mode change, you must restart the dynamic flow capture process manually by disabling and then re-enabling the CLI configuration.

FlowTapLite uses the same DTCP-SSH architecture to install the Dynamic Tasking Control Protocol (DTCP) filters and authenticate the users as the original flow-tap application and supports up to 3000 filters per chassis.

**NOTE:** The original flow-tap application and FlowTapLite cannot be used at the same time.

To configure FlowTapLite, include the **flow-tap** statement at the **[edit services]** hierarchy level:

```
flow-tap {
 tunnel-interface interface-name;
}
```

For the Packet Forwarding Engine to encapsulate the intercepted packet, it must send the packet to a tunnel logical (**vt-**) interface. You need to allocate a tunnel interface and assign it to the dynamic flow capture process for FlowTapLite to use. To create the tunnel interface, include the following configuration:

```
chassis {
 fpc number {
 pic number {
 tunnel-services {
 bandwidth (1g | 10g);
 }
 }
 }
}
```

**NOTE:** Currently FlowTapLite supports only one tunnel interface per instance.

For more information about this configuration, see the *Junos OS Administration Library for Routing Devices*.

To configure the logical interfaces and assign them to the dynamic flow capture process, include the following configuration:

```

interfaces {
 vt-fpc/pic/port {
 unit 0 {
 family inet;
 family inet6;
 }
 }
}

```

**NOTE:** If a service PIC or DPC is available, you can use its tunnel interface for the same purpose.

**NOTE:** If you do not include the `family inet6` statement in the configuration, IPv6 flows will not be intercepted.

**NOTE:** With FlowTapLite configured and traceoptions enabled, if you add more than two content destinations by including the X-JTAP-CDEST-DEST-ADDRESS line in the Dynamic Tasking Control Protocol (DTCP) parameter file and initiate a DTCP session by sending a DTCP ADD message, a '400 BAD request' message is received. Although you can specify more than two content destinations in the DTCP file that is sent from the mediation device, this error message occurs when the DTCP ADD message is sent. This behavior is expected with more than two content destinations. You must specify only two content destinations per DTCP ADD message.

## Examples: Configuring Junos Packet Vision

The following example shows all parts of a complete Junos Packet Vision configuration with IPv4 and IPv6 flow intercepts

**NOTE:** The following example applies only to M Series and T Series routers, except M160 and TX Matrix routers. For MX Series routers, because the flow-tap application resides in the Packet Forwarding Engine rather than a service PIC or Dense Port Concentrator (DPC), the Packet Forwarding Engine must send the packet to a tunnel logical (vt-) interface to encapsulate the intercepted packet. In such a scenario, you need to allocate a tunnel interface and assign it to the dynamic flow capture process for FlowTapLite to use.

```
services {
 flow-tap {
 interface sp-1/2/0.100;
 }
}
interfaces {
 sp-1/2/0 {
 unit 100 {
 family inet;
 family inet6;
 }
 }
}
system {
 services {
 flow-tap-dtcp {
 ssh {
 connection-limit 5;
 rate-limit 5;
 }
 }
 }
 login {
 class ft-class {
 permissions flow-tap-operation;
 }
 user ft-user1 {
 class ft-class;
 authentication {
 encrypted-password "xxxx";
 }
 }
 }
}
```

The following example shows a FlowTapLite configuration that intercepts IPv4 and IPv6 flows:

```
system {
 login {
 class flowtap {
 permissions flow-tap-operation;
 }
 user ftap {
 uid 2000;
 class flowtap;
 authentication {
 encrypted-password "1nZfwNn4L$TWi/oxFwFZyOyyxN/87Jv0"; ##
 SECRET-DATA
 }
 }
 }
 services {
 flow-tap-dtcp {
 ssh;
 }
 }
}
```

```
 }
 }
 chassis {
 fpc 0 {
 pic 0 {
 tunnel-services {
 bandwidth 10g;
 }
 }
 }
 }
 interfaces {
 vt-0/0/0 {
 unit 0 {
 family inet;
 family inet6;
 }
 }
 }
 services {
 flow-tap {
 tunnel-interface vt-0/0/0.0;
 }
 }
}
```

## Configuring Traffic Sampling

---

Traffic sampling enables you to copy traffic to a Physical Interface Card (PIC) that performs flow accounting while the router forwards the packet to its original destination. You can configure the router to perform sampling in either of two locations:

- On the Routing Engine, using the sampled process. To select this method, use a filter (input or output) with a matching term that contains the **then sample** statement.
- On the Monitoring Services, Adaptive Services, or Multiservices PIC.

**NOTE:** Routing Engine based sampling is not supported on VPN routing and forwarding (VRF) instances.

The following sections provide configuration instructions for traffic sampling:

- [Configuring Firewall Filter for Traffic Sampling on page 871](#)
- [Configuring Traffic Sampling on a Logical Interface on page 873](#)
- [Disabling Traffic Sampling on page 874](#)
- [Sampling Once on page 874](#)
- [Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets on page 875](#)
- [Configuring Traffic Sampling Output on page 876](#)
- [Tracing Traffic Sampling Operations on page 878](#)
- [Traffic Sampling Examples on page 878](#)

## Configuring Firewall Filter for Traffic Sampling

To configure firewall filter for traffic sampling, you must perform the following tasks:

- Create a firewall filter to apply to the logical interfaces being sampled by including the **filter** statement at the **[edit firewall family *family-name*]** hierarchy level. In the filter **then** statement, you must specify the action modifier **sample** and the action **accept**.

```
filter filter-name {
 term term-name {
 then {
 sample;
 accept;
 }
 }
}
```

For more information about firewall filter actions and action modifiers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

- Apply the filter to the interfaces on which you want to sample traffic by including the **address** and **filter** statements at the **[edit interfaces *interface-name* unit *logical-unit-number* family *family-name*]** hierarchy level:

```
address address {
}
filter {
 input filter-name;
}
```

The following prerequisites apply to M, MX, and T Series routers when you configure traffic sampling on interfaces and in firewall filters:

- If you configure a sample action in a firewall filter for an inet or inet6 family on an interface without configuring the forwarding-options settings, operational problems might occur if you also configure port mirroring or flow-tap functionalities. In such a scenario, all the packets that match the firewall filter are incorrectly sent to the service PIC.
- If you include the **then sample** statement at the **[edit firewall family inet filter *filter-name* term *term-name*]** hierarchy level to specify a sample action in a firewall filter for IPv4 packets, you must also include the **family inet** statement at the **[edit forwarding-options sampling]** hierarchy level or the **instance *instance-name* family inet** statement at the **[edit forwarding-options sampling]** hierarchy level. Similarly, if you include the **then sample** statement at the **[edit firewall family inet6 filter *filter-name* term *term-name*]** hierarchy level to specify a sample action in a firewall filter for IPv6 packets, you must also include **family inet6** statement at the **[edit forwarding-options sampling]** hierarchy level or the **instance *instance-name* family inet6** statement at the **[edit forwarding-options sampling]** hierarchy level. Otherwise, a commit error occurs when you attempt to commit the configuration.
- Also, if you configure traffic sampling on a logical interface by including the sampling input or sampling output statements at the **[edit interface *interface-name* unit *logical-unit-number*]** hierarchy level, you must also include the **family inet | inet6** statement at the **[edit forwarding-options sampling]** hierarchy level, or the **instance *instance-name* family inet | inet6** statement at the **[edit forwarding-options sampling]** hierarchy level.

## Configuring Traffic Sampling on a Logical Interface

To configure traffic sampling on any logical interface, enable sampling and specify a non zero sampling rate by including the sampling statement at the **[edit forwarding-options]** hierarchy level:

```
sampling {
 input {
 rate number;
 run-length number;
 max-packets-per-second number;
 maximum-packet-length bytes;
 }
}
```

When you use Routing Engine-based sampling, specify the threshold traffic value by including the **max-packets-per-second** statement. The value is the maximum number of packets to be sampled, beyond which the sampling mechanism begins dropping packets. The range is from 0 through 65,535. A value of 0 instructs the Packet Forwarding Engine not to sample any packets. The default value is 1000.

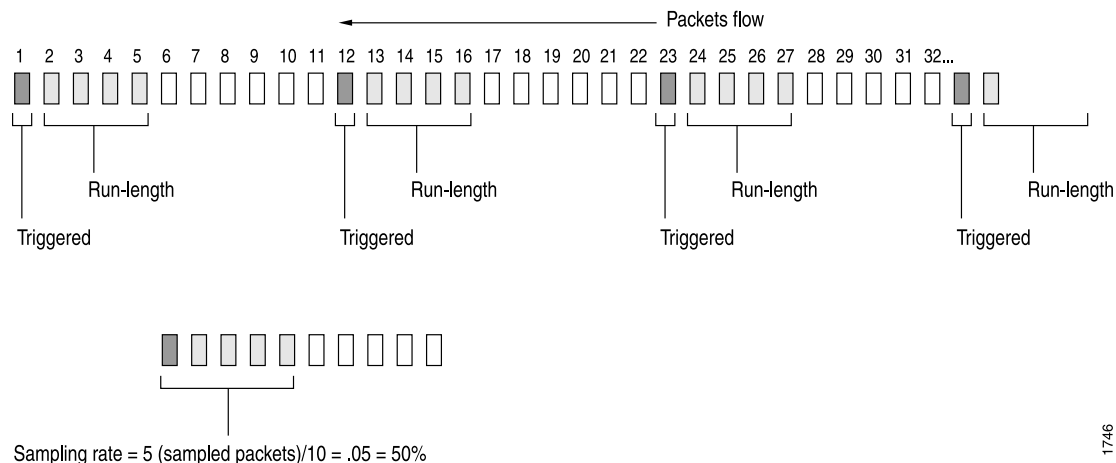

**NOTE:** When you configure active monitoring and specify a Monitoring Services, Adaptive Services, or Multiservices PIC in the output statement, the **max-packets-per-second** value is ignored.

Specify the sampling rate by setting the values for **rate** and **run-length** (see [Figure 34 on page 873](#)).

**Figure 34: Configuring Sampling Rate**

### Rate and Run-length

Case #1 Rate = 10, run-length = 4

1746

**NOTE:** If PIC-based flow monitoring is enabled on an *ms-fpc/pic/port.logical-unit* interface, a commit check error occurs when you attempt to configure ingress traffic sampling on that interface. This error occurs because a combination of ingress sampling and PIC-based flow monitoring operations on an ms- logical interface causes undesired flow monitoring behavior and might result in repeated sampling of a single packet. You must not configure ingress sampling on ms- logical interfaces on which PIC-based flow monitoring is enabled.

The **rate** statement specifies the ratio of packets to be sampled. For example, if you configure a rate of 10, x number of packets out of every 10 is sampled, where  $x = \text{run length} + 1$ . By default, the rate is 0, which means that no traffic is sampled.

The **run-length** statement specifies the number of matching packets to sample following the initial one-packet trigger event. By default, the run length is 0, which means that no more traffic is sampled after the trigger event. The range is from 0 through 20. Configuring a run length greater than 0 allows you to sample packets following those already being sampled.

**NOTE:** The **run-length** and **maximum-packet-length** configuration statements are not supported on MX80 routers.

If you do not include the **input** statement, sampling is disabled.

To collect the sampled packets in a file, include the **file** statement at the **[edit forwarding-options sampling output]** hierarchy level. Output file formats are discussed later in the chapter.

## Disabling Traffic Sampling

To explicitly disable traffic sampling on the router, include the **disable** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
disable;
```

## Sampling Once

To explicitly sample a packet for active monitoring only once, include the **sample-once** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
sample-once;
```

Setting this option avoids duplication of packets in cases where sampling is enabled at both the ingress and egress interfaces and simplifies analysis of the sampled traffic.

## Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets

To preserve the prenormalized type-of-service (ToS) value in egress sampled or mirrored packets, include the **pre-rewrite-tos** statement at the **[edit forwarding-options sampling]** hierarchy level.

On MPC-based interfaces, you can configure ToS rewrite either using class-of-service (CoS) configuration by including the **rewrite-rules dscp rule\_name** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level or using firewall filter configuration by including the **dscp** statement at the **[edit firewall family family-name filter filter-name term term-name then]** hierarchy level. If ToS rewrite is configured, the egress mirrored or sampled copies contain the post-rewrite ToS values by default. With the **pre-rewrite-tos** configuration, you can retain the prerewrite ToS value in the sampled or mirrored packets.

### NOTE:

- If ToS rewrite is configured on the egress interface by using both CoS and firewall filter configuration, and if the **pre-rewrite-tos** statement is also configured, then the egress sampled packets contain the DSCP value set using the firewall filter configuration. However, if the **pre-rewrite-tos** statement is not configured, the egress sampled packets contain the DSCP value set by the CoS configuration.
- With the **pre-rewrite-tos** statement, you can configure retaining prenormalization ToS values only for sampling done under family inet and family inet6.
- This feature cannot be configured at the **[edit logical-systems]** hierarchy level. It can be configured only at the global level under the forwarding-option configuration.
- When ToS rewrite is configured by using a firewall filter on both ingress and egress interfaces, the egress sampled packets contain the DSCP value set by the ingress ToS rewrite configuration if the **pre-rewrite-tos** statement is configured. However, if the **pre-rewrite-tos** statement is not configured, the egress sampled packets contain the DSCP value set by the ToS rewrite configuration for the egress firewall filter.
- If the **pre-rewrite-tos** statement is configured, and a deactivate or delete operation is performed at the **[edit forwarding-options]** hierarchy level, **pre-rewrite-tos** configuration still remains active. To disable the **pre-rewrite-tos** configuration for such a case, you must explicitly deactivate or delete the **pre-rewrite-tos** statement at the **[edit forwarding-options sampling]** hierarchy level before performing a deactivate or delete operation at the **[edit forwarding-options]** hierarchy level.

## Configuring Traffic Sampling Output

To configure traffic sampling output, include the following statements at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output]** hierarchy level:

```
aggregate-export-interval seconds;
flow-active-timeout seconds;
flow-inactive-timeout seconds;
extension-service service-name;
flow-server hostname {
 aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
 source-prefix;
 }
 autonomous-system-type (origin | peer);
 (local-dump | no-local-dump);
 port port-number;
 source-address address;
 version format;
 version9 {
 template template-name;
 }
}
interface interface-name {
 engine-id number;
 engine-type number;
 source-address address;
}
file {
 disable;
 filename filename;
 files number;
 size bytes;
 (stamp | no-stamp);
 (world-readable | no-world-readable);
}
```

To configure inline flow monitoring on MX Series routers, include the **inline-jflow** statement at the **[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls) output]** hierarchy level. Inline sampling exclusively supports a new format called IP\_FIX that uses UDP as the transport protocol. When you configure inline sampling, you must include the **version-ipfix** statement at the **[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls) output flow-server address]** hierarchy level and also at the **[edit services flow-monitoring]** hierarchy level. For more information about configuring inline flow monitoring, see [“Configuring Inline Active flow Monitoring” on page 890](#).

To direct sampled traffic to a flow-monitoring interface, include the **interface** statement. The **engine-id** and **engine-type** statements specify the identity and type numbers of the

interface; they are dynamically generated based on the Flexible PIC Concentrator (FPC), PIC, and slot numbers and the chassis type. The **source-address** statement specifies the traffic source.

To configure flow sampling version 9 output, you need to include the **template** statement at the **[edit forwarding-options sampling output version9]** hierarchy level. For information on cflowd, see [“Enabling Flow Aggregation” on page 898](#).

The **aggregate-export-interval** statement is described in [“Configuring Discard Accounting” on page 883](#), and the **flow-active-timeout** and **flow-inactive-timeout** statements are described in [“Configuring Flow Monitoring” on page 818](#).

Traffic sampling results are automatically saved to a file in the **/var/tmp** directory. To collect the sampled packets in a file, include the **file** statement at the **[edit forwarding-options sampling family inet output]** hierarchy level:

```
file {
 disable;
 filename filename;
 files number;
 size bytes;
 (stamp | no-stamp);
 (world-readable | no-world-readable);
}
```

### Traffic Sampling Output Format

Traffic sampling output is saved to an ASCII text file. The following is an example of the traffic sampling output that is saved to a file in the **/var/tmp** directory. Each line in the output file contains information for one sampled packet. You can optionally display a timestamp for each line.

The column headers are repeated after each group of 1000 packets.

```
Apr 7 15:48:50
Time Dest Src Dest Src Proto TOS Pkt Intf IP TCP
 addr addr port port len num frag flags
Apr 7 15:48:54 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:55 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:56 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:57 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:58 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
```

To set the timestamp option for the file **my-sample**, enter the following:

```
[edit forwarding-options sampling output file]
user@host# set filename my-sample files 5 size 2m world-readable stamp;
```

Whenever you toggle the timestamp option, a new header is included in the file. If you set the **stamp** option, the **Time** field is displayed.

```
Apr 7 15:48:50
Time Dest Src Dest Src Proto TOS Pkt Intf IP TCP
addr addr port port len num frag flags
Feb 1 20:31:21
```

| # | Dest | Src  | Dest | Src  | Proto | TOS | Pkt | Intf | IP   | TCP   |
|---|------|------|------|------|-------|-----|-----|------|------|-------|
| # | addr | addr | port | port |       |     | len | num  | frag | flags |

## Tracing Traffic Sampling Operations

Tracing operations track all traffic sampling operations and record them in a log file in the `/var/log` directory. By default, this file is named `/var/log/sampled`. The default file size is 128K, and 10 files are created before the first one gets overwritten.

To trace traffic sampling operations, include the **traceoptions** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
traceoptions {
 no-remote-trace;
 file filename <files number> <size bytes> <match expression> <world-readable |
 no-world-readable>;
}
```

## Traffic Sampling Examples

The following sections provide examples of configuring traffic sampling:

- [Example: Sampling a Single SONET/SDH Interface on page 878](#)
- [Example: Sampling All Traffic from a Single IP Address on page 879](#)
- [Example: Sampling All FTP Traffic on page 880](#)

---

### Example: Sampling a Single SONET/SDH Interface

The following configuration gathers statistical sampling information from a small percentage of all traffic on a single SONET/SDH interface and collects it in a file named **sonet-samples.txt**.

Create the filter:

```
[edit firewall family inet]
filter {
 input sample-sonet {
 then {
 sample;
 accept;
 }
 }
}
```

Apply the filter to the SONET/SDH interface:

```
[edit interfaces]
so-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input sample-sonet;
 }
 address 10.127.68.254/32 {
 destination 172.16.74.7;
```

```

 }
 }
}

```

Finally, configure traffic sampling:

```

[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 100;
 run-length 2;
 }
 }
 family inet {
 output {
 file {
 filename sonet-samples.txt;
 files 40;
 size 5m;
 }
 }
 }
}

```

### Example: Sampling All Traffic from a Single IP Address

The following configuration gathers statistical information about every packet entering the router on a specific Gigabit Ethernet port originating from a single source IP address of 172.16.92.31, and collects it in a file named **samples-172-16-92-31.txt**.

Create the filter:

```

[edit firewall family inet]
filter one-ip {
 term get-ip {
 from {
 source-address 172.16.92.31;
 }
 then {
 sample;
 accept;
 }
 }
}

```

Apply the filter to the Gigabit Ethernet interface:

```

[edit interfaces]
ge-4/1/1 {
 unit 0 {
 family inet {
 filter {
 input one-ip;
 }
 address 10.45.92.254;
 }
 }
}

```

```
 }
 }
}
```

Finally, gather statistics on all the candidate samples; in this case, gather all statistics:

```
[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 1;
 }
 }
 family inet {
 output {
 file {
 filename samples-172-16-92-31.txt;
 files 100;
 size 100k;
 }
 }
 }
}
```

---

### Example: Sampling All FTP Traffic

The following configuration gathers statistical information about a moderate percentage of packets using the FTP data transfer protocol in the output path of a specific T3 interface, and collects the information in a file named **t3-ftp-traffic.txt**.

Create a filter:

```
[edit firewall family inet]
filter ftp-stats {
 term ftp-usage {
 from {
 destination-port [ftp ftp-data];
 }
 then {
 sample;
 accept;
 }
 }
}
```

Apply the filter to the T3 interface:

```
[edit interfaces]
t3-7/0/2 {
 unit 0 {
 family inet {
 filter {
 input ftp-stats;
 }
 address 10.35.78.254/32 {
 destination 10.35.78.4;
 }
 }
 }
}
```

```

 }
 }
}

```

Finally, gather statistics on 10 percent of the candidate samples:

```

[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 10;
 }
 }
 family inet {
 output {
 file {
 filename t3-ftp-traffic.txt;
 files 50;
 size 1m;
 }
 }
 }
}

```

  - [Sampling Instance Configuration on page 881](#)

## Sampling Instance Configuration

You can configure active sampling by defining a sampling instance that specifies a name for the sampling parameters and bind the instance name to an FPC, MPC, or DPC. This configuration enables you to define multiple named sampling parameter sets associated with multiple destinations and protocol families per sampling destination. With the cflowd version 5 and version 8 and flow aggregation version 9, you can use templates to organize the data gathered from sampling.

To implement this feature, you include the **instance** statement at the **[edit forwarding-options sampling]** hierarchy level.

The following considerations apply to the sampling instance configuration:

- This configuration is supported on the IP version 4 (**inet**), IP version 6 (**ipv6**), and MPLS protocol families.
- You can configure the router to perform sampling in either of two locations:
  - On the Routing Engine, using the sampled process. To select this method, use a filter (input or output) with a matching term that contains the **then** sample statement.
  - On the Monitoring Services, Adaptive Services, or Multiservices PIC. Specify the interface name at the **[forwarding-options sampling instance *instance-name* family inet output interface]** hierarchy level. You can configure the same or different services PICs in a set of sampling instances.

- You can configure the **rate** and **run-length** options at the **[edit forwarding-options sampling input]** hierarchy level to apply common values for all families on a global basis. Alternatively, you can configure these options at the **[edit forwarding-options sampling instance *instance-name* input]** hierarchy level to apply specific values for each instance or at the **[edit forwarding-options sampling instance *instance-name* family *family* input]** hierarchy level to apply specific values for each protocol family you configure.
- For MX Series devices with Modular Port Concentrators (MPCs), port-mirrored or sampled packets can be truncated (or clipped) to any length in the range of 1 through 255 bytes. Only the values 1 to 255 are valid for packet truncation on these devices. For other devices, the range is from 0 through 9216. A maximum-packet-length value of zero (0) represents that truncation is disabled, and the entire packet is mirrored or sampled.

**NOTE:** The **run-length** and **maximum-packet-length** configuration statements are not supported on MX80 routers.

---

To associate the defined instance with a particular FPC, MPC, or DPC, you include the **sampling-instance** statement at the **[edit chassis fpc *number*]** hierarchy level, as in the following example:

```
chassis {
 fpc 2 {
 sampling-instance samp1;
 }
}
```

To associate a sampling instance with an FPC in the MX Series Virtual Chassis master or backup router, use the **sampling-instance *instance-name*** statement at the **[edit chassis member *member-number* fpc slot *slot-number*]** hierarchy level, where *member-number* is 0 (for the master router) or 1 (for the backup router), and *slot-number* is a number in the range 0 through 11.

## Configuring Discard Accounting

---

Discard accounting is similar to traffic sampling, but varies from it in two ways:

- In discard accounting, the packet is intercepted by the monitoring PIC and is not forwarded to its destination.
- Traffic sampling allows you to limit the number of packets sampled by configuring the **max-packets-per-second**, **rate**, and **run-length** statements. Discard accounting does not provide these options, and a high packet count can potentially overwhelm the monitoring PIC.

A discard instance is a named entity that specifies collector information under the **accounting name** statement. Discard instances are referenced in firewall filter **term** statements by including the **then discard accounting name** statement.

Most of the other statements are also found at the **[edit forwarding-options sampling]** hierarchy level. For information on cflowd, see [“Enabling Flow Aggregation” on page 898](#). The **flow-active-timeout** and **flow-inactive-timeout** statements are described in [“Configuring Flow Monitoring” on page 818](#).

To direct sampled traffic to a flow-monitoring interface, include the **interface** statement. The **engine-id** and **engine-type** statements specify the accounting interface used on the traffic, and the **source-address** statement specifies the traffic source.

You cannot use rate-limiting with discard accounting; however, you can specify the duration of the interval for exporting aggregated accounting information by including the **aggregate-export-interval** statement in the configuration. This enables you to put a boundary on the amount of traffic exported to a flow-monitoring interface.

## Understanding Inline Active Flow Monitoring

---

This topic provides an overview of the inline active flow monitoring feature and IPFIX and Version 9 flow collection templates used for inline active flow monitoring.

This topic contains the following sections:

- [Inline Active Flow Monitoring on page 885](#)
- [Inline Active Flow Monitoring Limitations and Restrictions on page 886](#)
- [IPFIX and Version 9 Templates on page 887](#)

## Inline Active Flow Monitoring

The inline active flow monitoring is implemented on the Packet Forwarding Engine. All the functions like flow creation, flow update, and flow records export are done by the Packet Forwarding Engine. The flow records are sent out in industry standard IPFIX format.

Inline active flow monitoring provides for higher scalability and performance as the scaling and performance are not dependent on the capacity of the services interface. It is also cost effective in more than one way as there is no need to invest in additional hardware or to dedicate a PIC slot for the services PIC. You can make full use of the available slots for handling traffic on the device.

Junos OS Release 13.2 extends inline active flow monitoring support to VPLS flows. Now, you can configure inline active flow monitoring for IPv4, IPv6, and VPLS traffic.

The inline active flow monitoring configuration can be broadly classified into four categories:

1. Configurations at the **[edit services flow-monitoring]** hierarchy level—At this level, you configure the template properties for inline flow monitoring.
2. Configurations at the **[edit forwarding-options]** hierarchy level—At this level, you configure a sampling instance and associate the template (configured at the **[edit**

**services flow-monitoring**] hierarchy level) with the sampling instance. At this level, you also configure the flow-server IP address and port number as well as the flow export rate.

3. Configurations at the **[edit chassis]** hierarchy level—At this level, you associate the sampling instance with the FPC on which the media interface is present. If you are configuring sampling of IPv6 flows, you must also specify the flow hash table size.
4. Configurations at the **[edit firewall]** hierarchy level—At this level you configure a firewall filter for the family of traffic to be sampled. You must attach this filter to the interface on which you want to sample the traffic.

Inline active flow monitoring supports version 9 and IPFIX flow collection templates. Support for version 9 template was introduced in Junos OS Release 13.2, and is limited to IPv4 flows. IPFIX template is supported for IPv4, IPv6, and VPLS flows. IPFIX template uses UDP as the transport protocol, whereas version 9 is transport protocol-independent.

Before you configure inline active flow monitoring, you should ensure that you have adequately-sized hash tables for IPv4 and IPv6 flow sampling. These tables can use one to fifteen 256k areas, and each table is assigned a default value of one such area. When anticipated traffic volume requires larger tables, allocate larger tables.

**NOTE:** Starting with Junos OS Release 13.3, you can configure flow collectors to be reachable through non-default VPN routing and forwarding (VRF) instances by including the `routing-instance instance-name` statement at the **[edit forwarding-options sampling instance instance-name family (inet |inet6 |mpls) output flow-server hostname]** hierarchy level for inline flow monitoring. You cannot configure a flow collector to be reachable through non-default VRF instances for version 5 and version 8 flows. You must configure the routing instance to be a VRF instance by including the `instance-type vrf` statement at the **[edit routing-instances instance-name]** hierarchy level.

---

## Inline Active Flow Monitoring Limitations and Restrictions

The following limitations and restrictions apply to the inline active flow monitoring feature in Junos OS:

- You can configure inline active flow monitoring only on MX Series routers with Trio-based line cards and T4000 routers with Type 5 FPCs.
- You can apply Version 9 flow template only to IPv4 traffic.
- You can configure only one sampling instance on an Flexible PIC Concentrator (FPC).
- You can configure only one type of sampling—either PIC-based sampling or inline sampling—per family in a sampling instance. However, you can configure PIC-based and inline sampling for different families in a sampling instance.
- You can configure only one collector for inline active flow monitoring.

- The following considerations apply to the inline flow-monitoring instance configuration:
  - Sampling run-length and clip-size are not supported.
  - For inline configurations, each family can support only one collector.
  - The user-defined sampling instance gets precedence over the global instance. When a user-defined sampling instance is attached to the FPC, the global instance is removed from the FPC and the user-defined sampling instance is applied to the FPC.
- On routers with Multiservices PICs or Multiservices DPCs, all fragments of a fragmented IPv4 packet other than the first fragment of the packet are processed accurately by the flow monitoring application running on MS-PIC or MS-DPC. The flow monitoring mechanism handles such fragments accurately by setting the layer 4 related fields in the associated flows to zero.
- Flow records and templates cannot be exported if the flow collector is reachable through any management interface.
- The flow collector should be reachable through the default routing table (inet.0 or inet6.0). If the flow collector is reachable via a non-default VPN routing and forwarding table (VRF), flow records and templates cannot be exported.

**NOTE:** Starting with Junos OS Release 13.3, you can configure the flow collector to be reachable through non-default VRF instances apart from being reachable over the default VRF instance. Flow records and templates can be exported even with non-default VRF instances.

- If the destination of the sampled flow is reachable through multiple paths, the IP\_NEXT\_HOP (Element ID 15) and OUTPUT\_SNMP (Element ID 14) in the IPv4 flow record would be set to the Gateway Address and SNMP Index of the first path seen in the forwarding table.
- If the destination of the sampled flow is reachable through multiple paths, the IP\_NEXT\_HOP (Element ID 15) and OUTPUT\_SNMP (Element ID 14) in the IPv6 flow records would be set to 0.
- The Incoming Interface (IIF) and Outgoing Interface (OIF) should be part of the same VRF. If OIF is in a different VRF, DST\_MASK (Element ID 13), DST\_AS (Element ID 17), IP\_NEXT\_HOP (Element ID 15), and OUTPUT\_SNMP (Element ID 14) would be set to 0 in the flow records.
- Each Lookup Chip (LU) maintains and exports flows independent of other LUs. Traffic received on a media interface is distributed across all LUs in a multi-LU platform. It is likely that a single flow will be processed by multiple LUs. Therefore, each LU creates a unique flow and exports it to the flow collector. This can cause duplicate flows records to be seen on the flow collector. The flow collector should aggregate PKTS\_COUNT and BYTES\_COUNT for duplicate flow records to derive a single flow record.

## IPFIX and Version 9 Templates

The following sections list the fields included in IPFIX and Version 9 templates.

### Fields Included in the IPFIX IPv4 Template

---

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS
- Destination AS
- IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum TTL (time to live)
- Maximum TTL (time to live)
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

### Fields Included in the IPFIX IPv6 Template

---

- IPv6 Source Address
- IPv6 Destination Address
- IPv6 TOS
- IPv6 Protocol
- L4 Source Port

- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv6 Source Mask
- IPv6 Destination Mask
- Source AS
- Destination AS
- IPv6 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum Hop Limits
- Maximum Hop Limits
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

---

#### Fields Included in the Version 9 IPv4 Template

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS

- Destination AS
- IPv4 Next Hop Address
- BGP IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Time when the first packet of the flow was switched.
- Time when the last packet of flow was switched.
- Internet Protocol Version

---

## Configuring Inline Active flow Monitoring

The inline active flow monitoring is implemented on the Packet Forwarding Engine. All the functions like flow creation, flow update, and flow records export are done by the Packet Forwarding Engine. The flow records are sent out in industry standard IPFIX format.

The inline active flow monitoring configuration can be broadly classified into four categories:

1. Configurations at the **[edit services flow-monitoring]** hierarchy level—At this level, you configure the template properties for inline flow monitoring.
2. Configurations at the **[edit forwarding-options]** hierarchy level—At this level, you configure a sampling instance and associate the template (configured at the **[edit services flow-monitoring]** hierarchy level) with the sampling instance. At this level, you also configure the flow-server IP address and port number as well as the flow export rate.
3. Configurations at the **[edit chassis]** hierarchy level—At this level, you associate the sampling instance with the FPC on which the media interface is present. If you are configuring sampling of IPv6 flows, you must also specify the flow hash table size.
4. Configurations at the **[edit firewall]** hierarchy level—At this level you configure a firewall filter for the family of traffic to be sampled. You must attach this filter to the interface on which you want to sample the traffic.

Before you configure inline active flow monitoring, you should ensure that you have adequately-sized hash tables for IPv4 and IPv6 flow sampling. These tables can use one to fifteen 256k areas, and each table is assigned a default value of one such area. When anticipated traffic volume requires larger tables, allocate larger tables.

**NOTE:** For Junos OS releases earlier than Release 12.1, the following points are applicable for supporting backward compatibility when you configure the IPv4 and IPv6 flow table sizes for inline active flow monitoring:

- If you do not configure the `flow-table-size` statement at the `[edit chassis fpc slot-number inline-services]` hierarchy level, fifteen 256K entries are allocated by default for the IPv4 flow table and one 1K entry is allocated by default for the IPv6 flow table on the Packet Forwarding Engine.
- If you configure the `ipv4-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level and if you do not configure the `ipv6-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level, the number of units of 256K entries that you configure for the IPv4 flow table is allocated. For the IPv6 flow table, a default size of one 1K entry is allocated on the Packet Forwarding Engine.
- If you do not configure the `ipv4-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level and if you configure the `ipv6-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level, the number of units of 256K entries that you configure for the IPv6 flow table is allocated. For the IPv4 flow table, a default size of one 1K entry is allocated on the Packet Forwarding Engine.
- If you configure the sizes of both the IPv4 and IPv6 flow tables, the flow tables are created on the Packet Forwarding Engine based on the size that you specified.

**NOTE:** The functionality to log the cflowd records in a log file before they are exported to a cflowd server (by including the `local-dump` statement at the `[edit forwarding-options sampling instance instance-name family (inet |inet6 |mpls) output flow-server hostname]` hierarchy level) is not supported when you configure inline flow monitoring (by including the `inline-jflow` statement at the `[edit forwarding-options sampling instance instance-name family inet output]` hierarchy level).

To allocate IPv4 and IPv6 flow hash tables:

1. Go to the `flow-table-size` hierarchy level for inline services on the FPC that processes the monitored flows.

```
[edit]
user@host# edit chassis fpc 0 inline-services flow-table-size
```

2. Specify the required sizes for the sampling hash tables.

```
[edit chassis fpc 0 inline-services flow-table-size]
user@host# set ipv4-flow-table-size 5
user@host# set ipv6-flow-table-size 5
```

**NOTE:** When you set the flow hash table sizes, remember:

- Any change in the configured size of flow hash table sizes initiates an automatic reboot of the FPC.
- The total number of units used for both IPv4 and IPv6 cannot exceed 15.

To configure inline active flow monitoring on all other MX Series routers (except for MX80 routers), EX Series switches, and T4000 routers with Type 5 FPC:

1. Enable inline active flow monitoring and specify the source address for the traffic.

```
[edit forwarding-options sampling instance instance-name family inet output]
user@host# set inline-jflow source address address
```

2. Specify the IP\_FIX output format.

```
[edit forwarding-options sampling instance instance-name family inet output flow-server
address]
user@host# set version-ipfix template ipv4
```

3. Specify the output properties.

```
[edit services flow-monitoring]
user@host# set version-ipfix
```

The output format properties are common to other output formats and are described in [“Configuring Flow Aggregation to Use IPFIX Flow Templates” on page 912](#).

The following is an example of the sampling configuration for an instance that supports inline active flow monitoring on **family inet** and PIC-based sampling on **family inet6**:

```
[edit forwarding-options]
sampling {
 instance {
 sample-ins1 {
 input {
 rate 1;
 }
 family inet {
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version-ipfix {
 template {
 ipv4;
 }
 }
 }
 }
 inline-jflow {
 source-address 10.11.12.13;
 }
 }
 }
 }
}
```

```

family inet6 {
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version-ipfix {
 template {
 ipv6;
 }
 }
 }
 }
 interface sp-0/1/0 {
 source-address 10.11.12.13;
 }
}
}
}

```

The following example shows the output format configuration:

```

services {
 flow-monitoring {
 version-ipfix {
 template ipv4 {
 flow-active-timeout 60;
 flow-inactive-timeout 60;
 ipv4-template;
 template-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 option-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 }
}
}

```

The following considerations apply to the inline flow-monitoring instance configuration:

- Sampling run-length and clip-size are not supported.
- For inline configurations, each family can support only one collector.

**NOTE:** On routers with Multiservices PICs or Multiservices DPCs, IPv4 and IPv6 fragments are processed accurately. The flow monitoring application creates two flows for every fragmented flow. The first fragment that has the complete Layer 4 information forms the first flow with 5-tuple data and subsequently, all the fragmented packets related to this flow form another flow with the Layer 4 fields set to zero.

- Related Documentation**

---

## Configuring Inline Active Flow Monitoring on MX80 Routers

---

To configure inline active flow monitoring on MX80 routers:

1. Associate a sampling instance with the Forwarding Engine Processor.

