| <b>Failed Adjustments</b>       | Number of failed automatic bandwidth adjustments.                                                                                                                                | <b>detail extensive</b> |

## Sample Output

### show mpls lsp autobandwidth

```

user@host> show mpls lsp autobandwidth extensive
To: 10.255.106.133,
From: 10.255.106.135, LSPname: r0-r1
Min BW: 100kbps, Max BW: 0bps, Max AvgBW util: 2.33249Mbps
Overflow limit: 0, Overflow sample count: 0
Underflow limit: 0, Underflow sample count: 0
Adjustment Timer: 300 sec, Adjustment Threshold: 0
Time for Next Adjustment: 23 sec, Time of Last Adjustment: Fri Jun 3 21:05:37
2011
Last BW: 100kbps, Last Requested BW: 2.2169Mbps, Last Signaled BW: 2.2169Mbps,
Highest Watermark BW: 2.33249Mbps
Total AutoBw Adjustments: 1, Successful Adjustments: 1, Failed Adjustments: 0

```

## show mpls path

**List of Syntax** [Syntax on page 5197](#)  
[Syntax \(EX Series Switches\) on page 5197](#)

**Syntax** show mpls path  
 <instance *instance-name*>  
 <logical-system (all | *logical-system-name*)>  
 <path-name>

**Syntax (EX Series Switches)** show mpls path  
 <path-name>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.5 for EX Series switches.  
**instance *instance-name*** option added in Junos OS Release 15.1.

**Description** Display dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

**Options** **none**—Display standard information about all MPLS LSPs.

**instance *instance-name***—(Optional) Display the dynamic MPLS LSP for the specified instance. If ***instance-name*** is omitted, dynamic MPLS LSP for the master instance is displayed.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**path-name**—(Optional) Display information about the specified LSP only.

**Required Privilege Level** view

**List of Sample Output** [show mpls path on page 5198](#)

**Output Fields** [Table 407](#) describes the output fields for the **show mpls path** command. Output fields are listed in the approximate order in which they appear.

**Table 407: show mpls path Output Fields**

| Field Name                  | Field Description                                                 |
|-----------------------------|-------------------------------------------------------------------|
| <b>Path name</b>            | Information about ingress LSPs. Each path has one line of output. |
| <b>Address</b>              | Addresses of the routing devices that form the LSP.               |
| <b>Strict/loose address</b> | Whether the address is configured as a strict or loose address.   |

## Sample Output

show mpls path

```
user@host> show mpls path
Path name Address Strict/loose address
p1 123.456.55.6 Strict
 123.456.1.6 Loose
p2 191.456.1.4 Strict
```

## show route table

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <i>number routes</i>       | <p>Number of routes in the routing table and total number of routes in the following states:</p> <ul style="list-style-type: none"> <li>• <b>active</b> (routes that are active)</li> <li>• <b>holddown</b> (routes that are in the pending state before being declared inactive)</li> <li>• <b>hidden</b> (routes that are not used because of a routing policy)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Table 408: show route table Output Fields (*continued*)

| Field Name                                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>route-destination</i><br>(entry, announced) | <p>Route destination (for example:10.0.0.1/24). The <b>entry</b> value is the number of routes for this destination, and the <b>announced</b> value is the number of routes being announced for this destination. Sometimes the route destination is presented in another format, such as:</p> <ul style="list-style-type: none"> <li>• <b>MPLS-label</b> (for example, 80001).</li> <li>• <b>interface-name</b> (for example, ge-1/0/2).</li> <li>• <b>neighbor-address:control-word-status:encapsulation type:vc-id:source</b> (Layer 2 circuit only; for example, 10.1.1.195:NoCtrlWord:1:1:Local/96). <ul style="list-style-type: none"> <li>• <b>neighbor-address</b>—Address of the neighbor.</li> <li>• <b>control-word-status</b>—Whether the use of the control word has been negotiated for this virtual circuit: <b>NoCtrlWord</b> or <b>CtrlWord</b>.</li> <li>• <b>encapsulation type</b>—Type of encapsulation, represented by a number: (1) Frame Relay DLCI, (2) ATM AAL5 VCC transport, (3) ATM transparent cell transport, (4) Ethernet, (5) VLAN Ethernet, (6) HDLC, (7) PPP, (8) ATM VCC cell transport, (10) ATM VPC cell transport.</li> <li>• <b>vc-id</b>—Virtual circuit identifier.</li> <li>• <b>source</b>—Source of the advertisement: <b>Local</b> or <b>Remote</b>.</li> </ul> </li> <li>• <b>inclusive multicast Ethernet tag route</b>—Type of route destination represented by (for example, 3:100.100.100.10:100::0::10::100.100.100.10/384): <ul style="list-style-type: none"> <li>• <b>route distinguisher</b>—(8 octets) Route distinguisher (RD) must be the RD of the EVPN instance (EVI) that is advertising the NLRI.</li> <li>• <b>Ethernet tag ID</b>—(4 octets) Identifier of the Ethernet tag. Can set to 0 or to a valid Ethernet tag value.</li> <li>• <b>IP address length</b>—(1 octet) Length of IP address in bits.</li> <li>• <b>originating router's IP address</b>—(4 or 16 octets) Must set to the provider edge (PE) device's IP address. This address should be common for all EVIs on the PE device, and may be the PE device's loopback address.</li> </ul> </li> </ul> |
| label stacking                                 | <p>(Next-to-the-last-hop routing device for MPLS only) Depth of the MPLS label stack, where the label-popping operation is needed to remove one or more labels from the top of the stack. A pair of routes is displayed, because the pop operation is performed only when the stack depth is two or more labels.</p> <ul style="list-style-type: none"> <li>• <b>S=0 route</b> indicates that a packet with an incoming label stack depth of 2 or more exits this routing device with one fewer label (the label-popping operation is performed).</li> <li>• If there is no <b>S=</b> information, the route is a normal MPLS route, which has a stack depth of 1 (the label-popping operation is not performed).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| [ <i>protocol, preference</i> ]                | <p>Protocol from which the route was learned and the preference value for the route.</p> <ul style="list-style-type: none"> <li>• <b>+</b>—A plus sign indicates the active route, which is the route installed from the routing table into the forwarding table.</li> <li>• <b>-</b>—A hyphen indicates the last active route.</li> <li>• <b>*</b>—An asterisk indicates that the route is both the active and the last active route. An asterisk before a <b>to</b> line indicates the best subpath to the route.</li> </ul> <p>In every routing metric except for the BGP <b>LocalPref</b> attribute, a lesser value is preferred. In order to use common comparison routines, Junos OS stores the 1's complement of the <b>LocalPref</b> value in the <b>Preference2</b> field. For example, if the <b>LocalPref</b> value for Route 1 is 100, the <b>Preference2</b> value is -101. If the <b>LocalPref</b> value for Route 2 is 155, the <b>Preference2</b> value is -156. Route 2 is preferred because it has a higher <b>LocalPref</b> value and a lower <b>Preference2</b> value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 408: show route table Output Fields (*continued*)

| Field Name                                    | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level                                         | (IS-IS only). In IS-IS, a single AS can be divided into smaller groups called areas. Routing between areas is organized hierarchically, allowing a domain to be administratively divided into smaller areas. This organization is accomplished by configuring Level 1 and Level 2 intermediate systems. Level 1 systems route within an area. When the destination is outside an area, they route toward a Level 2 system. Level 2 intermediate systems route between areas and toward other ASs.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Route Distinguisher                           | IP subnet augmented with a 64-bit prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PMSI                                          | Provider multicast service interface (MVPN routing table).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Next-hop type                                 | Type of next hop. For a description of possible values for this field, see <a href="#">Table 300</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Next-hop reference count                      | Number of references made to the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Flood nexthop branches exceed maximum message | Indicates that the number of flood next-hop branches exceeded the system limit of 32 branches, and only a subset of the flood next-hop branches were installed in the kernel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source                                        | IP address of the route source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Next hop                                      | Network layer address of the directly reachable neighboring system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| via                                           | Interface used to reach the next hop. If there is more than one interface available to the next hop, the name of the interface that is actually used is followed by the word <b>Selected</b> . This field can also contain the following information: <ul style="list-style-type: none"> <li>Weight—Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.</li> <li>Balance—Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a routing device is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.</li> </ul> |
| Label-switched-path <i>lsp-path-name</i>      | Name of the LSP used to reach the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Label operation                               | MPLS label and operation occurring at this routing device. The operation can be <b>pop</b> (where a label is removed from the top of the stack), <b>push</b> (where another label is added to the label stack), or <b>swap</b> (where a label is replaced by another label).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Interface                                     | (Local only) Local interface name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Protocol next hop                             | Network layer address of the remote routing device that advertised the prefix. This address is used to derive a forwarding next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Indirect next hop                             | Index designation used to specify the mapping between protocol next hops, tags, kernel export policy, and the forwarding next hops.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| State                                         | State of the route (a route can be in more than one state). See <a href="#">Table 301</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 408: show route table Output Fields (*continued*)