```
[edit]
user@host# set chassis tfeb slot number sampling-instance sampling-instance
```

The Forwarding Engine Processor slot is always 0 because MX80 routers have only one Packet Forwarding Engine. In this configuration, the sampling instance is **sample-ins1**.

```
[edit]
user@host# set chassis tfeb slot 0 sampling-instance sample-ins1
```

**NOTE:** MX80 routers support only one sampling instance.

2. Under forwarding-options, configure a sampling instance for the flow server and inline jflow instances (these will be configured in the following steps):

```
[edit forwarding-options sampling]
user@host# edit instance inline_sample
```

3. Configure the rate at the **[edit forwarding-options sampling instance instance-name input]** hierarchy level to apply specific values for the sampling instance **sample-ins1**.

```
[edit forwarding-options sampling instance sample-ins1 input]
user@host# set rate number
```

In this configuration, the rate is 1000.

```
[edit forwarding-options sampling instance sample-ins1 input]
user@host# set rate 1000
```

4. Navigate to the output hierarchy and from there, enable a flow server and then specify the output address and port:

```
[edit] forwarding-options sampling instance inline_sample family inet output]
user@host# edit flow-server address
```

```
[edit forwarding-options sampling instance inline_sample family inet output flow-server
<address>]
user@host# set port number
```

5. Return to the output hierarchy and specify the source address for inline jflow:

```
[edit forwarding-options sampling instance sample-ins1 family inet output]
user@host# set inline-jflow source-address address
```

In this configuration, the source address is 10.11.12.13.

```
[edit forwarding-options sampling instance sample-ins1 family inet output]
```

```
user@host# set inline-jflow source-address 10.11.12.13
```

6. Specify the output properties.

```
[edit services flow-monitoring]
```

```
user@host# set version-ipfix
```

The output format properties are common to other output formats and are described in [“Configuring Flow Aggregation to Use IPFIX Flow Templates” on page 912](#).

The following is an example of the sampling configuration for an instance that supports inline active flow monitoring on MX80 routers:

```
[edit forwarding-options]
user@host# show
sampling {
 instance {
 sample-ins1 {
 input {
 rate 1000;
 }
 family inet {
 flow-server 133..13.13.122{
 port 1333;
 inline-jflow {
 source-address 10.11.12.13;
 }
 }
 }
 }
 }
}
```

**NOTE:** You need not configure a Flexible PIC Concentrator (FPC) slot because MX80 routers have only one Packet Forwarding Engine.

The following considerations apply to the inline flow-monitoring instance configuration:

- This configuration does not support MPLS-IPv6.
- Clip-size is not supported.

## Understanding Flow Aggregation

---

You can collect an aggregate of sampled flows and send the aggregate to a specified host that runs either the cflowd application available from CAIDA (<http://www.caida.org>) or the newer version 9 format defined in RFC 3954, *Cisco Systems NetFlow Services Export Version 9*. Before you can perform flow aggregation, the routing protocol process must export the autonomous system (AS) path and routing information to the sampling process.

By using flow aggregation, you can obtain various types of byte and packet counts of flows through a router. The application collects the sampled flows over a period of 1 minute. At the end of the minute, the number of samples to be exported are divided over the period of another minute and are exported over the course of the same minute.

You configure flow aggregation in different ways, depending on whether you want to export flow records in cflowd version 5 or 8 format, or the separate version 9 format. The latter allows you to sample MPLS, IPv4, IPv6, and peer AS billing traffic. You can also combine configuration statements between the MPLS and IPv4 formats.

**NOTE:** When PIC-based sampling is enabled, collection of flow statistics for sampled packets on flows in virtual private networks (VPNs) is also supported. No additional CLI configuration is required.

---

## Enabling Flow Aggregation

Before you can perform flow aggregation, the routing protocol process must export the autonomous system (AS) path and routing information to the sampling process. To enable the export of AS path and the routing information to the sampling process, one or more of the following needs to be configured:

- At the **[edit forwarding-options]** hierarchy level (for routing instances, at the **[edit routing-instance *routing-instance-name* forwarding-options]** hierarchy level), configure **sampling family** or **sampling output** or **sampling instance** or **monitoring** or **accounting**.
- At the **[edit routing-options]** hierarchy level (for routing instances, at the **[edit routing-instance *routing-instance-name* routing-options]** hierarchy level), configure **route record**.
- At the **[edit chassis fpc *slot-number* pic *pic-number* adaptive-services service-package extension-provider]** hierarchy level, configure **forwarding-db-size**.

---

## Configuring Flow Aggregation to Use Version 5 or Version 8 cflowd

To enable the collection of cflowd version 5 or version 8 flow formats, include the **flow-server** statement:

```
flow-server hostname {
 aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
 }
}
```

```

 }
 source-prefix;
 }
 autonomous-system-type (origin | peer);
 (local-dump | no-local-dump);
 port port-number;
 version format;
}

```

You can include this statement at the following hierarchy levels:

- [edit forwarding-options sampling family (inet | inet6 | mpls) output]
- [edit forwarding-options sampling instance *instance-name* output]
- [edit forwarding-options accounting *name* output cflowd *hostname*]

You must configure the **family inet** statement on logical interface **unit 0** on the monitoring interface, as in the following example:

```

[edit interfaces]
sp-3/0/0 {
 unit 0 {
 family inet {
 ...
 }
 }
}

```

**NOTE:** Boot images for monitoring services interfaces are specified at the [edit chassis images pic] hierarchy level. You must enable the NTP client to make the cflowd feature operable, by including the following configuration:

```

[edit system]
ntp {
 boot-server ntp.juniper.net;
 server 172.17.28.5;
}
processes {
 ntp enable;
}

```

For more information, see the *Junos OS Administration Library for Routing Devices*.

You can also configure cflowd version 5 for flow-monitoring applications by including the **cflowd** statement at the [edit forwarding-options monitoring *name* family inet output] hierarchy level:

```

cflowd hostname {
 port port-number;
}

```

The following restrictions apply to cflowd flow formats:

- You can configure up to one version 5 and one version 8 flow format at the **[edit forwarding-options accounting *name* output]** hierarchy level.
- You can configure up to eight version 5 or one version 8 flow format at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output]** hierarchy level for Routing Engine-based sampling by including the **flow-server** statement. In contrast, PIC-based sampling allows you to specify one cflowd version 5 server and one version 8 server simultaneously. However, the two cflowd servers must have different IP addresses.
- You can configure up to eight version 5 flow formats at the **[edit forwarding-options monitoring *name* output]** hierarchy level. Version 8 flow formats and aggregation are not supported for flow-monitoring applications.
- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created on the monitoring PIC only after the route record resynchronization operation is complete, which is 60 seconds after the PIC comes up. Any packets sent to the PIC would be dropped until the synchronization process is complete.
- The configuration includes a proprietary v5 extension template for supporting 4-byte AS information in flow records. Its template version is set to 500, indicating it to be proprietary. All other fields remain the same; the source AS and destination AS are each 4 bytes long, rather than 2 bytes as in the traditional v5 template. This option is available at the **[edit forwarding-options sampling family inet output flow-server server-name version]** hierarchy level.

In the **cflowd** statement, specify the name or identifier of the host that collects the flow aggregates. You must also include the User Datagram Protocol (UDP) port number on the host and the version, which gives the format of the exported cflowd aggregates. To collect cflowd records in a log file before exporting, include the **local-dump** statement.

**NOTE:** You can specify both host (cflowd) sampling and port mirroring in the same configuration; however, only one action takes effect at any one time. Port mirroring takes precedence. For more information, see [“Configuring Port Mirroring” on page 931](#).

For cflowd version 8 only, you can specify aggregation of specific types of traffic by including the **aggregation** statement. This conserves memory and bandwidth by enabling cflowd to export targeted flows rather than all aggregated traffic. To specify a flow type, include the **aggregation** statement:

```
aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
}
```

```

 }
 source-prefix;
 }

```

You can include this statement at the following hierarchy levels:

- [edit forwarding-options sampling family (inet | inet6 | mpls) output flow-server *hostname*]
- [edit forwarding-options accounting *name* output cflowd *hostname*]

The **autonomous-system** statement configures aggregation by the AS number; this statement might require setting the separate cflowd **autonomous-system-type** statement to include either **origin** or **peer** AS numbers. The **origin** option specifies to use the origin AS of the packet source address in the Source Autonomous System cflowd field. The **peer** option specifies to use the peer AS through which the packet passed in the Source Autonomous System cflowd field. By default, cflowd exports the origin AS number.

The **destination-prefix** statement configures aggregation by the destination prefix only.

The **protocol-port** statement configures aggregation by the protocol and port number; requires setting the separate **cflowd port** statement.

The **source-destination-prefix** statement configures aggregation by the source and destination prefix. Version 2.1b1 of CAIDA's cflowd application does not record source and destination mask length values in compliance with CAIDA's *cflowd Configuration Guide*, dated August 30, 1999. If you configure the **caida-compliant** statement, the Junos OS complies with Version 2.1b1 of cflowd. If you do not include the **caida-compliant** statement in the configuration, the Junos OS records source and destination mask length values in compliance with the *cflowd Configuration Guide*.

The **source-prefix** statement configures aggregation by the source prefix only.

Collection of sampled packets in a local ASCII file is not affected by the **cflowd** statement.

The following commands enable RE- and PIC-based sampling at the **set forwarding options sampling** hierarchy level:

- set input rate *rate*
- set input run-length *length*
- set family inet output flow-server *flowcollector* port *udp port*
- set family inet output flow-server *flowcollector* no-local-dump
- set family inet output flow-server *flowcollector* version <5/8>

The following commands enable RE- and PIC-based sampling at the **set interfaces** hierarchy level:

- *interface to be sampled* unit *unit* family inet filter *input/output filename*

The following commands enable RE- and PIC-based sampling at the **set firewall family** hierarchy level:

- `set inet filter filtername term 1 then count filternameing`
- `set inet filter filtername term 1 then sample`
- `set inet filter filtername term 1 then accept`

The following command enables PIC-based sampling at the **set forwarding options sampling** hierarchy level:

- `set family inet output interface sp-*/*/* source address source address`

The following example shows a PIC-based flow aggregation configuration using version 5:

```
family inet {
 output {
 flow-inactive-timeout 15;
 flow-active-timeout 60;
 flow-server 153.104.248.37 {
 port 9996;
 version 5;
 }
 interface sp-2/2/0 {
 engine-id 4;
 source-address 153.104.0.254;
 }
 }
}
```

The following example shows an RE-based flow aggregation configuration using version 5:

```
family inet {
 output {
 flow-inactive-timeout 15;
 flow-active-timeout 60;
 flow-server 153.104.248.37 {
 port 9996;
 source-address 153.104.0.254;
 version 5;
 }
 }
}
```

---

## Configuring Flow Aggregation to Use Version 9 Flow Templates

Use of version 9 allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic.

Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration.

**NOTE:** Version 9 requires that you install a services PIC, such as the Adaptive Services PIC or Multiservices PIC in the router. On MX Series routers, the Multiservices DPC fulfills this requirement. For more information on determining which services PIC is suitable for your router, see [“Enabling Service Packages” on page 11](#) or the appropriate hardware documentation.

**NOTE:** If multiple protocol families are configured for a particular flow collector, the export packets will originate from multiple Source IDs, with each Source ID corresponding to a particular protocol. The multiple Source IDs do not indicate that the export packets are originating from multiple Service PICs.

The following sections contain additional information:

- [Configuring the Traffic to Be Sampled on page 903](#)

## Configuring the Traffic to Be Sampled

To specify sampling of IPv4, IPv6, MPLS, or peer AS billing traffic, include the appropriate configuration of the **family** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
[edit forwarding-options]
sampling {
 family (inet | inet6 | mpls);
}
```

You can include **family inet**, **family inet6**, or **family mpls**.

**NOTE:** If you specify sampling for peer AS billing traffic, the **family** statement supports only IPv4 and IPv6 traffic (inet or inet6). Peer AS billing traffic is enabled only at the global instance hierarchy level and is not available for per Packet Forwarding Engine instances.

After you specify the family of traffic to be sampled, configure the sampling parameters such as the maximum packet length (beyond which the packets are truncated), maximum packets to be sampled per second (beyond which the packets are dropped), the rate (for example, if you specify 10, every 10th packet is sampled), and run length (which specify the number of packets to be sampled after the trigger; that is if the **rate** is set to 10 and **run-length** to 5, five packets starting the 10th packet are sampled).

```
[edit forwarding-options sampling]
input {
 maximum-packet-length bytes
 max-packets-per-second number;
 rate number;
 run-length number;
}
```

## Configuring the Version 9 Template Properties

To define the version 9 templates, include the following statements at the **[edit services flow-monitoring version9]** hierarchy level:

```
[edit services flow-monitoring version9]
template name {
 options-template-id
 template-id
 source-id
 flow-active-timeout seconds;
 flow-inactive-timeout seconds;
 option-refresh-rate packets packets seconds seconds;
 template-refresh-rate packets packets seconds seconds;
 (ipv4-template | ipv6-template | mpls-ipv4-template | mpls-template |
 peer-as-billing-template) {
 label-position [positions];
 }
}
```

The following details apply to the configuration statements:

- You assign each template a unique name by including the **template name** statement.
- You then specify each template for the appropriate type of traffic by including the **ipv4-template**, **ipv6-template**, **mpls-ipv4-template**, **mpls-template**, or **peer-as-billing-template**.
- If the template is used for MPLS traffic, you can also specify up to three label positions for the MPLS header label data by including the **label-position** statement; the default values are **[1 2 3]**.
- Within the template definition, you can optionally include values for the **flow-active-timeout** and **flow-inactive-timeout** statements. These statements have specific default and range values when they are used in template definitions; the default is 60 seconds and the range is from 10 through 600 seconds. Values you specify in template definitions override the global timeout values configured at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output flow-server]** hierarchy level.

- You can also include settings for the **option-refresh-rate** and **template-refresh-rate** statements within a template definition. For both of these properties, you can include a timer value (in seconds) or a packet count (in number of packets). For the **seconds** option, the default value is 60 and the range is from 10 through 600. For the **packets** option, the default value is 4800 and the range is from 1 through 480,000.
- To filter IPV6 traffic on a media interface, the following configuration is supported:

```

interfaces interface-name {
 unit 0 {
 family inet6 {
 sampling {
 input;
 output;
 }
 }
 }
}

```

## Customizing Template ID, Observation Domain ID, and Source ID for Version 9 flow Templates

Use of version 9 and IPFIX allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic. Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration. Starting with Junos OS Release 14.1, you can specify the unique identifier for the version 9 and IPFIX templates. The identifier of a template is locally unique within a combination of a transport session and an observation domain. Template IDs 0 through 255 are reserved for template sets, options template sets, and other sets for future use. Template IDs of data sets are numbered from 256 through 65535. Typically, this information element or field in the template is used to define the characteristics or properties of other information elements in a template. After a restart of the export process of templates is performed, template IDs can be reassigned. In Junos OS releases earlier than Release 14.1, template IDs and options template IDs were predefined for each address family and could not be modified.

This functionality to configure template ID, options template ID, observation domain ID, and source ID is supported on all routers with MPCs (Trio chip-based FPCs).

The following values were assigned by default for the template IDs of IPFIX templates for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 flow template ID—256
- IPv6 flow template ID—257
- VPLS flow template ID—258
- Options template ID for all address families—512

The corresponding data sets and option data sets contain the value of the template IDs and options template IDs respectively in the set ID field. This method enables the collector to match a data record with a template record.

For more information about specifying the source ID, observation domain ID, template ID, and options template ID for version 9 and IPFIX flows, see [“Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows” on page 918](#) and [“Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows” on page 921](#).

## Restrictions

The following restrictions apply to version 9 templates:

- You cannot apply the two different types of flow aggregation configuration (cflowd version 5/8 and flow aggregation version 9) at the same time.
- Flow export based on an **mpls-ipv4** template assumes that the IPv4 header follows the MPLS header. In the case of Layer 2 VPNs, the packet on the provider router (P router) would look like this:

MPLS | Layer 2 Header | IPv4

In this case, **mpls-ipv4** flows are not created on the PIC, because the IPv4 header does not directly follow the MPLS header. Packets are dropped on the PIC and are accounted as parser errors.

- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created on the monitoring PIC only after the route record resynchronization operation is complete, which is 60 seconds after the PIC comes up. Any packets sent to the PIC would be dropped until the synchronization process is complete.

**NOTE:** "Because the forwarding of a packet that arrives with MPLS labels is performed based on the MPLS label and not based on the IP address contained in the packet, the packet is sampled at the output interface with the MPLS label that was popped not being available at the time of sampling. In such a case, depending on the incoming interface (IIF), the VRF index is identified and the route for the sampled packet is determined in the VRF table. Because a specific route is not available in the VRF that is different from the VRF on which the packet is received, the Output Interface Index, Source Mask, and Destination Mask fields are incorrectly populated. This behavior occurs when an IPv4 template is applied as a firewall filter on an egress interface with sample as the action."

---

## Fields Included in Each Template Type

The following fields are common to all template types:

- Input interface
- Output interface
- Number of bytes

- Number of packets
- Flow start time
- Flow end time

The IPv4 template includes the following specific fields:

- IPv4 Source Address
- IPv4 Destination Address
- L4 Source Port
- L4 Destination Port
- IPv4 TOS
- IPv4 Protocol
- ICMP type and code
- TCP Flags
- IPv4 Next Hop Address
- Source autonomous system (AS) number
- Destination AS number

The IPv6 template includes the following specific fields:

- IPv6 Source Address and Mask
- IPv6 Destination Address and Mask
- L4 Source Port
- L4 Destination Port
- IPv6 TOS
- IPv6 Protocol
- TCP Flags
- IP Protocol Version
- IPv6 Next Hop Address
- Egress Interface Information
- Source Autonomous System (AS) number
- Destination AS number

The MPLS template includes the following specific fields:

- MPLS Label #1
- MPLS Label #2
- MPLS Label #3

- MPLS EXP Information
- FEC IP Address

The MPLS-IPv4 template includes all the fields found in the IPv4 and MPLS templates.

The peer AS billing template includes the following specific fields:

- IPv4 Class of Service (TOS)
- Ingress Interface
- BGP IPv4 Next Hop Address
- BGP Peer Destination AS Number

## MPLS Sampling Behavior

This section describes the behavior when MPLS sampling is used on egress interfaces in various scenarios (label pop or swap) on provider routers (P routers). For more information on configuration and background specific to MPLS applications, see the *MPLS Applications Feature Guide for Routing Devices*.

1. You configure MPLS sampling on an egress interface on the P router and configure an MPLS flow aggregation template. The route action is label *pop* because penultimate hop popping (PHP) is enabled.

Previously, IPv4 packets (only) would have been sent to the PIC for sampling even though you configured MPLS sampling. No flows should be created, with the result that the parser fails.

With the current capability of applying MPLS templates, MPLS flows are created.

2. As in the first case, you configure MPLS sampling on an egress interface on the P router and configure an MPLS flow aggregation template. The route action is label *swap* and the swapped label is 0 (explicit null).

The resulting behavior is that MPLS packets are sent to the PIC. The flow being sampled corresponds to the label before the swap.

3. You configure a Layer 3 VPN network, in which a customer edge router (CE-1) sends traffic to a provider edge router (PE-A), through the P router, to a similar provider edge router (PE-B) and customer edge router (CE-2) on the remote end.

The resulting behavior is that you cannot sample MPLS packets on the PE-A to P router link.

## Verification

To verify the configuration properties, you can use the **show services accounting aggregation template template-name name** operational mode command.

All other **show services accounting** commands also support version 9 templates, except for **show services accounting flow-detail** and **show services accounting aggregation aggregation-type**. For more information about operational mode commands, see the [CLI Explorer](#).

## Examples: Configuring Version 9 Flow Templates

The following is a sample version 9 template configuration:

```
services {
 flow-monitoring {
 version9 {
 template ip-template {
 flow-active-timeout 20;
 flow-inactive-timeout 120;
 ipv4-template;
 }
 template mpls-template-1 {
 mpls-template {
 label-position [1 3 4];
 }
 }
 template mpls-ipv4-template-1 {
 mpls-ipv4-template {
 label-position [1 5 7];
 }
 }
 template peer-as-billing-template-1 {
 peer-as-billing-template;
 }
 }
 }
}
```

The following is a sample firewall filter configuration for MPLS traffic:

```
firewall {
 family mpls {
 filter mpls_sample {
 term default {
 then {
 accept;
 sample;
 }
 }
 }
 }
}
```

The following sample configuration applies the MPLS sampling filter on a networking interface and configures the AS PIC to accept both IPv4 and MPLS traffic:

```
interfaces {
 at-0/1/1 {
 unit 0 {
 family mpls {
 filter {
 input mpls_sample;
 }
 }
 }
 }
}
```

```
 }
 }
 sp-7/0/0 {
 unit 0 {
 family inet;
 family mpls;
 }
 }
}
```

The following example applies the MPLS version 9 template to the sampling output and sends it to the AS PIC:

```
forwarding-options {
 sampling {
 input {
 family mpls {
 rate 1;
 }
 }
 family mpls {
 output {
 flow-active-timeout 60;
 flow-inactive-timeout 30;
 flow-server 1.2.3.4 {
 port 2055;
 version9 {
 template mpls-ipv4-template-1;
 }
 }
 }
 }
 interface sp-7/0/0 {
 source-address 1.1.1.1;
 }
 }
}
```

The following is a sample firewall filter configuration for the peer AS billing traffic:

```
firewall {
 family inet {
 filter peer-as-filter {
 term 0 {
 from {
 destination-class dcu-1;
 interface ge-2/1/0;
 forwarding-class class-1;
 }
 then count count_team_0;
 }
 }
 term 1 {
 from {
 destination-class dcu-2;
 interface ge-2/1/0;
 }
 }
 }
}
```

```

 forwarding-class class-1;
 }
 then count count_team_1;
}
term 2 {
 from {
 destination-class dcu-3;
 interface ge-2/1/0;
 forwarding-class class-1;
 }
 then count count_team_2;
}
}
}
}

```

The following sample configuration applies the peer AS firewall filter as a filter attribute under the forwarding-options hierarchy for CoS-level data traffic usage information collection:

```

forwarding-options {
 family inet {
 filter output peer-as-filter;
 }
}

```

The following sample configuration applies the peer AS DCU policy options to collect usage statistics for the traffic stream for as-path ingressing at a specific input interface with the firewall configuration hierarchy applied as Forwarding Table Filters (FTFs). The configuration functionality with COS capability can be achieved through FTFs for destination-class usage with forwarding-class for specific input interfaces:

```

policy-options {
 policy-statement P1 {
 from {
 protocol bgp;
 neighbor 10.2.25.5; #BGP router configuration;
 as-path AS-1; #AS path configuration;
 }
 then destination-class dcu-1; #Destination class configuration;
 }
 policy-statement P2 {
 from {
 neighbor 1.2.25.5;
 as-path AS-2;
 }
 then destination-class dcu2;
 }
 policy-statement P3 {
 from {
 protocol bgp;
 neighbor 192.2.1.1;
 as-path AS-3;
 }
 then destination-class dcu3;
 }
}

```

```
as-path AS-1 3131:1111:1123;
as-path AS-2 100000;
as-path AS-3 192:29283:2;
}
```

The following example applies the peer-as-billing version 9 template to enable sampling of traffic for billing purposes:

```
forwarding-options {
 sampling {
 }
 input {
 rate 1;
 }
 family inet {
 output {
 flow-server 10.209.15.58 {
 port 300;
 version9 {
 template {
 peer-as;
 }
 }
 }
 }
 interface sp-5/2/0 {
 source-address 2.3.4.5;
 }
 }
}
}
family inet {
 filter {
 output peer-as-filter;
 }
}
```

## Configuring Flow Aggregation to Use IPFIX Flow Templates

Use of IPFIX allows you to define a flow record template suitable for IPv4 traffic or IPv6 traffic. Templates are transmitted to the collector periodically, and the collector need not be aware of the router configuration. You can define template refresh rate, flow active timeout and inactive timeout.

If flow records are being sent for multiple protocol families (for example, for IPv4 and IPv6), each protocol family flow will have a unique Observation Domain ID.

The following sections contain additional information:

- [Configuring the IPFIX Template Properties on page 913](#)
- [Restrictions on page 914](#)
- [Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates on page 914](#)

- [Fields Included in the IPv6 Template on page 916](#)
- [Verification on page 916](#)
- [Example: Configuring an IPFIX Flow Templates and Flow Sampling on page 917](#)

## Configuring the IPFIX Template Properties

To define the IPFIX templates, include the following statements at the **[edit services flow-monitoring version-ipfix]** hierarchy level:

```
[edit services flow-monitoring IPFIX]
template name {
 options-template-id
 template-id
 observation-domain-id
 flow-active-timeout seconds;
 flow-inactive-timeout seconds;
 option-refresh-rate packets packets seconds seconds;
 template-refresh-rate packets packets seconds seconds;
 (ipv4-template | ipv6-template);
}
```

The following details apply to the configuration statements:

- You assign each template a unique name by including the **template *name*** statement.
- You then specify each template for the appropriate type of traffic by including the **ipv4-template** or **ipv6-template**.
- Within the template definition, you can optionally include values for the **flow-active-timeout** and **flow-inactive-timeout** statements. These statements have specific default and range values when they are used in template definitions; the default is 60 seconds and the range is from 10 through 600 seconds.
- You can also include settings for the **option-refresh-rate** and **template-refresh-rate** statements within a template definition. For both of these properties, you can include a timer value (in seconds) or a packet count (in number of packets). For the **seconds** option, the default value is 600 and the range is from 10 through 600. For the **packets** option, the default value is 4800 and the range is from 1 through 480,000.
- To filter IPV6 traffic on a media interface, the following configuration is supported:

```
interfaces interface-name {
 unit 0 {
```

```
family inet6 {
 sampling {
 input;
 output;
 }
}
```

## Restrictions

The following restrictions apply to IPFIX templates:

- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created only after the route record resynchronization operation is complete, which takes 120 seconds.
- VLAN ID field is not valid for egress traffic, and returns a value of 0 for egress traffic.
- The VLAN ID field is updated when a new flow record is created and so, any change in VLAN ID after the record has been created might not be updated in the record.

## Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates

Use of version 9 and IPFIX allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic. Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration. Starting with Junos OS Release 14.1, you can specify the unique identifier for the version 9 and IPFIX templates. The identifier of a template is locally unique within a combination of a transport session and an observation domain. Template IDs 0 through 255 are reserved for template sets, options template sets, and other sets for future use. Template IDs of data sets are numbered from 256 through 65535. Typically, this information element or field in the template is used to define the characteristics or properties of other information elements in a template. After a restart of the export process of templates is performed, template IDs can be reassigned. In Junos OS releases earlier than Release 14.1, template IDs and options template IDs were predefined for each address family and could not be modified.

This functionality to configure template ID, options template ID, observation domain ID, and source ID is supported on all routers with MPCs (Trio chip-based FPCs).

The following values were assigned by default for the template IDs of version 9 templates for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 flow template ID—272
- IPv6 flow template ID—273

- VPLS flow template ID—274
- Options template ID for all address families—520

The corresponding data sets and option data sets contain the value of the template IDs and options template IDs respectively in the set ID field. This method enables the collector to match a data record with a template record.

For more information about specifying the source ID, observation domain ID, template ID, and options template ID for version 9 and IPFIX flows, see [“Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows” on page 918](#) and [“Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows” on page 921](#).

### Fields Included in the IPv4 Template

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS
- Destination AS
- IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum TTL (time to live)
- Maximum TTL (time to live)
- Flow Start Time
- Flow End Time
- Flow End Reason

- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

### Fields Included in the IPv6 Template

- IPv6 Source Address
- IPv6 Destination Address
- IPv6 TOS
- IPv6 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv6 Source Mask
- IPv6 Destination Mask
- Source AS
- Destination AS
- IPv6 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum Hop Limits
- Maximum Hop Limits
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)
- Fragment Identification
- IPv6 Extension Headers

### Verification

The following show commands are supported for IPFIX:

- `show services accounting flow inline-jflow fpc-slot fpc-slot`
- `show services accounting errors inline-jflow fpc-slot fpc-slot`
- `show services accounting status inline-jflow fpc-slot fpc-slot`

### Example: Configuring an IPFIX Flow Templates and Flow Sampling

The following is a sample IPFIX template configuration:

```
services {
 flow-monitoring {
 version-ipfix {
 template ipv4 {
 flow-active-timeout 60;
 flow-inactive-timeout 70;
 template-refresh-rate seconds 30;
 option-refresh-rate seconds 30;
 ipv4-template;
 }
 }
 }
}

chassis {
 fpc 0 {
 sampling-instance s1;
 }
}
```

The following example applies the IPFIX template to enable sampling of traffic for billing:

```
forwarding-options {
 sampling {
 instance {
 s1 {
 input {
 rate 10;
 }
 family inet {
 output {
 flow-server 11.11.4.2 {
 port 2055;
 version-ipfix {
 template {
 ipv4;
 }
 }
 }
 }
 inline-jflow {
 source-address 11.11.2.1;
 }
 }
 }
 }
 }
}
```

## Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows

---

For IPFIX flows, an identifier of an Observation Domain is locally unique to an exporting process of the templates. The export process uses the Observation Domain ID to uniquely identify to the collection process in which the flows were metered. We recommend that you configure this ID to be unique for each IPFIX flow. A value of 0 indicates that no specific Observation Domain is identified by this information element. Typically, this attribute is used to limit the scope of other information elements. If the observation domain is not unique, the collector cannot uniquely identify an IPFIX device.

If you configure the same Observation Domain ID for different template types, such as for IPv4 and IPv6, it does not impact flow monitoring because the actual or the base observation domain ID is transmitted in the flow. The actual observation domain ID is derived from the value you configure and also in conjunction with other parameters such as the slot number, lookup chip (LU) instance, Packet Forwarding Engine instance. Such a method of computation of the observation domain ID ensures that this ID is not the same for two IPFIX devices.

Until Junos OS Release 13.3, the observation domain ID is predefined and is set to a fixed value, which is derived from the combination of FPC slot, sampling protocol, PFE Instance and LU Instance fields. This derivation creates a unique observation domain per LU per family. Starting with Junos OS Release 14.1, you can configure the observation domain ID, which causes the first 8 bits of the field to be configured.

The following modifications have been made:

- FPC slots are expanded to 8 bits to enable more slots to be configured in an MX Series Virtual Chassis configuration.
- 8 bits of the configured observation domain ID are used.
- You can configure a value for the observation domain ID in the range of 0 through 255.
- The Protocol field is increased to 3 bits to provide support for additional protocols in inline flow monitoring.
- You can associate the observation domain ID with templates by using the **observation-domain-id *domain-id*** statement at the **[edit services flow- monitoring version-ipfix template *template-name*]** hierarchy level.

For version 9 flows, a 32-bit value that identifies the Exporter Observation Domain is called the source ID. NetFlow collectors use the combination of the source IP address

and the source ID field to separate different export streams originating from the same exporter.

To specify the observation domain ID for IPFIX flows, include the **observation-domain-id domain-id** statement at the **[edit services flow-monitoring version-ipfix template template-name]** hierarchy level.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 observation-domain-id domain-id;
}
```

To specify the source ID for version 9 flows, include the **source-id source-id** statement at the **[edit services flow-monitoring version9 template template-name]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 source-id source-id;
}
```

Table 32 on page 919 describes observation domain ID values for different combinations of the configured domain ID, protocol family, FPC slot, and the Packet Forwarding Engine and lookup chip instances.

**Table 32: Example of Observation Domain ID**

Configured Value	Protocol Family	FPC Slot	PFE Inst	LU Inst	Observation Domain Id Conf val rsvd 1proto slot LUInst PFEInst  xxxx xxxx xxxx 1xxx xxxx xxxx xxxx xxxx
None	IPv4 (0)	1	1	0	0000 0000 0000 1000 0000 0001 0000 0001 0x00080101

## Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows

Starting with Junos OS Release 14.1, you can define the template ID for version 9 and IPFIX templates for inline flow monitoring. To specify the template ID for version 9 flows, include the **template-id** *id* statement at the **[edit services flow-monitoring version9 template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 template-id id;
}
```

To specify the template ID for version IPFIX flows, include the **template-id** statement at the **[edit services flow-monitoring version-ipfix template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 template-id id;
}
```

To specify the options template ID for version 9 flows, include the **options-template-id** statement at the **[edit services flow-monitoring version9 template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 options-template-id id;
}
```

To specify the options template ID for version IPFIX flows, include the **options-template-id** statement at the **[edit services flow-monitoring version-ipfix template *template-name*]** hierarchy level. The template ID and options template ID can be a value in the range of 1024 through 65535.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 options-template-id id;
}
```

The template ID and options template ID can be a value in the range of 1024 through 65535. If you do not configure values for the template ID and options template ID, default values are assumed for these IDs, which are different for the various address families. If you configure the same template ID or options template ID value for different address families, such a setting is not processed properly and might cause unexpected behavior. For example, if you configure the same template ID value for both IPv4 and IPv6, the collector validates the export data based on the template ID value that it last receives. In this case, if IPv6 is configured after IPv4, the value is effective for IPv6 and the default value is used for IPv4.

The following are the default values of template IDs for IPFIX flows for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 IPFIX flow template ID—256
- IPv6 IPFIX flow template ID—257
- VPLS IPFIX flow template ID—258
- MPLS IPFIX flow template ID—259

The following are the default values of template IDs for version 9 flows for the different protocols or address families, starting with Junos OS Release 14.1:

- IPv4 version 9 flow template ID—320
- IPv6 version 9 flow template ID—321
- VPLS version 9 flow template ID—322
- MPLS version 9 flow template ID—323

The following are the default values of template IDs for IPFIX flows for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 IPFIX flow options template ID—512
- IPv6 IPFIX flow options template ID—513
- VPLS IPFIX flow options template ID—514
- MPLS IPFIX flow options template ID—515

The following are the default values of template IDs for version 9 flows for the different protocols or address families, starting with Junos OS Release 14.1:

- IPv4 version 9 flow options template ID—576
- IPv6 version 9 flow options template ID—577
- VPLS version 9 flow options template ID—578
- MPLS version 9 flow options template ID—579

[Table 33 on page 923](#) describes the values of data template and option template IDs for different protocols with default and configured values for IPFIX flows.

## Directing Replicated Flows to Multiple Flow Servers

You can configure replication of the sampled flow records for use by multiple flow servers. You can use either sampling based on the Routing Engine, using cflowd version 5 or version 8, or sampling based on the services PIC, using flow aggregation version 9, as described in the following sections:

- [Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers on page 926](#)
- [Directing Replicated Version 9 Flow Aggregates to Multiple Servers on page 927](#)

### Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers

Routing Engine–based sampling supports up to eight flow servers for both cflowd version 5 and version 8 configurations. The total number of servers is limited to eight regardless of how many are configured for cflowd v5 or v8.

When you configure cflowd-based sampling, the export packets are replicated to all flow servers configured to receive them. If two servers are configured to receive v5 records, both the servers will receive records for a specified flow.

**NOTE:** With Routing Engine–based sampling, if multiple flow servers are configured with version 8 export format, all of them must use the same aggregation type. For example, all servers receiving version 8 export could be configured for source-destination aggregation type.

The following configuration example allows replication of export packets to two flow servers.

```
forwarding-options {
 sampling {
 instance inst1 {
 input {
 rate 1;
 }
 family inet;
 output {
 flow-server 10.10.3.2 {
 port 2055;
 version 5;
 source-address 192.168.164.119;
 }
 flow-server 172.17.20.62 {
 port 2055;
 version 5;
 source-address 192.168.164.119;
 }
 }
 }
 }
}
```

```
 }
 }
}
```

## Directing Replicated Version 9 Flow Aggregates to Multiple Servers

The export packets generated for a template are replicated to all the flow servers that are configured to receive information for that template. The maximum number of servers supported is eight.

This also implies that periodic updates required by version 9 (RFC 3954) are sent to each configured collector. The following updates are sent periodically as part of this requirement:

- Options data
- Template definition

The refresh period for options data and template definition is configured on a per-template basis at the **[edit services flow-monitoring]** hierarchy level.

The following configuration example allows replication of version 9 export packets to two flow servers.

```
forwarding-options {
 sampling {
 instance inst1 {
 input {
 rate 1;
 }
 family inet;
 output {
 flow-server 10.10.3.2 {
 port 2055;
 version9 {
 template {
 ipv4;
 }
 }
 }
 flow-server 172.17.20.62 {
 port 2055;
 version9 {
 template {
 ipv4;
 }
 }
 }
 }
 flow-inactive-timeout 30;
 flow-active-timeout 60;
 interface sp-4/0/0 {
 source-address 10.10.3.4;
 }
 }
 }
}
```

```
}
}
```

## Logging cflowd Flows Before Export

To collect the cflowd flows in a log file before they are exported, include the **local-dump** statement at the **[edit forwarding-options sampling output flow-server *hostname*]** hierarchy level:

```
[edit forwarding-options sampling output flow-server hostname]
local-dump;
```

By default, the flows are collected in **/var/log/sampled**; to change the filename, include the **filename** statement at the **[edit forwarding-options sampling traceoptions]** hierarchy level. For more information about changing the filename, see [“Configuring Traffic Sampling Output” on page 876](#).

**NOTE:** Because the **local-dump** statement adds extra overhead, you should use it only while debugging cflowd problems, not during normal operation.

The following is an example of the flow information. The AS number exported is the origin AS number. All flows that belong under a cflowd header are dumped, followed by the header itself:

```
Jun 27 18:35:43 v5 flow entry
Jun 27 18:35:43 Src addr: 192.53.127.1
Jun 27 18:35:43 Dst addr: 192.6.255.15
Jun 27 18:35:43 Nhop addr: 192.6.255.240
Jun 27 18:35:43 Input interface: 5
Jun 27 18:35:43 Output interface: 3
Jun 27 18:35:43 Pkts in flow: 15
Jun 27 18:35:43 Bytes in flow: 600
Jun 27 18:35:43 Start time of flow: 7230
Jun 27 18:35:43 End time of flow: 7271
Jun 27 18:35:43 Src port: 26629
Jun 27 18:35:43 Dst port: 179
Jun 27 18:35:43 TCP flags: 0x10
Jun 27 18:35:43 IP proto num: 6
Jun 27 18:35:43 TOS: 0xc0
Jun 27 18:35:43 Src AS: 7018
Jun 27 18:35:43 Dst AS: 11111
Jun 27 18:35:43 Src netmask len: 16
Jun 27 18:35:43 Dst netmask len: 0
```

[... 41 more version 5 flow entries; then the following header:]

```
Jun 27 18:35:43 cflowd header:
Jun 27 18:35:43 Num-records: 42
Jun 27 18:35:43 Version: 5
Jun 27 18:35:43 low seq num: 118
Jun 27 18:35:43 Engine id: 0
Jun 27 18:35:43 Engine type: 3
```

# Sending Packets for Analysis Using Port Mirroring

- [Understanding Port Mirroring on page 931](#)
- [Configuring Port Mirroring on page 931](#)
- [Defining a Next-Hop Group for Port Mirroring on page 948](#)
- [Example: Multiple Port Mirroring with Next-Hop Groups Configuration on page 949](#)

## Understanding Port Mirroring

---

On routers containing an Internet Processor II application-specific integrated circuit (ASIC) or T Series Internet Processor, you can send a copy of an IP version 4 (IPv4) or IP version 6 (IPv6) packet from the router to an external host address or a packet analyzer for analysis. This is known as *port mirroring*.

Port mirroring is different from traffic sampling. In traffic sampling, a sampling key based on the IPv4 header is sent to the Routing Engine. There, the key can be placed in a file, or cflowd packets based on the key can be sent to a cflowd server. In port mirroring, the entire packet is copied and sent out through a next-hop interface.

You can configure simultaneous use of sampling and port mirroring, and set an independent sampling rate and run-length for port-mirrored packets. However, if a packet is selected for both sampling and port mirroring, only one action can be performed and port mirroring takes precedence. For example, if you configure an interface to sample every packet input to the interface and a filter also selects the packet to be port mirrored to another interface, only the port mirroring would take effect. All other packets not matching the explicit filter port-mirroring criteria continue to be sampled when forwarded to their final destination.

### Related Documentation

- [Configuring Port Mirroring on page 931](#)
- [Example: Multiple Port Mirroring with Next-Hop Groups Configuration on page 949](#)

## Configuring Port Mirroring

---

To prepare traffic for port mirroring, include the **filter** statement at the **[edit firewall family inet]** hierarchy level:

```
filter filter-name;
```

This filter at the `[edit firewall family (inet | inet6)]` hierarchy level selects traffic to be port-mirrored:

```
filter filter-name {
 term term-name {
 then {
 port-mirror;
 accept;
 }
 }
}
```

To configure port mirroring on a logical interface, configure the following statements at the `[edit forwarding-options port-mirroring]` hierarchy level:

```
[edit forwarding-options port-mirroring family inet]
input {
 maximum-packet-length bytes;
 rate rate;
 run-length number;
}
family (inet|inet6) {
 output {
 interface interface-name {
 next-hop address;
 }
 no-filter-check;
 }
}
```

or

```
[edit forwarding-options port-mirroring]
input {
 maximum-packet-length bytes;
 rate rate;
 run-length number;
}
family inet6 {
 output {
 next-hop-group group-name{
 group-type inet6;
 interface interface-name {
 next-hop ipv6-address;
 }
 }
 next-hop-subgroup group-name{
 interface interface-name {
 next-hop ipv6-address;
 }
 }
 }
}
```

**NOTE:** The input statement can also be configured at the [edit forwarding-options port-mirroring] hierarchy level. This is only maintained for backward compatibility. However, the configuration of the output statement is deprecated at the [edit forwarding-options port-mirroring] hierarchy level.

Specify the port-mirroring destination by including the **next-hop** statement at the [edit forwarding-options port-mirroring output interface *interface-name*] hierarchy level:

```
next-hop address;
```

**NOTE:** For IPv4 port mirroring to reach a next-hop destination, you must manually include a static Address Resolution Protocol (ARP) entry in the router configuration.

You can also specify the port-mirroring destination by including the **next-hop-group** statement at the [edit forwarding-options port-mirroring family inet6 output] hierarchy level:

```
next-hop-group group-name {
 group-type inet6;
 interface interface-name {
 next-hop ipv6-address;
 }
 next-hop-subgroup group-name {
 interface interface-name {
 next-hop ipv6-address;
 }
 }
}
```

The **no-filter-check** statement is required when you send port-mirrored traffic to a Tunnel PIC that has a filter applied to it. en

The interface used to send the packets to the analyzer is the output interface configured above at the [edit forwarding-options port-mirroring family (inet | inet6) output] hierarchy level. You can use any physical interface type, including generic routing encapsulation (GRE) tunnel interfaces. The next-hop address specifies the destination address; this statement is mandatory for non point-to-point interfaces, such as Ethernet interfaces.

To configure the sampling rate or duration, include the **rate** or **run-length** statement at the [edit forwarding-options port-mirroring input] hierarchy level.

You can trace port-mirroring operations the same way you trace sampling operations. For more information, see [“Tracing Traffic Sampling Operations” on page 878](#).

For more information about port mirroring, see the following sections:

- [Configuring Tunnels on page 934](#)
- [Port Mirroring with Next-Hop Groups on page 936](#)

- [Configuring Inline Port Mirroring on page 937](#)
- [Filter-Based Forwarding with Multiple Monitoring Interfaces on page 938](#)
- [Restrictions on page 938](#)
- [Configuring Port Mirroring on Services Interfaces on page 939](#)
- [Examples: Configuring Port Mirroring on page 940](#)

## Configuring Tunnels

In typical applications, you send the sampled packets to an analyzer or a workstation for analysis, rather than another router. If you must send this traffic over a network, you should use tunnels. For more information about tunnel interfaces, see *Tunnel Properties*.

The MX Series routers support Dense Port Concentrators (DPCs) with built-in Ethernet ports, which do not support Tunnel Services PICs. To create tunnel interfaces on an MX Series router with a DPC, you configure the DPC and the corresponding Packet Forwarding Engine to use for tunneling services at the **[edit chassis]** hierarchy level. You also configure the amount of bandwidth reserved for tunnel services. The Junos OS creates tunnel interfaces on the Packet Forwarding Engine.

To create tunnel interfaces on MX Series routers, include the following statements at the **[edit chassis]** hierarchy level:

```
[edit chassis]
fpc slot-number {
 pic number {
 tunnel-services {
 bandwidth bandwidth-value;
 }
 }
}
```

Include the **fpc slot-number** statement to specify the slot number of the DPC. If two SCBs are installed, the range is 0 through 1. If three SCBs are installed, the range is 0 through 5 and 7 through 11.

Include the **pic number** statement to specify the number of the Packet Forwarding Engine on the DPC. The range is 0 through 3.

You can also specify the amount of bandwidth to allocate for tunnel traffic on each Packet Forwarding Engine by including the **bandwidth bandwidth-value** statement at the **[edit chassis fpc slot-number pic pic-number]** hierarchy level:

- **1g** indicates that 1 Gbps of bandwidth is reserved for tunnel traffic. Configure this option only for a Packet Forwarding Engine on a Gigabit Ethernet 40-port DPC.
- **10g** indicates that 10 Gbps of bandwidth is reserved for tunnel traffic. Configure this option only for a Packet Forwarding Engine on a 10-Gigabit Ethernet 4-port DPC.
- **20g** or **40g**—Configure 20 gigabits per second or 40 gigabits per second only on an MX Series router with the MPC3E and the 100-Gigabit CFP MIC.

If you specify a bandwidth that is not compatible with the type of DPC and Packet Forwarding Engine, tunnel services are not activated. For example, you cannot specify a

bandwidth of 1 Gbps for a Packet Forwarding Engine on a 10-Gigabit Ethernet 4-port DPC.

When you configure tunnel interfaces on the Packet Forwarding Engine of a 10-Gigabit Ethernet 4-port DPC, the Ethernet interfaces for that port are removed from service and are no longer visible in the command-line interface (CLI). The Packet Forwarding Engine of a 10-Gigabit Ethernet 4-port DPC supports either tunnel interfaces or Ethernet interfaces, but not both. Each port on the 10-Gigabit Ethernet 4-port DPC includes two LEDs, one for tunnel services and one for Ethernet services, to indicate which type of service is being used. On the Gigabit Ethernet 40-port DPC, you can configure both tunnel and Ethernet interfaces at the same time.

If your router is equipped with a Tunnel PIC, you can forward duplicate packets to multiple interfaces by configuring a next-hop group. To configure a next-hop group, include the **next-hop-group** statement at the **[edit forwarding-options]** hierarchy level:

```
[edit forwarding-options]
next-hop-group group-names {
 interface interface-name {
 next-hop address;
 }
}
```

The **interface** statement specifies the interface that sends out sampled information. The **next-hop** statement specifies the next-hop addresses to which to send the sampled information.

For IPv6 port mirroring to reach next-hop destination, you can configure a **next-hop-group** statement at the **[edit forwarding-options port-mirroring family inet6 output]** hierarchy level:

```
next-hop-group group-name {
 group-type inet6;
 interface interface-name {
 next-hop ipv6-address;
 }
 next-hop-subgroup group-name {
 interface interface-name {
 next-hop ipv6-address;
 }
 }
}
```

Next-hop groups have the following restrictions:

- Next-hop groups are supported for inet, inet6, and bridge family.
- Next-hop groups are supported on M Series and MX Series routers.
- Next-hop groups or next-hop subgroups support up to 16 next-hop addresses.
- Up to 30 next-hop groups are supported.
- Each next-hop group is expected to have at least two next-hop addresses.
- Each next-hop subgroup supports up to 16 next-hop groups.

## Port Mirroring with Next-Hop Groups

You can configure next-hop groups for M Series, MX Series, and TX Series routers using either IP addresses or Layer 2 addresses for the next hops. Use the **group-type [ inet | inet6 | layer-2 ]** statement at **[edit forwarding-options next-hop-group next-hop-group-name]** hierarchy level to establish the next-hop groups. You can reference more than one port mirroring instance in a filter on MX Series routers. Use the **port-mirror-instance instance-name** statement at the **[edit firewall family family-name filter filter-name term term-name]** hierarchy level to refer to one of several port mirroring instances. For more information about this configuration, see the *Layer 2 Port Mirroring Feature Guide for Routing Devices*.

**NOTE:** On MX Series routers with MPCs, port mirroring instances can only be bound to the FPC level and not up to the PIC level. For MX series routers with a DPC card, both levels are supported.

On M Series, MX Series, and T Series routers only, you can configure port mirroring using next-hop groups, also known as *multipacket port mirroring*, without the presence of a Tunnel PIC. To configure this functionality, include the **next-hop-group** statement at the **[edit forwarding-options port-mirror family [inet | inet6] output]** or **[edit forwarding-options port-mirror instance instance-name family inet output]** hierarchy level:

```
[edit forwarding-options]
port-mirror {
 family inet {
 output {
 next-hop-group group-name {
 interface interface-name {
 next-hop address;
 }
 }
 }
 }
}
or
[edit forwarding-options]
port-mirror {
 family inet6 {
 output {
 next-hop-group group-name {
 group-type inet6;
 interface interface-name {
 next-hop ipv6-address;
 }
 }
 next-hop-subgroup group-name {
 interface interface-name {
 next-hop ipv6-address;
 }
 }
 }
 }
}
```

```

 }
 }
}
or
[edit forwarding-options]
port-mirror {
 instance instance-name {
 family (inet | vpls) {
 output {
 next-hop-group group-name;
 }
 }
 }
}

```

You define the next-hop group by including the **next-hop-group** statement at the **[edit forwarding-options]** hierarchy level. For an example, see [“Examples: Configuring Port Mirroring” on page 940](#). This configuration is supported with IPv4 and IPv6 addresses.

You can disable this configuration by including a **disable** or **disable-all-instances** statement at the **[edit forwarding-options port-mirror]** hierarchy level or by including a **disable** statement at the **[edit forwarding-options port-mirror instance *instance-name*]** hierarchy level. You can display the settings and network status by issuing the **show forwarding-options next-hop-group** and **show forwarding-options port-mirroring** operational commands.

**NOTE:** If you try to bind any derived instance to the FPC, a commit error will occur.

## Configuring Inline Port Mirroring

Inline port mirroring provides you with the ability to specify instances that are not bound to the flexible PIC concentrator (FPC) in the firewall filter’s **then port-mirror-instance** action. This way, you are not limited to only two port-mirror instances per FPC. Inline port mirroring decouples the port-mirror destination from the input parameters like **rate**. While the input parameters are programmed in the switch interface board, the next-hop destination of the mirrored packet is available in the packet itself. Inline port mirroring is supported only on MX Series routers with MPCs.

Using inline port mirroring, a port-mirror instance will have an option to inherit input parameters from another instance that specifies it, as shown in the following CLI configuration example:

```

instance pm2 {
 + input-parameters-instance pm1;
 family inet {
 output {
 interface ge-1/2/3.0 {
 next-hop 50.0.0.3;
 }
 }
 }
}

```

```
 }
 }
}
```

Multiple levels of inheritance are not allowed. One instance can be referred by multiple instances. An instance can refer to another instance that is defined before it. Forward references are not allowed and an instance cannot refer to itself, doing so will cause an error during configuration parsing.

The user can specify an instance that is not bound to the FPC in the firewall filter. The specified filter should inherit one of the two instances that have been bound to the FPC. If it does not, the packet is not marked for port-mirroring. If it does, then the packet will be sampled using the input parameters specified by the referred instance but the copy will be sent to the its own destination.

## Filter-Based Forwarding with Multiple Monitoring Interfaces

If port-mirrored packets are to be distributed to multiple monitoring or collection interfaces based on patterns in packet headers, it is helpful to configure a filter-based forwarding (FBF) filter on the port-mirroring egress interface.

When an FBF filter is installed as an output filter, a packet that is forwarded to the filter has already undergone at least one route lookup. After the packet is classified at the egress interface by the FBF filter, it is redirected to another routing table for additional route lookup. Obviously, the route lookup in the latter routing table (designated by an FBF routing instance) must result in a different next hop from those from the previous tables the packet has passed through, to avoid packet looping inside the Packet Forwarding Engine.

For more information about FBF configuration, see the *Junos OS Routing Protocols Library for Routing Devices*. For an example of FBF applied to an output interface, see [“Examples: Configuring Port Mirroring” on page 940](#).

## Restrictions

The following restrictions apply to port-mirroring configurations:

- The interface you configure for port mirroring should not participate in any kind of routing activity.
- The destination address you specify should not have a route to the ultimate traffic destination. For example, if the sampled IPv4 packets have a destination address of **10.68.9.10** and the port-mirrored traffic is sent to **10.68.20.15** for analysis, the device associated with the latter address should not know a route to **10.68.9.10**. Also, it should not send the sampled packets back to the source address.
- IPv4 and IPv6 traffic is supported. For IPv6 port mirroring, you must configure the next-hop router with an IPv6 neighbor before mirroring the traffic, similar to an ARP request for IPv4 traffic. All the restrictions applied to IPv4 configurations should also apply to IPv6.
- On M120 and M320 routers, multiple next-hop mirroring is not supported.

- Because M320 routers do not support multiple bindings of port-mirror instances per FPC, the **port-mirror-instance** action is not supported in firewall filters for these routers.
- Port mirroring in the ingress and egress direction is not supported for link services IQ (lsq-) interfaces.
- On M Series routers other than the M120 and M320 routers, only one family protocol (either IPv4 or IPv6) is supported at a time.
- Port mirroring supports up to 16 next hops.
- Only transit data is supported.
- You can configure multiple port-mirroring interfaces per router.
- On routers containing an Internet Processor II application-specific integrated circuit (ASIC), you must include a firewall filter with both the **accept** action and the **port-mirror** action modifier on the inbound interface. Do not include the **discard** action, or port mirroring will not work.
- If the port-mirroring interface is a non-point-to-point interface, you must include an IP address under the **port-mirroring** statement to identify the other end of the link. This IP address must be reachable for you to see the sampled traffic. If the port-mirroring interface is an Ethernet interface, the router should have an Address Resolution Protocol (ARP) entry for it. The following sample configuration sets up a static ARP entry.
- You do not need to configure firewall filters on both inbound and outbound interfaces, but at least one is necessary on the inbound interface to provide the copies of the packets to send to an analyzer.
- Inline port mirroring is supported only on MX Series routers with MPCs.
- Configuration for both port mirroring and traffic sampling are handled by the same daemon, so in order to view a trace log file for port mirroring, you must configure the **traceoptions** option under traffic sampling.

## Configuring Port Mirroring on Services Interfaces

A special situation arises when you configure unit **0** of a services interface (AS or Multiservices PIC) to be the port-mirroring logical interface, as in the following example:

```
[edit forwarding-options]
port-mirroring {
 input {
 rate 1;
 }
 family inet {
 output {
 interface sp-1/0/0.0;
 }
 }
}
```

Since any traffic directed to unit **0** on a services interface is targeted for monitoring (cflowd packets are generated for it), the sample port-mirroring configuration indicates

that the customer would like to have cflowd records generated for the port-mirrored traffic.

However, generation of cflowd records requires the following additional configuration; if it is missing, the port-mirrored traffic is simply dropped by the services interface without generating any cflowd packets.

```
[edit forwarding-options]
sampling {
 instance instance1 { # named instances of sampling parameters
 input {
 rate 1;
 }
 family inet {
 output {
 flow-server 172.16.28.65 {
 port 1230;
 }
 }
 interface sp-1/0/0 { # If the port-mirrored traffic requires monitoring, this
 # interface must be same as that specified in the
 # port-mirroring configuration.
 source-address 3.1.2.3;
 }
 }
 }
}
```

**NOTE:** Another way to configure sp-1/0/0 to generate cflowd records is to use only the sampling configuration, but include a firewall filter `sample` action instead of a `port-mirror` action.

---

## Examples: Configuring Port Mirroring

The following example sends port-mirrored traffic to multiple cflowd servers or packet analyzers:

```
[edit interfaces]
ge-1/0/0 { # This is the input interface where packets enter the router.
 unit 0 {
 family inet {
 filter {
 input mirror_pkts; # Here is where you apply the first filter.
 }
 address 10.11.0.1/24;
 }
 }
}
ge-1/1/0 { # This is an exit interface for HTTP packets.
 unit 0 {
 family inet {
 address 10.12.0.1/24;
 }
 }
}
```

```

 }
 }
 ge-1/2/0 { # This is an exit interface for HTTP packets.
 unit 0 {
 family inet {
 address 10.13.0.1/24;
 }
 }
 }
 so-0/3/0 { # This is an exit interface for FTP packets.
 unit 0 {
 family inet {
 address 10.1.1.1/30;
 }
 }
 }
 so-4/3/0 { # This is an exit interface for FTP packets.
 unit 0 {
 family inet {
 address 10.2.2.2/30;
 }
 }
 }
 so-7/0/0 { # This is an exit interface for all remaining packets.
 unit 0 {
 family inet {
 address 10.5.5.5/30;
 }
 }
 }
 so-7/0/1 { # This is an exit interface for all remaining packets.
 unit 0 {
 family inet {
 address 10.6.6.6/30;
 }
 }
 }
 vt-3/3/0 { # The tunnel interface is where you send the port mirrored traffic.
 unit 0 {
 family inet;
 }
 unit 1 {
 family inet {
 filter {
 input collect_pkts; # This is where you apply the second firewall filter.
 }
 }
 }
 }
}
[edit forwarding-options]
port-mirroring { # This is required when you configure next-hop groups.
 input {
 rate 1; # This rate port mirrors one packet for every one received (1:1 = all
 # packets).
 }
 family inet {

```

```
 output { # This sends traffic to a tunnel interface to prepare for multiport mirroring.
 interface vt-3/3/0.1;
 no-filter-check;
 }
 }
}
next-hop-group ftp-traffic { # Point-to-point interfaces require you to specify the interface
 # name only.
 interface so-4/3/0.0;
 interface so-0/3/0.0;
}
next-hop-group http-traffic { # You need to configure a next hop for multipoint interfaces
 # (Ethernet).
 interface ge-1/1/0.0 {
 next-hop 10.12.0.2;
 }
 interface ge-1/2/0.0 {
 next-hop 10.13.0.2;
 }
}
next-hop-group default-collect {
 interface so-7/0/0.0;
 interface so-7/0/1.0;
}
[edit firewall]
family inet {
 filter mirror_pkts { # Apply this filter to the input interface.
 term catch_all {
 then {
 count input_mirror_pkts;
 port-mirror; # This action sends traffic to be copied and port mirrored.
 accept;
 }
 }
 }
 filter collect_pkts { # Apply this filter to the tunnel interface.
 term ftp-term { # This term sends FTP traffic to an FTP next-hop group.
 from {
 protocol ftp;
 }
 then next-hop-group ftp-traffic;
 }
 term http-term { # This term sends HTTP traffic to an HTTP next-hop group.
 from {
 protocol http;
 }
 then next-hop-group http-traffic;
 }
 term default { # This term sends all remaining traffic to a final next-hop group.
 then next-hop-group default-collectors;
 }
 }
}
```

The following example demonstrates configuration of filter-based forwarding at the output interface. In this example, the packet flow follows this path:

1. A packet arrives at interface **fe-1/2/0.0** with source and destination addresses **10.50.200.1** and **10.50.100.1**, respectively.
2. The route lookup in routing table **inet.0** points to the egress interface **so-0/0/3.0**.
3. The output filter installed at **so-0/0/3.0** redirects the packet to routing table **fbf.inet.0**.
4. The packet matches the entry **10.50.100.0/25**, and finally leaves the router from interface **so-2/0/0.0**.

```
[edit interfaces]
so-0/0/3 {
 unit 0 {
 family inet {
 filter {
 output fbf;
 }
 address 10.50.10.2/25;
 }
 }
}
fe-1/2/0 {
 unit 0 {
 family inet {
 address 10.50.50.2/25;
 }
 }
}
so-2/0/0 {
 unit 0 {
 family inet {
 address 10.50.20.2/25;
 }
 }
}
[edit firewall]
filter fbf {
 term 0 {
 from {
 source-address {
 10.50.200.0/25;
 }
 }
 then routing-instance fbf;
 }
 term d {
 then count d;
 }
}
[edit routing-instances]
fbf {
 instance-type forwarding;
 routing-options {
```

```
 static {
 route 10.50.100.0/25 next-hop so-2/0/0.0;
 }
 }
}
[edit routing-options]
interface-routes {
 rib-group inet fbf-group;
}
static {
 route 10.50.100.0/25 next-hop 10.50.10.1;
}
rib-groups {
 fbf-group {
 import-rib [inet.0 fbf.inet.0];
 }
}
```

The following example shows configuration of port mirroring using next-hop groups or multipacket port mirroring:

```
forwarding-options {
 next-hop-group inet_nhg {
 group-type inet;
 interface ge-2/0/2.101 {
 next-hop 10.2.0.2;
 }
 interface ge-2/2/8.2 {
 next-hop 10.8.0.2;
 }
 }
 next-hop-group vpls_nhg {
 group-type layer-2;
 interface ge-2/0/1.100;
 interface ge-2/2/9.0;
 inactive: next-hop-subgroup vpls_subg {
 interface ge-2/0/1.101;
 interface ge-2/2/9.1;
 }
 }
 next-hop-group vpls_nhg_2 {
 group-type layer-2;
 interface ge-2/2/1.100;
 interface ge-2/3/9.0;
 }
}
port-mirror {
 disable-all-instances; /* Disable all port-mirroring instances */
 disable; /* Disable the global instance */
 input {
 rate 10; # start mirroring every 10th packet
 run-length 4; # mirror 4 additional packets
 }
 family inet {
 output {
 next-hop-group inet_nhg;
 }
 }
}
```

```

}
family inet6 {
 output {
 next-hop-group inet6_nhg6 {
 group-type inet6;
 interface ge-2/0/3.102 {
 next-hop 10::1:1:10;
 }
 interface ge-2/0/4.103 {
 next-hop 20::1:1:10;
 }
 next-hop-subgroup vpls_subg {
 interface ge-2/0/.101 {
 next-hop 3::1:1:1;
 }
 interface ge-2/2/9.1 {
 next-hop 4::1:1:1;
 }
 }
 }
 }
}
family vpls {
 output {
 next-hop-group vpls_nhg;
 }
}
instance {
 inst1 {
 disable; /* Disable this instance */
 input {
 rate 1;
 maximum-packet-length 200;
 }
 family inet {
 output {
 next-hop-group inet_nhg;
 }
 }
 family inet6 {
 output {
 next-hop-group inet6_nhg6;
 }
 }
 family vpls {
 output {
 next-hop-group vpls_nhg_2;
 }
 }
 }
}
}

```

The following example shows configuration of port mirroring using next-hop groups or multipacket port mirroring on a T Series router:

```
forwarding-options {
 next-hop-group inet_nhg {
 group-type inet;
 interface so-0/0/0.0; # There is no need for the nexthop address on T Series routers
 interface ge-2/0/2.0 {
 next-hop 1.2.3.4
 }
 }
 next-hop-subgroup sub_inet {
 interface so-1/2/0.0;
 interface ge-6/1/2.0 {
 next-hop 6.7.8.9;
 }
 }
 next-hop-group vpls_nhg_2 {
 group-type layer-2;
 interface ge-2/2/1.100;
 interface ge-2/3/9.0;
 }
}
port-mirroring {
 disable-all-instances; /*Disable all port-mirroring instances */
 disable; /* Disable the global instance */
 input {
 rate 10;
 run-length 4;
 }
 family inet {
 output {
 next-hop-group inet_nhg;
 }
 }
 family vpls {
 output {
 next-hop-group vpls_nhg;
 }
 }
 instance {
 inst1 {
 disable; /* Disable this instance */
 input {
 rate 1;
 maximum-packet-length 200;
 }
 family inet {
 output {
 next-hop-group inet_nhg;
 }
 }
 family vpls {
 output {
 next-hop-group vpls_nhg_2;
 }
 }
 }
 }
}
```

```
}

```

The following example shows configuration of inline port mirroring using PM1, PM2, and PM3 as our port mirror instances.

```
instance {
 pm1 {
 input {
 rate 3;
 }
 family inet {
 output {
 interface ge-1/2/2.0 {
 next-hop 40.0.0.2;
 }
 }
 }
 }
 pm2 {
 input-parameters-instance pm1;
 family inet {
 output {
 interface ge-1/2/3.0 {
 next-hop 50.0.0.3;
 }
 }
 }
 }
 pm3 {
 input {
 rate 3;
 }
 family inet6 {
 output {
 interface ge-1/2/3.0 {
 next-hop 5::5:5:1;
 }
 }
 }
 }
}
firewall {
 filter pm_filter {
 term t1 {
 then port-mirror-instance pm2;
 }
 }
 filter nhg6_filter6 {
 term t6 {
 then next-hop-group inet6-nhg6;
 }
 }
}
chassis {
 fpc 1 {
 port-mirror-instance pm1;
 }
}
```

```
}
```

The packets will be sampled at a rate of 3, and the copy is sent to 50.0.0.3.

## Defining a Next-Hop Group for Port Mirroring

On routers containing an Internet Processor II application-specific integrated circuit (ASIC) or T Series Internet Processor, you can send a copy of an IP version 4 (IPv4) or IP version 6 (IPv6) packet from the router to an external host address or a packet analyzer for analysis. This is known as *port mirroring*.

Port mirroring is different from traffic sampling. In traffic sampling, a sampling key based on the IPv4 header is sent to the Routing Engine. There, the key can be placed in a file, or cflowd packets based on the key can be sent to a cflowd server. In port mirroring, the entire packet is copied and sent out through a next-hop interface.

You can configure simultaneous use of sampling and port mirroring, and set an independent sampling rate and run-length for port-mirrored packets. However, if a packet is selected for both sampling and port mirroring, only one action can be performed, and port mirroring takes precedence. For example, if you configure an interface to sample every packet input to the interface and a filter also selects the packet to be port mirrored to another interface, only the port mirroring would take effect. All other packets not matching the explicit filter port-mirroring criteria continue to be sampled when forwarded to their final destination.

Next-hop groups allow you to include port mirroring multiple interfaces used to forward duplicate packets used in port mirroring.

On MX Series routers, you can mirror tunnel interface input traffic to multiple destinations. To this form of multipacket port mirroring, you specify two or more additional destinations in a next-hop group, define a firewall filter that references the next-hop group as the filter action, and then apply the filter to a logical tunnel interface (lt-) or virtual tunnel interface (vt-) on the MX Series router.

To define a next-hop group for a Layer 2 port-mirroring firewall filter action:

1. Enable the configuration of forwarding options.

```
[edit]
user@host set forwarding-options port-mirroring family (inet | inet6) output
```

2. Enable configuration of a next-hop-group for Layer 2 port mirroring.

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output]
user@host# set next-hop-group next-hop-group-name
```

3. Specify the type of addresses to be used in the next-hop group configuration.

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output next-hop-group
next-hop-group-name]
user@host# set group-type inet6
```

- Specify the interfaces of the next-hop route.

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output next-hop-group
next-hop-group-name]
user@host# set interface logical-interface-name-1
user@host# set interface logical-interface-name-2
```

or

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output next-hop-group
next-hop-group-name]
user@host# set interface interface-name next-hop next-hop-address
```

The MX Series router supports up to 30 next-hop groups. Each next-hop group supports up to 16 next-hop addresses. Each next-hop group must specify at least two addresses. The *next-hop-address* can be an IPv4 or IPv6 address.

- (Optional) Specify the next-hop subgroup.

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output next-hop-group
next-hop-group-name]
user@host# set next-hop-subgroup subgroup-name interface interface-name next-hop
next-hop-address
```

- Verify the configuration of the next-hop group.

```
[edit forwarding-options port-mirroring ... family (inet | inet6) output next-hop-group
next-hop-group-name]
user@host# top
[edit]
user@host# show forwarding-options
```

```
...
next-hop-group next-hop-group-name {
 group-type inet6;
 interface logical-interface-name-1;
 interface interface-name{
 next-hop next-hop-address;
 }
 next-hop-subgroup subgroup-name{
 interface interface-name{
 next-hop next-hop-address;
 }
 }
}
...
```

## Example: Multiple Port Mirroring with Next-Hop Groups Configuration

When you need to analyze traffic containing more than one packet type, or you wish to perform multiple types of analysis on a single type of traffic, you can implement multiple

port mirroring and next-hop groups. You can make up to 16 copies of traffic per group and send the traffic to next-hop group members. A maximum of 30 groups can be configured on a router at any given time. The port-mirrored traffic can be sent to any interface, except aggregated SONET/SDH, aggregated Ethernet, loopback (**lo0**), or administrative (**fxp0**) interfaces. To send port-mirrored traffic to multiple flow servers or packet analyzers, you can use the **next-hop-group** statement at the **[edit forwarding-options]** hierarchy level.

**Figure 35: Active Flow Monitoring—Multiple Port Mirroring with Next-Hop Groups Topology Diagram**

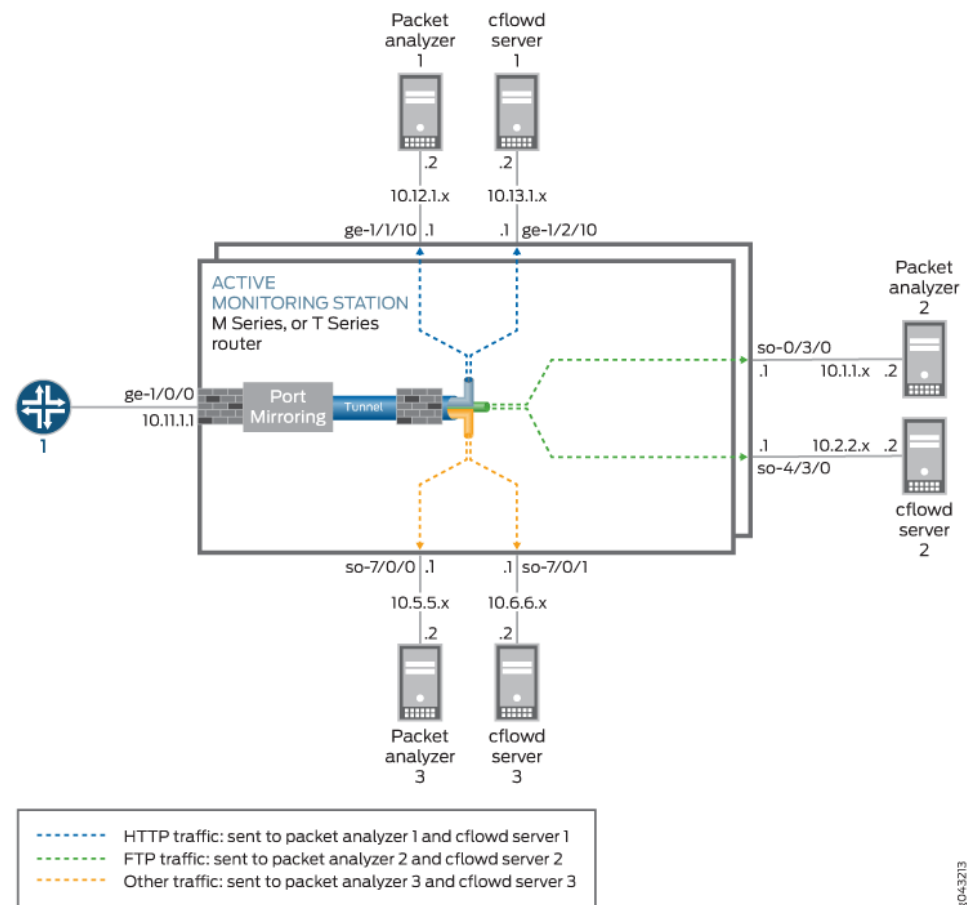

Figure 35 on page 950 shows an example of how to configure multiple port mirroring with next-hop groups. All traffic enters the monitoring router at interface **ge-1/0/0**. A firewall filter counts and port-mirrors all incoming packets to a Tunnel Services PIC. A second filter is applied to the tunnel interface and splits the traffic into three categories: HTTP traffic, FTP traffic, and all other traffic. The three types of traffic are assigned to three separate next-hop groups. Each next-hop group contains a unique pair of exit interfaces that lead to different groups of packet analyzers and flow servers.

**NOTE:** Instances enabled to mirror packets to different destinations from the same PFE, also use different sampling parameters for each instance. When we configure Layer2 Port-mirroring with both global port-mirroring and instance based port-mirroring, PIC level instances will override FPC level and the FPC level will override the Global instance.

```
[edit]
interfaces {
 ge-1/0/0 { # This is the input interface where packets enter the router.

## Real-Time Performance Monitoring Services Overview

---

Real-Time Performance Monitoring (RPM) enables you to configure active probes to track and monitor traffic. Probes collect packets per destination and per application, including PING Internet Control Message Protocol (ICMP) packets, User Datagram Protocol and Transmission Control Protocol (UDP/TCP) packets with user-configured ports, user-configured Differentiated Services code point (DSCP) type-of-service (ToS) packets, and Hypertext Transfer Protocol (HTTP) packets. RPM provides Management Information Base (MIB) support with extensions for RFC 2925, *Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations*.

You can also configure RPM services to determine automatically whether a path exists between a host router and its configured BGP neighbors. You can view the results of the discovery using an SNMP client. Results are stored in **pingResultsTable**, **jnxPingResultsTable**, **jnxPingProbeHistoryTable**, and **pingProbeHistoryTable**.

Probe configuration and probe results are supported by the command-line interface (CLI) and SNMP.