| Field Name        | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Local AS          | AS number of the local routing device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Age               | How long the route has been known.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| AIGP              | Accumulated interior gateway protocol (AIGP) BGP attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Metric            | Cost value of the indicated route. For routes within an AS, the cost is determined by IGP and the individual protocol metrics. For external routes, destinations, or routing domains, the cost is determined by a preference value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| MED-plus-IGP      | Metric value for BGP path selection to which the IGP cost to the next-hop destination has been added.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| TTL-Action        | For MPLS LSPs, state of the TTL propagation attribute. Can be enabled or disabled for all RSVP-signaled and LDP-signaled LSPs or for specific VRF routing instances.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Task              | Name of the protocol that has added the route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Announcement bits | <p>The number of BGP peers or protocols to which Junos OS has announced this route, followed by the list of the recipients of the announcement. Junos OS can also announce the route to the KRT for installing the route into the Packet Forwarding Engine, to a resolve tree, a L2 VC, or even a VPN. For example, <i>n-Resolve inet</i> indicates that the specified route is used for route resolution for next hops found in the routing table.</p> <ul style="list-style-type: none"> <li><i>n</i>—An index used by Juniper Networks customer support only.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| AS path           | <p>AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated:</p> <ul style="list-style-type: none"> <li><b>I</b>—IGP.</li> <li><b>E</b>—EGP.</li> <li><b>Recorded</b>—The AS path is recorded by the sample process (sampled).</li> <li><b>?</b>—Incomplete; typically, the AS path was aggregated.</li> </ul> <p>When AS path numbers are included in the route, the format is as follows:</p> <ul style="list-style-type: none"> <li><b>[ ]</b>—Brackets enclose the number that precedes the AS path. This number represents the number of ASs present in the AS path, when calculated as defined in RFC 4271. This value is used in the AS-path merge process, as defined in RFC 4893.</li> <li><b>[ ]</b>—If more than one AS number is configured on the routing device, or if AS path prepending is configured, brackets enclose the local AS number associated with the AS path.</li> <li><b>{ }</b>—Braces enclose AS sets, which are groups of AS numbers in which the order does not matter. A set commonly results from route aggregation. The numbers in each AS set are displayed in ascending order.</li> <li><b>( )</b>—Parentheses enclose a confederation.</li> <li><b>( [ ] )</b>—Parentheses and brackets enclose a confederation set.</li> </ul> <p><b>NOTE:</b> In Junos OS Release 10.3 and later, the AS path field displays an unrecognized attribute and associated hexadecimal value if BGP receives attribute 128 (attribute set) and you have not configured an independent domain in any routing instance.</p> |

Table 408: show route table Output Fields (*continued*)

| Field Name              | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| validation-state        | <p>(BGP-learned routes) Validation status of the route:</p> <ul style="list-style-type: none"> <li>• <b>Invalid</b>—Indicates that the prefix is found, but either the corresponding AS received from the EBGp peer is not the AS that appears in the database, or the prefix length in the BGP update message is longer than the maximum length permitted in the database.</li> <li>• <b>Unknown</b>—Indicates that the prefix is not among the prefixes or prefix ranges in the database.</li> <li>• <b>Unverified</b>—Indicates that the origin of the prefix is not verified against the database. This is because the database got populated and the validation is not called for in the BGP import policy, although origin validation is enabled, or the origin validation is not enabled for the BGP peers.</li> <li>• <b>Valid</b>—Indicates that the prefix and autonomous system pair are found in the database.</li> </ul> |
| FECs bound to route     | Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Primary Upstream        | When multipoint LDP with multicast-only fast reroute (MoFRR) is configured, the primary upstream path. MoFRR transmits a multicast join message from a receiver toward a source on a primary path, while also transmitting a secondary multicast join message from the receiver toward the source on a backup path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| RPF Nexthops            | When multipoint LDP with MoFRR is configured, the reverse-path forwarding (RPF) next-hop information. Data packets are received from both the primary path and the secondary paths. The redundant packets are discarded at topology merge points due to the RPF checks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Label                   | Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| weight                  | Value used to distinguish MoFRR primary and backup routes. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| VC Label                | MPLS label assigned to the Layer 2 circuit virtual connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| MTU                     | Maximum transmission unit (MTU) of the Layer 2 circuit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| VLAN ID                 | VLAN identifier of the Layer 2 circuit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Prefixes bound to route | Forwarding equivalent class (FEC) bound to this route. Applicable only to routes installed by LDP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Communities             | Community path attribute for the route. | Accepted Multipath                  | Current active path when BGP multipath is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Accepted LongLivedStale             | The LongLivedStale flag indicates that the route was marked LLGR-stale by this router, as part of the operation of LLGR receiver mode. Either this flag or the LongLivedStaleImport flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.                                                                                                                                                                  |
| Accepted LongLivedStaleImport       | <p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy. Either this flag or the LongLivedStale flag might be displayed for a route. Neither of these flags is displayed at the same time as the Stale (ordinary GR stale) flag.</p> <p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and import into the inet.0 routing table</p> |
| ImportAccepted LongLivedStaleImport | <p>Accept all received BGP long-lived graceful restart (LLGR) and LLGR stale routes learned from configured neighbors and imported into the inet.0 routing table</p> <p>The LongLivedStaleImport flag indicates that the route was marked LLGR-stale when it was received from a peer, or by import policy.</p>                                                                                                                                                                       |
| Accepted MultipathContrib           | Path currently contributing to BGP multipath.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Localpref                           | Local preference value included in the route.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Router ID                           | BGP router ID as advertised by the neighbor in the open message.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Primary Routing Table               | In a routing table group, the name of the primary routing table in which the route resides.                                                                                                                                                                                                                                                                                                                                                                                           |
| Secondary Tables                    | In a routing table group, the name of one or more secondary tables in which the route resides.                                                                                                                                                                                                                                                                                                                                                                                        |

Table 300 describes all possible values for the Next-hop Types output field.

Table 409: Next-hop Types Output Field Values

| Next-Hop Type     | Description                                                                                                                                                                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Broadcast (bcast) | Broadcast next hop.                                                                                                                                                                                                                                                            |
| Deny              | Deny next hop.                                                                                                                                                                                                                                                                 |
| Discard           | Discard next hop.                                                                                                                                                                                                                                                              |
| Flood             | Flood next hop. Consists of components called branches, up to a maximum of 32 branches. Each flood next-hop branch sends a copy of the traffic to the forwarding interface. Used by point-to-multipoint RSVP, point-to-multipoint LDP, point-to-multipoint CCC, and multicast. |

Table 409: Next-hop Types Output Field Values (*continued*)

| Next-Hop Type            | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hold                     | Next hop is waiting to be resolved into a unicast or multicast type.                                                                                                                                                                                                                                                                                                                                       |
| Indexed (idxd)           | Indexed next hop.                                                                                                                                                                                                                                                                                                                                                                                          |
| Indirect (indr)          | Used with applications that have a protocol next hop address that is remote. You are likely to see this next-hop type for internal BGP (IBGP) routes when the BGP next hop is a BGP neighbor that is not directly connected.                                                                                                                                                                               |
| Interface                | Used for a network address assigned to an interface. Unlike the router next hop, the interface next hop does not reference any specific node on the network.                                                                                                                                                                                                                                               |
| Local (locl)             | Local address on an interface. This next-hop type causes packets with this destination address to be received locally.                                                                                                                                                                                                                                                                                     |
| Multicast (mcst)         | Wire multicast next hop (limited to the LAN).                                                                                                                                                                                                                                                                                                                                                              |
| Multicast discard (mdsc) | Multicast discard.                                                                                                                                                                                                                                                                                                                                                                                         |
| Multicast group (mgrp)   | Multicast group member.                                                                                                                                                                                                                                                                                                                                                                                    |
| Receive (recv)           | Receive.                                                                                                                                                                                                                                                                                                                                                                                                   |
| Reject (rjct)            | Discard. An ICMP unreachable message was sent.                                                                                                                                                                                                                                                                                                                                                             |
| Resolve (rslv)           | Resolving next hop.                                                                                                                                                                                                                                                                                                                                                                                        |
| Routed multicast (mcrtr) | Regular multicast next hop.                                                                                                                                                                                                                                                                                                                                                                                |
| Router                   | <p>A specific node or set of nodes to which the routing device forwards packets that match the route prefix.</p> <p>To qualify as next-hop type router, the route must meet the following criteria:</p> <ul style="list-style-type: none"> <li>• Must not be a direct or local subnet for the routing device.</li> <li>• Must have a next hop that is directly connected to the routing device.</li> </ul> |
| Table                    | Routing table next hop.                                                                                                                                                                                                                                                                                                                                                                                    |
| Unicast (ucst)           | Unicast.                                                                                                                                                                                                                                                                                                                                                                                                   |
| Unilist (ulst)           | List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.                                                                                                                                                                                                                                                                                                                |

Table 301 describes all possible values for the State output field. A route can be in more than one state (for example, <Active NoReadvrt Int Ext>).

**Table 410: State Output Field Values**

| Value                                       | Description                                                                                                                                                                          |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Accounting                                  | Route needs accounting.                                                                                                                                                              |
| Active                                      | Route is active.                                                                                                                                                                     |
| Always Compare MED                          | Path with a lower multiple exit discriminator (MED) is available.                                                                                                                    |
| AS path                                     | Shorter AS path is available.                                                                                                                                                        |
| Cisco Non-deterministic MED selection       | Cisco nondeterministic MED is enabled, and a path with a lower MED is available.                                                                                                     |
| Clone                                       | Route is a clone.                                                                                                                                                                    |
| Cluster list length                         | Length of cluster list sent by the route reflector.                                                                                                                                  |
| Delete                                      | Route has been deleted.                                                                                                                                                              |
| Ex                                          | Exterior route.                                                                                                                                                                      |
| Ext                                         | BGP route received from an external BGP neighbor.                                                                                                                                    |
| FlashAll                                    | Forces all protocols to be notified of a change to any route, active or inactive, for a prefix. When not set, protocols are informed of a prefix only when the active route changes. |
| Hidden                                      | Route not used because of routing policy.                                                                                                                                            |
| IfCheck                                     | Route needs forwarding RPF check.                                                                                                                                                    |
| IGP metric                                  | Path through next hop with lower IGP metric is available.                                                                                                                            |
| Inactive reason                             | Flags for this route, which was not selected as best for a particular destination.                                                                                                   |
| Initial                                     | Route being added.                                                                                                                                                                   |
| Int                                         | Interior route.                                                                                                                                                                      |
| Int Ext                                     | BGP route received from an internal BGP peer or a BGP confederation peer.                                                                                                            |
| Interior > Exterior > Exterior via Interior | Direct, static, IGP, or EBGp path is available.                                                                                                                                      |