The following probe types are supported with DSCP marking:

- ICMP echo
- ICMP timestamp
- HTTP get (not available for BGP RPM services)
- UDP echo
- TCP connection
- UDP timestamp

With probes, you can monitor the following:

- Minimum round-trip time
- Maximum round-trip time
- Average round-trip time
- Standard deviation of the round-trip time
- Jitter of the round-trip time—The difference between the minimum and maximum round-trip time

One-way measurements for ICMP timestamp probes include the following:

- Minimum, maximum, standard deviation, and jitter measurements for egress and ingress times
- Number of probes sent
- Number of probe responses received
- Percentage of lost probes

**NOTE:** Timestamping is not supported on PTX Series Packet Transport Routers.

---

You can configure the following RPM thresholds:

- Round-trip time
- Ingress/egress delay
- Standard deviation
- Jitter
- Successive lost probes
- Total lost probes (per test)

Support is also implemented for user-configured CoS classifiers and for prioritization of RPM packets over regular data packets received on an input interface.

- Related Documentation**

  - [Examples: Configuring BGP Neighbor Discovery Through RPM on page 973](#)

## Configuring RPM Probes

The owner name and test name identifiers of an RPM probe together represent a single RPM configuration instance. When you specify the test name, you also can configure the test parameters.

To configure the probe owner, test name, and test parameters, include the **probe** statement at the **[edit services rpm]** hierarchy level:

```
probe owner {
 test test-name {
 data-fill data;
 data-size size;
 destination-interface interface-name;
 destination-port port;
 dscp-code-point dscp-bits;
 hardware-timestamp;
 history-size size;
 moving-average-size number;
 one-way-hardware-timestamp;
 probe-count count;
 probe-interval seconds;
 probe-type type;
 routing-instance instance-name;
 source-address address;
 target (url url | address address);
 test-interval interval;
 thresholds thresholds;
 traps traps;
 }
}
```

Keep the following points in mind when you configure RPM clients and RPM servers:

- You cannot configure an RPM client that is PIC-based and an RPM server that is based on either the Packet Forwarding Engine or Routing Engine to receive the RPM probes.
- You cannot configure an RPM client that is Packet Forwarding Engine-based and an RPM server that receives the RPM probes to be on the PIC or Routing Engine.
- The RPM client and RPM server must be located on the same type of module. For example, if the RPM client is PIC-based, the RPM server must also be PIC-based, and if the RPM server is Packet Forwarding Engine-based, the RPM client must also be Packet Forwarding Engine-based.

- To specify a probe owner, include the **probe** statement at the **[edit services rpm]** hierarchy level. The probe owner identifier can be up to 32 characters in length.
- To specify a test name, include the **test** statement at the **[edit services rpm probe owner]** hierarchy level. The test name identifier can be up to 32 characters in length. A test represents the range of probes over which the standard deviation, average, and jitter are calculated.
- To specify the contents of the data portion of Internet Control Message Protocol (ICMP) probes, include the **data-fill** statement at the **[edit services rpm probe owner]** hierarchy level. The value can be a hexadecimal value. The **data-fill** statement is not valid with the **http-get** or **http-metadata-get** probe types.
- To specify the size of the data portion of ICMP probes, include the **data-size** statement at the **[edit services rpm probe owner]** hierarchy level. The size can be from 0 through 65400 and the default size is 0. The **data-size** statement is not valid with the **http-get** or **http-metadata-get** probe types.

**NOTE:** If you configure the hardware timestamp feature (see [“Configuring RPM Timestamping” on page 964](#)):

- The **data-size** default value is 32 bytes and 32 is the minimum value for explicit configuration. The UDP timestamp probe type is an exception; it requires a minimum data size of 44 bytes.
  - The **data-size** must be at least 100 bytes smaller than the default MTU of the interface of the RPM client interface.
- 
- On M Series and T Series routers, you configure the **destination-interface** statement to enable hardware timestamping of RPM probe packets. You specify an **sp-** interface to have the AS or Multiservices PIC add the hardware timestamps; for more information, see [“Configuring RPM Timestamping” on page 964](#). You can also include the **one-way-hardware-timestamp** statement to enable one-way delay and jitter measurements.
  - To specify the User Datagram Protocol (UDP) port or Transmission Control Protocol (TCP) port to which the probe is sent, include the **destination-port** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. The **destination-port** statement is used only for the UDP and TCP probe types. The value can be 7 or from 49160 through 65535.

When you configure either **probe-type udp-ping** or **probe-type udp-ping-timestamp** along with hardware timestamping, the value for the **destination-port** can be only 7. A constraint check prevents you from configuring any other value for the destination port in this case. This constraint does not apply when you are using one-way hardware timestamping.

- To specify the value of the Differentiated Services (DiffServ) field within the IP header, include the **dscp-code-point** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. The DiffServ code point (DSCP) bits value can be set to a valid 6-bit pattern; for example, 001111. It also can be set using an alias configured at

the **[edit class-of-service code-point-aliases dscp]** hierarchy level. The default is 000000.

- To specify the number of stored history entries, include the **history-size** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. Specify a value from 0 to 512. The default is 50.
- To specify a number of samples for making statistical calculations, include the **moving-average-size** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. Specify a value from 0 through 255.
- To specify the number of probes within a test, include the **probe-count** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. Specify a value from 1 through 15.
- To specify the time to wait between sending packets, include the **probe-interval** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. Specify a value from 1 through 255 seconds.
- To specify the packet and protocol contents of the probe, include the **probe-type** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. The following probe types are supported:
  - **http-get**—Sends a Hypertext Transfer Protocol (HTTP) get request to a target URL.
  - **http-metadata-get**—Sends an HTTP get request for metadata to a target URL.
  - **icmp-ping**—Sends ICMP echo requests to a target address.
  - **icmp-ping-timestamp**—Sends ICMP timestamp requests to a target address.
  - **tcp-ping**—Sends TCP packets to a target.
  - **udp-ping**—Sends UDP packets to a target.
  - **udp-ping-timestamp**—Sends UDP timestamp requests to a target address.

The following probe types support hardware timestamping of probe packets: **icmp-ping**, **icmp-ping-timestamp**, **udp-ping**, **udp-ping-timestamp**.

**NOTE:** Some probe types require additional parameters to be configured. For example, when you specify the **tcp-ping** or **udp-ping** option, you must configure the destination port using the **destination-port** statement. The **udp-ping-timestamp** option requires a minimum data size of 12; any smaller data size results in a commit error. The minimum data size for TCP probe packets is 1.

When you configure either **probe-type udp-ping** or **probe-type udp-ping-timestamp** along with the **one-way-hardware-timestamp** command, the value for the **destination-port** can be only 7. A constraint check prevents you for configuring any other value for the destination port in this case.

- To specify the routing instance used by ICMP probes, include the **routing-instance** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. The default routing instance is Internet routing table **inet.0**.
- To specify the source IP address used for ICMP probes, include the **source-address** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. If the source IP address is not one of the router's assigned addresses, the packet will use the outgoing interface's address as its source.
- To specify the destination address used for the probes, include the **target** statement at the **[edit services rpm probe owner test test-name]** hierarchy level.
  - For HTTP probe types, specify a fully formed URL that includes **http://** in the URL address.
  - For all other probe types, specify an IP version 4 (IPv4) address for the target host.
- To specify the time to wait between tests, include the **test-interval** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. Specify a value from 1 through 86400 seconds.

**NOTE:** Starting with Junos OS Release 15.1, the minimum period for which the RPM client waits between two tests is modified to be 1 second instead of 0 seconds. Also, if you do not configure the test interval, the default value is 1 second.

---

- To specify thresholds used for the probes, include the **thresholds** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. A system log message is generated when the configured threshold is exceeded. Likewise, an SNMP trap (if configured) is generated when a threshold is exceeded. The following options are supported:
  - **egress-time**—Measures maximum source-to-destination time per probe.
  - **ingress-time**—Measures maximum destination-to-source time per probe.
  - **jitter-egress**—Measures maximum source-to-destination jitter per test.
  - **jitter-ingress**—Measures maximum destination-to-source jitter per test.
  - **jitter-rtt**—Measures maximum jitter per test, from 0 through 60000000 microseconds.
  - **rtt**—Measures maximum round-trip time per probe, in microseconds.
  - **std-dev-egress**—Measures maximum source-to-destination standard deviation per test.
  - **std-dev-ingress**—Measures maximum destination-to-source standard deviation per test.
  - **std-dev-rtt**—Measures maximum standard deviation per test, in microseconds.

- **successive-loss**—Measures successive probe loss count, indicating probe failure.
- **total-loss**—Measures total probe loss count indicating test failure, from 0 through 15.
- Traps are sent if the configured threshold is met or exceeded. To set the trap bit to generate traps, include the **traps** statement at the **[edit services rpm probe owner test test-name]** hierarchy level. The following options are supported:
  - **egress-jitter-exceeded**—Generates traps when the jitter in egress time threshold is met or exceeded.
  - **egress-std-dev-exceeded**—Generates traps when the egress time standard deviation threshold is met or exceeded.
  - **egress-time-exceeded**—Generates traps when the maximum egress time threshold is met or exceeded.
  - **ingress-jitter-exceeded**—Generates traps when the jitter in ingress time threshold is met or exceeded.
  - **ingress-std-dev-exceeded**—Generates traps when the ingress time standard deviation threshold is met or exceeded.
  - **ingress-time-exceeded**—Generates traps when the maximum ingress time threshold is met or exceeded.
  - **jitter-exceeded**—Generates traps when the jitter in round-trip time threshold is met or exceeded.
  - **probe-failure**—Generates traps for successive probe loss thresholds crossed.
  - **rtt-exceeded**—Generates traps when the maximum round-trip time threshold is met or exceeded.
  - **std-dev-exceeded**—Generates traps when the round-trip time standard deviation threshold is met or exceeded.
  - **test-completion**—Generates traps when a test is completed.
  - **test-failure**—Generates traps when the total probe loss threshold is met or exceeded.

## Configuring RPM Receiver Servers

The RPM TCP and UDP probes are proprietary to Juniper Networks and require a receiver to receive the probes. To configure a server to receive the probes, include the **probe-server** statement at the **[edit services rpm]** hierarchy level:

```
[edit services rpm]
probe-server {
```

```
tcp {
 destination-interface interface-name;
 port number;
}
udp {
 port number;
}
}
```

The port number specified for the UDP and TCP server can be 7 or from 49160 through 65535.

**NOTE:** The `destination-interface` statement is not supported on PTX Series Packet Transport Routers.

When you configure either `probe-type udp-ping` or `probe-type udp-ping-timestamp` along with the `one-way-hardware-timestamp` command, the value for the `destination-port` can be only 7. A constraint check prevents you for configuring any other value for the destination port in this case.

---

## Limiting the Number of Concurrent RPM Probes

To configure the maximum number of concurrent probes allowed, include the `probe-limit` statement at the `[edit services rpm]` hierarchy level:

```
probe-limit limit;
```

Specify a limit from 1 through 500. The default maximum number is 100.

## Configuring RPM Timestamping

To account for latency in the communication of probe messages, you can enable timestamping of the probe packets. You can timestamp the following RPM probe types: `icmp-ping`, `icmp-ping-timestamp`, `udp-ping`, and `udp-ping-timestamp`.

On M Series and T Series routers with an Adaptive Services (AS) or Multiservices PIC, and on EX Series switches with a Multiservices DPC, and on EX Series switches, you can enable hardware timestamping of RPM probe messages. The timestamp is applied on both the RPM client router (the router or switch that originates the RPM probes) and the RPM probe server and applies only to IPv4 traffic. It is supported on the following:

- Layer 2 services package on all Multiservices PICs and DPCs.
- Layer 3 service package on AS and Multiservices PICs and Multiservices DPCs.
- Extension-provider services package on M Series, MX Series, and T Series services PICs that support the Extension-Provider packages (In Junos OS releases earlier than 12.3, the extension-provider packages were variously referred to as Junos Services Framework (JSF), MP-SDK, and eJunos.)
- Layer 2, Layer 3, SDK Services, and PFE RPM timestamping interoperate with each other. Here, the RPM client can be on the Layer 3 **sp-** interface and the RPM server can be on an SDK Services package.

**NOTE:** Hardware timestamping is not supported on PTX Series Packet Transport Routers.

Two-way timestamping is available on **sp-** and **ms-** interfaces. To configure two-way timestamping on M Series and T Series routers, include the **destination-interface** statement at the **[edit services rpm probe probe-owner test test-name]** hierarchy level:

```
destination-interface sp-fpc/pic/port.logical-unit
destination-interface ms-fpc/pic/port.logical-unit
```

Specify the RPM client router and the RPM server router on the adaptive services logical interface or the multiservices interface by including the **rpm** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level:

```
rpm (client | server);
```

The logical interface must be dedicated to the RPM task. It requires configuration of the **family inet** statement and a **/32** address, as shown in the example. This configuration is also needed for other services such as NAT and stateful firewall. You cannot configure RPM service on **unit 0** because RPM requires a dedicated logical interface; the same unit cannot support both RPM and other services. Because active flow monitoring requires **unit 0**, but RPM can function on any logical interface, a constraint check prevents you from committing an RPM configuration there.

**NOTE:** If you configure RPM timestamping on an AS PIC, you cannot configure the **source-address** statement at the **[edit services rpm probe probe-name test test-name]** hierarchy level.

On MX Series routers, on M-320 routers using the Enhanced Queuing MPC, and on EX Series switches, you include the **hardware-timestamp** statement at the **[edit services rpm**

**probe *probe-name* test *test-name*]** hierarchy level to specify that the probes are to be timestamped in the Packet Forwarding Engine host processor:

**hardware-timestamp;**

On the client side, these probes are timestamped in the Packet Forwarding Engine host processor on the egress DPC on the MX or M-320 Series router or EX Series switch originating the RPM probes (RPM client). On the responder side (RPM server), the RPM probes to be timestamped are handled by the Packet Forwarding Engine host processor, which generates the response instead of the RPM process. The RPM probes are timestamped only on the router that originates them (RPM client). As a result, only round-trip time is measured for these probes.

When using the **hardware-timestamp**, the **data-size** value for the probe must be at least 100 bytes smaller than the default MTU of the interface of the RPM client interface (see [“Configuring RPM Probes” on page 959](#)). If hardware timestamping of RPM probe messages is enabled, the maximum data size that you can configure by using the data-size statement is limited to 1400.

**NOTE:** The Packet Forwarding Engine-based RPM feature does not support any stateful firewall configurations. If you need to combine RPM timestamping with a stateful firewall, you should use the interface-based RPM timestamping service described earlier in this section. Multiservices DPCs support stateful firewall processing as well as RPM timestamping.

---

To configure one-way timestamping, you must also include the **one-way-hardware-timestamp** statement at the **[edit services rpm probe *probe-owner* test *test-name*]** hierarchy level:

**one-way-hardware-timestamp;**

**NOTE:** If you configure RPM probes for a services interface (sp-), you need to announce local routes in a specific way for the following routing protocols:

- For OSPF, you can announce the local route by including the services interface in the OSPF area. To configure this setting, include the interface `sp-fpc/pic/port` statement at the [edit protocols ospf area *area-number*] hierarchy level.
- For BGP and IS-IS, you must export interface routes and create a policy that accepts the services interface local route. To export interface routes, include the point-to-point and lan statements at the [edit routing-options interface-routes family inet export] hierarchy level. To configure an export policy that accepts the services interface local route, include the protocol local, rib inet.0, and route-filter `sp-interface-ip-address/32` exact statements at the [edit policy-options policy-statement *policy-name* term *term-name* from] hierarchy level and the accept action at the [edit policy-options policy-statement *policy-name* term *term-name* then] hierarchy level. For the export policy to take effect, apply the policy to BGP or IS-IS with the export *policy-name* statement at the [edit protocols *protocol-name*] hierarchy level.

For more information about these configurations, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices* or the *Junos OS Routing Protocols Library for Routing Devices*.

Routing the probe packets through the adaptive services or Multiservices PIC also enables you to filter the probe packets to particular queues. The following example shows the RPM configuration and the filter that specifies queuing:

```
services rpm {
 probe p1 {
 test t1 {
 probe-type icmp-ping;
 target address 10.8.4.1;
 probe-count 10;
 probe-interval 10;
 test-interval 10;
 dscp-code-points af11;
 data-size 100;
 destination-interface sp-1/2/0.0;
 }
 }
}
firewall {
 filter f1 {
 term t1 {
 from {
 dscp af11;
 }
 then {
 forwarding-class assured-forwarding;
 }
 }
 }
}
```

```
 }
 }
}
interfaces sp-1/2/0 {
 unit 2 {
 rpm client;
 family inet {
 address 10.8.4.2/32;
 filter {
 input f1;
 }
 }
 }
}
interfaces sp-1/2/1 {
 unit 2 {
 rpm server;
 family inet {
 address 10.8.3.2/32;
 filter {
 input f1;
 }
 }
 }
}
```

For more information about firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*; for more information about queuing, see the *Class of Service Feature Guide for Routing Devices*.

## Configuring TWAMP

You can configure the Two-Way Active Measurement Protocol (TWAMP) on all M Series and T Series routers that support Multiservices PICs (running in either Layer 2 or Layer 3 mode), and on MX Series routers. Only the responder (server) side of TWAMP is supported.

**NOTE:** TWAMP is not supported on EX Series switches and PTX Series Packet Transport Routers.

For more information on TWAMP, see RFC 5357, *A Two-Way Active Measurement Protocol (TWAMP)*.

To configure TWAMP properties, include the **twamp** statement at the [\[edit services rpm\]](#) hierarchy level:

```
[edit services rpm]
```

```

twamp {
 server {
 client-list list-name {
 [address address];
 }
 authentication-mode mode;
 max-connection-duration hours;
 maximum-connections count;
 maximum-connections-per-client count;
 maximum-sessions count;
 maximum-sessions-per-connection count;
 port number;
 routing-instance-list {
 instance-name {
 port number;
 }
 }
 server-inactivity-timeout minutes;
 }
}

```

The TWAMP configuration process includes the following tasks:

- [Configuring TWAMP Interfaces on page 969](#)
- [Configuring TWAMP Servers on page 969](#)

## Configuring TWAMP Interfaces

To specify the service PIC logical interface that provides the TWAMP service, include the **twamp-server** statement at the **[edit interfaces sp-fpc/pic/port unit logical-unit-number]** hierarchy level:

```
twamp-server;
```

**NOTE:** On MX Series routers that do not include a Multiservices DPC, you can configure the **twamp-server** statement on any interface (for example, **ge-1/0/1.10**). It is not necessary to configure this statement on a service interface (**sp-** or **ms-**) but you do need to include it in the configuration to activate the TWAMP reflector functionality.

## Configuring TWAMP Servers

You can specify a number of TWAMP server properties, some of which are optional, by including the **server** statement at the **[edit services rpm twamp]** hierarchy level:

```

[edit services rpm twamp]
server {
 client-list list-name {
 [address address];
 }
 authentication-mode mode;
 max-connection-duration hours;
 maximum-connections count;

```

```
maximum-connections-per-client count;
maximum-sessions count;
maximum-sessions-per-connection count;
port number;
routing-instance-list {
 instance-name {
 port number;
 }
}
server-inactivity-timeout minutes;
}
```

The preceding configuration settings that are described define a TWAMP server on the router that enables a TWAMP client to connect to the server using any media interface IP address such as a **ge-** interface. In such a scenario, the router functions as a TWAMP server and timestamping is performed in the ukernel of the media-facing FPC.

To configure an inline TWAMP server, which causes timestamping to be performed as part of the inline services (**si-**) interface processing, configure the amount of bandwidth reserved on each Packet Forwarding Engine for tunnel traffic using inline services by including the **bandwidth (1g | 10g)** statement at the **[edit chassis fpc slot-number pic number inline-services]** hierarchy level and specify the service PIC logical interface that provides the TWAMP service by including the **twamp-server** statement at the **[edit interfaces sp-fpc/pic/port unit logical-unit- number family inet]** hierarchy level.

- To specify the list of allowed control client hosts that can connect to this server, include the **client-list** statement at the **[edit services rpm twamp server]** hierarchy level. Each value you include must be a Classless Interdomain Routing (CIDR) address (IP address plus mask) that represents a network of allowed hosts. You can include multiple client lists, each of which can contain a maximum of 64 entries. You must configure at least one client address to enable TWAMP.
- You must specify the authentication mode by including the **authentication-mode** statement at the **[edit services rpm twamp server]** hierarchy level. There is no default value. You can configure **authenticated** or **encrypted** mode, based on RFC 4656; if there is no authentication or encryptions mode specified, you should set the value to **none**. This statement is required in the TWAMP configuration.
- To specify the inactivity timeout period in seconds, include the **inactivity-timeout** statement at the **[edit services rpm twamp server]** hierarchy level. By default, the value is **1800**; the range is 0 through 3600 seconds.
- To specify the maximum number of concurrent connections the server can have to client hosts, include the **maximum-connections** statement at the **[edit services rpm twamp server]** hierarchy level. The allowed range of values is 1 through 1000 and the default value is 64. You can also limit the number of connections the server can make to a particular client host by including the **maximum-connections-per-client** statement. The allowed range of values is 1 through 500 and the default value is 64.
- To specify the maximum number of sessions the server can have running at one time, include the **maximum-sessions** statement at the **[edit services rpm twamp server]** hierarchy level. The allowed range of values is 1 through 2048 and the default value is

64. You can also limit the number of sessions the server can have on a single connection by including the **maximum-sessions-per-connection** statement.

- To specify the TWAMP server listening port, include the **port** statement at the **[edit services rpm twamp server]** hierarchy level. The range is 1 through 65,535.
- To specify the server inactivity timeout period in minutes, include the **server-inactivity-timeout** statement at the **[edit services rpm twamp server]** hierarchy level. The range is 0 through 30 minutes.
- To specify the TWAMP servers on specific routing instances, instead of associating the TWAMP server at the system-level to apply to all routing instances configured on a router, include the **routing-instance-list instance-name port port-number** statement at the **[edit services rpm twamp server]** hierarchy level. The port number of the specified routing instance is used for TWAMP probes that are received by a TWAMP server. The default routing instance is Internet routing table inet.0. If you do not specify a routing instance, the TWAMP probe applies to all routing instances. To apply the TWAMP probe to only the default routing instance, you must explicitly set the value of instance-name to default. If an interface is not part of any routing instance, the default port is used for TWAMP probes. You can configure up to 100 routing instances for a TWAMP server.

## Configuring BGP Neighbor Discovery Through RPM

BGP neighbors can be configured at the following hierarchy levels:

- **[edit protocols bgp group group-name]**—Default logical system and default routing instance.
- **[edit routing-instances instance-name protocols bgp group group-name]**—Default logical system with a specified routing instance.
- **[edit logical-systems logical-system-name protocols bgp group group-name]**—Configured logical system and default routing instance.
- **[edit logical-systems logical-system-name routing-instances instance-name protocols bgp group group-name]**—Configured logical system with a specified routing instance.

When you configure BGP neighbor discovery through RPM, if you do not specify a logical system, the RPM probe applies to configured BGP neighbors for all logical systems. If you do not specify a routing instance, the RPM probe applies to configured BGP neighbors in all routing instances. You can explicitly configure RPM probes to apply only to the default logical system, the default routing instance, or to a particular logical system or routing instance.

To configure BGP neighbor discovery through RPM, configure the probe properties at the **[edit services rpm bgp]** hierarchy:

```
data-fill data;
data-size size;
destination-port port;
history-size size;
logical-system logical-system-name [routing-instances routing-instance-name];
```

**moving-average-size** *number*;  
**probe-count** *count*;  
**probe-interval** *seconds*;  
**probe-type** *type*;  
**routing-instances** *instance-name*;  
**test-interval** *interval*;

- To specify the contents of the data portion of Internet Control Message Protocol (ICMP) probes, include the **data-fill** statement at the **[edit services rpm bgp]** hierarchy level. The value can be a hexadecimal value.
- To specify the size of the data portion of ICMP probes, include the **data-size** statement at the **[edit services rpm bgp]** hierarchy level. The size can be from 0 through 65400 and the default size is 0.
- To specify the User Datagram Protocol (UDP) port or Transmission Control Protocol (TCP) port to which the probe is sent, include the **destination-port** statement at the **[edit services rpm bgp]** hierarchy level. The **destination-port** statement is used only for the UDP and TCP probe types. The value can be 7 or from 49160 through 65535.
- To specify the number of stored history entries, include the **history-size** statement at the **[edit services rpm bgp]** hierarchy level. Specify a value from 0 to 512. The default is 50.
- To specify the logical system used by ICMP probes, include the **logical-system** *logical-system-name* statement at the **[edit services rpm bgp]** hierarchy level. If you do not specify a logical system, the RPM probe applies to configured BGP neighbors for all logical systems. To apply the probe to only the default logical system, you must set the value of *logical-system-name* to null.
- To specify a number of samples for making statistical calculations, include the **moving-average-size** statement at the **[edit services rpm bgp]** hierarchy level. Specify a value from 0 through 255.
- To specify the number of probes within a test, include the **probe-count** statement at the **[edit services rpm bgp]** hierarchy level. Specify a value from 1 through 15.
- To specify the time to wait between sending packets, include the **probe-interval** statement at the **[edit services rpm bgp]** hierarchy level. Specify a value from 1 through 255 seconds.
- To specify the packet and protocol contents of the probe, include the **probe-type** statement at the **[edit services rpm bgp]** hierarchy level. The following probe types are supported:
  - **icmp-ping**—Sends ICMP echo requests to a target address.
  - **icmp-ping-timestamp**—Sends ICMP timestamp requests to a target address.
  - **tcp-ping**—Sends TCP packets to a target.
  - **udp-ping**—Sends UDP packets to a target.
  - **udp-ping-timestamp**—Sends UDP timestamp requests to a target address.

**NOTE:** Some probe types require additional parameters to be configured. For example, when you specify the `tcp-ping` or `udp-ping` option, you must configure the destination port using the `destination-port port` statement. The `udp-ping-timestamp` option requires a minimum data size of 12; any smaller data size results in a commit error. The minimum data size for TCP probe packets is 1.

- To specify the routing instance used by ICMP probes, include the **routing-instances** statement at the `[edit services rpm bgp]` hierarchy level. The default routing instance is Internet routing table `inet.0`. If you do not specify a routing instance, the RPM probe applies to configured BGP neighbors in all routing instances. To apply the RPM probe to only the default routing instance, you must explicitly set the value of *instance-name* to **default**.
- To specify the time to wait between tests, include the **test-interval** statement at the `[edit services bgp probe]` hierarchy level. Specify a value from 1 through 86400 seconds.

**NOTE:** Starting with Junos OS Release 15.1, the minimum period for which the RPM client waits between two tests is modified to be 1 second instead of 0 seconds. Also, if you do not configure the test interval, the default value is 1 second.

#### Related Documentation

- [\[edit services rpm\] Hierarchy Level on page 1631](#)
- [Examples: Configuring BGP Neighbor Discovery Through RPM on page 973](#)

## Examples: Configuring BGP Neighbor Discovery Through RPM

Configure BGP neighbor discovery through RPM for all logical systems and all routing instances:

```
[edit services rpm]
bgp {
 probe-type icmp-ping;
 probe-count 5;
 probe-interval 1;
 test-interval 60;
 history-size 10;
 data-size 255;
 data-fill 0123456789;
}
```

Configure BGP neighbor discovery through RPM for only the following logical systems and routing instances: **LS1/RI1**, **LS1/RI2**, **LS2**, and **RI3**:

```
[edit services rpm]
bgp {
```

```
probe-type icmp-ping;
probe-count 5;
probe-interval 1;
test-interval 60;
history-size 10;
data-size 255;
data-fill 0123456789;
logical-system {
 LS1 {
 routing-instances {
 RI1;
 RI2;
 }
 }
 LS2;
}
routing-instance {
 RI3;
}
}
```

**NOTE:** The `logical-system` statement is not supported on PTX Series Packet Transport Routers.

Configure BGP neighbor discovery through RPM for only the default logical system and default routing instance:

```
[edit services rpm]
bgp {
 probe-type icmp-ping;
 probe-count 5;
 probe-interval 1;
 test-interval 60;
 history-size 10;
 data-size 255;
 data-fill 0123456789;
 logical-system {
 null {
 routing-instances {
 default;
 }
 }
 }
}
```

- [\[edit services rpm\] Hierarchy Level on page 1631](#)

## Tracing RPM Operations

Tracing operations track all RPM operations and record them in a log file. The logged error descriptions provide detailed information to help you solve problems faster.

By default, no events are traced. If you include the **traceoptions** statement at the **[edit services rpm]** hierarchy level, the default tracing behavior is the following:

- Important events are logged in a file called **rmopd** located in the **/var/log** directory.
- When the log file reaches 128 kilobytes (KB), it is renamed **rmopd.0**, then **rmopd.1**, and so on, until there are three trace files. Then the oldest trace file (**rmopd.2**) is overwritten. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)
- Log files can be accessed only by the user who configures the tracing operation.

You can change this default behavior by using the **traceoptions** statements. Changing the defaults is described in the following sections:

1. [Configuring the RPM Log File Name on page 975](#)
2. [Configuring the Number and Size of RPM Log Files on page 975](#)
3. [Configuring Access to the Log File on page 976](#)
4. [Configuring a Regular Expression for Lines to Be Logged on page 976](#)
5. [Configuring the Trace Operations on page 976](#)

### Configuring the RPM Log File Name

By default, the name of the file that records RPM trace output is **rmopd**. To specify a different file name:

```
[edit services rpm traceoptions]
user @host set file filename
```

### Configuring the Number and Size of RPM Log Files

To configure the limits on the number and size of RPM trace files:

```
[edit services rpm traceoptions]
user@host set file filename files number size size
```

The number of files can be from 2 through 1000 files. The file size of each file can be from 10 KB through 1 gigabyte (GB).

For example, set the maximum file size to 2 MB, and the maximum number of files to 20 for a log file named **rpmtrace**:

```
[edit services rpm traceoptions]
user@host set file rpmtrace files 20 size 2MB
```

When the **rpmtrace** file reaches 2 MB, it is renamed **rpmtrace.0**, and a new file called **rpmtrace** is created. When the new **rpmtrace** reaches 2 MB, **rpmtrace.0** is renamed

**rpmtrace.1** and **rpmtrace** is renamed **rpmtrace.0**. This process repeats until there are 20 trace files. Then the oldest file (**rpmtrace.19**) is overwritten by **rpmtrace.18**.

## Configuring Access to the Log File

By default, log files can be accessed only by the user who configures the tracing operation.

To specify that any user can read all log files:

```
[edit services rpm traceoptions]
user@host set file filename world-readable
```

To explicitly set the default behavior:

```
[edit services rpm traceoptions]
user@host set file filename no-world-readable
```

## Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

To refine the output by specifying a regular expression (regex) to be matched:

```
[edit services rpm traceoptions]
user@host set file filename match regular-expression
```

## Configuring the Trace Operations

By default, if the **traceoptions** configuration is present, only important events are logged. You can configure the trace operations to be logged by including the following statements at the **[edit services rpm traceoptions]** hierarchy level:

```
flag {
 all;
 configuration;
 error;
 ipc;
 ppm;
 statistics
}
```

[Table 7 on page 51](#) describes the meaning of the RPM tracing flags.

**Table 36: RPM Tracing Flags**

Flag	Description	Default Setting
<b>all</b>	Trace all operations.	Off
<b>configuration</b>	Trace configuration events.	Off
<b>error</b>	Trace events related to catastrophic errors in daemon.	Off
<b>ipc</b>	Trace IPC events.	Off

Table 36: RPM Tracing Flags (*continued*)

Flag	Description	Default Setting
<b>ppm</b>	Trace ppm events.	Off
<b>statistics</b>	Trace statistics.	Off

## Examples: Configuring Real-Time Performance Monitoring

Configure an RPM instance identified by the probe name **probe1** and the test name **test1**:

```
[edit services rpm]
probe probe1 {
 test test1 {
 dscp-code-points 001111;
 probe-interval 1;
 probe-type icmp-ping;
 target address 172.17.20.182;
 test-interval 20;
 thresholds rtt 10;
 traps rtt-exceeded;
 }
}
probe-server {
 tcp {
 destination-interface lt-0/0/0.0
 port 50000;
 }
 udp {
 destination-interface lt-0/0/0.0
 port 50001;
 }
}
probe-limit 200;
```

Configure packet classification, using **lt-** interfaces to send the probe packets to a logical tunnel input interface. By sending the packet to the logical tunnel interface, you can configure regular and multifield classifiers, firewall filters, and header rewriting for the probe packets. To use the existing tunnel framework, the **dlci** and **encapsulation** statements must be configured.

```
[edit services rpm]
probe p1 {
 test t1 {
 probe-type icmp-ping;
 target address 10.8.4.1;
 probe-count 10;
 probe-interval 10;
 test-interval 10;
 source-address 10.8.4.2;
 dscp-code-points ef;
 data-size 100;
 destination-interface lt-0/0/0.0;
 }
}
```

```
}
[edit interfaces]
lt-0/0/0 {
 unit 0 {
 encapsulation frame-relay;
 dlci 10;
 peer-unit 1;
 family inet;
 }
 unit 1 {
 encapsulation frame-relay;
 dlci 10;
 peer-unit 0;
 family inet;
 }
}
[edit class-of-service]
interfaces {
 lt-0/0/0 {
 unit 1 {
 classifiers {
 dscp default;
 }
 }
 }
}
```

Configure an input filter on the interface on which the RPM probes are received. This filter enables prioritization of the received RPM packets, separating them from the regular data packets received on the same interface.

```
[edit firewall]
filter recos {
 term recos {
 from {
 source-address {
 10.8.4.1/32;
 }
 destination-address {
 10.8.4.2/32;
 }
 }
 then {
 loss-priority high;
 forwarding-class network-control;
 }
 }
}
[edit interfaces]
fe-5/0/0 {
 unit 0 {
 family inet {
 filter {
 input recos;
 }
 address 10.8.4.2/24;
 }
 }
}
```

```

 }
 }
}

```

Configure an RPM instance and enable RPM for the extension-provider packages on the adaptive services interface:

```

[edit services rpm]
probe probe1 {
 test test1 {
 data-size 1024;
 data-fill 0;
 destination-interface ms-1/2/0.10;
 dscp-code-points 001111;
 probe-count 10;
 probe-interval 1;
 probe-type icmp-ping;
 target address 172.17.20.182;
 test-interval 20;
 thresholds rtt 10;
 traps rtt-exceeded;
 }
}
[edit interfaces]
ms-1/2/0 {
 unit 0 {
 family inet;
 }
 unit 10 {
 rpm client;
 family inet {
 address 1.1.1.1/32;
 }
 }
}
[edit chassis]
fpc 1 {
 pic 2 {
 adaptive-services {
 service-package {
 extension-provider {
 control-cores 1;
 data-cores 1;
 object-cache-size 512;
 policy-db-size 64;
 package jservices-rpm;
 syslog {
 daemon any;
 }
 }
 }
 }
 }
}
}
}
}

```

**NOTE:** TWAMP is not supported on PTX Series Packet Transport Routers.

Configure the minimum statements necessary to enable TWAMP:

```
[edit services]
rpm {
 twamp {
 server {
 authentication-mode none;
 port 10000; # Twamp server's listening port
 client-list LIST-1 { # LIST-1 is the name of the client-list. Multiple lists can be
 configured.
 address {
 20.0.0.2/30; # IP address of the control client.
 }
 }
 }
 }
}
[edit interfaces sp-5/0/0]
unit 0 {
 family inet;
}
unit 10 {
 rpm {
 twamp-server; # You must configure a separate logical interface on the service PIC
 interface for the TWAMP server.
 }
 family inet {
 address 50.50.50.50/32; # This address must be a host address with a 32-bit mask.
 }
}
[edit chassis]
fpc 5 {
 pic 0 {
 adaptive-services {
 service-package layer-2; # Configure the service PIC to run in Layer 2 mode.
 }
 }
}
```

Configure additional TWAMP settings:

```
[edit services]
rpm {
 twamp {
 server {
 maximum-sessions 5;
 maximum-sessions-per-connection 2;
 maximum-connections 3;
 maximum-connections-per-client 1;
 port 10000;
 server-inactivity-timeout ;
 client-list LIST-1 {
 address {
```

```

 20.0.0.2/30;
 }
}
}
}
}

```

#### Related Documentation

## Enabling RPM for the Junos OS extension-provider package

Real-time performance monitoring (RPM), which has been supported on the adaptive services interface, is now supported by the Junos OS extension-provider package. RPM is supported on all platforms and service PICs that support the extension-provider package.

**NOTE:** In Junos OS releases earlier than 12.3, the extension provider package was variously known as MP-SDK, Junos Services Framework (JSF), and eJunos.

To enable RPM for the Junos OS extension-provider package on the adaptive services interface, configure the **object-cache-size**, **policy-db-size**, and **package** statements at the **[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]** hierarchy level. For the extension-provider package, **package-name** in the **package package-name** statement is **jservices-rpm**.

For more information about the extension-provider package, see the *SDK Applications Configuration Guide and Command Reference*.

The following example shows how to enable RPM for the extension-provider package on the adaptive services interface:

```

chassis fpc 1 {
 pic 2 {
 adaptive-services {
 service-package {
 extension-provider {
 control-cores 1;
 data-cores 1;
 object-cache-size 512;
 policy-db-size 64;
 package jservices-rpm;
 syslog daemon any;
 }
 }
 }
 }
}

```

}

## RFC2544-Based Benchmarking Tests Overview

---

RFC2544 defines a series of tests that can be used to describe the performance characteristics of a network-interconnecting device, such as a router, and outlines specific formats to report the results of the tests. These tests can be used to benchmark interconnected network devices and devise a guideline or a measurement pattern to analyze the health and efficiency of the network devices. These tests are the standard benchmarking tests for Ethernet networks and are known as RFC2544-based benchmarking tests. These tests measure throughput, latency, frame loss rate, and bursty frames. The test methodology enables you to define various parameters such as different frame sizes to be examined (64, 128, 256, 512, 1024, 1280, and 1518 bytes), the test time for each test iteration (10 seconds to 1,728,000 seconds), and the frame format (UDP-over-IP).

**NOTE:** RFC2544-based benchmarking tests support only UDP over IPv4 test traffic.

An RFC2544-based benchmarking test is performed by transmitting test packets from a device that functions as the generator or the initiator (which is also called the originator). These packets are sent to a device that functions as a reflector, which receives and returns the packets to the initiator.

Juniper Networks MX104 3D Universal Edge Routers support only the reflector function and the corresponding benchmarking tests. These tests display only the reflecting benchmarking tests. These benchmarking tests display the results of the test. For instance, in the case of the throughput test, the results display the number of transmitted frames and the number of received frames.

The RFC2544-based benchmarking test methodology assesses different parameters that are defined in service-level agreements (SLAs). By measuring the performance availability, transmission delay, link bursts, and service integrity, a carrier provider can certify that the working parameters of the deployed Ethernet circuit comply with the SLA and other defined policies.

[Table 37 on page 984](#) describes the different network topologies in which the benchmarking test is supported.

**Table 37: Supported Network Topologies for RFC2544 Benchmarking Tests**

Service Type	Traffic Direction	Mode	Initial Release on MX104 Routers	Whether the Benchmarking Test Is Supported
E-Line and E-LAN (family <b>bridge</b> )	(UNI) Egress	Port Port, VLAN	14.2R1 (E-Line and E-LAN family bridge)	Supported
E-Line (family <b>ccc</b> )	Ingress Egress		13.3R1 (E-Line Pseudowire)	Supported
IP Services (family <b>inet</b> )	NNI		13.3R1	Supported

**NOTE:** You can configure a total of four simultaneous active reflection sessions. The four active reflection sessions can be of the same type or can be a combination of the different types of reflection sessions. For instance, you can configure either four IPv4 reflection sessions or two pseudowire reflection sessions, one Layer 2 reflection session, and one IPv4 reflection session. The maximum reflection bandwidth supported is 4Gbps.

[Table 38 on page 985](#) lists the interfaces and the reflection type on which the benchmarking tests are supported.

**Table 38: Supported Interfaces for RFC2544 Benchmarking Tests**

Type of Reflection	Gigabit Interfaces (ge)	Aggregated Interfaces (ae)	10G Interfaces (xe)	Pseudo Interfaces (irb, lt, vt, lo0, and others)
IPv4	Yes	No	No	No
Pseudowire Ingress	Yes	No	No	No
Pseudowire Egress	Yes	No	No	No
Layer 2 Bridge	Yes	Yes	Yes	No

All active RFC2544-based benchmarking tests are stopped when any of the following events takes place either in the initiator or in the reflector:

- System events such as Packet Forwarding Engine restarts, routing engine restarts, and so on.
- Test interface change events such as deactivation and reactivation of the interface, disabling and enabling of the interface, and so on.

After the benchmarking tests are stopped, the test states of the tests are removed and the user can restart the same test. Other ongoing tests on other interfaces are not interrupted.

**NOTE:** RFC2544-based benchmarking tests are not supported during unified in-service software upgrade (ISSU) and graceful routing engine switchover (GRES).

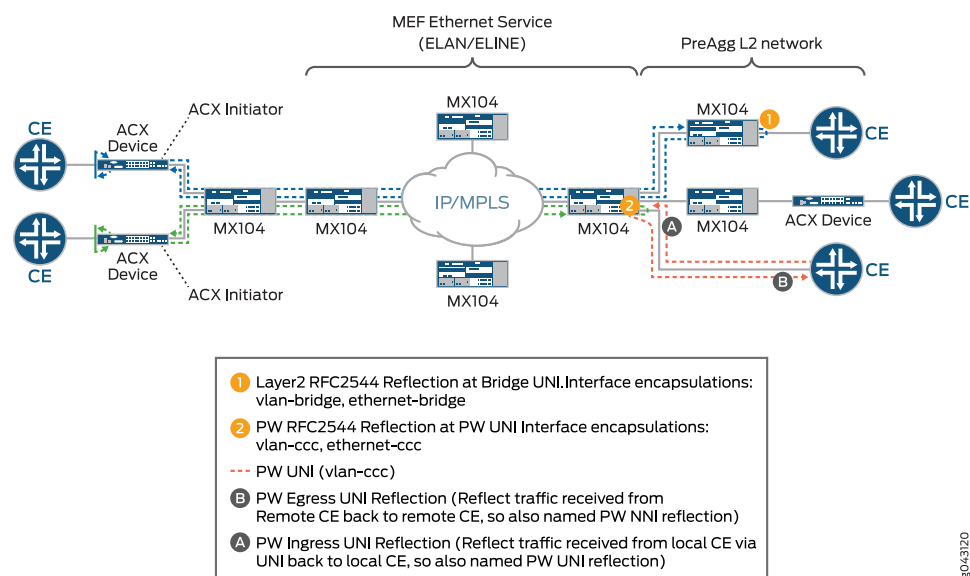

#### Related Documentation

- [Supported RFC2544-Based Benchmarking Statements on MX104 Routers on page 988](#)

## Layer 2 RFC2544-Based Benchmarking Tests Overview

The Metro Ethernet Forum (MEF) defines two Ethernet service types—E-LAN and E-Line—and specifies the associated service attributes and parameters. These services can be supported within the Metro Ethernet Network (MEN) and also supported over different transport technologies such as SONET, MPLS, and so on. Juniper networks ACX Series routers and MX104 routers provide support for Layer 2 E-LAN and E-Line services, pseudowire reflection, as well as IPv4 services. [Figure 36 on page 986](#) shows a sample topology for the E-LAN and E-Line reflection supported on MX104 routers.

**Figure 36: E-LAN and E-Line Reflection in Metro Solution**

MX104 routers support RFC2544-based benchmarking tests for Layer 2 reflection (E-LAN service) in basic bridge domains only. RFC2544-based benchmarking and performance measurement testing for Layer 2 services is supported on unicast traffic in egress direction only.

In an E-LAN service, during the benchmarking tests, the initiator or generator transmits a test packet (unicast) to a reflector. The reflector receives and reflects the test packet back to the initiator. The test packet is an UDP-over-IP packet with a source and destination MAC address. A Layer 2 traffic reflection session is identified by the source MAC address, the destination MAC address, and the egress interface. By default, RFC2544-based benchmarking tests are performed when there is no other service traffic. This mode of operation is known as out-of-service mode. The default service mode for the reflecting egress interface for an E-LAN service is also out-of-service mode. In out-of-service mode, while the test is running, all the data traffic sent to and from the UNI port under test on the service is interrupted. Control protocol peering is not interrupted whereas pass through control protocol packets such as end-to-end CFM sessions are interrupted. If you do not want the control protocol packets interrupted, you can configure the E-LAN service mode as in-service mode. In the in-service mode, while the test is

running, the rest of the data traffic flow sent to and from the UNI port under test on the service is not interrupted. Both peering and pass through control protocols are not interrupted.

By default, for E-LAN services, the default behavior of the reflector is to swap MAC addresses. The reflector swaps the source and destination MAC addresses and sends the packet back to the initiator. [Table 39 on page 987](#) describes the MAC address swapping behavior for the service types.

**Table 39: MAC Address Swapping Behavior for E-LAN and E-Line Services**

Family	Direction	Default Behavior	User-configurable
bridge	Egress	MAC address swap (E-LAN service type)	No
		No MAC address swap (E-Line service type)	Yes
ccc	Egress	No MAC address swap	No
	Ingress	MAC address swap	No

By default, the IP addresses and UDP ports are not modified. Optionally, you can configure the reflector to swap the source and destination IP address and the source and destination UDP ports.

You can configure an ACX Series router to operate as an initiator as well as a reflector. The MX104 router can be configured to operate only as a reflector.

**NOTE:** The maximum reflection bandwidth supported is 4Gbps. Because RFC2544 reflection shares system bandwidth with other loopback services such as tunnel services, you must manage the sharing of bandwidth for performing RFC2544-based performance tests.

**NOTE:** RFC2544-based benchmarking tests are not supported during unified in-service software upgrade (ISSU) and graceful routing engine switchover (GRES).

- [Configuring an RFC 2544-Based Benchmarking Test on page 989](#)
  - [Example: Configuring RFC2544-Based Benchmarking Tests for Layer 2 E-LAN Services in Bridge Domains on page 1016](#)

## Configuring an RFC 2544-Based Benchmarking Test

You can configure a benchmarking test to detect and measure performance attributes, such as throughput, latency, frame loss, and bursty or back-to-back frames, of network devices. RFC 2544-based benchmarking test is performed by transmitting test packets from a device that functions as the generator or the initiator. These packets are sent to a device that functions as the reflector, which receives and returns the packets back to the initiator.

**NOTE:** The test configuration is applied only when you start the test. If you update the test configuration during the test, you have to start the test again for the updated configuration to take effect.

You must configure a test profile and reference the test profile in a unique test name that defines the parameters for the test to be performed on a certain device. However, the test profile is required when the test mode is configured as initiation and termination. The **test-profile** parameter is disregarded when the test mode is configured as reflection. MX104 routers support only the reflection function in the RFC 2544-based benchmarking tests. A reflection service does not use the parameters specified in the test profile.

The following topics describe how to configure a test name for an RFC 2544-based benchmarking test on an MX104 router for Layer 3 IPv4, Ethernet pseudowire, and Layer 2 bridge networks:

- [Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a IPv4 Network on page 989](#)
- [Configuring a Test Name for an RFC 2544-Based Benchmarking Test for an Ethernet Pseudowire on page 991](#)
- [Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a Layer 2 E-LAN Service in Bridge Domain on page 992](#)

### Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a IPv4 Network

You can configure a test name by including the **test-name test-name** statement at the **[edit services rpm rfc2544-benchmarking]** hierarchy level. In the test name, you can configure attributes of the test iteration, such as the address family (type of service, IPv4 or Ethernet), the logical interface, and test duration that are used for a benchmarking test to be run.

To configure a test name and define its attributes for an IPv4 network:

1. In configuration mode, go to the **[edit services]** hierarchy level.

**[edit]**

```
user@host# edit services
```

2. Configure a instance.

```
[edit services]
user@host# edit rpm
```

3. Configure an RFC 2544-based benchmarking test for the RPM instance.

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```

4. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```

5. Specify the test mode for the packets that are sent during the benchmarking test. The **reflect** option causes the test frames to be reflected on the IPv4 network.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode reflect
```

6. Configure the address type family for the benchmarking test. The **inet** option indicates that the test is run on an IPv4 service.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family inet
```

7. Configure the destination IPv4 address for the test packets. This parameter is required only if you configure IPv4 family **inet**. If you do not configure the destination IPv4 address, the default value of 192.168.1.20 is used.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set destination-ipv4-address address
```

8. Specify the UDP port of the destination to be used in the UDP header for the generated frames. If you do not specify the UDP port, the default value of 4041 is used.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set destination-udp-port port-number
```

9. (Optional) Specify the source IPv4 address to be used in generated test frames. If you do not configure the source IPv4 address for **inet** family, the source address of the interface is used to transmit the test frames.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set source-ipv4-address address
```

10. Specify the UDP port of the source to be used in the UDP header for the generated frames. If you do not specify the UDP port, the default value of 4041 is used.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set source-udp-port port-number
```

11. Specify the logical interface on which the RFC 2544-based benchmarking test is run. If you configure an **inet** family and the test mode to reflect the frames back on the sender from the other end, then the logical interface is used as the interface to enable the reflection service (reflection is performed on the packets entering the specified interface). If you not configure the logical interface for reflection test mode, then a

lookup is performed on the source IPv4 address to determine the interface that hosts the address.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface interface-name
```

## Configuring a Test Name for an RFC 2544-Based Benchmarking Test for an Ethernet Pseudowire

You can configure a test name by including the **test-name test-name** statement at the **[edit services rpm rfc2544-benchmarking]** hierarchy level. In the test name, you can configure attributes of the test iteration, such as the address family (type of service IPv4 or Ethernet), the logical interface, and test duration, that are used for a benchmarking test to be run. The test name combined with the test profile represent a single real-time performance monitoring (RPM) configuration instance.

To configure a test name and define its attributes for an Ethernet Pseudowire:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure an RPM service instance.

```
[edit services]
user@host# edit rpm
```

3. Configure an RFC 2544-based benchmarking test for the RPM instance.

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```

4. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```

5. Specify the test mode for the packets that are sent during the benchmarking test. The **reflect** option causes the test frames to be reflected on the Ethernet pseudowire.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode reflect
```

6. Configure the address type family for the benchmarking test. The **ccc** option indicates that the test is run on a CCC or Ethernet pseudowire service.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family ccc
```

7. Specify the direction of the interface on which the test must be run. This parameter is valid only for a family. To enable the test to be run in the egress direction of the interface (network-to-network interface (NNI)), use the **egress** option. To enable the test to be run in the ingress direction of the interface (user-to-network interface (UNI)), use the **ingress** option.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set direction egress
```

8. (Optional) Specify the source IPv4 address to be used in generated test frames. If you do not configure the source IPv4 address for family, the default value of 192.168.1.10 is used.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set source-ipv4-address address
```

9. Specify the logical interface on which the RFC 2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface interface-name
```

## Configuring a Test Name for an RFC 2544-Based Benchmarking Test for a Layer 2 E-LAN Service in Bridge Domain

You can configure a test name by including the **test-name test-name** statement at the **[edit services rpm rfc2544-benchmarking]** hierarchy level. In the test name, you can configure attributes of the test iteration, such as the address family (bridge), the logical interface, and test duration, that are used for a benchmarking test to be run. The test name combined with the test profile represent a single real-time performance monitoring (RPM) configuration instance.

To configure a test name and define its attributes for a layer 2 E-LAN service in Bridge domains:

1. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

2. Configure an RPM service instance.

```
[edit services]
user@host# edit rpm
```

3. Configure an RFC 2544-based benchmarking test for the RPM instance.

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```

4. Define a name for the test—for example, l2b-test1. The test name identifier can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name l2b-test1
```

5. Specify the source and destination MAC addresses of the test packet. Both these parameters are valid only for the bridge family.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set source-mac-address address destination-mac-address address
```

6. Specify the service type under test. This parameter is applicable only for the bridge family.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set service-type elan
```

7. Specify the test mode for the packets that are sent during the benchmarking test. The **reflect** option causes the test frames to be reflected over the Layer 2 bridge.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set mode reflect
```

8. Configure the address type family for the benchmarking test. The **bridge** option indicates that the test is run on a E-LAN service over a bridge domain.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set family bridge
```

9. Specify the direction of the interface on which the test must be run. This parameter is valid only for a family. To enable the test to be run in the egress direction of the interface (network-to-network interface (NNI)), use the **egress** option. To enable the test to be run in the ingress direction of the interface (user-to-network interface (UNI)), use the **ingress** option.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set direction egress
```

10. Specify the logical interface on which the RFC 2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-test1]
user@host# set test-interface interface-name
```

### Requirements

This example uses the following hardware and software components:

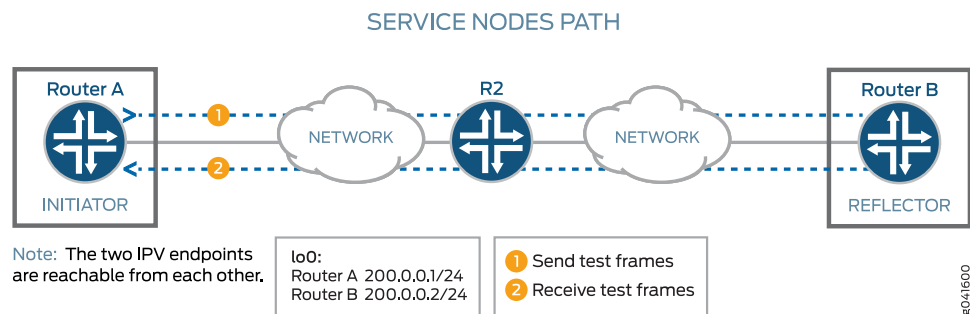

- 
- An ACX Series Universal Access Router—
- Junos OS Release or later

## Overview

Consider a sample topology in which a router, Router A, functions as an initiator and terminator of the test frames for an RFC 2544-based benchmarking test. Router A is connected over a Layer 3 network to another router, Router B, which functions as a reflector to reflect back the test frames it receives from Router A. IPv4 is used for transmission of test frames over the Layer 3 network. This benchmarking test is used to compute the IPv4 service parameters between Router A and Router B. Logical interfaces on both the routers are configured with IPv4 addresses to measure the performance attributes, such as throughput, latency, frame loss, and bursty frames, of network devices for the IPv4 service.

Figure 37 on page 994 shows the sample topology to perform an RFC 2544 test for a Layer 3 IPv4 service.

Figure 37: RFC 2544-Based Benchmarking Test for a Layer 3 IPv4 Service

## Configuration

In this example, you configure the benchmarking test for a Layer 3 IPv4 service that is between interface ge-0/0/0 on Router A and interface ge-0/0/4 on Router B to detect and analyze the performance of the interconnecting routers.

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

### Configuring Benchmarking Test Parameters on Router A

```
set interfaces ge-0/0/0 unit 0 family inet address 200.0.0.1/24
set interfaces ge-0/0/0 unit 0 family mpls
set rfc2544-benchmarking profiles test-profile throughput test-type throughput
```

### Configuring Benchmarking Test Parameters on Router B

```
set rfc2544-benchmarking profiles test-profile throughput packet-size 64
set rfc2544-benchmarking profiles test-profile throughput test-duration 20m
set rfc2544-benchmarking profiles test-profile throughput bandwidth-kbps 500
set rfc2544-benchmarking tests test-name test1 test-profile throughput
set rfc2544-benchmarking tests test-name test1 interface ge-0/0/0.1
set rfc2544-benchmarking tests test-name test1 mode initiate-and-terminate
set rfc2544-benchmarking tests test-name test1 family inet
set rfc2544-benchmarking tests test-name test1 dest-address 200.0.0.2
set rfc2544-benchmarking tests test-name test1 udp-port 4001
```

```
set interfaces ge-0/0/4 unit 0 family inet address 200.0.0.2/24
set interfaces ge-0/0/4 unit 0 family mpls
set services rpm rfc2544-benchmarking tests test-name test1 interface ge-0/0/4.1
set services rpm rfc2544-benchmarking tests test-name test1 mode reflect
set services rpm rfc2544-benchmarking tests test-name test1 family inet
set services rpm rfc2544-benchmarking tests test-name test1 dest-address 200.0.0.1
set services rpm rfc2544-benchmarking tests test-name test1 udp-port 4001
```

### Configuring Benchmarking Test Parameters on Router A

#### Step-by-Step Procedure

The following require you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router A:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:  

```
[edit]
user@host# edit interfaces
```
2. Configure the interface on which the test must be run.  

```
[edit interfaces]
user@host# edit ge-0/0/0
```
3. Configure a logical unit and specify the protocol family.  

```
[edit interfaces ge-0/0/0]
user@host# edit unit 0 family inet
```
4. Specify the address for the logical interface.  

```
[edit interfaces ge-0/0/0 unit 0 family inet]
user@host# set address 200.0.0.1/24
```
5. Enter the **up** command to go the previous level in the configuration hierarchy.  

```
[edit interfaces ge-0/0/0 unit 0 family inet]
user@host# up
```
6. Configure the MPLS family on the logical interface.  

```
[edit interfaces ge-0/0/0 unit 0]
user@host# set family mpls
```

7. Go to the top level of the configuration command mode.  

```
[edit interfaces ge-0/0/0 unit 0]
user@host# top
```
8. In configuration mode, go to the **[edit services]** hierarchy level.  

```
[edit]
user@host# edit services
```
9. Configure a real-time performance monitoring service (RPM) instance.  

```
[edit services]
user@host# edit rpm
```
10. Configure an RFC 2544-based benchmarking test for the RPM instance.  

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```
11. Define a name for a test profile—for example, throughput.  

```
[edit services rpm rfc2544-benchmarking]
user@host# edit profiles test-profile throughput
```
12. Configure the type of test to be performed as throughput.  

```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type throughput
```
13. Specify the size of the test packet as 64 bytes.  

```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type packet-size 64
```
14. Specify the period for which the test is to be performed in hours, minutes, or seconds by specifying a number followed by the letter h (for hours), m (for minutes), or s (for seconds), respectively.  

```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type test-duration 20m
```
15. Define the theoretical maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.  

```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type bandwidth-kbps 500
```
16. Enter the **up** command to go the previous level in the configuration hierarchy.  

```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# up
```
17. Enter the **up** command to go the previous level in the configuration hierarchy.  

```
[edit services rpm rfc2544-benchmarking profiles]
user@host# up
```
18. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.  

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```

19. Specify the name of the test profile—for example, throughput—to be associated with a particular test name.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-profile throughput
```

20. Specify the logical interface, ge-0/0/0.1, on which the RFC 2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface ge-0/0/0.1
```

21. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode initiate-and-terminate
```

22. Configure the address type family, **inet**, for the benchmarking test.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family inet
```

23. Configure the destination IPv4 address for the test packets.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set dest-address 200.0.0.2
```

24. Specify the UDP port of the destination to be used in the UDP header for the generated frames as 4001.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set udp-port 4001
```

25. Start the benchmarking test on the initiator.

```
user@> test services rpm rfc2544-benchmarking test test1 start
```

After the test is successfully completed, it is automatically stopped at the initiator.

---

### Configuring Benchmarking Test Parameters on Router B

#### Step-by-Step Procedure

The following you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router B:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure the interface on which the test must be run.

```
[edit interfaces]
user@host# edit ge-0/0/4
```

3. Configure a logical unit and specify the protocol family as **inet**.

```
[edit interfaces ge-0/0/4]
```

- user@host# edit unit 0 family inet
4. Specify the address for the logical interface.  
[edit interfaces ge-0/0/4 unit 0 family inet]  
user@host# set address 200.0.0.2/24
  5. Enter the **up** command to go the previous level in the configuration hierarchy.  
[edit interfaces ge-0/0/4 unit 0 family inet]  
user@host# up
  6. Configure the MPLS family on the logical interface.  
[edit interfaces ge-0/0/4 unit 0]  
user@host# set family mpls
  7. Go to the top level of the configuration command mode.  
[edit interfaces ge-0/0/4 unit 0]  
user@host# top
  8. In configuration mode, go to the **[edit services]** hierarchy level.  
[edit]  
user@host# edit services
  9. Configure a real-time performance monitoring service (RPM) instance.  
[edit services]  
user@host# edit rpm
  10. Configure an RFC 2544-based benchmarking test for the RPM instance.  
[edit services rpm]  
user@host# edit rfc2544-benchmarking
  11. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.  
[edit services rpm rfc2544-benchmarking]  
user@host# edit tests test-name test1
  12. Specify the logical interface, ge-0/0/4.1, on which the RFC 2544-based benchmarking test is run.  
[edit services rpm rfc2544-benchmarking tests test-name test1]  
user@host# set test-interface ge-0/0/4.1
  13. Specify **reflect** as the test mode for the packets that are sent during the benchmarking test.  
[edit services rpm rfc2544-benchmarking tests test-name test1]  
user@host# set mode reflect
  14. Configure the address type family, **inet**, for the benchmarking test.  
[edit services rpm rfc2544-benchmarking tests test-name test1]  
user@host# set family inet
  15. Configure the destination IPv4 address for the test packets as 200.0.0.1.  
[edit services rpm rfc2544-benchmarking tests test-name test1]  
user@host# set dest-address 200.0.0.1

16. Specify the UDP port of the destination to be used in the UDP header for the generated frames as 4001.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set udp-port 4001
```

17. Start the benchmarking test on the reflector.

```
user@host> test services rpm rfc2544-benchmarking test test1 start
```

After the test is successfully completed at the initiator, you can stop the test at the reflector by entering the `test services rpm rfc2544-benchmarking test test1` command.

## Results

In configuration mode, confirm your configuration on Router A and Router B by entering the `show` command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Benchmarking Test Parameters on Router A:

```
[edit interfaces]
ge-0/0/0 {
 unit 0 {
 family inet {
 address 200.0.0.1/24;
 }
 family mpls;
 }
}

[edit services rpm]
rfc2544-benchmarking {
 profiles {
 test-profile throughput {
 test-type throughput
 packet-size 64;
 test-duration 20m;
 bandwidth-kbps 500;
 }
 }

 tests {
 test-name test1 {
 test-profile throughput;
 interface ge-0/0/0.1;
 mode initiate,terminate;
 family inet;
 dest-address 200.0.0.2
 udp-port 4001;
 }
 }
}
```

Benchmarking Test Parameters on Router B:

```
[edit interfaces]
ge-0/0/4 {
 unit 0 {
```

```
 family inet {
 address 200.0.0.2/24;
 }
 family mpls;
 }

[edit services rpm]
rfc2544-benchmarking {
 # Note, When in reflector mode, test profile is not needed
 tests {
 test-name test1 {
 interface ge-0/0/4.1;
 mode reflect;
 family inet;
 dest-address 200.0.0.1;
 udp-port 4001;
 }
 }
}
```

After you have configured the device, enter the **commit** command in configuration mode.

## Verifying the Results of the Benchmarking Test for Layer 3 IPv4 Services

Examine the results of the benchmarking test that is performed on the configured service between Router A and Router B.

- [Verifying the Benchmarking Test Results on page 1000](#)

---

### Verifying the Benchmarking Test Results

<b>Purpose</b>	Verify that the necessary and desired statistical values are displayed for the benchmarking test that is run on the configured service between Router A and Router B.
<b>Action</b>	In operational mode, enter the <b>show services rpm rfc2544-benchmarking (aborted-tests   active-tests   completed-tests   summary)</b> command to display information about the results of each category or state of the RFC 2544-based benchmarking test, such as aborted tests, active tests, and completed tests, for each real-time performance monitoring (RPM) instance.
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>• <a href="#">RFC2544-Based Benchmarking Tests Overview on page 983</a></li><li>• <a href="#">Configuring an RFC 2544-Based Benchmarking Test on page 989</a></li></ul>

## Example: Configuring an RFC 2544-Based Benchmarking Test for UNI Direction of Ethernet Pseudowires

---

This example shows how to configure the benchmarking test for the user-to-network interface (UNI) direction of an Ethernet pseudowire service.

- [Requirements on page 1001](#)
- [Overview on page 1001](#)
- [Configuration on page 1002](#)
- [Verifying the Results of the Benchmarking Test for UNI Direction of an Ethernet Pseudowire Service on page 1008](#)

### Requirements

This example uses the following hardware and software components:

- An ACX Series router—f
- Junos OS Release or later

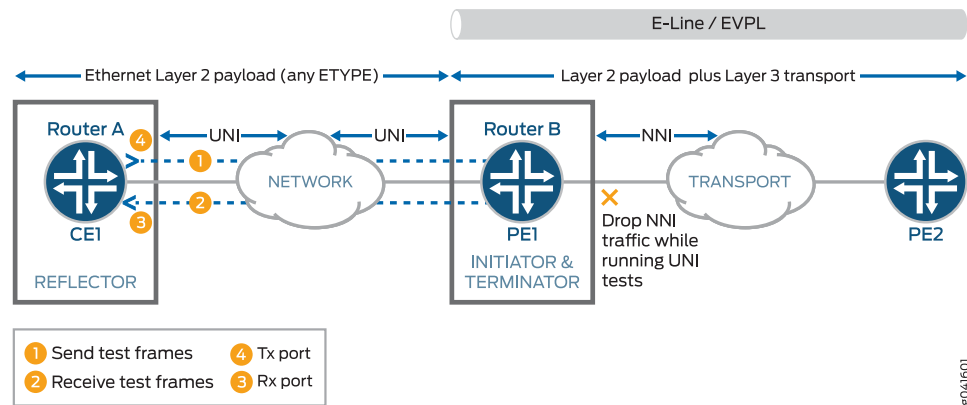

### Overview

Consider a sample topology in which a router, Router A, functions as a reflector of the test frames for an RFC 2544-based benchmarking test. The logical customer edge (CE)-facing interface and **inet** family are configured on Router A. Router A is not part of a pseudowire and therefore, a Layer 3 family configuration is required on it. Router A, which is a customer edge device CE1 is connected to Router B, which functions as a provider edge device PE1 over an Ethernet pseudowire in the UNI direction with EtherType or Layer 2 Ethernet payload. The logical interface, family, and UNI direction are configured on Router B. Router B or PE1 is connected over an Ethernet pseudowire in the NNI direction to a provider edge device at the remote site, PE2. The link between CE1 and PE1 is an Ethernet Layer 2 network and it can be configured with any EtherType value. The link between PE1 and PE2 is an Ethernet line (E-LINE) or an Ethernet Private Line (EPL) that has Layer 2 payload and Layer 3 transport sent over it. Router B or PE1 functions as an initiator and terminator of the test frames that are sent to Router A and reflected back from it.

This benchmarking test is used to compute the performance attributes in the user-to-network interface (UNI) direction of an Ethernet pseudowire service between Router A and Router B. Data traffic arriving from a network-to-network interface (NNI) toward the customer edge is ignored while the test is in progress. Packets from the CE are not sent toward the NNI because all packets are assumed to be test probes.

[Figure 38 on page 1002](#) shows the sample topology to perform an RFC 2544 test for the UNI direction of an Ethernet pseudowire service.

Figure 38: RFC 2544-Based Benchmarking Test for UNI Direction of an Ethernet Pseudowire

## Configuration

In this example, you configure the benchmarking test for the UNI direction of an Ethernet pseudowire service that is enabled between two routers to detect and analyze the performance of the interconnecting routers.

set services rpm rfc2544-benchmarking tests test-name test1 mode reflect
set services rpm rfc2544-benchmarking tests test-name test1 mode family ccc
set services rpm rfc2544-benchmarking tests test-name test1 direction uni
```

---

### Configuring Benchmarking Test Parameters on Router A

#### Step-by-Step Procedure

The following require you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router A:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:  

```
[edit]
user@host# edit interfaces
```
2. Configure the interface on which the test must be run.  

```
[edit interfaces]
user@host# edit ge-0/0/0
```
3. Configure VLAN tagging for transmission and reception of 802.1Q VLAN-tagged frames.  

```
[edit interfaces ge-0/0/0]
user@host# set vlan-tagging
```
4. Configure a logical unit and specify the protocol family as **inet**.  

```
[edit interfaces ge-0/0/0]
user@host# edit unit 0 family inet
```
5. Specify the address for the logical interface.  

```
[edit interfaces ge-0/0/0 unit 0 family inet]
user@host# set address 200.0.0.1/24
```
6. Configure the VLAN ID on the logical interface as 101.  

```
[edit interfaces ge-0/0/0 unit 0]
user@host# set vlan-id 101
```
7. Go to the top level of the configuration command mode.  

```
[edit interfaces ge-0/0/0 unit 0]
user@host# top
```
8. In configuration mode, go to the **[edit services]** hierarchy level.  

```
[edit]
user@host# edit services
```

9. Configure a real-time performance monitoring service (RPM) instance.  
[edit services]  
user@host# **edit rpm**
10. Configure an RFC 2544-based benchmarking test for the RPM instance.  
[edit services rpm]  
user@host# **edit rfc2544-benchmarking**
11. Define a name for a test profile—for example, throughput.  
[edit services rpm rfc2544-benchmarking]  
user@host# **edit profiles test-profile throughput**
12. Configure the type of test to be performed as throughput.  
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]  
user@host# **set test-type throughput**
13. Specify the size of the test packet as 64 bytes.  
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]  
user@host# **set test-type packet-size 64**
14. Specify the period for which the test is to be performed in hours, minutes, or seconds by specifying a number followed by the letter h (for hours), m (for minutes), or s (for seconds). In this example, you configure the period as 20 minutes.  
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]  
user@host# **set test-type test-duration 20m**
15. Define the theoretical maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.  
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]  
user@host# **set test-type bandwidth-kbps 500**
16. Enter the **up** command to go the previous level in the configuration hierarchy.  
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]  
user@host# **up**
17. Enter the **up** command to go the previous level in the configuration hierarchy.  
[edit services rpm rfc2544-benchmarking profiles]  
user@host# **up**
18. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.  
[edit services rpm rfc2544-benchmarking]  
user@host# **edit tests test-name test1**
19. Specify the name of the test profile—for example, throughput—to be associated with a particular test name.  
[edit services rpm rfc2544-benchmarking tests test-name test1]  
user@host# **set test-profile throughput**
20. Specify the logical interface, ge-0/0/0.1, on which the RFC 2544-based benchmarking test is run.  
[edit services rpm rfc2544-benchmarking tests test-name test1]

```
user@host# set test-interface ge-0/0/0.1
```

21. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode initiate-and-terminate
```

22. Configure the address type family, **inet**, for the benchmarking test.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family inet
```

23. Configure the destination IPv4 address for the test packets as 200.0.0.2.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set dest-address 200.0.0.2
```

24. Specify the UDP port of the destination to be used in the UDP header for the generated frames as 4001.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set udp-port 4001
```

---

### Configuring Benchmarking Test Parameters on Router B

#### Step-by-Step Procedure

The following require you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router B:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure the interface on which the test must be run.

```
[edit interfaces]
user@host# edit ge-0/0/4
```

3. Configure VLAN tagging for transmission and reception of 802.1Q VLAN-tagged frames.

```
[edit interfaces ge-0/0/4]
user@host# set vlan-tagging
```

4. Configure a logical unit for the interface.

```
[edit interfaces ge-0/0/4]
user@host# edit unit 0
```

5. Specify the encapsulation for Ethernet VLAN circuits.

```
[edit interfaces ge-0/0/4 unit 0]
user@host# set encapsulation vlan-ccc
```

6. Configure the VLAN ID as 101 on the logical interface.

```
[edit interfaces ge-0/0/4 unit 0]
user@host# set vlan-id 101
```

7. Go to the top level of the configuration command mode.  

```
[edit interfaces ge-0/0/4 unit 0]
user@host# top
```
8. In configuration mode, go to the **[edit services]** hierarchy level.  

```
[edit]
user@host# edit services
```
9. Configure a real-time performance monitoring service (RPM) instance.  

```
[edit services]
user@host# edit rpm
```
10. Configure an RFC 2544-based benchmarking test for the RPM instance.  

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```
11. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.  

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```
12. Specify the logical interface on which the RFC 2544-based benchmarking test is run.  

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface ge-0/0/4.1
```
13. Specify **reflect** as the test mode for the packets that are sent during the benchmarking test.  

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode reflect
```
14. Configure the address type family, **ccc**, for the benchmarking test.  

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family ccc
```
15. Specify the direction of the interface on which the test must be run, which is UNI in this example.  

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set direction uni
```
16. Start the benchmarking test on the reflector.  