Table 410: State Output Field Values (*continued*)

| Value                          | Description                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local Preference               | Path with a higher local preference value is available.                                                                                                                                                                           |
| Martian                        | Route is a martian (ignored because it is obviously invalid).                                                                                                                                                                     |
| MartianOK                      | Route exempt from martian filtering.                                                                                                                                                                                              |
| Next hop address               | Path with lower metric next hop is available.                                                                                                                                                                                     |
| No difference                  | Path from neighbor with lower IP address is available.                                                                                                                                                                            |
| NoReadvrt                      | Route not to be advertised.                                                                                                                                                                                                       |
| NotBest                        | Route not chosen because it does not have the lowest MED.                                                                                                                                                                         |
| Not Best in its group          | Incoming BGP AS is not the best of a group (only one AS can be the best).                                                                                                                                                         |
| NotInstall                     | Route not to be installed in the forwarding table.                                                                                                                                                                                |
| Number of gateways             | Path with a greater number of next hops is available.                                                                                                                                                                             |
| Origin                         | Path with a lower origin code is available.                                                                                                                                                                                       |
| Pending                        | Route pending because of a hold-down configured on another route.                                                                                                                                                                 |
| Release                        | Route scheduled for release.                                                                                                                                                                                                      |
| RIB preference                 | Route from a higher-numbered routing table is available.                                                                                                                                                                          |
| Route Distinguisher            | 64-bit prefix added to IP subnets to make them unique.                                                                                                                                                                            |
| Route Metric or MED comparison | Route with a lower metric or MED is available.                                                                                                                                                                                    |
| Route Preference               | Route with lower preference value is available.                                                                                                                                                                                   |
| Router ID                      | Path through a neighbor with lower ID is available.                                                                                                                                                                               |
| Secondary                      | Route not a primary route.                                                                                                                                                                                                        |
| Unusable path                  | Path is not usable because of one of the following conditions: <ul style="list-style-type: none"> <li>• The route is damped.</li> <li>• The route is rejected by an import policy.</li> <li>• The route is unresolved.</li> </ul> |
| Update source                  | Last tiebreaker is the lowest IP address value.                                                                                                                                                                                   |

Table 302 describes the possible values for the Communities output field.

Table 411: Communities Output Field Values

| Value                                                          | Description                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>area-number</i>                                             | 4 bytes, encoding a 32-bit area number. For AS-external routes, the value is 0. A nonzero value identifies the route as internal to the OSPF domain, and as within the identified area. Area numbers are relative to a particular OSPF domain.                                        |
| <b>bandwidth:</b> <i>local AS number:link-bandwidth-number</i> | Link-bandwidth community value used for unequal-cost load balancing. When BGP has several candidate paths available for multipath purposes, it does not perform unequal-cost load balancing according to the link-bandwidth community unless all candidate paths have this attribute. |
| <b>domain-id</b>                                               | Unique configurable number that identifies the OSPF domain.                                                                                                                                                                                                                           |
| <b>domain-id-vendor</b>                                        | Unique configurable number that further identifies the OSPF domain.                                                                                                                                                                                                                   |
| <i>link-bandwidth-number</i>                                   | Link-bandwidth number: from 0 through 4,294,967,295 (bytes per second).                                                                                                                                                                                                               |
| <i>local AS number</i>                                         | Local AS number: from 1 through 65,535.                                                                                                                                                                                                                                               |
| <i>options</i>                                                 | 1 byte. Currently this is only used if the route type is 5 or 7. Setting the least significant bit in the field indicates that the route carries a type 2 metric.                                                                                                                     |
| <b>origin</b>                                                  | (Used with VPNs) Identifies where the route came from.                                                                                                                                                                                                                                |
| <i>ospf-route-type</i>                                         | 1 byte, encoded as 1 or 2 for intra-area routes (depending on whether the route came from a type 1 or a type 2 LSA); 3 for summary routes; 5 for external routes (area number must be 0); 7 for NSSA routes; or 129 for sham link endpoint addresses.                                 |
| <b>route-type-vendor</b>                                       | Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x8000. The format is <b>area-number:ospf-route-type:options</b> .                                                                                  |
| <b>rte-type</b>                                                | Displays the area number, OSPF route type, and option of the route. This is configured using the BGP extended community attribute 0x0306. The format is <b>area-number:ospf-route-type:options</b> .                                                                                  |
| <b>target</b>                                                  | Defines which VPN the route participates in; <b>target</b> has the format <b>32-bit IP address:16-bit number</b> . For example, 10.19.0.0:100.                                                                                                                                        |
| <b>unknown IANA</b>                                            | Incoming IANA codes with a value between 0x1 and 0x7fff. This code of the BGP extended community attribute is accepted, but it is not recognized.                                                                                                                                     |
| <b>unknown OSPF vendor community</b>                           | Incoming IANA codes with a value above 0x8000. This code of the BGP extended community attribute is accepted, but it is not recognized.                                                                                                                                               |

## Sample Output

### show route table bgp.l2vpn

```
user@host> show route table bgp.l2vpn
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.168.24.1:1:4:1/96
 *[BGP/170] 01:08:58, localpref 100, from 192.168.24.1
 AS path: I
 > to 10.0.16.2 via fe-0/0/1.0, label-switched-path am
```

### show route table bgp.l3vpn.0

```
user@host> show route table bgp.l3vpn.0
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.71.15:100:10.255.71.17/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100020, Push 100011(top)
10.255.71.15:200:10.255.71.18/32
 *[BGP/170] 00:03:59, MED 1, localpref 100, from
10.255.71.15
 AS path: I
 > via so-2/1/0.0, Push 100021, Push 100011(top)
```

### show route table bgp.l3vpn.0 detail

```
user@host> show route table bgp.l3vpn.0 detail
bgp.l3vpn.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)

### show route table mpls.0 (RSVP Route—Transit LSP)

In the sample output, the 1 in [RSVP/7/1] indicates the secondary preference value. The secondary preference value becomes significant when multiple RSVP LSPs of different types are signaled to the destination. The possible values of RSVP secondary preferences are:

1—Normal Point-to-Point RSVP-TE LSP

2—Point-to-Multipoint (P2MP) RSVP-TE LSP

3—Dynamic RSVP-TE LSP

```

### show route table MVPN.mvpn.0

Starting in Junos OS Release 15.1, multicast routes on the locally originated type 7 customer multicast routes are added exclusively by PIM. The functionality of the BGP-MVPN service (which, internally, depends on contributions of state from both the MVPN and PIM protocol components of Junos OS) remains unchanged. MVPN, however, no longer appears as the originator of the locally advertised route. Routes advertised by remote PEs are, as usual, always learned locally from their respective [BGP/...] protocol.

```

user@host> show route table MVPN.mvpn.0
MVPN.mvpn.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Options **all** and **vlan** introduced in Junos OS Release 9.6.

Command introduced in Junos OS Release 11.3 for the QFX Series.

Command introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.

**NOTE:** The Routing Engine copies the forwarding table to the Packet Forwarding Engine, the part of the router that is responsible for forwarding packets. To display the entries in the Packet Forwarding Engine's forwarding table, use the **show pfe route** command.

**Options** **none**—Display the routes in the forwarding tables. By default, the **show route forwarding-table** command does not display information about private, or internal, forwarding tables.

**detail | extensive | summary**—(Optional) Display the specified level of output.

**all**—(Optional) Display routing table entries for all forwarding tables, including private, or internal, tables.

**bridge-domain (all | bridge-domain-name)**—(MX Series routers only) (Optional) Display route entries for all bridge domains or the specified bridge domain.

**ccc interface-name**—(Optional) Display route entries for the specified circuit cross-connect interface.

**destination destination-prefix**—(Optional) Destination prefix.

**family family**—(Optional) Display routing table entries for the specified family: **fibre-channel**, **fmembers**, **inet**, **inet6**, **iso**, **mpls**, **tnp**, **unix**, **vpls**, or **vlan-classification**.

**interface-name interface-name**—(Optional) Display routing table entries for the specified interface.

**label name**—(Optional) Display route entries for the specified label.

**lcc number**—(TX Matrix and TX matrix Plus routers only) (Optional) On a routing matrix composed of a TX Matrix router and T640 routers, display information for the specified T640 router (or line-card chassis) connected to the TX Matrix router. On a routing matrix composed of the TX Matrix Plus router and T1600 or T4000 routers, display information for the specified router (line-card chassis) connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

**learning-vlan-id** *learning-vlan-id*—(MX Series routers only) (Optional) Display learned information for all VLANs or for the specified VLAN.

**matching** *matching*—(Optional) Display routing table entries matching the specified prefix or prefix length.

**multicast**—(Optional) Display routing table entries for multicast routes.

**table** (*default* | *logical-system-name/routing-instance-name* | *routing-instance-name*)—(Optional) Display route entries for all the routing tables in the main routing instance or for the specified routing instance. If your device supports logical systems, you can also display route entries for the specified logical system and routing instance. To view the routing instances on your device, use the [show route instance](#) command.

**vlan** (*all* | *vlan-name*)—(Optional) Display information for all VLANs or for the specified VLAN.

**vpn** *vpn*—(Optional) Display routing table entries for a specified VPN.

**Required Privilege Level**

**Output Fields** Table 306 lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified, or when the **detail** keyword is used instead of the **extensive** keyword.

Table 412: show route forwarding-table Output Fields

| Field Name              | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output         |

| Index                      | Software index of the next hop that is used to route the traffic for a given prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>detail extensive none</b> |
| Route interface-index      | Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>extensive</b>             |
| Reference (NhRef)          | Number of routes that refer to this next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <b>detail extensive none</b> |
| Next-hop interface (Netif) | Interface used to reach the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>detail extensive none</b> |
| Weight                     | Value used to distinguish primary, secondary, and fast reroute backup routes. Weight information is available when MPLS label-switched path (LSP) link protection, node-link protection, or fast reroute is enabled, or when the standby state is enabled for secondary paths. A lower weight value is preferred. Among routes with the same weight value, load balancing is possible (see the <b>Balance</b> field description).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>extensive</b>             |
| Balance                    | Balance coefficient indicating how traffic of unequal cost is distributed among next hops when a router is performing unequal-cost load balancing. This information is available when you enable BGP multipath load balancing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>extensive</b>             |
| RPF interface              | List of interfaces from which the prefix can be accepted. Reverse path forwarding (RPF) information is displayed only when <b>rpf-check</b> is configured on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>             |

## Sample Output

### show route forwarding-table extensive (RPF)

The next example is based on the following configuration, which enables an RPF check on all routes that are learned from this interface, including the interface route:

```

so-1/1/0 {
 unit 0 {
 family inet {
 rpf-check;
 address 15.95.1.2/30;
 }
 }
}

```

```

user@host> show route forwarding-table extensive
Routing table: inet [Index 0]
Internet:

## show mpls static-lsp

**Syntax** show mpls static-lsp  
 <brief | detail | extensive | terse>  
 <bypass>  
 <descriptions>  
 <down | up>  
 <ingress>  
 <instance *instance-name*>  
 <logical-system (all | *logical-system-name*)>  
 <lsp-type>  
 <name *name*>  
 <statistics>  
 <transit>

**Release Information** Command introduced in Junos OS Release 10.1.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Display information about configured and active static Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

**Options** **none**—Display standard information about all configured and active static MPLS LSPs.

**brief | detail | extensive | terse**—(Optional) Display the specified level of output. The **extensive** option displays the same information as the **detail** option, but covers the most recent 50 events.

**bypass**—(Optional) Display LSPs used for protecting other static LSPs.

**descriptions**—(Optional) Display the MPLS static LSP descriptions. To view this information, you must configure the description statement at the **[edit protocols mpls static-label-switched-path *path-name* bypass]**, **[edit protocols mpls static-label-switched-path *path-name* ingress]**, or **[edit protocols mpls static-label-switched-path *path-name* transit *incoming-label*]** hierarchy levels. Only static LSPs with a description are displayed.

**down | up**—(Optional) Display only static LSPs that are inactive or active, respectively.

**instance *instance-name***—(Optional) Display information about all configured and active static MPLS LSPs for the specified routing instance. If ***instance-name*** is omitted, information about all configured and active static MPLS LSPs for the master instance is displayed.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

***lsp-type***—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that pass through this routing device.

**name *name***—(Optional) Display information about the specified static LSP or group of LSPs.

**statistics**—(Optional) Display accounting information about static LSPs.

**transit**—(Optional) Display static LSPs transiting this routing device.

**Required Privilege Level** view

**List of Sample Output** [show mpls static-lsp extensive on page 5243](#)  
[show mpls static-lsp statistics ingress on page 5243](#)  
[show mpls static-lsp \(when MPLS stitching is used\) on page 5243](#)

**Output Fields** Table 413 describes the output fields for the **show mpls static-lsp** command. Output fields are listed in the approximate order in which they appear.

**Table 413: show mpls static-lsp Output Fields**

| Field Name                     | Field Description                                                                                                                                                                             | Level of Output          |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <b>Ingress LSPs</b>            | Information about the static LSPs on the ingress routing device. Each session has one line of output.                                                                                         | All levels               |
| <b>Transit LSPs</b>            | Number of static LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. | All levels               |
| <b>Bypass LSPs</b>             | Information about the bypass LSPs configured on the routing device. Each session has one line of output.                                                                                      | All levels               |
| <b>LSPname</b>                 | Name of the static LSP.                                                                                                                                                                       | All levels               |
| <b>To</b>                      | Destination (egress routing device) of the session.                                                                                                                                           | All levels               |
| <b>State</b>                   | State of the static LSP handled by this RSVP session: <b>Up</b> , <b>Dn</b> (down), or <b>Restart</b> .                                                                                       | All levels               |
| <b>Packets</b>                 | Number of packet transiting the static LSP ( <b>statistics</b> option only).                                                                                                                  | All levels               |
| <b>Bytes</b>                   | Number of bytes transiting the static LSP ( <b>statistics</b> option only).                                                                                                                   | All levels               |
| <b>Nexthop</b>                 | IP address for the next-hop router for the static LSP.                                                                                                                                        | <b>detail, extensive</b> |
| <b>Bypass</b>                  | (Bypass LSP) Destination address (egress routing device) for the bypass LSP.                                                                                                                  | All levels               |
| <b>Link protection desired</b> | Link protection has been requested by the ingress routing device.                                                                                                                             | <b>detail, extensive</b> |
| <b>LabelOperation</b>          | Label operation to perform: <b>Push</b> , <b>Pop</b> , <b>Swap</b> .                                                                                                                          | <b>detail, extensive</b> |
| <b>Outgoing-label</b>          | Outgoing label to use for the MPLS packet in either push or swap label operations.                                                                                                            | <b>detail, extensive</b> |

Table 413: show mpls static-lsp Output Fields (*continued*)

| Field Name        | Field Description                                                                                                                                                                                                                   | Level of Output          |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <b>Created</b>    | (Ingress LSP) Date and time the static LSP was created.                                                                                                                                                                             | <b>extensive</b>         |
| <b>Bandwidth</b>  | Bandwidth configured for the static LSP.                                                                                                                                                                                            | <b>detail, extensive</b> |
| <b>Resv style</b> | (Bypass) RSVP reservation style. This field consists of two parts: the number of active reservations and the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | All levels               |

## Sample Output

### show mpls static-lsp extensive

```

user@host> show mpls static-lsp extensive
Ingress LSPs:
LSPName: alpha-to-beta, To: 192.168.14.1
State: Dn
Nexthop: 192.168.10.1
LabelOperation: Push, Outgoing-label: 1000001
Created: Thu Jan 14 16:44:43 2010
Bandwidth: 0 bps
Total 1, displayed 1, Up 0, Down 1

Transit LSPs:
Total 0, displayed 0, Up 0, Down 0

Bypass LSPs:
Total 0, displayed 0, Up 0, Down 0

```

### show mpls static-lsp statistics ingress

```

user@host> show mpls static-lsp statistics ingress
Ingress LSPs:
LSPName To State Packets Bytes
alpha-to-beta 192.168.14.1 Dn NA NA
Total 1, displayed 1, Up 0, Down 1

```

### show mpls static-lsp (when MPLS stitching is used)

The show mpls static-lsp command was extended in Junos release 14.1X53-D25 to accommodate the stitching feature of MPLS. This example shows the LSP state as 'InProgress' because the LSP is waiting for protocol next-hop resolution. For more information, see

```

user@host> show mpls static-lsp
Ingress LSPs:
Total 0, displayed 0, Up 0, Down 0
Transit LSPs: LSPName Incoming-label State
to-165 1000000 InProgress

```

## show ted database

|--------------|---------------------------------------------------------------------------------|-----------------|
| TED database | Number of nodes and pseudonodes participating in IS-IS and OSPF domain routing. | All levels      |

Table 414: show ted database Output Fields (*continued*)

| Field Name                     | Field Description                                                                                                                                                                                                                                                                           | Level of Output         |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| ID                             | Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode. If the node contains a router ID, it is displayed in parentheses. | <b>brief</b>            |
| NodeID                         | Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.                                                                   | <b>extensive</b>        |
| Type                           | Type of node. It can be either <b>Rtr</b> (router) or <b>Net</b> (pseudonode).                                                                                                                                                                                                              | All levels              |
| Age(s)                         | How long since the node was last refreshed, in seconds.                                                                                                                                                                                                                                     | All levels              |
| LnkIn                          | Number of nodes pointing toward this node.                                                                                                                                                                                                                                                  | All levels              |
| LnkOut                         | Number of nodes to which this node points.                                                                                                                                                                                                                                                  | All levels              |
| Protocol                       | Protocol that reported the node information: <ul style="list-style-type: none"> <li>• <b>IS-IS(1)</b>—IS-IS Level 1.</li> <li>• <b>IS-IS(2)</b>—IS-IS Level 2.</li> <li>• <b>OSPF (area-number)</b>—OSPF from the specified area.</li> </ul>                                                | All levels              |
| To                             | Address on the far end of a link.                                                                                                                                                                                                                                                           | <b>detail extensive</b> |
| Local                          | Address of the local interface being used to reach the remote node.                                                                                                                                                                                                                         | <b>detail extensive</b> |
| Remote                         | Address of the interface on the remote node.                                                                                                                                                                                                                                                | <b>detail extensive</b> |
| Local interface index          | The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.                                                                                                                                                                                 | <b>detail extensive</b> |
| Remote interface index         | The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.                                                                                                                                                                                 | <b>detail extensive</b> |
| Metric                         | Configured traffic engineering metric.                                                                                                                                                                                                                                                      | <b>extensive</b>        |
| IGP metric                     | Configured interior gateway protocol metric.                                                                                                                                                                                                                                                | <b>extensive</b>        |
| Static BW                      | Total interface bandwidth in bps.                                                                                                                                                                                                                                                           | <b>extensive</b>        |
| Reservable bandwidth           | Subscription factor for the interface, which is the percentage of the link bandwidth that can be used for the RSVP reservation process. You configure this by including the <b>subscription</b> statement when configuring RSVP.                                                            | <b>extensive</b>        |
| <b>Available BW [priority]</b> | (Must include <b>diffserv-te</b> statement when configuring LSPs) Amount of bandwidth actually reserved by RSVP for each priority level. The bandwidth shown is for the entire interface, not for each individual LSP.                                                                      | <b>extensive</b>        |

| <b>Output Fields</b>               | Table 415 describes the output fields for the <b>show ted link</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 415: show ted link Output Fields

| Field Name | Field Description                                                                                                                                                                                                         | Level of Output |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| ID         | Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode. | <b>brief</b>    |
| -->ID      | Hostname and address of the node that the link is going to. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.    | <b>brief</b>    |