```
user@host> test services rpm rfc2544-benchmarking test test1 start
```

After the test is successfully completed at the initiator, you can stop the test at the reflector by entering the **test services rpm rfc2544-benchmarking test test1 stop** command.

## Results

In configuration mode, confirm your configuration on Router A and Router B by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Benchmarking Test Parameters on Router A:

```
[edit interfaces]
ge-0/0/0 {
 vlan-tagging;
 unit 0 {
 vlan-id 101;
 family inet {
 address 200.0.0.1/24;
 }
 }
}

[edit services rpm]
rfc2544-benchmarking {
 profiles {
 test-profile throughput {
 test-type throughput
 packet-size 64;
 test-duration 20m;
 bandwidth-kbps 500;
 }
 }

 tests {
 test-name test1 {
 interface ge-0/0/0.1;
 test-profile throughput;
 mode initiate,terminate;
 family inet;
 dest-address 200.0.0.2
 udp-port 4001;
 }
 }
}
```

Benchmarking Test Parameters on Router B:

```
[edit interfaces]
ge-0/0/4 {
 vlan-tagging;
 unit 0 {
 encapsulation vlan-ccc;
 vlan-id 101;
 }
}

[edit services rpm]
rfc2544-benchmarking {
 # Note, When in reflector mode, test profile is not needed
 tests {
 test-name test1 {
 interface ge-0/0/4.1;
```

```
 mode reflect;
 family ccc;
 direction uni;
 }
}
```

After you have configured the device, enter the **commit** command in configuration mode.

## Verifying the Results of the Benchmarking Test for UNI Direction of an Ethernet Pseudowire Service

Examine the results of the benchmarking test that is performed on the configured service between Router A and Router B.

- [Verifying the Benchmarking Test Results on page 1008](#)

## Example: Configuring an RFC 2544-Based Benchmarking Test for NNI Direction of Ethernet Pseudowires

This example shows how to configure the benchmarking test for a network-to-network interface (NNI) direction of an Ethernet pseudowire service.

- [Requirements on page 1009](#)
- [Overview on page 1009](#)
- [Configuration on page 1010](#)
- [Verifying the Results of the Benchmarking Test for NNI Direction of an Ethernet Pseudowire Service on page 1016](#)

## Requirements

This example uses the following hardware and software components:

- An ACX Series router
- Junos OS Release or later

## Overview

Consider a sample topology in which a router, Router A, functions as an initiator and terminator of the test frames for an RFC 2544-based benchmarking test. Router A operates as a provider edge device PE1, which is connected to a customer edge device CE1 on one side and over an Ethernet pseudowire to another router Router B, which functions as a reflector to reflect back the test frames it receives from Router A. Router B operates as a provider edge device, PE2, which is the remote router located at the other side of the service provider core. The UNI direction of CE1 is connected to the NNI direction of PE1. An MPLS tunnel connects PE1 and PE2 over the Ethernet pseudowire or the Ethernet line (E-LINE).

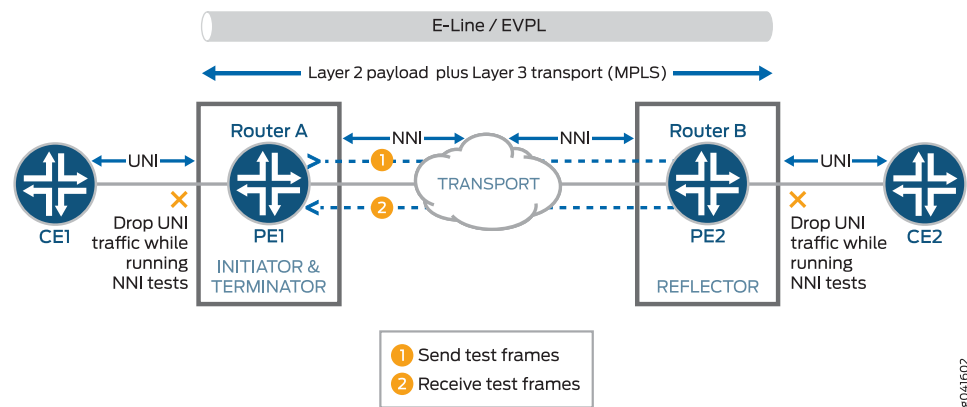

**NOTE:** When pseudowire reflection is enabled on an interface, the router does not block the ingress or egress traffic through the test interface. To block other data traffic, you must explicitly configure firewall filters.

This benchmarking test is used to compute the performance attributes in the network-to-network interface (NNI) direction of an Ethernet pseudowire service between Router A and Router B. The logical interface under test on Router A is the CE1 interface with UNI as the direction, and the logical interface under test on Router B is the CE2 interface with NNI as the direction. Data traffic arriving from UNI toward NNI is ignored while the test is in progress. Packets from NNI are not sent toward the customer edge because all packets are assumed to be test frames. The family and NNI direction are configured on routers A and B.

[Figure 39 on page 1010](#) shows the sample topology to perform an RFC 2544 test for the NNI direction of an Ethernet pseudowire service.

Figure 39: RFC 2544-Based Benchmarking Test for NNI Direction of an Ethernet Pseudowire

## Configuration

In this example, you configure the benchmarking test for the NNI direction of an Ethernet pseudowire service that is enabled between two routers to detect and analyze the performance of the interconnecting routers.

- [Configuring Benchmarking Test Parameters on Router B on page 1013](#)
- [Results on page 1015](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

### Configuring Benchmarking Test Parameters on Router A

```
set interfaces ge-0/0/0 vlan-tagging
set interfaces ge-0/0/0 unit 0 encapsulation vlan-ccc
set interfaces ge-0/0/0 unit 0 vlan-id 101
set services rpm rfc2544-benchmarking profiles test-profile throughput test-type throughput
set services rpm rfc2544-benchmarking profiles test-profile throughput packet-size 64
set services rpm rfc2544-benchmarking profiles test-profile throughput test-duration 20
set services rpm rfc2544-benchmarking profiles test-profile throughput bandwidth-kbps 500
set services rpm rfc2544-benchmarking tests test-name test1 interface ge-0/0/0.1
set services rpm rfc2544-benchmarking tests test-name test1 test-profile throughput
set services rpm rfc2544-benchmarking tests test-name test1 mode initiate,terminate
set services rpm rfc2544-benchmarking tests test-name test1 family ccc
set services rpm rfc2544-benchmarking tests test-name test1 direction nni
```

### Configuring Benchmarking Test

**Parameters on Router****B**

```

set interfaces ge-0/0/4 vlan-tagging
set interfaces ge-0/0/4 unit 0 encapsulation vlan-ccc
set interfaces ge-0/0/4 unit 0 vlan-id 101
set services rpm rfc2544-benchmarking tests test-name test1 interface ge-0/0/4.1
set services rpm rfc2544-benchmarking tests test-name test1 mode reflect
set services rpm rfc2544-benchmarking tests test-name test1 mode family ccc
set services rpm rfc2544-benchmarking tests test-name test1 direction uni

```

**Configuring Benchmarking Test Parameters on Router****Step-by-Step  
Procedure**

The following require you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router A:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:
 

```

[edit]
user@host# edit interfaces

```
2. Configure the interface on which the test must be run.
 

```

[edit interfaces]
user@host# edit ge-0/0/0

```
3. Configure VLAN tagging for transmission and reception of 802.1Q VLAN-tagged frames.
 

```

[edit interfaces ge-0/0/0]
user@host# set vlan-tagging

```
4. Configure a logical unit for the interface.
 

```

[edit interfaces ge-0/0/0]
user@host# edit unit 0

```
5. Specify the encapsulation for Ethernet VLAN circuits.
 

```

[edit interfaces ge-0/0/0 unit 0]
user@host# set encapsulation vlan-ccc

```
6. Configure the VLAN ID on the logical interface.
 

```

[edit interfaces ge-0/0/0 unit 0]
user@host# set vlan-id 101

```
7. Go to the top level of the configuration command mode.
 

```

[edit interfaces ge-0/0/0 unit 0]
user@host# top

```
8. In configuration mode, go to the **[edit services]** hierarchy level.
 

```

[edit]
user@host# edit services

```
9. Configure a real-time performance monitoring service (RPM) instance.

- ```
[edit services]
user@host# edit rpm
```
10. Configure an RFC 2544-based benchmarking test for the RPM instance.
- ```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```
11. Define a name for a test profile—for example, throughput.
- ```
[edit services rpm rfc2544-benchmarking]
user@host# edit profiles test-profile throughput
```
12. Configure the type of test to be performed as throughput.
- ```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type throughput
```
13. Specify the size of the test packet as 64 bytes.
- ```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type packet-size 64
```
14. Specify the period—for example, 20 minutes—for which the test is to be performed in hours, minutes, or seconds by specifying a number followed by the letter h (for hours), m (for minutes), or s (for seconds).
- ```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type test-duration 20m
```
15. Define the theoretical maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.
- ```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# set test-type bandwidth-kbps 500
```
16. Enter the **up** command to go the previous level in the configuration hierarchy.
- ```
[edit services rpm rfc2544-benchmarking profiles test-profile throughput]
user@host# up
```
17. Enter the **up** command to go the previous level in the configuration hierarchy.
- ```
[edit services rpm rfc2544-benchmarking profiles]
user@host# up
```
18. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.
- ```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```
19. Specify the name of the test profile—for example, throughput—to be associated with a particular test name.
- ```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-profile throughput
```
20. Specify the logical interface, ge-0/0/0.1, on which the RFC 2544-based benchmarking test is run.
- ```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface ge-0/0/0.1
```

21. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode initiate-and-terminate
```

22. Configure the address type family, **ccc**, for the benchmarking test.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family ccc
```

23. Specify the direction of the interface on which the test must be run, which is **NNI** in this example.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set direction nni
```

---

### Configuring Benchmarking Test Parameters on Router B

#### Step-by-Step Procedure

The following require you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the test parameters on Router B:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level:

```
[edit]
user@host# edit interfaces
```

2. Configure the interface on which the test must be run.

```
[edit interfaces]
user@host# edit ge-0/0/4
```

3. Configure VLAN tagging for transmission and reception of 802.1Q VLAN-tagged frames.

```
[edit interfaces ge-0/0/4]
user@host# set vlan-tagging
```

4. Configure a logical unit for the interface.

```
[edit interfaces ge-0/0/4]
user@host# edit unit 0
```

5. Specify the encapsulation for Ethernet VLAN circuits.

```
[edit interfaces ge-0/0/4 unit 0]
user@host# set encapsulation vlan-ccc
```

6. Configure the VLAN ID on the logical interface.

```
[edit interfaces ge-0/0/4 unit 0]
user@host# set vlan-id 101
```

7. Go to the top level of the configuration command mode.

```
[edit interfaces ge-0/0/4 unit 0]
user@host# top
```

8. In configuration mode, go to the **[edit services]** hierarchy level.

```
[edit]
user@host# edit services
```

9. Configure a real-time performance monitoring service (RPM) instance.

```
[edit services]
user@host# edit rpm
```

10. Configure an RFC 2544-based benchmarking test for the RPM instance.

```
[edit services rpm]
user@host# edit rfc2544-benchmarking
```

11. Define a name for the test—for example, test1. The test name identifier can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name test1
```

12. Specify the logical interface, ge-0/0/4.1, on which the RFC 2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set test-interface ge-0/0/4.1
```

**NOTE:** When pseudowire reflection is enabled on an interface, the router does not block the ingress or egress traffic through the test interface. To block other data traffic, you must explicitly configure firewall filters.

13. Specify **reflect** as the test mode for the packets that are sent during the benchmarking test.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set mode reflect
```

14. Configure the address type family, **ccc**, for the benchmarking test.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set family ccc
```

15. Specify the direction of the interface on which the test must be run, which is **NNI** in this example.

```
[edit services rpm rfc2544-benchmarking tests test-name test1]
user@host# set direction nni
```

16. Start the benchmarking test on the reflector.

```
user@host> test services rpm rfc2544-benchmarking test test1 start
```

After the test is successfully completed at the initiator, you can stop the test at the reflector by entering the **test services rpm rfc2544-benchmarking test test1 stop** command.

## Results

In configuration mode, confirm your configuration on Router A and Router B by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Benchmarking Test Parameters on Router A:

```
[edit interfaces]
ge-0/0/0 {
 vlan-tagging;
 unit 0 {
 encapsulation vlan-ccc;
 vlan-id 101;
 }
}

[edit services rpm]
rfc2544-benchmarking {
 profiles {
 test-profile throughput {
 test-type throughput
 packet-size 64;
 test-duration 20m;
 bandwidth-kbps 500;
 }
 }

 tests {
 test-name test1 {
 interface ge-0/0/0.1;
 test-profile throughput;
 mode initiate,terminate;
 family ccc;
 direction nni;
 }
 }
}
```

Benchmarking Test Parameters on Router B:

```
[edit interfaces]
ge-0/0/4 {
 vlan-tagging;
 unit 0 {
 encapsulation vlan-ccc;
 vlan-id 101;
 }
}

[edit services rpm]
rfc2544-benchmarking {
 # Note, When in reflector mode, test profile is not needed
 tests {
 test-name test1 {
 interface ge-0/0/4.1;
 mode reflect;
 family ccc;
 }
 }
}
```

```
 direction nni;
 }
}
```

After you have configured the device, enter the **commit** command in configuration mode.

## Verifying the Results of the Benchmarking Test for NNI Direction of an Ethernet Pseudowire Service

Examine the results of the benchmarking test that is performed on the configured service between Router A and Router B.

---

## Example: Configuring RFC2544-Based Benchmarking Tests for Layer 2 E-LAN Services in Bridge Domains

This example shows how to configure benchmarking tests for the Layer 2 E-LAN services in bridge domains. The example covers the four basic tests: throughput, frame-loss, back-to-back, and latency.

- [Requirements on page 1017](#)
- [Overview on page 1017](#)
- [Configuration on page 1018](#)
- [Verifying the Results of the Benchmarking Tests for Layer 2 Services \(E-LAN\) in Bridge Domains on page 1032](#)

## Requirements

This example uses the following hardware and software components:

- An MX104 3D Universal Edge router
- An ACX Series router
- Junos OS Release 14.2 or later for MX Series routers

## Overview

Consider a sample topology in which an ACX router functions as an initiator and terminator of the test frames for an RFC2544-based benchmarking test. ACX router is connected to a customer edge device CE1, on one side and is connected over a Layer 2 network to an MX104 router. The MX104 router functions as a reflector to reflect the test frames it receives from the ACX Series initiator back to the initiator. The MX04 router is also connected to a customer edge device CE2.

**NOTE:** When Layer 2 reflection is enabled on an interface, filters are configured internally to block the ingress and egress traffic except test traffic through the test interface.

Figure 40 on page 1017 shows the sample topology to perform all four RFC2544-based benchmarking tests (throughput, back-to-back frames, latency, and frame-loss) for the UNI direction on a Layer 2 bridge network.

**Figure 40: Layer 2 reflection Simple Topology**

On the ACX router, ge-1/2/1.0 is the Layer 2 NNI interface and ge-1/1/3.0 is the Layer 2 UNI interface. On the MX104 router, ge-1/1/6.0 is the Layer 2 NNI interface and ge-1/1/5.0 is the Layer 2 UNI interface. The benchmarking tests are used to compute the performance attributes for an E-LAN service on a bridge domain.

**NOTE:** Test packets can be identified using the destination MAC address, source MAC address, and test interface. Both tagged and untagged interfaces are supported. For tagged interfaces, the test interface is the VLAN sub interface. For untagged interfaces, the physical port represents the test interface. Traffic through other VLAN sub interfaces, present in the same physical port, is not affected when you configure the benchmarking test on one of the sub interfaces.

## Configuration

In this example, you configure the benchmarking tests for the UNI direction for an E-LAN service on a Layer 2 bridge domain that is enabled between two routers to detect and analyze the performance of the interconnected routers. In this example, we start by configuring the ACX Series router. On the ACX router, you first configure each test by specifying the test profile, the test attributes, and then define the test by associating the test with the test profile with the relevant attributes. You can then configure the interface. On the MX104 router, you will perform the same steps. However, a few attributes such as the outer VLAN ID, source UDP port, destination UDP port, the duration of each iteration, and their values are only applicable to the initiator or the ACX router.

**NOTE:** When you configure the Layer 2 reflection, you can specify the service type under test as ELINE if you want to simulate an ELINE service using bridge encapsulation.

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level:

### Configuring Benchmarking Test

```
set services rpm rfc2544-benchmarking profiles test-profile tput test-type throughput
set services rpm rfc2544-benchmarking profiles test-profile tput packet-size 128
set services rpm rfc2544-benchmarking profiles test-profile tput bandwidth-kbps 900000
```

## Parameters on the ACX Series Router

```

set services rpm rfc2544-benchmarking profiles test-profile b2bt test-type
back-back-frames
set services rpm rfc2544-benchmarking profiles test-profile b2bt packet-size 512

### Configuring Throughput Benchmarking Test Parameters on the ACX Series Router

#### Step-by-Step Procedure

The following configuration requires you to configure a test profile for the throughput test and reference the test-profile in a unique test-name. The test-name defines the parameters for the throughput test to be performed on the ACX router.

To configure the throughput test parameters on the ACX Router:

1. In configuration mode, at the `[edit]` hierarchy level, configure a real-time performance monitoring service (RPM) instance and an RFC2544-based benchmarking test for the RPM instance.

```
[edit]
user@host# edit services rpm rfc2544-benchmarking
```

2. Define a name for the first test profile—for example, `tput` for the throughput test profile.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit profiles test-profile tput
```

3. Configure the type of test to be performed as throughput, specify the packet size as 128 bytes, and define the theoretical maximum bandwidth for the test in kilobits per second (Kbps), with a value from 1 Kbps through 1,000,000 Kbps.

```
[edit services rpm rfc2544-benchmarking profiles test-profile tput]
user@host# set test-type throughput packet-size 128 bandwidth-kbps 900000
```

4. Enter the `up` command twice to go to the `[edit services rpm rfc2544-benchmarking]` level in the configuration hierarchy.

```
[edit services rpm rfc2544-benchmarking profiles test-profile tput]
user@host# up
user@host# up
```

5. Define a name for the throughput test—for example, `tput-test`. The test name can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name tput-test
```

6. Specify the name of the test profile, `tput`, to be associated with the test name.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set test-profile tput
```

7. Configure the source and destination MAC address for the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set source-mac-address 00:00:00:00:11:11 destination-mac-address
00:00:00:00:22:22
```

8. Configure the outer VLAN ID for the test frames and specify the service type under test to be E-LAN.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set ovlan-id 400 service-type elan
```

9. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set mode initiate-and-terminate
```

10. Configure the family type, **bridge**, for the benchmarking test and specify the direction, egress. Also, specify the source and destination UDP port to be used in the UDP headers of the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set family bridge direction egress source-udp-port 200
destination-udp-port 200
```

11. Specify the duration of each iteration in seconds, with a value from 10 seconds to 1,728,000 seconds, and specify the logical interface, ge-0/2/1.0, on which the RFC2544-benchmarking tests are run.

```
[edit services rpm rfc2544-benchmarking tests test-name tput-test]
user@host# set test-iterator-duration 20 test-interface ge-1/1/3.0
```

### Configuring Back-to-Back Frames Benchmarking Test Parameters on the ACX Series Router

---

#### Step-by-Step Procedure

The following configuration requires you to configure a test profile for the back to back frames test and reference the test-profile in a unique test-name. The test-name defines the parameters for the back to back frames test to be performed on the ACX router.

To configure the back-to-back frames test parameters on the ACX Router:

1. In configuration mode, at the **[edit]** hierarchy level, configure a real-time performance monitoring service (RPM) instance and an RFC2544-based benchmarking test for the RPM instance.

```
[edit]
user@host# edit services rpm rfc2544-benchmarking
```

2. Define a name for the back-to-back test profile—for example, b2bt.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit profiles test-profile b2bt
```

3. Configure the type of test to be performed as back-to-back frames, specify the packet size as 128 bytes, and define the theoretical maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.

```
[edit services rpm rfc2544-benchmarking profiles test-profile b2bt]
user@host# set test-type back-to-back-frames packet-size 4444 bandwidth-kbps
950000
```

4. Enter the **up** command twice to go to the **[edit services rpm rfc2544-benchmarking]** level in the configuration hierarchy.

```
[edit services rpm rfc2544-benchmarking profiles test-profile b2bt]
user@host# up
user@host# up
```

5. Define a name for the back-to-back frames test—for example, b2bt-test. The test name can be up to 32 characters in length.  

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name b2bt-test
```
6. Specify the name of the test profile, b2bt, to be associated with the test name.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set test-profile b2bt
```
7. Configure the source and destination MAC address for the test packet.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set source-mac-address 00:00:00:00:11:11 destination-mac-address
00:00:00:00:22:22
```
8. Configure the outer VLAN ID for the test frames and specify the service type under test.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set ovlan-id 400 service-type elan
```
9. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set mode initiate-and-terminate
```
10. Configure the family type, **bridge**, for the benchmarking test and specify the direction, egress.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set family bridge direction egress
```
11. Specify the duration of each iteration in seconds, with a value from 10 seconds to 1,728,000 seconds. Also, specify the logical interface, ge-0/2/1.0, on which the RFC2544-based benchmarking test is run.  

```
[edit services rpm rfc2544-benchmarking tests test-name b2bt-test]
user@host# set test-iterator-duration 20 test-interface ge-1/1/3.0
```

### Configuring Latency Benchmarking Test Parameters on the ACX Series Router

#### Step-by-Step Procedure

The following configuration requires you to configure a test profile for the latency test and reference the test-profile in a unique test-name. The test-name defines the parameters for the latency test to be performed on the ACX router.

To configure the latency test parameters on the ACX Router:

1. In configuration mode, at the **[edit]** hierarchy level, configure a real-time performance monitoring service (RPM) instance and an RFC2544-based benchmarking test for the RPM instance.  

```
[edit]
user@host# edit services rpm rfc2544-benchmarking
```
2. Define a name for the latency test profile—for example, lty.  

```
[edit services rpm rfc2544-benchmarking]
```

```
user@host# edit profiles test-profile lty
```

3. Configure the type of test to be performed as latency, specify the packet size of the test packet, and define the maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.

```
[edit services rpm rfc2544-benchmarking profiles]
```

```
user@host# set test-profile lty test-type latency packet-size 512 bandwidth-kbps 1000000
```

4. Enter the **up** command twice to go to the previous level in the configuration hierarchy.

```
[edit services rpm rfc2544-benchmarking profiles test-profile lty]
```

```
user@host# up
```

```
user@host# up
```

5. Define a name for the latency test—for example, lty-test. The test name can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
```

```
user@host# edit tests test-name lty-test
```

6. Specify the name of the test profile, lty, to be associated with the test name.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set test-profile lty
```

7. Configure the source and destination MAC address for the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set source-mac-address 00:00:00:00:11:11 destination-mac-address 00:00:00:00:22:22
```

8. Configure the outer VLAN ID for the test frames and specify the service type under test.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set ovlan-id 400 service-type elan
```

9. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set mode initiate-and-terminate
```

10. Configure the family type, **bridge**, for the benchmarking test and specify the direction, egress. Also, specify the source and destination UDP port to be used in the UDP headers of the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set family bridge direction egress source-udp-port 200 destination-udp-port 200
```

11. Specify the duration of each iteration in seconds, with a value from 10 seconds to 1,728,000 seconds. Also, specify the logical interface, ge-0/2/1.0, on which the RFC2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name lty-test]
```

```
user@host# set test-iterator-duration 20 test-interface ge-1/1/3.0
```

### Configuring Frame Loss Benchmarking Test Parameters on the ACX Series Router

#### Step-by-Step Procedure

The following configuration requires you to configure a test profile for the frame loss test and reference the test-profile in a unique test-name. The test-name defines the parameters for the frame loss test to be performed on the ACX router.

To configure the frame loss test parameters on the ACX Router:

1. In configuration mode, at the `[edit]` hierarchy level, configure a real-time performance monitoring service (RPM) instance and an RFC2544-based benchmarking test for the RPM instance.

```
[edit]
user@host# edit services rpm rfc2544-benchmarking
```

2. Define a name for the frame loss test profile—for example, `frloss`.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit profiles test-profile frloss
```

3. Configure the type of test performed as frame loss, specify the packet size of the test packet, and define the maximum bandwidth for the test in kilobits per second, with a value from 1 Kbps through 1,000,000 Kbps.

```
[edit services rpm rfc2544-benchmarking profiles]
user@host# set test-profile frloss test-type frame-loss packet-size 1600
bandwidth-kbps 1000000
```

4. Enter the `up` command to go to the previous level in the configuration hierarchy.

```
[edit services rpm rfc2544-benchmarking profiles]
user@host# up
```

5. Define a name for the frame loss test—for example, `frloss-test`. The test name can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name frloss-test
```

6. Specify the name of the test profile, `frloss`, to be associated with the test name.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
user@host# set test-profile frloss
```

7. Configure the source and destination MAC address for the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
user@host# set source-mac-address 00:00:00:00:11:11 destination-mac-address
00:00:00:00:22:22
```

8. Configure the outer VLAN ID for the test frames and specify the service type under test.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
user@host# set ovlan-id 400 service-type elan
```

9. Specify the test mode for the packets that are sent during the benchmarking test as initiation and termination.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
```

```
user@host# set mode initiate-and-terminate
```

10. Configure the family type, **bridge**, for the benchmarking test and specify the direction, egress. Also, specify the source and destination UDP port to be used in the UDP headers of the test packet.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
user@host# set family bridge direction egress source-udp-port 200
destination-udp-port 200
```

11. Specify the duration of each iteration in seconds, with a value from 10 seconds to 1,728,000 seconds. Also, specify the logical interface, ge-0/2/1.0, on which the RFC2544-based benchmarking test is run.

```
[edit services rpm rfc2544-benchmarking tests test-name frloss-test]
user@host# set test-iterator-duration 20 test-interface ge-1/1/3.0
```

12. Enter the **exit** command to go to the [edit] hierarchy level.

```
[edit services rpm rfc2544-benchmarking tests test-name test4]
user@host# exit
```

---

### Configuring Other Benchmarking Test Parameters on the ACX Series Router

---

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure the interface and bridge domain on the ACX Router:

1. Configure the Layer 2 NNI interface on which the tests must be run from the **[edit]** hierarchy level.

```
[edit]
user@host# edit interfaces ge-1/2/1
```

2. Configure flexible VLAN tagging for the transmission of untagged frames or 802.1Q single-tagged and dual-tagged frames on the logical interface. You can also specify the maximum transmission unit (MTU) size for the interface and the encapsulation.

```
[edit interfaces ge-1/2/1]
user@host# set flexible-vlan-tagging mtu 9192 encapsulation
flexible-ethernet-services
```

3. Configure a logical unit for the interface, specify the encapsulation, and configure the VLAN ID on the logical interfaces.

```
[edit interfaces ge-1/2/1]
user@host# set unit 0 encapsulation vlan-bridge vlan-id 400
```

4. Configure the Layer 2 UNI interface.

```
[edit]
user@host# edit interfaces ge-1/1/3
```

5. Configure flexible VLAN tagging for transmission of non-tagged frames or 802.1Q single-tag and dual-tag frames on the logical interface. You can also specify the maximum transmission unit (MTU) size for the interface and the encapsulation.

```
[edit interfaces ge-1/1/3]
user@host# set flexible-vlan-tagging mtu 9192 encapsulation
flexible-ethernet-services
```

6. Configure a logical unit for the interface and specify the encapsulation and configure the VLAN ID on the logical interfaces.

```
[edit interfaces ge-1/1/3]
user@host# set unit 0 encapsulation vlan-bridge vlan-id 400
```

7. Configure the bridge domain, bd1, and specify the VLAN ID associated with the bridge domain and the associated interfaces from the [edit] hierarchy level.

```
[edit]
user@host# set bridge-domains bd1 vlan-id 600 interface ge-1/2/1.0
user@host# set bridge-domains bd1 vlan-id 600 interface ge-1/1/3.0
```

### Configuring Benchmarking Test Parameters on the MX104 Router

#### Step-by-Step Procedure

The following configuration requires you to configure a unique test-name for the benchmarking test on the MX104 router. The test-name defines the parameters for the benchmarking test to be performed. Because the test interface and test MAC addresses are the same, you can create a single test configuration at the reflector (MX104).

To configure the benchmarking test parameters on the MX104 Router:

1. In configuration mode, at the [edit] hierarchy level, configure a real-time performance monitoring service (RPM) instance and an RFC2544-based benchmarking test for the RPM instance.

```
[edit]
user@host# edit services rpm rfc2544-benchmarking
```

2. Define a name for the test—for example, l2b-reflector. The test name can be up to 32 characters in length.

```
[edit services rpm rfc2544-benchmarking]
user@host# edit tests test-name l2b-reflector
```

3. Specify the source and destination MAC addresses of the test packet.

```
[edit services rpm rfc2544-benchmarking test-name l2b-reflector]
user@host# set source-mac-address 00:00:00:00:11:11 destination-mac-address
00:00:00:00:22:22
```

4. Specify the service type under test and the mode which is reflect, at the reflector.

```
[edit services rpm rfc2544-benchmarking test-name l2b-reflector]
user@host# set service-type elan
```

5. Specify the mode which is reflect at the reflector.

```
[edit services rpm rfc2544-benchmarking test-name l2b-reflector]
user@host# set mode reflect
```

6. Configure the family type, **bridge**, for the benchmarking test and specify the direction, egress. Also, specify the logical interface, ge-1/1/5.0, on which the RFC2544-based benchmarking test is being run.

```
[edit services rpm rfc2544-benchmarking tests test-name l2b-reflector]
```

```
user@host# set family bridge direction egress test-interface ge-1/1/5.0
```

### Configuring Other Benchmarking Test Parameters on the MX104 Router

#### **Step-by-Step Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure the interface and bridge domain on the MX104 Router:

1. Configure the Layer 2 NNI interface on which the tests must be run.  

```
[edit]
user@host# edit interfaces ge-1/1/6
```
2. Configure flexible VLAN tagging for transmission of untagged frames or 802.1Q single-tagged and dual-tagged frames on the logical interface. You can also specify the maximum transmission unit (MTU) size for the interface and the encapsulation.  

```
[edit interfaces ge-1/1/6]
user@host# set flexible-vlan-tagging mtu 9192 encapsulation
flexible-ethernet-services
```
3. Configure a logical unit for the interface, specify the encapsulation, and configure the VLAN ID on the logical interface.  

```
[edit interfaces ge-1/1/6]
user@host# set unit 0 encapsulation vlan-bridge vlan-id 400
```
4. Configure the Layer 2 NNI interface.  

```
[edit]
user@host# edit interfaces ge-1/1/5
```
5. Configure flexible VLAN tagging for transmission of untagged frames or 802.1Q single-tagged and dual-tagged frames on the logical interface. You can also specify the maximum transmission unit (MTU) size for the interface and the encapsulation.  

```
[edit interfaces ge-1/1/5]
user@host# set flexible-vlan-tagging mtu 9192 encapsulation
flexible-ethernet-services
```
6. Configure a logical unit for the interface, specify the encapsulation, and configure the VLAN ID on the logical interfaces.  

```
[edit interfaces ge-1/1/5]
user@host# set unit 0 encapsulation vlan-bridge vlan-id 400
```
7. Configure the bridge domain, bd1, and specify the VLAN ID associated with the bridge domain, and the associated interfaces from the [edit] hierarchy level.  

```
[edit]
user@host# set bridge-domains bd1 vlan-id 500 interface ge-1/1/6.0
user@host# set bridge-domains bd1 vlan-id 500 interface ge-1/1/5.0
```
8. Start the benchmarking test on the reflector.  

```
user@host> test services rpm rfc2544-benchmarking test l2b-reflector start
```

After the test is successfully completed at the initiator, you can stop the test at the reflector by entering the **test services rpm rfc2544-benchmarking test l2b-reflector stop** command.

## Results

---

In configuration mode, confirm your configuration on the ACX Router and the MX104 Router by entering the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

Benchmarking Test Parameters on the ACX Router :

```
[edit interfaces]
ge-1/2/1 {
 flexible-vlan-tagging;
 mtu 9192;
 encapsulation flexible-ethernet-services;
 unit 0 {
 encapsulation vlan-bridge;
 vlan-id 400;
 }
}
ge-1/1/3 {
 flexible-vlan-tagging;
 mtu 9192;
 encapsulation flexible-ethernet-services;
 unit 0 {
 encapsulation vlan-bridge;
 vlan-id 400;
 }
}

[edit bridge-domains]
bd1 {
 vlan-id 600;
 interface ge-1/2/1.0;
 interface ge-1/1/3.0;
}

```

## Verifying the Results of the Benchmarking Tests for Layer 2 Services (E-LAN) in Bridge Domains

Examine the results of the benchmarking tests that are performed on the configured service between the ACX Router and the MX104 Router. Start the test on the reflector first and then start the test on the initiator.

- [Verifying the Throughput Benchmarking Test Results on page 1032](#)
- [Verifying the Back-to-Back Benchmarking Test Results on page 1034](#)
- [Verifying the Frame Loss Benchmarking Test Results on page 1036](#)
- [Verifying the Latency Benchmarking Test Results on page 1038](#)

### Verifying the Throughput Benchmarking Test Results

**Purpose** Verify that the necessary and statistical values are displayed for the benchmarking tests that are run on the configured service between the ACX router and the MX104 router.

**Action** In operational mode, enter the **show services rpm rfc2544-benchmarking test-id test-id-number detail** command on the ACX router.

```
user@host> show services rpm rfc2544-benchmarking test-id 1 detail
Test information :

# Tracking Streaming Media Traffic Using Inline Video Monitoring

- [Inline Video Monitoring Overview on page 1043](#)
- [Configuring Inline Video Monitoring on page 1045](#)
- [Inline Video Monitoring Syslog Messages on page 1047](#)

## Inline Video Monitoring Overview

---

Junos OS supports inline video monitoring using Media Delivery Index (MDI) metrics.

Inline video monitoring is available on MX Series routers using only the following MPCs:

- MPCE1
- MPCE2
- MPC-16XGE

You use the **video-monitoring** statement at the **[edit services]** hierarchy level to specify monitoring criteria for two key indicators of video traffic problems: delay factor and media loss rate (MLR), and to apply these metrics to flows on designated interfaces.

Before you use the inline video monitoring feature, ensure that you understand the following terms:

- **media delivery index**—These metrics facilitate identification of buffering needs for streaming media. Buffering must be adequate to compensate for packet jitter, measured by the MDI delay factor, and quality problems indicated by lost packets, measured by the MDI media loss rate (MLR). By performing measurements under varying load conditions, you can identify sources of significant jitter or packet loss and take appropriate action.
- **delay factor** —Delay factor is the maximum observed time difference between the arrival of media data and the drain of media data. The expected drain rate is the nominal, constant traffic rate for constant bit rate streams or the computed traffic rate of variable rate media stream packet data.

For typical stream rates of 1 megabit per second and higher, an interval of one second provides an adequate sample time. The delay factor indicates how long a data stream must be buffered (delayed) at its nominal bit rate to prevent packet loss.

The delay factor suggests the minimum size of the buffer required at the next downstream node. As a stream progresses, the variation of the delay factor indicates packet bunching or packet gaps (jitter). Greater delay factor values also indicate that more network latency is needed to deliver a stream due to the need to pre-fill a receive buffer before beginning the drain to guarantee no underflow.

When the nominal drain bit rate at a receiving node is known, the delay factor's maximum indicates the size of buffer required to accommodate packet jitter.

- **Media rate variation (MRV)**—This value is the difference between the expected packet rate and actual packet rate expressed as a percentage of the expected packet rate.
- **Media loss rate (MLR)**—This value is the number of media packets lost over a configurable time interval (*interval-duration*,) where the flow packets are packets carrying streaming application information. A single IP packet can contain zero or more streaming packets. For example, an IP packet typically contains seven 188-byte MPEG transport stream packets. In this case, a single IP packet loss results in seven lost packets counted (if those seven lost packets did not include null packets). Including out-of-order packets is important, because many stream consumer-type devices do not attempt to reorder packets that are received out of order.

To configure the monitoring process, define criteria templates and apply them to the interfaces and flows you want to monitor. Monitoring templates include the following criteria:

- Duration of each measurement cycle
- Flow rate information used to establish expected flow rates
- Threshold levels for media rate variation and media loss rate that trigger desired syslog alerts

For each interface you want to monitor, you can define one or more filters to select flows for monitoring. Flows are designated as input or output flows and are uniquely identified by:

- Source IP address
- Source port
- Destination IP address
- Destination port

Junos OS supports the definition of filters for up to 256 flows, which can consist of input flows, output flows, or a combination of input and output flows. These filters provide criteria for selecting flows for monitoring. If the selection criteria consist of lists of IP addresses or ports, you could exceed the maximum number of match conditions for flows. Video monitoring selects a widely variable number of flows based on flow filters. The total number of flows that can be measured at a time depends on the specific MPC card being used, as shown in [Table 41 on page 1045](#).

When you do not define input or output flow filters for a monitored interfaces, all flows on the interface are subject to monitoring.

**Table 41: MPC Flow Monitoring Capacity by Model**

MPC Model	Maximum Number of Flows Monitored Simultaneously
MPCE1	1000
MPCE2	2000
MPC-16XGE	4000

**NOTE:** Junos OS measures both UDP flows (the default) and RTP flows. Junos OS differentiates media traffic over UDP or RTP by inspecting the first byte in the UDP payload. If the first byte of the UDP payload is 0x47 (MPEG2-TS sync byte), the traffic is treated as media traffic over UDP. Traffic is treated as media traffic over RTP if the version field is 2 and the payload type is 33 in the RTP header. When neither of these criteria are met, the packet is not considered for video monitoring.

## Configuring Inline Video Monitoring

To configure inline video monitoring, perform the following tasks.