Table 415: show ted link Output Fields (*continued*)

| Field Name             | Field Description                                                                                                                                                                                                         | Level of Output         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <i>hostname</i>        | Hostname and address of the node that the link is coming from. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode. | <b>detail</b>           |
| <i>hostname</i>        | Hostname and address of the node that the link is going to. An address of .00 indicates that the node is the routing device itself. An address in the range 0.01 through 0.FF indicates that the node is a pseudonode.    | <b>detail</b>           |
| Local Path             | Number of paths CSPF on the local routing device has placed on the link.                                                                                                                                                  | All levels              |
| Metric                 | Configured traffic engineering metric.                                                                                                                                                                                    | <b>extensive</b>        |
| IGP metric             | Configured interior gateway protocol metric.                                                                                                                                                                              | <b>detail</b>           |
| Local BW               | Amount of bandwidth the local routing device has placed on the link.                                                                                                                                                      | All levels              |
| Local                  | Address of the local interface being used to reach the remote node.                                                                                                                                                       | <b>detail extensive</b> |
| Remote                 | Address of the interface on the remote node.                                                                                                                                                                              | <b>detail extensive</b> |
| Local interface index  | The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.                                                                                                               | <b>detail</b>           |
| Remote interface index | The interface indexes enable Junos OS to support unnumbered extensions for IS-IS, as described in RFC 4205.                                                                                                               | <b>detail</b>           |

## Sample Output

### show ted link brief

```

user@host> show ted link brief
ID ->ID LocalPath LocalBW
Router-B.02 Router-A.00 0 0bps

## Understanding MPLS Components for QFX Series and EX4600 Switches

---

MPLS devices include a number of components. While some components are required for all MPLS applications, others might not be, depending on the specific application.

This topic includes:

- [Provider Edge Switches on page 5259](#)
- [Provider Switch on page 5261](#)
- [Components Required for All Switches in the MPLS Network on page 5261](#)

### Provider Edge Switches

To implement MPLS on a network, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch. In addition, you must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets.

The ingress PE switch (the entry point to the MPLS tunnel) receives a packet, analyzes it, and pushes an MPLS label onto it. This label places the packet in a forwarding equivalence class (FEC) and determines its handling and destination through the MPLS tunnel. The egress PE switch (the exit point from the MPLS tunnel) pops the MPLS label off the outgoing packet.

Within an MPLS tunnel, the network traffic is bidirectional. Therefore, each PE switch can be configured to be both an ingress switch and an egress switch, depending on the direction of the traffic.

The following MPLS components are configured on the PE switches but not on the provider switches:

- [MPLS Protocol and Label-Switched Paths on page 5260](#)
- [IP Over MPLS for Customer Edge Interfaces on page 5260](#)
- [BGP Layer 3 VPN Configuration on page 5260](#)
- [Routing Instances for Layer 3 VPN on page 5260](#)
- [Routing Instances for Layer 2 VPN and Layer 3 VPN on page 5260](#)
- [Ethernet Encapsulation for Layer 2 VPN on page 5261](#)

---

### MPLS Protocol and Label-Switched Paths

Each PE switch must be configured to support the MPLS protocol. You must also configure label-switched paths (LSPs) at the **[edit protocols mpls]** hierarchy level.

---

### IP Over MPLS for Customer Edge Interfaces

You can configure the customer edge interfaces of the PE switches for IP over MPLS using a Layer 3 interface and a static route from the ingress PE switch to the egress PE switch. See “[Configuring MPLS on Provider Edge Switches](#)” on page 4981.

---

### BGP Layer 3 VPN Configuration

If you are implementing a Layer 3 virtual private network (VPN), you must configure the BGP routing protocol on the PE switches.

---

### Routing Instances for Layer 3 VPN

If you are implementing a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series and EX4600 devices support VPN routing and forwarding (VRF) routing instances for Layer 3 VPNs.

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

---

### Routing Instances for Layer 2 VPN and Layer 3 VPN

If you are implementing a Layer 2 VPN or a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series devices support the following types of routing instances:

- Layer 2 VPN—To support a Layer 2 VPN
- VPN routing and forwarding (VRF)—To support a Layer 3 VPN

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

### Ethernet Encapsulation for Layer 2 VPN

If you are implementing a Layer 2 VPN, you must also configure the physical layer encapsulation type on the customer edge interface and within the routing instance.

## Provider Switch

You must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets. You can add provider switches without changing the configuration of the PE switches.

A provider switch does not analyze packets. It refers to an MPLS label forwarding table and swaps one label for another. The new label determines the next hop along the MPLS tunnel. A provider switch cannot perform push or pop operations.

## Components Required for All Switches in the MPLS Network

The following MPLS components are configured on both the PE switches and the provider switches:

- [Interior Gateway Protocol on page 5261](#)
- [Traffic Engineering on page 5262](#)
- [MPLS Protocol on page 5262](#)
- [RSVP on page 5262](#)
- [Family mpls on page 5262](#)

### Interior Gateway Protocol

MPLS works in coordination with OSPF as the interior gateway protocol (IGP). Therefore, you must configure OSPF as the IGP on the loopback interface and CE-facing interfaces of both the PE switches and the provider switches.

The CE-facing interfaces can be either Gigabit Ethernet or 10-Gigabit Ethernet interfaces, and they can be configured as either individual interfaces or as aggregated Ethernet interfaces.

**NOTE:** The CE-facing interfaces cannot be configured with VLAN tagging or a VLAN ID. When you configure them to belong to family **mpls**, they are removed from the default VLAN if they were members of that VLAN. They operate as an exclusive tunnel for MPLS traffic.

## Traffic Engineering

---

Traffic engineering maps traffic flows onto an existing physical topology and provides the ability to move traffic flow away from the shortest path selected by the IGP and to a potentially less congested physical path across a network.

Traffic engineering enables the selection of specific end-to-end paths to send given types of traffic through your network. You must configure OSPF traffic engineering on the PE switches and the provider switches.

## MPLS Protocol

---

You must enable the MPLS protocol on all switches that participate in the MPLS network and apply it to the core interfaces of both the PE and provider switches. You do not need to apply it to the loopback interface because the MPLS protocol uses the framework established by the RSVP signaling protocol to create LSPs. On the PE switches, the configuration of the MPLS protocol must also include the definition of an LSP.

## RSVP

---

RSVP is a signaling protocol that allocates and distributes labels throughout an MPLS network. RSVP sets up unidirectional paths between the ingress PE switch and the egress PE switch. RSVP makes the LSPs dynamic; it can detect topology changes and outages and establish new LSPs to allow traffic to move around a failure.

You must enable RSVP and apply it to the loopback interface and the core interface of both the PE and provider switches. The path message contains the configured information about the resources required for the LSP to be established.

When the egress PE switch receives the path message, it sends a reservation message back to the ingress PE switch. This reservation message is passed along from switch to switch along the same path as the original path message. Once the ingress PE switch receives this reservation message, an RSVP path is established.

The established LSP stays active as long as the RSVP session remains active. RSVP continues activity through the transmissions and responses to RSVP path and reservation messages. If the messages stop for three minutes, the RSVP session terminates and the LSP is lost.

RSVP runs as a separate software process in Junos OS and is not in the packet-forwarding path.

## Family mpls

---

You must configure the core interfaces used for MPLS traffic to belong to **family mpls**.

**NOTE:** You can enable **family mpls** on either individual interfaces or on aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

## RSVP Overview

The RSVP protocol is used by routers to deliver quality-of-service (QoS) requests to all nodes along data flow path(s) and to establish and maintain state for the requested service. RSVP requests generally result in resource reservations in each node along the data path. RSVP has the following attributes:

- Makes resource reservations for unidirectional data flows.
- Allows the receiver of a data flow to initiate and maintain the resource reservation used for that flow, as shown in [Figure 150](#).
- Maintains a soft state in routers and hosts, providing graceful support for dynamic membership changes and automatic adaptation to routing changes.
- Depends upon present and future routing protocols, but is not a routing protocol itself.
- Provides several reservation models or styles to fit a variety of applications.
- Supports both IPv4 and IPv6. Note, you can configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. For more information, see the *MPLS Applications Feature Guide for Routing Devices*.

**Figure 150: RSVP Reservation Request and Data Flow**

## MTU Signaling in RSVP

---

The maximum transmission unit (MTU) is the largest size packet or frame, in bytes, that can be sent in a network. An MTU that is too large might cause retransmissions. Too small an MTU might cause the router to send and handle relatively more header overhead and acknowledgments. There are default values for MTUs associated with various protocols. You can also explicitly configure an MTU on an interface.

When an LSP is created across a set of links with different MTU sizes, the ingress router does not know what the smallest MTU is on the LSP path. By default, the MTU for an LSP is 1,500 bytes.

If this MTU is larger than the MTU of one of the intermediate links, traffic might be dropped, because MPLS packets cannot be fragmented. Also, the ingress router is not aware of this type of traffic loss, because the control plane for the LSP would still function normally.

To prevent this type of packet loss in MPLS LSPs, you can configure MTU signaling in RSVP. This feature is described in RFC 3209. Juniper Networks supports the Integrated Services object for MTU signaling in RSVP. The Integrated Services object is described in RFCs 2210 and 2215. MTU signaling in RSVP is disabled by default.

To avoid packet loss due to MTU mismatches, the ingress router needs to do the following:

- Signal the MTU on the RSVP LSP—To prevent packet loss from an MTU mismatch, the ingress router needs to know what the smallest MTU value is along the path taken by the LSP. Once this MTU value is obtained, the ingress router can assign it to the LSP.
- Fragment packets—Using the assigned MTU value, packets that exceed the size of the MTU can be fragmented into smaller packets on the ingress router before they are encapsulated in MPLS and sent over the RSVP-signaled LSP.

Once both MTU signaling and packet fragmentation have been enabled on an ingress router, any route resolving to an RSVP LSP on this router uses the signaled MTU value. For information about how to configure this feature, see *Configuring MTU Signaling in RSVP*.

The following sections describe how MTU signaling in RSVP works:

- *How the Correct MTU Is Signaled in RSVP*
- *Determining an Outgoing MTU Value*
- *MTU Signaling in RSVP Limitations*

## Tunneling LDP LSPs in RSVP LSPs

---

You can tunnel LDP LSPs over RSVP LSPs. The following sections describe how tunneling of LDP LSPs in RSVP LSPs works:

- [Tunneling LDP LSPs in RSVP LSPs Overview on page 4805](#)
- [Label Operations on page 4806](#)

## Tunneling LDP LSPs in RSVP LSPs Overview

If you are using RSVP for traffic engineering, you can run LDP simultaneously to eliminate the distribution of external routes in the core. The LSPs established by LDP are tunneled through the LSPs established by RSVP. LDP effectively treats the traffic-engineered LSPs as single hops.

When you configure the router to run LDP across RSVP-established LSPs, LDP automatically establishes sessions with the router at the other end of the LSP. LDP control packets are routed hop-by-hop, rather than carried through the LSP. This routing allows you to use simplex (one-way) traffic-engineered LSPs. Traffic in the opposite direction flows through LDP-established LSPs that follow unicast routing rather than through traffic-engineered tunnels.

If you configure LDP over RSVP LSPs, you can still configure multiple OSPF areas and IS-IS levels in the traffic engineered core and in the surrounding LDP cloud.

**NOTE:** Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance. This allows splitting of a single routing and MPLS domain into multiple domains so that each domain can be scaled independently. BGP labeled unicast can be used to stitch these domains for service FECs. Each domain uses intra-domain LDP over RSVP LSP for MPLS forwarding.

## Configuring MPLS on Provider Edge Switches

To implement MPLS, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure the customer edge (CE) interfaces on the PE switches of the MPLS network using IP over MPLS.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

1. [Configuring the Ingress PE Switch on page 5266](#)
2. [Configuring the Egress PE Switch on page 5267](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.10.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure OSPF traffic engineering:

```
[edit protocols ospf]
user@switch# set traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure MPLS traffic engineering.

```
[edit protocols mpls]
user@switch# set traffic-engineering
```

6. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 121.100.10.1/16
```

9. Configure this Layer 3 customer edge interface for the routing protocol:

- ```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3.0
```
10. Configure an LSP on the ingress PE switch (192.168.10.1) to send IP packets over MPLS to the egress PE switch (192.168.12.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 to 192.168.12.1
```
 11. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_1 no-cspf
```
 12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 2.2.2.0/24 next-hop 192.168.10.1
user@switch# set static route 2.2.2.0/24 resolve
```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.12.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.21.1/24
```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

- ```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```
3. Configure RSVP on the loopback interface and the core interfaces:
 

```
[edit protocols rsvp]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface xe-0/0/5.0
user@switch# set rsvp interface xe-0/0/6.0
```
  4. Configure MPLS on the core interfaces:
 

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```
  5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/5 unit 0 family mpls
```

```
user@switch# set xe-0/0/6 unit 0 family mpls
```

6. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/3 unit 0 family inet address 2.2.2.1/16
```

7. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
```

```
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3
```

8. Configure an LSP on the egress PE switch (192.168.12.1) to send IP packets over MPLS to the ingress PE switch (192.168.10.1):

```
[edit protocols mpls]
```

```
user@switch# set label-switched-path lsp_2 to 192.168.10.1
```

9. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
```

```
user@switch# set label-switched-path lsp_2 no-cspf
```

10. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
```

```
user@switch# set static route 121.121.121.0/24 next-hop 192.168.12.1
```

```
user@switch# set static route 121.121.121.0/24 resolve
```

## Configuring MPLS on Provider Switches

To implement MPLS, you must configure at least one provider switch as a transit switch for the MPLS packets.

MPLS requires the configuration of an interior gateway protocol (OSPF) and a signaling protocol (RSVP) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch.

To configure the provider switch, complete the following tasks:

1. Configure OSPF on the loopback and core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
user@switch# set area 0.0.0.0 interface ae0
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

4. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set ae0 unit 0 family inet address 10.1.9.2/24
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
user@switch# set ae0 unit 0 family mpls
```

**NOTE:** You can configure **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot configure it on tagged VLAN interfaces.

## Verifying That MPLS Is Working Correctly

To verify that MPLS is working correctly, perform the following tasks:

1. [Verifying the Physical Layer on the Switches on page 5270](#)
2. [Verifying the Routing Protocol on page 5271](#)
3. [Verifying the Core Interfaces Being Used for the MPLS Traffic on page 5271](#)
4. [Verifying RSVP on page 5271](#)

### Verifying the Physical Layer on the Switches

**Purpose** Verify that the interfaces are up. Perform this verification task on each of the switches.

**Action** `user@switch> show interfaces xe-* terse`

| Interface  | Admin | Link | Proto        | Local       | Remote |
|------------|-------|------|--------------|-------------|--------|
| xe-0/0/0   | up    | up   |              |             |        |
| xe-0/0/0.0 | up    | up   |              |             |        |
| xe-0/0/1.0 | up    | up   |              |             |        |
| xe-0/0/2.0 | up    | up   |              |             |        |
| xe-0/0/3.0 | up    | up   | inet         | 2.2.2.1/16  |        |
| xe-0/0/4.0 | up    | up   |              |             |        |
| xe-0/0/5.0 | up    | up   | inet<br>mpls | 10.1.5.1/24 |        |
| xe-0/0/6.0 | up    | up   | inet<br>mpls | 10.1.6.1/24 |        |

**Meaning** The `show interfaces terse` command displays status information about the 10-Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (Proto column) of the core interfaces (xe-0/0/5.0 and xe-0/0/6.0), shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

## Verifying the Routing Protocol

**Purpose** Verify the state of the configured routing protocol. You should perform this verification task on each of the switches. The state should be **Full**. If you have configured OSPF as the routing protocol, use the **show ospf neighbor** command to verify that the routing protocol is communicating with the switch neighbors.

**Action** user@switch> **show ospf neighbor**

| Address   | Interface | State | ID          | Pri | Dead |
|-----------|-----------|-------|-------------|-----|------|
| 127.1.1.1 | xe-0/0/5  | Full  | 10.10.10.10 | 128 | 39   |

**Meaning** The **show ospf neighbor** command displays the status of the routing protocol that has been configured on this switch. The output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors. For additional information on checking and monitoring routing protocols, see the [Junos OS Routing Protocols and Policies Command Reference](#).

## Verifying the Core Interfaces Being Used for the MPLS Traffic

**Purpose** Verify that the state of the MPLS interface is **Up**. You should perform this verification task on each of the switches.

**Action** user@switch> **show mpls interface**

| Interface | State | Administrative groups |
|-----------|-------|-----------------------|
| ge-0/0/5  | Up    | <none>                |
| ge-0/0/6  | Up    | <none>                |