- [Configuring Media Delivery Indexing Criteria on page 1045](#)
- [Configuring Interface Flow Criteria on page 1047](#)

### Configuring Media Delivery Indexing Criteria

To configure media delivery indexing criteria:

1. In edit mode, create a named template for video monitoring.  

```
user@host# edit services video-monitoring templates template-name
```

For example,

```
user@host# edit services video-monitoring templates t1
```

2. Set the duration for sampling in seconds. Flow media delivery indexing statistics are updated at the end of this interval.

```
[edit services video-monitoring templates t1]
```

```
user@host# set interval-duration 1
```

**BEST PRACTICE:** If you change the interval duration when a template is being used, you cause a change in the calculated number of expected packets in an measurement interval for the template. We recommend that you do not change the interval duration for a template that is in use.

3. Set the inactivity timeout.

```
[edit services video-monitoring templates t1]
user@host# set inactivity-timeout 30
```

4. Configure either **media-rate** or **layer3-packet-rate** to establish expected flow rates used to compare to monitored flow rates.

**NOTE:** The media rate is the configured media bit rate for the stream. The media rate is used to establish *expected packets per second (pps)*.

The layer 3 packet rate in packets per second (pps) and is used to establish *expected bits per second (bps)*.

```
[edit services video-monitoring templates t1]
user@host# set media-rate 2972400
```

5. Set delay factor thresholds for syslog message levels.

```
[edit services video-monitoring templates t1]
user@host# set delay-factor threshold info 100
user@host# set delay-factor threshold warning 200
user@host# set delay-factor threshold critical 300
```

6. Set media loss rate thresholds for syslog message levels. You can set the threshold based on number of packets lost, or percentage of packets lost.

Or

```
[edit services video-monitoring templates t1]
user@host# set media-loss-rate threshold info percentage 5
user@host# set media-loss-rate threshold warning percentage 10
user@host# set media-loss-rate threshold critical percentage 20
```

7. Set the media rate variation thresholds for syslog message levels. The threshold is based on the ratio of the *difference* between the configured media rate and the monitored media rate to the configured media rate, expressed as a percentage.

```
[edit services video-monitoring templates t1]
user@host# set media-rate-variation threshold info 10
user@host# set media-rate-variation threshold warning 15
user@host# set media-rate-variation threshold critical 20
```

## Configuring Interface Flow Criteria

To configure monitoring of flows for interfaces:

1. In edit mode, identify an interface for monitoring .

```
user@host# edit services video-monitoring interfaces interface-name
```

2. Identify input flows for monitoring. Flows are uniquely identified by source IP address, source port, destination IP address, and destination port. You can restrict flow measurement by specifying values for these identifiers. You can specify individual addresses or ports or lists of addresses and ports. If you do not specify any identifiers, all flows on the interface are monitored.

```
[edit services video-monitoring interfaces interface-name]
user@host# set input-flows input-flow-name
user@host# set input-flows input-flow-name source-address address
user@host# set input-flows input-flow-name source-port port
user@host# set input-flows input-flow-name destination-address address
user@host# set input-flows input-flow-name destination-port port
```

**NOTE:** You can configure a maximum of 256 flow definitions. If your flow definitions contain lists of addresses and ports, you may exceed the number of match conditions. When you exceed the limits for flows or match conditions, you receive the following constraint message when you commit:

```
'interfaces xe-0/2/2.0'
 Number of flows or Number of match condition under flows exceeded
 limit
error: configuration check-out failed
```

3. Identify output flows for monitoring, using the same options listed in Step 2.
4. Identify the template used to monitor the flows on the interface.

```
[edit services video-monitoring interfaces interface-name]
set template t1
```

## Configuring Traffic Sampling

---

Traffic sampling enables you to copy traffic to a Physical Interface Card (PIC) that performs flow accounting while the router forwards the packet to its original destination. You can configure the router to perform sampling in either of two locations:

- On the Routing Engine, using the sampled process. To select this method, use a filter (input or output) with a matching term that contains the **then sample** statement.
- On the Monitoring Services, Adaptive Services, or Multiservices PIC.

**NOTE:** Routing Engine based sampling is not supported on VPN routing and forwarding (VRF) instances.

The following sections provide configuration instructions for traffic sampling:

- [Configuring Firewall Filter for Traffic Sampling on page 1051](#)
- [Configuring Traffic Sampling on a Logical Interface on page 1053](#)
- [Disabling Traffic Sampling on page 1054](#)
- [Sampling Once on page 1054](#)
- [Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets on page 1055](#)
- [Configuring Traffic Sampling Output on page 1056](#)
- [Tracing Traffic Sampling Operations on page 1058](#)
- [Traffic Sampling Examples on page 1058](#)

## Configuring Firewall Filter for Traffic Sampling

To configure firewall filter for traffic sampling, you must perform the following tasks:

- Create a firewall filter to apply to the logical interfaces being sampled by including the **filter** statement at the **[edit firewall family *family-name*]** hierarchy level. In the filter **then** statement, you must specify the action modifier **sample** and the action **accept**.

```
filter filter-name {
 term term-name {
 then {
 sample;
 accept;
 }
 }
}
```

For more information about firewall filter actions and action modifiers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

- Apply the filter to the interfaces on which you want to sample traffic by including the **address** and **filter** statements at the **[edit interfaces *interface-name* unit *logical-unit-number* family *family-name*]** hierarchy level:

```
address address {
}
filter {
 input filter-name;
}
```

The following prerequisites apply to M, MX, and T Series routers when you configure traffic sampling on interfaces and in firewall filters:

- If you configure a sample action in a firewall filter for an inet or inet6 family on an interface without configuring the forwarding-options settings, operational problems might occur if you also configure port mirroring or flow-tap functionalities. In such a scenario, all the packets that match the firewall filter are incorrectly sent to the service PIC.
- If you include the **then sample** statement at the **[edit firewall family inet filter *filter-name* term *term-name*]** hierarchy level to specify a sample action in a firewall filter for IPv4 packets, you must also include the **family inet** statement at the **[edit forwarding-options sampling]** hierarchy level or the **instance *instance-name* family inet** statement at the **[edit forwarding-options sampling]** hierarchy level. Similarly, if you include the **then sample** statement at the **[edit firewall family inet6 filter *filter-name* term *term-name*]** hierarchy level to specify a sample action in a firewall filter for IPv6 packets, you must also include **family inet6** statement at the **[edit forwarding-options sampling]** hierarchy level or the **instance *instance-name* family inet6** statement at the **[edit forwarding-options sampling]** hierarchy level. Otherwise, a commit error occurs when you attempt to commit the configuration.
- Also, if you configure traffic sampling on a logical interface by including the sampling input or sampling output statements at the **[edit interface *interface-name* unit *logical-unit-number*]** hierarchy level, you must also include the **family inet | inet6** statement at the **[edit forwarding-options sampling]** hierarchy level, or the **instance *instance-name* family inet | inet6** statement at the **[edit forwarding-options sampling]** hierarchy level.

## Configuring Traffic Sampling on a Logical Interface

To configure traffic sampling on any logical interface, enable sampling and specify a non zero sampling rate by including the sampling statement at the **[edit forwarding-options]** hierarchy level:

```
sampling {
 input {
 rate number;
 run-length number;
 max-packets-per-second number;
 maximum-packet-length bytes;
 }
}
```

When you use Routing Engine-based sampling, specify the threshold traffic value by including the **max-packets-per-second** statement. The value is the maximum number of packets to be sampled, beyond which the sampling mechanism begins dropping packets. The range is from 0 through 65,535. A value of 0 instructs the Packet Forwarding Engine not to sample any packets. The default value is 1000.

**NOTE:** When you configure active monitoring and specify a Monitoring Services, Adaptive Services, or Multiservices PIC in the output statement, the **max-packets-per-second** value is ignored.

Specify the sampling rate by setting the values for **rate** and **run-length** (see [Figure 34 on page 873](#)).

**Figure 41: Configuring Sampling Rate**

### Rate and Run-length

Case #1 Rate = 10, run-length = 4

1746

**NOTE:** If PIC-based flow monitoring is enabled on an *ms-fpc/pic/port.logical-unit* interface, a commit check error occurs when you attempt to configure ingress traffic sampling on that interface. This error occurs because a combination of ingress sampling and PIC-based flow monitoring operations on an *ms-* logical interface causes undesired flow monitoring behavior and might result in repeated sampling of a single packet. You must not configure ingress sampling on *ms-* logical interfaces on which PIC-based flow monitoring is enabled.

The **rate** statement specifies the ratio of packets to be sampled. For example, if you configure a rate of 10, *x* number of packets out of every 10 is sampled, where *x*=run length + 1. By default, the rate is 0, which means that no traffic is sampled.

The **run-length** statement specifies the number of matching packets to sample following the initial one-packet trigger event. By default, the run length is 0, which means that no more traffic is sampled after the trigger event. The range is from 0 through 20. Configuring a run length greater than 0 allows you to sample packets following those already being sampled.

**NOTE:** The **run-length** and **maximum-packet-length** configuration statements are not supported on MX80 routers.

If you do not include the **input** statement, sampling is disabled.

To collect the sampled packets in a file, include the **file** statement at the **[edit forwarding-options sampling output]** hierarchy level. Output file formats are discussed later in the chapter.

## Disabling Traffic Sampling

To explicitly disable traffic sampling on the router, include the **disable** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
disable;
```

## Sampling Once

To explicitly sample a packet for active monitoring only once, include the **sample-once** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
sample-once;
```

Setting this option avoids duplication of packets in cases where sampling is enabled at both the ingress and egress interfaces and simplifies analysis of the sampled traffic.

## Preserving Prerewrite ToS Value for Egress Sampled or Mirrored Packets

To preserve the prenormalized type-of-service (ToS) value in egress sampled or mirrored packets, include the **pre-rewrite-tos** statement at the **[edit forwarding-options sampling]** hierarchy level.

On MPC-based interfaces, you can configure ToS rewrite either using class-of-service (CoS) configuration by including the **rewrite-rules dscp rule\_name** statement at the **[edit class-of-service interfaces interface-name unit logical-unit-number]** hierarchy level or using firewall filter configuration by including the **dscp** statement at the **[edit firewall family family-name filter filter-name term term-name then]** hierarchy level. If ToS rewrite is configured, the egress mirrored or sampled copies contain the post-rewrite ToS values by default. With the **pre-rewrite-tos** configuration, you can retain the prerewrite ToS value in the sampled or mirrored packets.

### NOTE:

- If ToS rewrite is configured on the egress interface by using both CoS and firewall filter configuration, and if the **pre-rewrite-tos** statement is also configured, then the egress sampled packets contain the DSCP value set using the firewall filter configuration. However, if the **pre-rewrite-tos** statement is not configured, the egress sampled packets contain the DSCP value set by the CoS configuration.
- With the **pre-rewrite-tos** statement, you can configure retaining prenormalization ToS values only for sampling done under family inet and family inet6.
- This feature cannot be configured at the **[edit logical-systems]** hierarchy level. It can be configured only at the global level under the forwarding-option configuration.
- When ToS rewrite is configured by using a firewall filter on both ingress and egress interfaces, the egress sampled packets contain the DSCP value set by the ingress ToS rewrite configuration if the **pre-rewrite-tos** statement is configured. However, if the **pre-rewrite-tos** statement is not configured, the egress sampled packets contain the DSCP value set by the ToS rewrite configuration for the egress firewall filter.
- If the **pre-rewrite-tos** statement is configured, and a deactivate or delete operation is performed at the **[edit forwarding-options]** hierarchy level, **pre-rewrite-tos** configuration still remains active. To disable the **pre-rewrite-tos** configuration for such a case, you must explicitly deactivate or delete the **pre-rewrite-tos** statement at the **[edit forwarding-options sampling]** hierarchy level before performing a deactivate or delete operation at the **[edit forwarding-options]** hierarchy level.

## Configuring Traffic Sampling Output

To configure traffic sampling output, include the following statements at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output]** hierarchy level:

```
aggregate-export-interval seconds;
flow-active-timeout seconds;
flow-inactive-timeout seconds;
extension-service service-name;
flow-server hostname {
 aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
 source-prefix;
 }
 autonomous-system-type (origin | peer);
 (local-dump | no-local-dump);
 port port-number;
 source-address address;
 version format;
 version9 {
 template template-name;
 }
}
interface interface-name {
 engine-id number;
 engine-type number;
 source-address address;
}
file {
 disable;
 filename filename;
 files number;
 size bytes;
 (stamp | no-stamp);
 (world-readable | no-world-readable);
}
```

To configure inline flow monitoring on MX Series routers, include the **inline-jflow** statement at the **[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls) output]** hierarchy level. Inline sampling exclusively supports a new format called IP\_FIX that uses UDP as the transport protocol. When you configure inline sampling, you must include the **version-ipfix** statement at the **[edit forwarding-options sampling instance instance-name family (inet | inet6 | mpls) output flow-server address]** hierarchy level and also at the **[edit services flow-monitoring]** hierarchy level. For more information about configuring inline flow monitoring, see [“Configuring Inline Active flow Monitoring” on page 890](#).

To direct sampled traffic to a flow-monitoring interface, include the **interface** statement. The **engine-id** and **engine-type** statements specify the identity and type numbers of the

interface; they are dynamically generated based on the Flexible PIC Concentrator (FPC), PIC, and slot numbers and the chassis type. The **source-address** statement specifies the traffic source.

To configure flow sampling version 9 output, you need to include the **template** statement at the **[edit forwarding-options sampling output version9]** hierarchy level. For information on cflowd, see [“Enabling Flow Aggregation” on page 898](#).

The **aggregate-export-interval** statement is described in [“Configuring Discard Accounting” on page 883](#), and the **flow-active-timeout** and **flow-inactive-timeout** statements are described in [“Configuring Flow Monitoring” on page 818](#).

Traffic sampling results are automatically saved to a file in the **/var/tmp** directory. To collect the sampled packets in a file, include the **file** statement at the **[edit forwarding-options sampling family inet output]** hierarchy level:

```
file {
 disable;
 filename filename;
 files number;
 size bytes;
 (stamp | no-stamp);
 (world-readable | no-world-readable);
}
```

### Traffic Sampling Output Format

Traffic sampling output is saved to an ASCII text file. The following is an example of the traffic sampling output that is saved to a file in the **/var/tmp** directory. Each line in the output file contains information for one sampled packet. You can optionally display a timestamp for each line.

The column headers are repeated after each group of 1000 packets.

```
Apr 7 15:48:50
Time Dest Src Dest Src Proto TOS Pkt Intf IP TCP
 addr addr port port len num frag flags
Apr 7 15:48:54 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:55 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:56 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:57 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
Apr 7 15:48:58 192.168.9.194 192.168.9.195 0 0 1 0x0 84 8 0x0 0x0
```

To set the timestamp option for the file **my-sample**, enter the following:

```
[edit forwarding-options sampling output file]
user@host# set filename my-sample files 5 size 2m world-readable stamp;
```

Whenever you toggle the timestamp option, a new header is included in the file. If you set the **stamp** option, the **Time** field is displayed.

```
Apr 7 15:48:50
Time Dest Src Dest Src Proto TOS Pkt Intf IP TCP
addr addr port port len num frag flags
Feb 1 20:31:21
```

#	Dest	Src	Dest	Src	Proto	TOS	Pkt	Intf	IP	TCP
#	addr	addr	port	port			len	num	frag	flags

## Tracing Traffic Sampling Operations

Tracing operations track all traffic sampling operations and record them in a log file in the `/var/log` directory. By default, this file is named `/var/log/sampled`. The default file size is 128K, and 10 files are created before the first one gets overwritten.

To trace traffic sampling operations, include the **traceoptions** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
traceoptions {
 no-remote-trace;
 file filename <files number> <size bytes> <match expression> <world-readable |
 no-world-readable>;
}
```

## Traffic Sampling Examples

The following sections provide examples of configuring traffic sampling:

- [Example: Sampling a Single SONET/SDH Interface on page 1058](#)
- [Example: Sampling All Traffic from a Single IP Address on page 1059](#)
- [Example: Sampling All FTP Traffic on page 1060](#)

---

### Example: Sampling a Single SONET/SDH Interface

The following configuration gathers statistical sampling information from a small percentage of all traffic on a single SONET/SDH interface and collects it in a file named **sonet-samples.txt**.

Create the filter:

```
[edit firewall family inet]
filter {
 input sample-sonet {
 then {
 sample;
 accept;
 }
 }
}
```

Apply the filter to the SONET/SDH interface:

```
[edit interfaces]
so-0/0/1 {
 unit 0 {
 family inet {
 filter {
 input sample-sonet;
 }
 address 10.127.68.254/32 {
 destination 172.16.74.7;
```

```

 }
 }
}

```

Finally, configure traffic sampling:

```

[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 100;
 run-length 2;
 }
 }
 family inet {
 output {
 file {
 filename sonet-samples.txt;
 files 40;
 size 5m;
 }
 }
 }
}

```

### Example: Sampling All Traffic from a Single IP Address

The following configuration gathers statistical information about every packet entering the router on a specific Gigabit Ethernet port originating from a single source IP address of 172.16.92.31, and collects it in a file named **samples-172-16-92-31.txt**.

Create the filter:

```

[edit firewall family inet]
filter one-ip {
 term get-ip {
 from {
 source-address 172.16.92.31;
 }
 then {
 sample;
 accept;
 }
 }
}

```

Apply the filter to the Gigabit Ethernet interface:

```

[edit interfaces]
ge-4/1/1 {
 unit 0 {
 family inet {
 filter {
 input one-ip;
 }
 address 10.45.92.254;
 }
 }
}

```

```
 }
 }
}
```

Finally, gather statistics on all the candidate samples; in this case, gather all statistics:

```
[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 1;
 }
 }
 family inet {
 output {
 file {
 filename samples-172-16-92-31.txt;
 files 100;
 size 100k;
 }
 }
 }
}
```

---

### Example: Sampling All FTP Traffic

The following configuration gathers statistical information about a moderate percentage of packets using the FTP data transfer protocol in the output path of a specific T3 interface, and collects the information in a file named **t3-ftp-traffic.txt**.

Create a filter:

```
[edit firewall family inet]
filter ftp-stats {
 term ftp-usage {
 from {
 destination-port [ftp ftp-data];
 }
 then {
 sample;
 accept;
 }
 }
}
```

Apply the filter to the T3 interface:

```
[edit interfaces]
t3-7/0/2 {
 unit 0 {
 family inet {
 filter {
 input ftp-stats;
 }
 address 10.35.78.254/32 {
 destination 10.35.78.4;
 }
 }
 }
}
```

```

 }
 }
}

```

Finally, gather statistics on 10 percent of the candidate samples:

```

[edit forwarding-options]
sampling {
 input {
 family inet {
 rate 10;
 }
 }
 family inet {
 output {
 file {
 filename t3-ftp-traffic.txt;
 files 50;
 size 1m;
 }
 }
 }
}

```

  - [Sampling Instance Configuration on page 881](#)

## Sampling Instance Configuration

You can configure active sampling by defining a sampling instance that specifies a name for the sampling parameters and bind the instance name to an FPC, MPC, or DPC. This configuration enables you to define multiple named sampling parameter sets associated with multiple destinations and protocol families per sampling destination. With the cflowd version 5 and version 8 and flow aggregation version 9, you can use templates to organize the data gathered from sampling.

To implement this feature, you include the **instance** statement at the **[edit forwarding-options sampling]** hierarchy level.

The following considerations apply to the sampling instance configuration:

- This configuration is supported on the IP version 4 (**inet**), IP version 6 (**ipv6**), and MPLS protocol families.
- You can configure the router to perform sampling in either of two locations:
  - On the Routing Engine, using the sampled process. To select this method, use a filter (input or output) with a matching term that contains the **then** sample statement.
  - On the Monitoring Services, Adaptive Services, or Multiservices PIC. Specify the interface name at the **[forwarding-options sampling instance *instance-name* family inet output interface]** hierarchy level. You can configure the same or different services PICs in a set of sampling instances.

- You can configure the **rate** and **run-length** options at the **[edit forwarding-options sampling input]** hierarchy level to apply common values for all families on a global basis. Alternatively, you can configure these options at the **[edit forwarding-options sampling instance *instance-name* input]** hierarchy level to apply specific values for each instance or at the **[edit forwarding-options sampling instance *instance-name* family *family* input]** hierarchy level to apply specific values for each protocol family you configure.
- For MX Series devices with Modular Port Concentrators (MPCs), port-mirrored or sampled packets can be truncated (or clipped) to any length in the range of 1 through 255 bytes. Only the values 1 to 255 are valid for packet truncation on these devices. For other devices, the range is from 0 through 9216. A maximum-packet-length value of zero (0) represents that truncation is disabled, and the entire packet is mirrored or sampled.

**NOTE:** The **run-length** and **maximum-packet-length** configuration statements are not supported on MX80 routers.

---

To associate the defined instance with a particular FPC, MPC, or DPC, you include the **sampling-instance** statement at the **[edit chassis fpc *number*]** hierarchy level, as in the following example:

```
chassis {
 fpc 2 {
 sampling-instance samp1;
 }
}
```

To associate a sampling instance with an FPC in the MX Series Virtual Chassis master or backup router, use the **sampling-instance *instance-name*** statement at the **[edit chassis member *member-number* fpc slot *slot-number*]** hierarchy level, where *member-number* is 0 (for the master router) or 1 (for the backup router), and *slot-number* is a number in the range 0 through 11.

## Configuring Discard Accounting

---

Discard accounting is similar to traffic sampling, but varies from it in two ways:

- In discard accounting, the packet is intercepted by the monitoring PIC and is not forwarded to its destination.
- Traffic sampling allows you to limit the number of packets sampled by configuring the **max-packets-per-second**, **rate**, and **run-length** statements. Discard accounting does not provide these options, and a high packet count can potentially overwhelm the monitoring PIC.

A discard instance is a named entity that specifies collector information under the **accounting name** statement. Discard instances are referenced in firewall filter **term** statements by including the **then discard accounting name** statement.

Most of the other statements are also found at the **[edit forwarding-options sampling]** hierarchy level. For information on cflowd, see [“Enabling Flow Aggregation” on page 898](#). The **flow-active-timeout** and **flow-inactive-timeout** statements are described in [“Configuring Flow Monitoring” on page 818](#).

To direct sampled traffic to a flow-monitoring interface, include the **interface** statement. The **engine-id** and **engine-type** statements specify the accounting interface used on the traffic, and the **source-address** statement specifies the traffic source.

You cannot use rate-limiting with discard accounting; however, you can specify the duration of the interval for exporting aggregated accounting information by including the **aggregate-export-interval** statement in the configuration. This enables you to put a boundary on the amount of traffic exported to a flow-monitoring interface.

## Understanding Inline Active Flow Monitoring

---

This topic provides an overview of the inline active flow monitoring feature and IPFIX and Version 9 flow collection templates used for inline active flow monitoring.

This topic contains the following sections:

- [Inline Active Flow Monitoring on page 1065](#)
- [Inline Active Flow Monitoring Limitations and Restrictions on page 1066](#)
- [IPFIX and Version 9 Templates on page 1067](#)

## Inline Active Flow Monitoring

The inline active flow monitoring is implemented on the Packet Forwarding Engine. All the functions like flow creation, flow update, and flow records export are done by the Packet Forwarding Engine. The flow records are sent out in industry standard IPFIX format.

Inline active flow monitoring provides for higher scalability and performance as the scaling and performance are not dependent on the capacity of the services interface. It is also cost effective in more than one way as there is no need to invest in additional hardware or to dedicate a PIC slot for the services PIC. You can make full use of the available slots for handling traffic on the device.

Junos OS Release 13.2 extends inline active flow monitoring support to VPLS flows. Now, you can configure inline active flow monitoring for IPv4, IPv6, and VPLS traffic.

The inline active flow monitoring configuration can be broadly classified into four categories:

1. Configurations at the **[edit services flow-monitoring]** hierarchy level—At this level, you configure the template properties for inline flow monitoring.
2. Configurations at the **[edit forwarding-options]** hierarchy level—At this level, you configure a sampling instance and associate the template (configured at the **[edit**

**services flow-monitoring**] hierarchy level) with the sampling instance. At this level, you also configure the flow-server IP address and port number as well as the flow export rate.

3. Configurations at the **[edit chassis]** hierarchy level—At this level, you associate the sampling instance with the FPC on which the media interface is present. If you are configuring sampling of IPv6 flows, you must also specify the flow hash table size.
4. Configurations at the **[edit firewall]** hierarchy level—At this level you configure a firewall filter for the family of traffic to be sampled. You must attach this filter to the interface on which you want to sample the traffic.

Inline active flow monitoring supports version 9 and IPFIX flow collection templates. Support for version 9 template was introduced in Junos OS Release 13.2, and is limited to IPv4 flows. IPFIX template is supported for IPv4, IPv6, and VPLS flows. IPFIX template uses UDP as the transport protocol, whereas version 9 is transport protocol-independent.

Before you configure inline active flow monitoring, you should ensure that you have adequately-sized hash tables for IPv4 and IPv6 flow sampling. These tables can use one to fifteen 256k areas, and each table is assigned a default value of one such area. When anticipated traffic volume requires larger tables, allocate larger tables.

**NOTE:** Starting with Junos OS Release 13.3, you can configure flow collectors to be reachable through non-default VPN routing and forwarding (VRF) instances by including the `routing-instance instance-name` statement at the `[edit forwarding-options sampling instance instance-name family (inet |inet6 |mpls) output flow-server hostname]` hierarchy level for inline flow monitoring. You cannot configure a flow collector to be reachable through non-default VRF instances for version 5 and version 8 flows. You must configure the routing instance to be a VRF instance by including the `instance-type vrf` statement at the `[edit routing-instances instance-name]` hierarchy level.

---

## Inline Active Flow Monitoring Limitations and Restrictions

The following limitations and restrictions apply to the inline active flow monitoring feature in Junos OS:

- You can configure inline active flow monitoring only on MX Series routers with Trio-based line cards and T4000 routers with Type 5 FPCs.
- You can apply Version 9 flow template only to IPv4 traffic.
- You can configure only one sampling instance on an Flexible PIC Concentrator (FPC).
- You can configure only one type of sampling—either PIC-based sampling or inline sampling—per family in a sampling instance. However, you can configure PIC-based and inline sampling for different families in a sampling instance.
- You can configure only one collector for inline active flow monitoring.

- The following considerations apply to the inline flow-monitoring instance configuration:
  - Sampling run-length and clip-size are not supported.
  - For inline configurations, each family can support only one collector.
  - The user-defined sampling instance gets precedence over the global instance. When a user-defined sampling instance is attached to the FPC, the global instance is removed from the FPC and the user-defined sampling instance is applied to the FPC.
- On routers with Multiservices PICs or Multiservices DPCs, all fragments of a fragmented IPv4 packet other than the first fragment of the packet are processed accurately by the flow monitoring application running on MS-PIC or MS-DPC. The flow monitoring mechanism handles such fragments accurately by setting the layer 4 related fields in the associated flows to zero.
- Flow records and templates cannot be exported if the flow collector is reachable through any management interface.
- The flow collector should be reachable through the default routing table (inet.0 or inet6.0). If the flow collector is reachable via a non-default VPN routing and forwarding table (VRF), flow records and templates cannot be exported.

**NOTE:** Starting with Junos OS Release 13.3, you can configure the flow collector to be reachable through non-default VRF instances apart from being reachable over the default VRF instance. Flow records and templates can be exported even with non-default VRF instances.

- If the destination of the sampled flow is reachable through multiple paths, the IP\_NEXT\_HOP (Element ID 15) and OUTPUT\_SNMP (Element ID 14) in the IPv4 flow record would be set to the Gateway Address and SNMP Index of the first path seen in the forwarding table.
- If the destination of the sampled flow is reachable through multiple paths, the IP\_NEXT\_HOP (Element ID 15) and OUTPUT\_SNMP (Element ID 14) in the IPv6 flow records would be set to 0.
- The Incoming Interface (IIF) and Outgoing Interface (OIF) should be part of the same VRF. If OIF is in a different VRF, DST\_MASK (Element ID 13), DST\_AS (Element ID 17), IP\_NEXT\_HOP (Element ID 15), and OUTPUT\_SNMP (Element ID 14) would be set to 0 in the flow records.
- Each Lookup Chip (LU) maintains and exports flows independent of other LUs. Traffic received on a media interface is distributed across all LUs in a multi-LU platform. It is likely that a single flow will be processed by multiple LUs. Therefore, each LU creates a unique flow and exports it to the flow collector. This can cause duplicate flows records to be seen on the flow collector. The flow collector should aggregate PKTS\_COUNT and BYTES\_COUNT for duplicate flow records to derive a single flow record.

## IPFIX and Version 9 Templates

The following sections list the fields included in IPFIX and Version 9 templates.

### Fields Included in the IPFIX IPv4 Template

---

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS
- Destination AS
- IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum TTL (time to live)
- Maximum TTL (time to live)
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

### Fields Included in the IPFIX IPv6 Template

---

- IPv6 Source Address
- IPv6 Destination Address
- IPv6 TOS
- IPv6 Protocol
- L4 Source Port

- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv6 Source Mask
- IPv6 Destination Mask
- Source AS
- Destination AS
- IPv6 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum Hop Limits
- Maximum Hop Limits
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

---

#### Fields Included in the Version 9 IPv4 Template

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS

- Destination AS
- IPv4 Next Hop Address
- BGP IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Time when the first packet of the flow was switched.
- Time when the last packet of flow was switched.
- Internet Protocol Version

## Configuring Inline Active flow Monitoring

The inline active flow monitoring is implemented on the Packet Forwarding Engine. All the functions like flow creation, flow update, and flow records export are done by the Packet Forwarding Engine. The flow records are sent out in industry standard IPFIX format.

The inline active flow monitoring configuration can be broadly classified into four categories:

1. Configurations at the **[edit services flow-monitoring]** hierarchy level—At this level, you configure the template properties for inline flow monitoring.
2. Configurations at the **[edit forwarding-options]** hierarchy level—At this level, you configure a sampling instance and associate the template (configured at the **[edit services flow-monitoring]** hierarchy level) with the sampling instance. At this level, you also configure the flow-server IP address and port number as well as the flow export rate.
3. Configurations at the **[edit chassis]** hierarchy level—At this level, you associate the sampling instance with the FPC on which the media interface is present. If you are configuring sampling of IPv6 flows, you must also specify the flow hash table size.
4. Configurations at the **[edit firewall]** hierarchy level—At this level you configure a firewall filter for the family of traffic to be sampled. You must attach this filter to the interface on which you want to sample the traffic.

Before you configure inline active flow monitoring, you should ensure that you have adequately-sized hash tables for IPv4 and IPv6 flow sampling. These tables can use one to fifteen 256k areas, and each table is assigned a default value of one such area. When anticipated traffic volume requires larger tables, allocate larger tables.

**NOTE:** For Junos OS releases earlier than Release 12.1, the following points are applicable for supporting backward compatibility when you configure the IPv4 and IPv6 flow table sizes for inline active flow monitoring:

- If you do not configure the `flow-table-size` statement at the `[edit chassis fpc slot-number inline-services]` hierarchy level, fifteen 256K entries are allocated by default for the IPv4 flow table and one 1K entry is allocated by default for the IPv6 flow table on the Packet Forwarding Engine.
- If you configure the `ipv4-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level and if you do not configure the `ipv6-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level, the number of units of 256K entries that you configure for the IPv4 flow table is allocated. For the IPv6 flow table, a default size of one 1K entry is allocated on the Packet Forwarding Engine.
- If you do not configure the `ipv4-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level and if you configure the `ipv6-flow-table-size size` statement at the `[edit chassis fpc slot-number inline-services flow-table-size]` hierarchy level, the number of units of 256K entries that you configure for the IPv6 flow table is allocated. For the IPv4 flow table, a default size of one 1K entry is allocated on the Packet Forwarding Engine.
- If you configure the sizes of both the IPv4 and IPv6 flow tables, the flow tables are created on the Packet Forwarding Engine based on the size that you specified.

**NOTE:** The functionality to log the cflowd records in a log file before they are exported to a cflowd server (by including the `local-dump` statement at the `[edit forwarding-options sampling instance instance-name family (inet |inet6 |mpls) output flow-server hostname]` hierarchy level) is not supported when you configure inline flow monitoring (by including the `inline-jflow` statement at the `[edit forwarding-options sampling instance instance-name family inet output]` hierarchy level).

To allocate IPv4 and IPv6 flow hash tables:

1. Go to the `flow-table-size` hierarchy level for inline services on the FPC that processes the monitored flows.

```
[edit]
user@host# edit chassis fpc 0 inline-services flow-table-size
```

2. Specify the required sizes for the sampling hash tables.

```
[edit chassis fpc 0 inline-services flow-table-size]
user@host# set ipv4-flow-table-size 5
user@host# set ipv6-flow-table-size 5
```

**NOTE:** When you set the flow hash table sizes, remember:

- Any change in the configured size of flow hash table sizes initiates an automatic reboot of the FPC.
- The total number of units used for both IPv4 and IPv6 cannot exceed 15.

To configure inline active flow monitoring on all other MX Series routers (except for MX80 routers), EX Series switches, and T4000 routers with Type 5 FPC:

1. Enable inline active flow monitoring and specify the source address for the traffic.

```
[edit forwarding-options sampling instance instance-name family inet output]
user@host# set inline-jflow source address address
```

2. Specify the IP\_FIX output format.

```
[edit forwarding-options sampling instance instance-name family inet output flow-server
address]
user@host# set version-ipfix template ipv4
```

3. Specify the output properties.

```
[edit services flow-monitoring]
user@host# set version-ipfix
```

The output format properties are common to other output formats and are described in [“Configuring Flow Aggregation to Use IPFIX Flow Templates” on page 912](#).

The following is an example of the sampling configuration for an instance that supports inline active flow monitoring on **family inet** and PIC-based sampling on **family inet6**:

```
[edit forwarding-options]
sampling {
 instance {
 sample-ins1 {
 input {
 rate 1;
 }
 family inet {
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version-ipfix {
 template {
 ipv4;
 }
 }
 }
 }
 inline-jflow {
 source-address 10.11.12.13;
 }
 }
 }
 }
}
```

```

family inet6 {
 output {
 flow-server 2.2.2.2 {
 port 2055;
 version-ipfix {
 template {
 ipv6;
 }
 }
 }
 }
 interface sp-0/1/0 {
 source-address 10.11.12.13;
 }
}
}
}

```

The following example shows the output format configuration:

```

services {
 flow-monitoring {
 version-ipfix {
 template ipv4 {
 flow-active-timeout 60;
 flow-inactive-timeout 60;
 ipv4-template;
 template-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 option-refresh-rate {
 packets 1000;
 seconds 10;
 }
 }
 }
}
}

```

The following considerations apply to the inline flow-monitoring instance configuration:

- Sampling run-length and clip-size are not supported.
- For inline configurations, each family can support only one collector.

**NOTE:** On routers with Multiservices PICs or Multiservices DPCs, IPv4 and IPv6 fragments are processed accurately. The flow monitoring application creates two flows for every fragmented flow. The first fragment that has the complete Layer 4 information forms the first flow with 5-tuple data and subsequently, all the fragmented packets related to this flow form another flow with the Layer 4 fields set to zero.

- Related Documentation**
- [Configuring Inline Active Flow Monitoring on MX80 Routers on page 894](#)
  - [inline-jflow on page 1687](#)

---

## Configuring Inline Active Flow Monitoring on MX80 Routers

---

To configure inline active flow monitoring on MX80 routers:

1. Associate a sampling instance with the Forwarding Engine Processor.

```
[edit]
user@host# set chassis tfeb slot number sampling-instance sampling-instance
```

The Forwarding Engine Processor slot is always 0 because MX80 routers have only one Packet Forwarding Engine. In this configuration, the sampling instance is **sample-ins1**.

```
[edit]
user@host# set chassis tfeb slot 0 sampling-instance sample-ins1
```

**NOTE:** MX80 routers support only one sampling instance.

2. Under forwarding-options, configure a sampling instance for the flow server and inline jflow instances (these will be configured in the following steps):

```
[edit forwarding-options sampling]
user@host# edit instance inline_sample
```

3. Configure the rate at the **[edit forwarding-options sampling instance instance-name input]** hierarchy level to apply specific values for the sampling instance **sample-ins1**.

```
[edit forwarding-options sampling instance sample-ins1 input]
user@host# set rate number
```

In this configuration, the rate is 1000.

```
[edit forwarding-options sampling instance sample-ins1 input]
user@host# set rate 1000
```

4. Navigate to the output hierarchy and from there, enable a flow server and then specify the output address and port:

```
[edit] forwarding-options sampling instance inline_sample family inet output]
user@host# edit flow-server address
```

```
[edit forwarding-options sampling instance inline_sample family inet output flow-server
<address>]
user@host# set port number
```

5. Return to the output hierarchy and specify the source address for inline jflow:

```
[edit forwarding-options sampling instance sample-ins1 family inet output]
user@host# set inline-jflow source-address address
```

In this configuration, the source address is 10.11.12.13.