**Meaning** The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is up.

## Verifying RSVP

**Purpose** Verify the state of the RSVP session. You should perform this verification task on each of the switches.

```
user@switch> show mpls session
```

```
Ingress RSVP: 1 sessions
To From State Rt Style Labelin Labelout LSPname
127.1.1.3 127.1.1.1 Up 0 1 FF - 300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0
```

```
Egress RSVP: 1 sessions
To From State Rt Style Labelin Labelout LSPname
127.1.1.1 127.1.1.3 Up 0 1 FF 299968 - lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0
```

```
Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** This output confirms that the RSVP sessions are up.

## Dynamic Bandwidth Management Using Container LSP Overview

RSVP LSPs with the autobandwidth feature are increasingly deployed in networks to meet traffic engineering needs. However, the current traffic engineering solutions for point-to-point LSPs are inefficient in terms of network bandwidth utilization, mainly because the ingress routers originating the RSVP LSPs either try to fit the LSPs along a particular path without creating parallel LSPs, or do not interact with the other routers in the network and probe for additional available bandwidth.

This feature provides an ingress router with the capability of acquiring as much network bandwidth as possible by creating parallel LSPs dynamically.

### Understanding RSVP Multipath Extensions

The RSVP multipath extensions proposed in the IETF [KOMPELLA-MLSP] allow the setup of traffic engineered multipath label-switched paths (container LSPs). The container LSPs, in addition to conforming to traffic engineering constraints, use multiple independent paths from a source to a destination, thereby facilitating load balancing of

traffic. The multipath extensions require changes to the RSVP-TE protocol and allow for merging of labels at the downstream nodes (similar to LDP), which also helps in preserving forwarding resources.

The multipath extensions to RSVP provide the following benefits:

- Ease of configuration. Typically, multiple RSVP LSPs are configured for either load balancing or bin packing. With a container LSP, there is a single entity to provision, manage, and monitor LSPs. Changes in topology are handled easily and autonomously by the ingress LSP, by adding, changing, or removing member LSPs to rebalance traffic, while maintaining the same traffic engineering constraints.
- RSVP equal-cost multipath (ECMP) inherits the standard benefits of ECMP by absorbing traffic surges.
- Multipath traffic engineering allows for better and complete usage of network resources.
- Knowing the relationship among LSPs helps in computing diverse paths with constraint-based routing. It allows adjustment of member LSPs while other member LSPs continue to carry traffic.
- The intermediate routers have an opportunity to merge the labels of member LSPs. This reduces the number of labels that need to get added to the forwarding plane and in turn reduces the convergence time.

If the number of independent ECMP paths is huge, label merging overcomes the platform limitations on maximum (ECMP) next hops. With point-to-point RSVP LSPs that require link or node protection, the next hops are doubled as each LSP is programmed with both primary and backup next hops. RSVP multipath (or ECMP) obviates the need for backup next hops.

- When there is a link failure, the router upstream to the link failure can distribute traffic from the failed link to the remaining ECMP branches, obviating the need for bypass LSPs. The bypass LSP approach not only requires more state when signaling backup LSPs, but also suffers from scaling issues that result in merge-point timing out a protected path state block (PSB) before point of local repair (PLR) gets a chance to signal the backup LSP.

## Junos OS RSVP Multipath Implementation

In order to deploy RSVP multipath (ECMP) in a network, all the nodes through which ECMP LSPs pass must understand RSVP ECMP protocol extensions. This can be a challenge, especially in a multivendor networks.

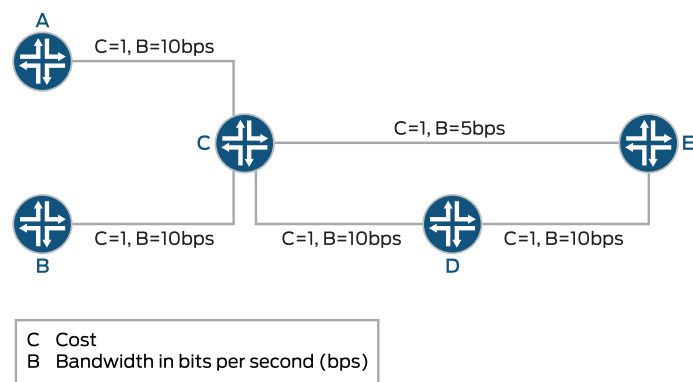

Junos OS implements the RSVP multipath extensions without the need for protocol extensions. A single container LSP, which has the characteristics of ECMP and RSVP TE, is provisioned. A container LSP consists of several member LSPs and is set up between the ingress and egress routing device. Each member LSP takes a different path to the same destination. The ingress routing device is configured with all the required parameters to compute the RSVP ECMP LSP. The parameters configured to compute a set of RSVP point-to-point LSPs can be used by the ingress routing device to compute the container LSP as well.

## Current Traffic Engineering Challenges

The main challenge for traffic engineering is to cope with the dynamics of both topology and traffic demands. Mechanisms are needed that can handle traffic load dynamics in scenarios with sudden changes in traffic demand and dynamically distribute traffic to benefit from available resources.

Figure 151 illustrates a sample network topology with all the LSPs having the same hold and setup priorities, and admission control restricted on the ingress router. All the links are annotated with a tuple (cost and capacity).

Figure 151: Sample Topology

Some of the traffic engineering problems seen in [Figure 151](#) are listed here:

- **Bin Packing**

This problem arises because of a particular order in which LSPs are signaled. The ingress routers might not be able to signal some LSPs with required demands although bandwidth is available in the network, leading to under-utilization of link capacity.

For example, the following LSPs arrive in the sequence mentioned in [Table 417](#).

**Table 417: LSP Sequence Order for Bin Packing**

| Time | Source | Destination | Demand | ERO     |
|------|--------|-------------|--------|---------|
| 1    | A      | E           | 5      | A-C-D-E |
| 2    | B      | E           | 10     | No ERO  |

The LSP originating at Router B is not routable as constraint-based routing fails to find a feasible path. However, if Router B is signaled first, both the LSPs are routable. Bin packing happens because of lack of visibility of individual per-LSP, per-device bandwidth demands at the ingress routing device.

Bin packing can also happen when there is no requirement for ordering of LSPs. For example, if there is an LSP with demand X and there are two different paths to the destination from the ingress router with available bandwidths Y1 and Y2, such that Y1 is less than X, Y2 is less than X, and Y1 plus Y2 is greater than or equal to X.

In this case, even though there are enough network resources in terms of available bandwidth to satisfy the aggregate LSP demand X, the LSP might not be signaled or re-optimized with the new demand. In [Figure 151](#), with container LSP support, the ingress B creates two LSPs each of size 5 when demand 10 is posed. One LSP is routed along B-C-E and another one along B-C-D-E.

- **Deadlock**

Considering [Figure 151](#), the LSPs follow the sequence mentioned in [Table 418](#).

**Table 418: LSP Sequence Order for Deadlock**

| Time | Source | Destination | Demand  | ERO     | Event                                             |
|------|--------|-------------|---------|---------|---------------------------------------------------|
| 1    | A      | E           | 2       | A-C-D-E | Constraint-based routing with RSVP signaling      |
| 2    | B      | E           | 2       | B-C-D-E | Constraint-based routing with RSVP signaling      |
| 3    | A      | E           | 2 to 20 | A-C-D-E | Constraint-based routing fails, no RSVP signaling |

At time 3, the demand on LSP from A to E increases from 2 to 20. If autobandwidth is configured, the change does not get detected until the adjustment timer expires. In the absence of admission control at A, the increased traffic demand might cause traffic to drop on other LSPs that share common links with the mis-behaving LSP.

This happens due to the following reasons:

- Lack of global state at all the ingress routers
- Signaling of mis-behaving demands
- Tearing down of mis-behaving demands

With container LSP configured, ingress A has more chances of splitting the load (even incrementally if not fully) across multiple LSPs. So, LSP from A is less likely to see prolonged traffic loss.

- **Latency Inflation**

Latency inflation is caused by the autobandwidth and other LSPs parameters. Some of the other factors that contribute to latency inflation include:

- LSP priority

LSPs choose longer paths because shorter paths between data centers located in the same city can be congested. The bandwidth on the shorter paths can get exhausted by equal or higher priority LSPs. Due to periodic LSP optimization by autobandwidth, LSP can get rerouted to a higher delay path. When many LSPs undergo less than optimal path selection, they can potentially form a chain of dependencies. Modifying the LSP priorities dynamically is a workaround to the issue; however, dynamically adjusting LSP priorities to find shorter paths is a challenging task.

- All or Nothing policy

When the demand on an LSP increases and at least one of the links along the shorter path is close to its reservation limit, LSP optimization can force the LSP to move to a longer latency path. LSP has to traverse a long path even though the short path is capable of carrying most of the traffic.

- Minimum and maximum bandwidth

Minimum and maximum bandwidth specify the boundaries for LSP sizes. If minimum bandwidth is small, an LSP is more prone to autobandwidth adjustment because a small change in bandwidth is enough to cross the threshold limits. LSPs might reroute although bandwidth is available. On the other hand, if the minimum bandwidth is large, network bandwidth might be wasted. If the maximum bandwidth value is small, a large number of LSPs might be needed at the ingress router to accommodate the application demand. If the maximum bandwidth is large, the LSPs can grow larger in size. Such LSPs can suffer because of an all or nothing policy.

- Autobandwidth adjustment threshold

Bandwidth threshold dictates if LSPs need to be re-optimized and resized. If the value is small, LSPs are frequently re-optimized and rerouted. That might cause CPU spike because applications or protocols, such as BGP resolving over the LSPs, might keep the Routing Engine busy doing next-hop resolution. A large value might make an LSP immobile. With container LSP configured, an LSP is less likely to get subjected

to one or no policy. An ingress router originates multiple LSPs, although not all LSPs potentially traverse high latency paths.

- **Predictability**

Service providers often want predictable behavior in terms of how LSPs get signaled and routed. Currently, without any global coordination, it is difficult to set up the same set of LSPs in a predictable way. Consider the two different orderings in [Table 419](#) and [Table 420](#). The ERO that an LSP uses depends on its signaling time.

**Table 419: LSP Sequence Order for Predictability**

| Time | Source | Destination | Demand | ERO     |
|------|--------|-------------|--------|---------|
| 1    | A      | E           | 5      | A-C-D-E |
| 2    | B      | E           | 5      | B-C-E   |

**Table 420: LSP Sequence Order for Predictability**

| Time | Source | Destination | Demand | ERO     |
|------|--------|-------------|--------|---------|
| 1    | B      | E           | 5      | B-C-E   |
| 2    | A      | E           | 5      | A-C-D-E |

Container LSP does not directly help LSPs find predictable EROs. If LSPs are getting rerouted because of an all or no policy without container LSP configured, such LSPs might see less churn if container LSPs are configured, because smaller LSPs have better chances of finding a shorter or same path.

## Using Container LSP as a Solution

A container LSP can be used as a solution to the challenges faced by the current traffic engineering features. Considering [Figure 151](#), when the demand X on a container LSP increases with the network capacity (max-flow) being more than the demand, the following approaches come into effect with a container LSP:

- [Accommodating the New Demand X on page 5277](#)
- [Creating New LSPs to Meet Demand X on page 5278](#)
- [Assigning Bandwidth to the New LSPs on page 5278](#)
- [Controlling the LSP Paths on page 5278](#)

### Accommodating the New Demand X

In the current implementation, autobandwidth attempts to re-signal an LSP with the new demand X and follows the all or nothing policy as mentioned earlier.

The container LSP approach computes several small (smaller than demand X) bandwidth LSPs such that the aggregate bandwidth is not less than X, and the ingress router performs this adjustment periodically. One of the triggers to create new LSPs or to delete old LSPs

can be changed in aggregate bandwidth. The ingress router then load-balances the incoming traffic across the newly created LSPs.

### Creating New LSPs to Meet Demand X

---

Although the number of new LSPs created can be a maximum of the allowed configurable limit, there is not much benefit from these LSPs once the number of LSPs exceeds the number of possible diverse paths or equal-cost multipaths (ECMPs). The benefit of creating the smaller LSPs is seen when an ingress router uses the newly created LSPs for load-balancing traffic. This, however, depends on the network topology and state.

Creating multiple parallel LSPs by all the ingress routers in the network can lead to scaling issues at the transit routers. Thus, the number of new LSPs to be created depends on the size of the individual LSPs and the given aggregate demand, X in this case.