```
[edit forwarding-options sampling instance sample-ins1 family inet output]
```

```
user@host# set inline-jflow source-address 10.11.12.13
```

6. Specify the output properties.

```
[edit services flow-monitoring]
```

```
user@host# set version-ipfix
```

The output format properties are common to other output formats and are described in [“Configuring Flow Aggregation to Use IPFIX Flow Templates” on page 912](#).

The following is an example of the sampling configuration for an instance that supports inline active flow monitoring on MX80 routers:

```
[edit forwarding-options]
user@host# show
sampling {
 instance {
 sample-ins1 {
 input {
 rate 1000;
 }
 family inet {
 flow-server 133..13.13.122{
 port 1333;
 inline-jflow {
 source-address 10.11.12.13;
 }
 }
 }
 }
 }
}
```

**NOTE:** You need not configure a Flexible PIC Concentrator (FPC) slot because MX80 routers have only one Packet Forwarding Engine.

The following considerations apply to the inline flow-monitoring instance configuration:

- This configuration does not support MPLS-IPv6.
- Clip-size is not supported.

## Understanding Flow Aggregation

---

You can collect an aggregate of sampled flows and send the aggregate to a specified host that runs either the cflowd application available from CAIDA (<http://www.caida.org>) or the newer version 9 format defined in RFC 3954, *Cisco Systems NetFlow Services Export Version 9*. Before you can perform flow aggregation, the routing protocol process must export the autonomous system (AS) path and routing information to the sampling process.

By using flow aggregation, you can obtain various types of byte and packet counts of flows through a router. The application collects the sampled flows over a period of 1 minute. At the end of the minute, the number of samples to be exported are divided over the period of another minute and are exported over the course of the same minute.

You configure flow aggregation in different ways, depending on whether you want to export flow records in cflowd version 5 or 8 format, or the separate version 9 format. The latter allows you to sample MPLS, IPv4, IPv6, and peer AS billing traffic. You can also combine configuration statements between the MPLS and IPv4 formats.

**NOTE:** When PIC-based sampling is enabled, collection of flow statistics for sampled packets on flows in virtual private networks (VPNs) is also supported. No additional CLI configuration is required.

## Enabling Flow Aggregation

Before you can perform flow aggregation, the routing protocol process must export the autonomous system (AS) path and routing information to the sampling process. To enable the export of AS path and the routing information to the sampling process, one or more of the following needs to be configured:

- At the `[edit forwarding-options]` hierarchy level (for routing instances, at the `[edit routing-instance routing-instance-name forwarding-options]` hierarchy level), configure `sampling family` or `sampling output` or `sampling instance` or `monitoring` or `accounting`.
- At the `[edit routing-options]` hierarchy level (for routing instances, at the `[edit routing-instance routing-instance-name routing-options]` hierarchy level), configure `route record`.
- At the `[edit chassis fpc slot-number pic pic-number adaptive-services service-package extension-provider]` hierarchy level, configure `forwarding-db-size`.

## Configuring Flow Aggregation to Use Version 5 or Version 8 cflowd

To enable the collection of cflowd version 5 or version 8 flow formats, include the `flow-server` statement:

```
flow-server hostname {
 aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
 }
}
```

```

 }
 source-prefix;
 }
 autonomous-system-type (origin | peer);
 (local-dump | no-local-dump);
 port port-number;
 version format;
}

```

You can include this statement at the following hierarchy levels:

- [edit forwarding-options sampling family (inet | inet6 | mpls) output]
- [edit forwarding-options sampling instance *instance-name* output]
- [edit forwarding-options accounting *name* output cflowd *hostname*]

You must configure the **family inet** statement on logical interface **unit 0** on the monitoring interface, as in the following example:

```

[edit interfaces]
sp-3/0/0 {
 unit 0 {
 family inet {
 ...
 }
 }
}

```

**NOTE:** Boot images for monitoring services interfaces are specified at the [edit chassis images pic] hierarchy level. You must enable the NTP client to make the cflowd feature operable, by including the following configuration:

```

[edit system]
ntp {
 boot-server ntp.juniper.net;
 server 172.17.28.5;
}
processes {
 ntp enable;
}

```

For more information, see the *Junos OS Administration Library for Routing Devices*.

You can also configure cflowd version 5 for flow-monitoring applications by including the **cflowd** statement at the [edit forwarding-options monitoring *name* family inet output] hierarchy level:

```

cflowd hostname {
 port port-number;
}

```

The following restrictions apply to cflowd flow formats:

- You can configure up to one version 5 and one version 8 flow format at the **[edit forwarding-options accounting *name* output]** hierarchy level.
- You can configure up to eight version 5 or one version 8 flow format at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output]** hierarchy level for Routing Engine-based sampling by including the **flow-server** statement. In contrast, PIC-based sampling allows you to specify one cflowd version 5 server and one version 8 server simultaneously. However, the two cflowd servers must have different IP addresses.
- You can configure up to eight version 5 flow formats at the **[edit forwarding-options monitoring *name* output]** hierarchy level. Version 8 flow formats and aggregation are not supported for flow-monitoring applications.
- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created on the monitoring PIC only after the route record resynchronization operation is complete, which is 60 seconds after the PIC comes up. Any packets sent to the PIC would be dropped until the synchronization process is complete.
- The configuration includes a proprietary v5 extension template for supporting 4-byte AS information in flow records. Its template version is set to 500, indicating it to be proprietary. All other fields remain the same; the source AS and destination AS are each 4 bytes long, rather than 2 bytes as in the traditional v5 template. This option is available at the **[edit forwarding-options sampling family inet output flow-server server-name version]** hierarchy level.

In the **cflowd** statement, specify the name or identifier of the host that collects the flow aggregates. You must also include the User Datagram Protocol (UDP) port number on the host and the version, which gives the format of the exported cflowd aggregates. To collect cflowd records in a log file before exporting, include the **local-dump** statement.

**NOTE:** You can specify both host (cflowd) sampling and port mirroring in the same configuration; however, only one action takes effect at any one time. Port mirroring takes precedence. For more information, see [“Configuring Port Mirroring” on page 931](#).

For cflowd version 8 only, you can specify aggregation of specific types of traffic by including the **aggregation** statement. This conserves memory and bandwidth by enabling cflowd to export targeted flows rather than all aggregated traffic. To specify a flow type, include the **aggregation** statement:

```
aggregation {
 autonomous-system;
 destination-prefix;
 protocol-port;
 source-destination-prefix {
 caida-compliant;
 }
}
```

```

 }
 source-prefix;
 }

```

You can include this statement at the following hierarchy levels:

- [edit forwarding-options sampling family (inet | inet6 | mpls) output flow-server *hostname*]
- [edit forwarding-options accounting *name* output cflowd *hostname*]

The **autonomous-system** statement configures aggregation by the AS number; this statement might require setting the separate cflowd **autonomous-system-type** statement to include either **origin** or **peer** AS numbers. The **origin** option specifies to use the origin AS of the packet source address in the Source Autonomous System cflowd field. The **peer** option specifies to use the peer AS through which the packet passed in the Source Autonomous System cflowd field. By default, cflowd exports the origin AS number.

The **destination-prefix** statement configures aggregation by the destination prefix only.

The **protocol-port** statement configures aggregation by the protocol and port number; requires setting the separate **cflowd port** statement.

The **source-destination-prefix** statement configures aggregation by the source and destination prefix. Version 2.1b1 of CAIDA's cflowd application does not record source and destination mask length values in compliance with CAIDA's *cflowd Configuration Guide*, dated August 30, 1999. If you configure the **caida-compliant** statement, the Junos OS complies with Version 2.1b1 of cflowd. If you do not include the **caida-compliant** statement in the configuration, the Junos OS records source and destination mask length values in compliance with the *cflowd Configuration Guide*.

The **source-prefix** statement configures aggregation by the source prefix only.

Collection of sampled packets in a local ASCII file is not affected by the **cflowd** statement.

The following commands enable RE- and PIC-based sampling at the **set forwarding options sampling** hierarchy level:

- set input rate *rate*
- set input run-length *length*
- set family inet output flow-server *flowcollector* port *udp port*
- set family inet output flow-server *flowcollector* no-local-dump
- set family inet output flow-server *flowcollector* version <5/8>

The following commands enable RE- and PIC-based sampling at the **set interfaces** hierarchy level:

- *interface to be sampled* unit *unit* family inet filter *input/output filename*

The following commands enable RE- and PIC-based sampling at the **set firewall family** hierarchy level:

- `set inet filter filtername term 1 then count filternameing`
- `set inet filter filtername term 1 then sample`
- `set inet filter filtername term 1 then accept`

The following command enables PIC-based sampling at the **set forwarding options sampling** hierarchy level:

- `set family inet output interface sp-*/*/* source address source address`

The following example shows a PIC-based flow aggregation configuration using version 5:

```
family inet {
 output {
 flow-inactive-timeout 15;
 flow-active-timeout 60;
 flow-server 153.104.248.37 {
 port 9996;
 version 5;
 }
 interface sp-2/2/0 {
 engine-id 4;
 source-address 153.104.0.254;
 }
 }
}
```

The following example shows an RE-based flow aggregation configuration using version 5:

```
family inet {
 output {
 flow-inactive-timeout 15;
 flow-active-timeout 60;
 flow-server 153.104.248.37 {
 port 9996;
 source-address 153.104.0.254;
 version 5;
 }
 }
}
```

## Configuring Flow Aggregation to Use Version 9 Flow Templates

Use of version 9 allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic.

Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration.

**NOTE:** Version 9 requires that you install a services PIC, such as the Adaptive Services PIC or Multiservices PIC in the router. On MX Series routers, the Multiservices DPC fulfills this requirement. For more information on determining which services PIC is suitable for your router, see [“Enabling Service Packages” on page 11](#) or the appropriate hardware documentation.

**NOTE:** If multiple protocol families are configured for a particular flow collector, the export packets will originate from multiple Source IDs, with each Source ID corresponding to a particular protocol. The multiple Source IDs do not indicate that the export packets are originating from multiple Service PICs.

The following sections contain additional information:

- [Configuring the Traffic to Be Sampled on page 1083](#)
- [Configuring the Version 9 Template Properties on page 1084](#)
- [Customizing Template ID, Observation Domain ID, and Source ID for Version 9 flow Templates on page 1085](#)

- [MPLS Sampling Behavior on page 1088](#)
- [Verification on page 1088](#)
- [Examples: Configuring Version 9 Flow Templates on page 1089](#)

## Configuring the Traffic to Be Sampled

To specify sampling of IPv4, IPv6, MPLS, or peer AS billing traffic, include the appropriate configuration of the **family** statement at the **[edit forwarding-options sampling]** hierarchy level:

```
[edit forwarding-options]
sampling {
 family (inet | inet6 | mpls);
}
```

You can include **family inet**, **family inet6**, or **family mpls**.

**NOTE:** If you specify sampling for peer AS billing traffic, the **family** statement supports only IPv4 and IPv6 traffic (inet or inet6). Peer AS billing traffic is enabled only at the global instance hierarchy level and is not available for per Packet Forwarding Engine instances.

After you specify the family of traffic to be sampled, configure the sampling parameters such as the maximum packet length (beyond which the packets are truncated), maximum packets to be sampled per second (beyond which the packets are dropped), the rate (for example, if you specify 10, every 10th packet is sampled), and run length (which specify the number of packets to be sampled after the trigger; that is if the **rate** is set to 10 and **run-length** to 5, five packets starting the 10th packet are sampled).

```
[edit forwarding-options sampling]
input {
 maximum-packet-length bytes
 max-packets-per-second number;
 rate number;
 run-length number;
}
```

## Configuring the Version 9 Template Properties

To define the version 9 templates, include the following statements at the **[edit services flow-monitoring version9]** hierarchy level:

```
[edit services flow-monitoring version9]
template name {
 options-template-id
 template-id
 source-id
 flow-active-timeout seconds;
 flow-inactive-timeout seconds;
 option-refresh-rate packets packets seconds seconds;
 template-refresh-rate packets packets seconds seconds;
 (ipv4-template | ipv6-template | mpls-ipv4-template | mpls-template |
 peer-as-billing-template) {
 label-position [positions];
 }
}
```

The following details apply to the configuration statements:

- You assign each template a unique name by including the **template name** statement.
- You then specify each template for the appropriate type of traffic by including the **ipv4-template**, **ipv6-template**, **mpls-ipv4-template**, **mpls-template**, or **peer-as-billing-template**.
- If the template is used for MPLS traffic, you can also specify up to three label positions for the MPLS header label data by including the **label-position** statement; the default values are **[1 2 3]**.
- Within the template definition, you can optionally include values for the **flow-active-timeout** and **flow-inactive-timeout** statements. These statements have specific default and range values when they are used in template definitions; the default is 60 seconds and the range is from 10 through 600 seconds. Values you specify in template definitions override the global timeout values configured at the **[edit forwarding-options sampling family (inet | inet6 | mpls) output flow-server]** hierarchy level.

- You can also include settings for the **option-refresh-rate** and **template-refresh-rate** statements within a template definition. For both of these properties, you can include a timer value (in seconds) or a packet count (in number of packets). For the **seconds** option, the default value is 60 and the range is from 10 through 600. For the **packets** option, the default value is 4800 and the range is from 1 through 480,000.
- To filter IPV6 traffic on a media interface, the following configuration is supported:

```

interfaces interface-name {
 unit 0 {
 family inet6 {
 sampling {
 input;
 output;
 }
 }
 }
}

```

## Customizing Template ID, Observation Domain ID, and Source ID for Version 9 flow Templates

Use of version 9 and IPFIX allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic. Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration. Starting with Junos OS Release 14.1, you can specify the unique identifier for the version 9 and IPFIX templates. The identifier of a template is locally unique within a combination of a transport session and an observation domain. Template IDs 0 through 255 are reserved for template sets, options template sets, and other sets for future use. Template IDs of data sets are numbered from 256 through 65535. Typically, this information element or field in the template is used to define the characteristics or properties of other information elements in a template. After a restart of the export process of templates is performed, template IDs can be reassigned. In Junos OS releases earlier than Release 14.1, template IDs and options template IDs were predefined for each address family and could not be modified.

This functionality to configure template ID, options template ID, observation domain ID, and source ID is supported on all routers with MPCs (Trio chip-based FPCs).

The following values were assigned by default for the template IDs of IPFIX templates for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 flow template ID—256
- IPv6 flow template ID—257
- VPLS flow template ID—258
- Options template ID for all address families—512

The corresponding data sets and option data sets contain the value of the template IDs and options template IDs respectively in the set ID field. This method enables the collector to match a data record with a template record.

For more information about specifying the source ID, observation domain ID, template ID, and options template ID for version 9 and IPFIX flows, see [“Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows” on page 918](#) and [“Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows” on page 921](#).

## Restrictions

The following restrictions apply to version 9 templates:

- You cannot apply the two different types of flow aggregation configuration (cflowd version 5/8 and flow aggregation version 9) at the same time.
- Flow export based on an **mpls-ipv4** template assumes that the IPv4 header follows the MPLS header. In the case of Layer 2 VPNs, the packet on the provider router (P router) would look like this:

MPLS | Layer 2 Header | IPv4

In this case, **mpls-ipv4** flows are not created on the PIC, because the IPv4 header does not directly follow the MPLS header. Packets are dropped on the PIC and are accounted as parser errors.

- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created on the monitoring PIC only after the route record resynchronization operation is complete, which is 60 seconds after the PIC comes up. Any packets sent to the PIC would be dropped until the synchronization process is complete.

**NOTE:** "Because the forwarding of a packet that arrives with MPLS labels is performed based on the MPLS label and not based on the IP address contained in the packet, the packet is sampled at the output interface with the MPLS label that was popped not being available at the time of sampling. In such a case, depending on the incoming interface (IIF), the VRF index is identified and the route for the sampled packet is determined in the VRF table. Because a specific route is not available in the VRF that is different from the VRF on which the packet is received, the Output Interface Index, Source Mask, and Destination Mask fields are incorrectly populated. This behavior occurs when an IPv4 template is applied as a firewall filter on an egress interface with sample as the action."

---

## Fields Included in Each Template Type

The following fields are common to all template types:

- Input interface
- Output interface
- Number of bytes

- Number of packets
- Flow start time
- Flow end time

The IPv4 template includes the following specific fields:

- IPv4 Source Address
- IPv4 Destination Address
- L4 Source Port
- L4 Destination Port
- IPv4 TOS
- IPv4 Protocol
- ICMP type and code
- TCP Flags
- IPv4 Next Hop Address
- Source autonomous system (AS) number
- Destination AS number

The IPv6 template includes the following specific fields:

- IPv6 Source Address and Mask
- IPv6 Destination Address and Mask
- L4 Source Port
- L4 Destination Port
- IPv6 TOS
- IPv6 Protocol
- TCP Flags
- IP Protocol Version
- IPv6 Next Hop Address
- Egress Interface Information
- Source Autonomous System (AS) number
- Destination AS number

The MPLS template includes the following specific fields:

- MPLS Label #1
- MPLS Label #2
- MPLS Label #3

- MPLS EXP Information
- FEC IP Address

The MPLS-IPv4 template includes all the fields found in the IPv4 and MPLS templates.

The peer AS billing template includes the following specific fields:

- IPV4 Class of Service (TOS)
- Ingress Interface
- BGP IPV4 Next Hop Address
- BGP Peer Destination AS Number

## MPLS Sampling Behavior

This section describes the behavior when MPLS sampling is used on egress interfaces in various scenarios (label pop or swap) on provider routers (P routers). For more information on configuration and background specific to MPLS applications, see the *MPLS Applications Feature Guide for Routing Devices*.

1. You configure MPLS sampling on an egress interface on the P router and configure an MPLS flow aggregation template. The route action is label *pop* because penultimate hop popping (PHP) is enabled.

Previously, IPv4 packets (only) would have been sent to the PIC for sampling even though you configured MPLS sampling. No flows should be created, with the result that the parser fails.

With the current capability of applying MPLS templates, MPLS flows are created.

2. As in the first case, you configure MPLS sampling on an egress interface on the P router and configure an MPLS flow aggregation template. The route action is label *swap* and the swapped label is 0 (explicit null).

The resulting behavior is that MPLS packets are sent to the PIC. The flow being sampled corresponds to the label before the swap.

3. You configure a Layer 3 VPN network, in which a customer edge router (CE-1) sends traffic to a provider edge router (PE-A), through the P router, to a similar provider edge router (PE-B) and customer edge router (CE-2) on the remote end.

The resulting behavior is that you cannot sample MPLS packets on the PE-A to P router link.

## Verification

To verify the configuration properties, you can use the **show services accounting aggregation template template-name name** operational mode command.

All other **show services accounting** commands also support version 9 templates, except for **show services accounting flow-detail** and **show services accounting aggregation aggregation-type**. For more information about operational mode commands, see the [CLI Explorer](#).

## Examples: Configuring Version 9 Flow Templates

The following is a sample version 9 template configuration:

```
services {
 flow-monitoring {
 version9 {
 template ip-template {
 flow-active-timeout 20;
 flow-inactive-timeout 120;
 ipv4-template;
 }
 template mpls-template-1 {
 mpls-template {
 label-position [1 3 4];
 }
 }
 template mpls-ipv4-template-1 {
 mpls-ipv4-template {
 label-position [1 5 7];
 }
 }
 template peer-as-billing-template-1 {
 peer-as-billing-template;
 }
 }
 }
}
```

The following is a sample firewall filter configuration for MPLS traffic:

```
firewall {
 family mpls {
 filter mpls_sample {
 term default {
 then {
 accept;
 sample;
 }
 }
 }
 }
}
```

The following sample configuration applies the MPLS sampling filter on a networking interface and configures the AS PIC to accept both IPv4 and MPLS traffic:

```
interfaces {
 at-0/1/1 {
 unit 0 {
 family mpls {
 filter {
 input mpls_sample;
 }
 }
 }
 }
}
```

```
 }
 }
 sp-7/0/0 {
 unit 0 {
 family inet;
 family mpls;
 }
 }
}
```

The following example applies the MPLS version 9 template to the sampling output and sends it to the AS PIC:

```
forwarding-options {
 sampling {
 input {
 family mpls {
 rate 1;
 }
 }
 family mpls {
 output {
 flow-active-timeout 60;
 flow-inactive-timeout 30;
 flow-server 1.2.3.4 {
 port 2055;
 version9 {
 template mpls-ipv4-template-1;
 }
 }
 }
 }
 interface sp-7/0/0 {
 source-address 1.1.1.1;
 }
 }
}
```

The following is a sample firewall filter configuration for the peer AS billing traffic:

```
firewall {
 family inet {
 filter peer-as-filter {
 term 0 {
 from {
 destination-class dcu-1;
 interface ge-2/1/0;
 forwarding-class class-1;
 }
 then count count_team_0;
 }
 }
 term 1 {
 from {
 destination-class dcu-2;
 interface ge-2/1/0;
 }
 }
 }
}
```

```

 forwarding-class class-1;
 }
 then count count_team_1;
}
term 2 {
 from {
 destination-class dcu-3;
 interface ge-2/1/0;
 forwarding-class class-1;
 }
 then count count_team_2;
}
}
}
}

```

The following sample configuration applies the peer AS firewall filter as a filter attribute under the forwarding-options hierarchy for CoS-level data traffic usage information collection:

```

forwarding-options {
 family inet {
 filter output peer-as-filter;
 }
}

```

The following sample configuration applies the peer AS DCU policy options to collect usage statistics for the traffic stream for as-path ingressing at a specific input interface with the firewall configuration hierarchy applied as Forwarding Table Filters (FTFs). The configuration functionality with COS capability can be achieved through FTFs for destination-class usage with forwarding-class for specific input interfaces:

```

policy-options {
 policy-statement P1 {
 from {
 protocol bgp;
 neighbor 10.2.25.5; #BGP router configuration;
 as-path AS-1; #AS path configuration;
 }
 then destination-class dcu-1; #Destination class configuration;
 }
 policy-statement P2 {
 from {
 neighbor 1.2.25.5;
 as-path AS-2;
 }
 then destination-class dcu2;
 }
 policy-statement P3 {
 from {
 protocol bgp;
 neighbor 192.2.1.1;
 as-path AS-3;
 }
 then destination-class dcu3;
 }
}

```

```
as-path AS-1 3131:1111:1123;
as-path AS-2 100000;
as-path AS-3 192:29283:2;
}
```

The following example applies the peer-as-billing version 9 template to enable sampling of traffic for billing purposes:

```
forwarding-options {
 sampling {
 }
 input {
 rate 1;
 }
 family inet {
 output {
 flow-server 10.209.15.58 {
 port 300;
 version9 {
 template {
 peer-as;
 }
 }
 }
 }
 interface sp-5/2/0 {
 source-address 2.3.4.5;
 }
 }
}
family inet {
 filter {
 output peer-as-filter;
 }
}
```

## Configuring Flow Aggregation to Use IPFIX Flow Templates

Use of IPFIX allows you to define a flow record template suitable for IPv4 traffic or IPv6 traffic. Templates are transmitted to the collector periodically, and the collector need not be aware of the router configuration. You can define template refresh rate, flow active timeout and inactive timeout.

If flow records are being sent for multiple protocol families (for example, for IPv4 and IPv6), each protocol family flow will have a unique Observation Domain ID.

The following sections contain additional information:

- [Configuring the IPFIX Template Properties on page 1093](#)
- [Restrictions on page 1094](#)
- [Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates on page 1094](#)

- [Fields Included in the IPv6 Template on page 1096](#)
- [Verification on page 1096](#)
- [Example: Configuring an IPFIX Flow Templates and Flow Sampling on page 1097](#)

## Configuring the IPFIX Template Properties

To define the IPFIX templates, include the following statements at the **[edit services flow-monitoring version-ipfix]** hierarchy level:

```
[edit services flow-monitoring IPFIX]
template name {
 options-template-id
 template-id
 observation-domain-id
 flow-active-timeout seconds;
 flow-inactive-timeout seconds;
 option-refresh-rate packets packets seconds seconds;
 template-refresh-rate packets packets seconds seconds;
 (ipv4-template | ipv6-template);
}
```

The following details apply to the configuration statements:

- You assign each template a unique name by including the **template *name*** statement.
- You then specify each template for the appropriate type of traffic by including the **ipv4-template** or **ipv6-template**.
- Within the template definition, you can optionally include values for the **flow-active-timeout** and **flow-inactive-timeout** statements. These statements have specific default and range values when they are used in template definitions; the default is 60 seconds and the range is from 10 through 600 seconds.
- You can also include settings for the **option-refresh-rate** and **template-refresh-rate** statements within a template definition. For both of these properties, you can include a timer value (in seconds) or a packet count (in number of packets). For the **seconds** option, the default value is 600 and the range is from 10 through 600. For the **packets** option, the default value is 4800 and the range is from 1 through 480,000.
- To filter IPV6 traffic on a media interface, the following configuration is supported:

```
interfaces interface-name {
 unit 0 {
```

```
family inet6 {
 sampling {
 input;
 output;
 }
}
```

## Restrictions

The following restrictions apply to IPFIX templates:

- Outbound Routing Engine traffic is not sampled. A firewall filter is applied as output on the egress interface, which samples packets and exports the data. For transit traffic, egress sampling works correctly. For internal traffic, the next hop is installed in the Packet Forwarding Engine but sampled packets are not exported.
- Flows are created only after the route record resynchronization operation is complete, which takes 120 seconds.
- VLAN ID field is not valid for egress traffic, and returns a value of 0 for egress traffic.
- The VLAN ID field is updated when a new flow record is created and so, any change in VLAN ID after the record has been created might not be updated in the record.

## Customizing Template ID, Observation Domain ID, and Source ID for IPFIX flow Templates

Use of version 9 and IPFIX allows you to define a flow record template suitable for IPv4 traffic, IPv6 traffic, MPLS traffic, a combination of IPv4 and MPLS traffic, or peer AS billing traffic. Templates and the fields included in the template are transmitted to the collector periodically, and the collector need not be aware of the router configuration. Starting with Junos OS Release 14.1, you can specify the unique identifier for the version 9 and IPFIX templates. The identifier of a template is locally unique within a combination of a transport session and an observation domain. Template IDs 0 through 255 are reserved for template sets, options template sets, and other sets for future use. Template IDs of data sets are numbered from 256 through 65535. Typically, this information element or field in the template is used to define the characteristics or properties of other information elements in a template. After a restart of the export process of templates is performed, template IDs can be reassigned. In Junos OS releases earlier than Release 14.1, template IDs and options template IDs were predefined for each address family and could not be modified.

This functionality to configure template ID, options template ID, observation domain ID, and source ID is supported on all routers with MPCs (Trio chip-based FPCs).

The following values were assigned by default for the template IDs of version 9 templates for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 flow template ID—272
- IPv6 flow template ID—273

- VPLS flow template ID—274
- Options template ID for all address families—520

The corresponding data sets and option data sets contain the value of the template IDs and options template IDs respectively in the set ID field. This method enables the collector to match a data record with a template record.

For more information about specifying the source ID, observation domain ID, template ID, and options template ID for version 9 and IPFIX flows, see [“Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows” on page 918](#) and [“Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows” on page 921](#).

### Fields Included in the IPv4 Template

- IPv4 Source Address
- IPv4 Destination Address
- IPv4 TOS
- IPv4 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv4 Source Mask
- IPv4 Destination Mask
- Source AS
- Destination AS
- IPv4 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum TTL (time to live)
- Maximum TTL (time to live)
- Flow Start Time
- Flow End Time
- Flow End Reason

- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)

### Fields Included in the IPv6 Template

- IPv6 Source Address
- IPv6 Destination Address
- IPv6 TOS
- IPv6 Protocol
- L4 Source Port
- L4 Destination Port
- ICMP Type and Code
- Input Interface
- VLAN ID
- IPv6 Source Mask
- IPv6 Destination Mask
- Source AS
- Destination AS
- IPv6 Next Hop Address
- TCP Flags
- Output Interface
- Number of Flow Bytes
- Number of Flow Packets
- Minimum Hop Limits
- Maximum Hop Limits
- Flow Start Time
- Flow End Time
- Flow End Reason
- 802.1Q VLAN identifier (dot1qVlanId)
- 802.1Q Customer VLAN identifier (dot1qCustomerVlanId)
- Fragment Identification
- IPv6 Extension Headers

### Verification

The following show commands are supported for IPFIX:

- `show services accounting flow inline-jflow fpc-slot fpc-slot`
- `show services accounting errors inline-jflow fpc-slot fpc-slot`
- `show services accounting status inline-jflow fpc-slot fpc-slot`

### Example: Configuring an IPFIX Flow Templates and Flow Sampling

The following is a sample IPFIX template configuration:

```
services {
 flow-monitoring {
 version-ipfix {
 template ipv4 {
 flow-active-timeout 60;
 flow-inactive-timeout 70;
 template-refresh-rate seconds 30;
 option-refresh-rate seconds 30;
 ipv4-template;
 }
 }
 }
}

chassis;
fpc 0 {
 sampling-instance s1;
}
```

The following example applies the IPFIX template to enable sampling of traffic for billing:

```
forwarding-options {
 sampling {
 instance {
 s1 {
 input {
 rate 10;
 }
 family inet {
 output {
 flow-server 11.11.4.2 {
 port 2055;
 version-ipfix {
 template {
 ipv4;
 }
 }
 }
 }
 inline-jflow {
 source-address 11.11.2.1;
 }
 }
 }
 }
 }
}
```

## Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows

For IPFIX flows, an identifier of an Observation Domain is locally unique to an exporting process of the templates. The export process uses the Observation Domain ID to uniquely identify to the collection process in which the flows were metered. We recommend that you configure this ID to be unique for each IPFIX flow. A value of 0 indicates that no specific Observation Domain is identified by this information element. Typically, this attribute is used to limit the scope of other information elements. If the observation domain is not unique, the collector cannot uniquely identify an IPFIX device.

If you configure the same Observation Domain ID for different template types, such as for IPv4 and IPv6, it does not impact flow monitoring because the actual or the base observation domain ID is transmitted in the flow. The actual observation domain ID is derived from the value you configure and also in conjunction with other parameters such as the slot number, lookup chip (LU) instance, Packet Forwarding Engine instance. Such a method of computation of the observation domain ID ensures that this ID is not the same for two IPFIX devices.

Until Junos OS Release 13.3, the observation domain ID is predefined and is set to a fixed value, which is derived from the combination of FPC slot, sampling protocol, PFE Instance and LU Instance fields. This derivation creates a unique observation domain per LU per family. Starting with Junos OS Release 14.1, you can configure the observation domain ID, which causes the first 8 bits of the field to be configured.

The following modifications have been made:

- FPC slots are expanded to 8 bits to enable more slots to be configured in an MX Series Virtual Chassis configuration.
- 8 bits of the configured observation domain ID are used.
- You can configure a value for the observation domain ID in the range of 0 through 255.
- The Protocol field is increased to 3 bits to provide support for additional protocols in inline flow monitoring.
- You can associate the observation domain ID with templates by using the **observation-domain-id *domain-id*** statement at the **[edit services flow- monitoring version-ipfix template *template-name*]** hierarchy level.

For version 9 flows, a 32-bit value that identifies the Exporter Observation Domain is called the source ID. NetFlow collectors use the combination of the source IP address

and the source ID field to separate different export streams originating from the same exporter.

To specify the observation domain ID for IPFIX flows, include the **observation-domain-id domain-id** statement at the **[edit services flow-monitoring version-ipfix template template-name]** hierarchy level.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 observation-domain-id domain-id;
}
```

To specify the source ID for version 9 flows, include the **source-id source-id** statement at the **[edit services flow-monitoring version9 template template-name]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 source-id source-id;
}
```

Table 32 on page 919 describes observation domain ID values for different combinations of the configured domain ID, protocol family, FPC slot, and the Packet Forwarding Engine and lookup chip instances.

**Related Documentation** • [Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows on page 921](#)

## Configuring Template ID and Options Template ID for Version 9 and IPFIX Flows

Starting with Junos OS Release 14.1, you can define the template ID for version 9 and IPFIX templates for inline flow monitoring. To specify the template ID for version 9 flows, include the **template-id** *id* statement at the **[edit services flow-monitoring version9 template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 template-id id;
}
```

To specify the template ID for version IPFIX flows, include the **template-id** statement at the **[edit services flow-monitoring version-ipfix template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 template-id id;
}
```

To specify the options template ID for version 9 flows, include the **options-template-id** statement at the **[edit services flow-monitoring version9 template *template-name*]** hierarchy level.

```
[edit services flow-monitoring version9]
template template-name {
 options-template-id id;
}
```

To specify the options template ID for version IPFIX flows, include the **options-template-id** statement at the **[edit services flow-monitoring version-ipfix template *template-name*]** hierarchy level. The template ID and options template ID can be a value in the range of 1024 through 65535.

```
[edit services flow-monitoring version-ipfix]
template template-name {
 options-template-id id;
}
```

The template ID and options template ID can be a value in the range of 1024 through 65535. If you do not configure values for the template ID and options template ID, default values are assumed for these IDs, which are different for the various address families. If you configure the same template ID or options template ID value for different address families, such a setting is not processed properly and might cause unexpected behavior. For example, if you configure the same template ID value for both IPv4 and IPv6, the collector validates the export data based on the template ID value that it last receives. In this case, if IPv6 is configured after IPv4, the value is effective for IPv6 and the default value is used for IPv4.

The following are the default values of template IDs for IPFIX flows for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 IPFIX flow template ID—256
- IPv6 IPFIX flow template ID—257
- VPLS IPFIX flow template ID—258
- MPLS IPFIX flow template ID—259

The following are the default values of template IDs for version 9 flows for the different protocols or address families, starting with Junos OS Release 14.1:

- IPv4 version 9 flow template ID—320
- IPv6 version 9 flow template ID—321
- VPLS version 9 flow template ID—322
- MPLS version 9 flow template ID—323

The following are the default values of template IDs for IPFIX flows for the different protocols or address families, until Junos OS Release 13.3:

- IPv4 IPFIX flow options template ID—512
- IPv6 IPFIX flow options template ID—513
- VPLS IPFIX flow options template ID—514
- MPLS IPFIX flow options template ID—515

The following are the default values of template IDs for version 9 flows for the different protocols or address families, starting with Junos OS Release 14.1:

- IPv4 version 9 flow options template ID—576
- IPv6 version 9 flow options template ID—577
- VPLS version 9 flow options template ID—578
- MPLS version 9 flow options template ID—579

[Table 33 on page 923](#) describes the values of data template and option template IDs for different protocols with default and configured values for IPFIX flows.

**Table 43: Values of Template and Option Template IDs for IPFIX Flows**

Family	Configured Value	Data Template	Option Template

**Related Documentation**

- [Configuring Observation Domain ID and Source ID for Version 9 and IPFIX Flows on page 918](#)

## Directing Replicated Flows to Multiple Flow Servers

You can configure replication of the sampled flow records for use by multiple flow servers. You can use either sampling based on the Routing Engine, using cflowd version 5 or version 8, or sampling based on the services PIC, using flow aggregation version 9, as described in the following sections:

- [Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers on page 1106](#)
- [Directing Replicated Version 9 Flow Aggregates to Multiple Servers on page 1107](#)

### Directing Replicated Routing Engine–Based Sampling Flows to Multiple Servers

Routing Engine–based sampling supports up to eight flow servers for both cflowd version 5 and version 8 configurations. The total number of servers is limited to eight regardless of how many are configured for cflowd v5 or v8.

When you configure cflowd-based sampling, the export packets are replicated to all flow servers configured to receive them. If two servers are configured to receive v5 records, both the servers will receive records for a specified flow.

**NOTE:** With Routing Engine–based sampling, if multiple flow servers are configured with version 8 export format, all of them must use the same aggregation type. For example, all servers receiving version 8 export could be configured for source-destination aggregation type.

The following configuration example allows replication of export packets to two flow servers.

```
forwarding-options {
 sampling {
 instance inst1 {
 input {
 rate 1;
 }
 family inet;
 output {
 flow-server 10.10.3.2 {
 port 2055;
 version 5;
 source-address 192.168.164.119;
 }
 flow-server 172.17.20.62 {
 port 2055;
 version 5;
 source-address 192.168.164.119;
 }
 }
 }
 }
}
```

```
 }
 }
```

## Directing Replicated Version 9 Flow Aggregates to Multiple Servers

The export packets generated for a template are replicated to all the flow servers that are configured to receive information for that template. The maximum number of servers supported is eight.

This also implies that periodic updates required by version 9 (RFC 3954) are sent to each configured collector. The following updates are sent periodically as part of this requirement:

- Options data
- Template definition

The refresh period for options data and template definition is configured on a per-template basis at the **[edit services flow-monitoring]** hierarchy level.