### Assigning Bandwidth to the New LSPs

---

In general, there can be a number of heuristics to allocate bandwidths to the newly created LSPs. An ingress router can solve an optimization problem in which it can maximize a given utility function. The output of an optimization problem is assigning optimal bandwidth values. However, to solve an optimization problem, the number of newly created LSPs has to be fixed. Therefore, it is complex to optimize the number and size of each LSP. Thus, to simplify the problem, the same amount of bandwidth is assumed for all the newly created LSPs, and then the number of required LSPs is computed.

### Controlling the LSP Paths

---

The flexibility to control the LSP paths is expressed in terms of the configuration for point-to-point LSPs and container LSPs. Controlling the LSP paths using the configuration parameters can be applied under two different aspects:

- **Topology**—There are no topology constraints with this feature. Each member LSP is treated like a point-to-point LSP and is re-optimized individually. An ingress router does not try to compute equal IGP cost paths for all its LSPs, but instead it computes paths for all the LSPs using current traffic engineering database information. While computing a path, constraint-based routing adheres to any constraints specified through the configuration, although there is no change in the constraint-based routing method for path computation.
- **When to create a new LSP**—When to create a new LSP can be explicitly specified. By default, an ingress router periodically computes the aggregate traffic rate by adding up the traffic rate of all the individual LSPs. Looking at the aggregate bandwidth and configuration, the ingress router recomputes the number of LSPs and the bandwidths of the LSPs. The new LSPs are then signaled or the existing LSPs are re-signaled with the updated bandwidth. Instead of looking at the instantaneous aggregate rate, the ingress routers can compute an average (of aggregates) over some duration by removing outlier samples (of aggregates). Managing the LSPs that remain outstanding and active by considering aggregate bandwidth is more scalable than creating the new LSPs based on the usage of a particular LSP. The intervals and thresholds can be configured to track the aggregate traffic and trigger adjustment. These dynamic LSPs co-exist and interoperate with per-LSP autobandwidth configuration.

## Junos OS Container LSP Implementation

A container LSP is an ECMP TE LSP that acts like a container LSP consisting of one or more member LSPs. A point-to-point TE LSP is equivalent to a container LSP with a single member LSP. Member LSPs are added to the container LSP through a process called splitting, and removed from the container LSP through a process called merging.

- [Container LSP Terminology on page 5279](#)
- [LSP Splitting on page 5280](#)
- [LSP Merging on page 5282](#)
- [Node and Link Protection on page 5284](#)
- [Naming Convention on page 5284](#)
- [Normalization on page 5285](#)
- [Constraint-Based Routing Path Computation on page 5290](#)
- [Sampling on page 5291](#)
- [Support for NSR, IPG-FA, and Static Routes on page 5291](#)

### Container LSP Terminology

The following terms are defined in the context of a container LSP:

- **Normalization**—An event occurring periodically when an action is taken to adjust the member LSPs, either to adjust their bandwidths, their number, or both. A normalization process is associated with a sampling process and periodically estimates aggregate utilization of a container LSP.
- **Nominal LSP**—The instance of a container LSP that is always present.
- **Supplementary LSP**—The instances or sub-LSPs of a container LSP, which are dynamically created or removed.

Autobandwidth is run over each of the member LSPs, and each LSP is resized according to the traffic it carries and the autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by adding up the bandwidth across all the member LSPs.

- **Minimum signaling-bandwidth**—The minimum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the minimum-bandwidth defined under autobandwidth.
- **Maximum signaling-bandwidth**—The maximum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the maximum-bandwidth defined under autobandwidth.
- **Merging-bandwidth**—Specifies the lower bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage falls below this value, the ingress router merges the member LSPs at the time of normalization.
- **Splitting-bandwidth**—Specifies the upper bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage exceeds this value, the ingress router splits the member LSPs at the time of normalization.

- **Aggregate minimum-bandwidth**—Sum of merging-bandwidth of the current active member LSPs. This minimum bandwidth is different from the autobandwidth minimum-bandwidth.
- **Aggregate maximum-bandwidth**—Sum of the splitting-bandwidth of the current active member LSPs. This maximum bandwidth is different from the autobandwidth maximum-bandwidth.

---

## LSP Splitting

- [Operational Overview on page 5280](#)
- [Operational Constraints on page 5281](#)
- [Supported Criteria on page 5281](#)
- [Splitting Triggers on page 5282](#)

### *Operational Overview*

The LSP splitting mechanism enables an ingress router to create new member LSPs or to re-signal existing LSPs with different bandwidths within a container LSP when a demand X is placed on the container LSP. With LSP splitting enabled, an ingress router periodically creates a number of LSPs (by signaling new ones or re-signaling existing ones) to accommodate a new aggregate demand X. In the current implementation, an ingress router tries to find an LSP path satisfying a demand X and other constraints. If no path is found, either the LSP is not signaled or it remains up, but with the old reserved bandwidth.

Between two normalization events (splitting or merging), individual LSPs might get re-sigaled with different bandwidths due to the autobandwidth adjustments. If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. There is no dynamic splitting in this case, as there is no dynamic estimation of aggregate bandwidth. The splitting adjustments with a specific bandwidth value can be manually triggered.

#### NOTE:

Be aware of the following considerations for LSP splitting:

- After LSP splitting, the ingress router continues to inject one forwarding adjacency. Forwarding adjacencies are not supported in IGP for this feature.
  - Between two normalization events, two LSPs might have different bandwidths subjected to autobandwidth constraints.
  - After LSPs are split (or merged), make-before-break uses the fixed filter (FF) style sharing unless the adaptive option is configured. However, two different LSPs do not do the shared explicit (SE) style sharing for this feature.
  - When LSPs are re-sigaled with modified bandwidths, some of the LSPs might not get signaled successfully, leading to failover options.
-

### ***Operational Constraints***

LSP splitting has the following operational constraints:

- LSP bandwidth—Although there are a number of ways to allocate bandwidth values to the LSPs, the Junos OS implementation supports only an equal-bandwidth allocation policy when normalization is done, wherein all the member LSPs are signaled or re-signaled with equal bandwidth.
- Number of LSPs—If an ingress router is configured to have a minimum number of LSPs, it maintains the minimum number of LSPs even if the demand can be satisfied with less than the minimum number of LSPs. In case the ingress router is unable to do constraint-based routing for computations on the sufficient number of LSPs or signal sufficient number of LSPs, the ingress router resorts to a number of fallback options.

By default, an incremental approach is supported as a fallback option (unless configured differently), where an ingress router makes attempts to bring up the sufficient number of LSPs, such that the new aggregate bandwidth exceeds the old aggregate bandwidth (and is as close to the desired demand as possible). The ingress router then load-balances traffic using the LSPs. The LSPs that could not be brought up are removed by the ingress router.

### ***Supported Criteria***

When a container LSP signals a member LSP, the member LSP gets signaled with minimum-signaling-bandwidth. Since each member LSP is configured with autobandwidth, between two normalization events, each LSP can undergo autobandwidth adjustment multiple times. As the traffic demand increases, the ingress router creates additional supplementary LSPs. All member LSPs are used for ECMP, so they should roughly have the same reserved bandwidth after normalization.

For example, if there are K LSPs signaled after normalization, each LSP is signaled with equal bandwidth B. The total aggregate bandwidth reserved is B.K, where B satisfies the following condition:

- Minimum signaling-bandwidth is less than or equal to B, which in turn is less than or equal to the maximum signaling-bandwidth  
(minimum-signaling-bandwidth  $\leq$  B  $\leq$  maximum-signaling-bandwidth)

Until the next normalization event, each member LSP undergoes several autobandwidth adjustments. After any autobandwidth adjustment, if there are N LSPs with reserved bandwidths  $b_i$ , where  $i=1,2,\dots, N$ , each  $b_i$  should satisfy the following condition:

- Minimum bandwidth is less than or equal to  $b_i$ , which in turn is less than or equal to the maximum bandwidth  
(minimum-bandwidth  $\leq b_i \leq$  maximum-bandwidth)

Both the above-mentioned conditions are applicable for per member LSP (nominal and supplementary), and essentially have the reserved bandwidth to exist within a range.

### ***Splitting Triggers***

Every time the normalization timer expires, the ingress router decides if LSP splitting is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

Taking for example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP splitting are as follows:

- Absolute trigger—LSP splitting is performed when **New-Aggr-Bw** is greater than **Aggregate-maximum-bandwidth**.

(**New-Aggr-Bw** > **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP splitting is performed when the difference in the bandwidth amount is off by a threshold.

$([1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw})$ , where  $0 \leq a \leq 1$

When **New-Aggr-Bw** is greater than or equal to  $[1+a]$  multiplied by **Current-Aggr-Bw**, the ingress routing device does not perform normalization, but instead LSP splitting is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

---

### ***LSP Merging***

- [Operational Overview on page 5282](#)
- [Operational Constraints on page 5283](#)
- [Merging Triggers on page 5283](#)

#### ***Operational Overview***

Junos OS supports two kinds of LSPs – CLI-configured LSPs and dynamically created LSPs. The CLI-configured LSPs are created manually and remain in the system until the configuration is modified. The dynamic LSPs are created dynamically by next generation MVPN, BGP virtual private LAN service (VPLS), or LDP, based on a template configuration, and are removed from the system when not used by any application for a certain duration. LSP merging follows a similar approach as dynamic LSPs.

LSP merging enables an ingress routing device to dynamically eliminate some member LSPs of the container LSP so less state information is maintained in the network. If an ingress router provisions several member LSPs between the ingress and egress routers, and there is an overall reduction in aggregate bandwidth (resulting in some LSPs being under-utilized), the ingress router distributes the new traffic load among fewer LSPs.

Although there are a number of ways to merge the member LSPs, Junos OS supports only overall-merge when normalization is being performed. An ingress router considers the aggregate demand and the minimum (or maximum) number of LSPs and revises the number of LSPs that should be active at an ingress routing device. As a result, the following can take place periodically as the normalization timer fires:

- Re-signaling some of the existing LSPs with updated bandwidth
- Creating new LSPs
- Removing some of the existing LSPs

### ***Operational Constraints***

If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. LSP merging does not happen because there is no dynamic estimation of aggregate bandwidth. However, a manual trigger for splitting and adjusting with a specific bandwidth value can be configured.

#### **NOTE:**

- Nominal LSPs are never deleted as part of LSP merging.
- Before deleting an LSP, the LSP is made inactive, so that traffic shifts to other LSPs before removing the LSP. This is because RSVP sends PathTear before deleting routes and next hops from the Packet Forwarding Engine.
- When member LSPs are re-signaled with modified bandwidth, it might happen that some LSPs do not get signaled successfully.

### ***Merging Triggers***

Every time the normalization timer expires, the ingress router decides if LSP merging is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

For example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP merging are as follows:

- Absolute trigger—LSP merging is performed when **New-Aggr-Bw** is less than **Aggregate-minimum-bandwidth**.

(**New-Aggr-Bw** < **Aggregate-maximum-bandwidth**)

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP merging is performed when the difference in the bandwidth amount is off by a threshold.

$$([1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw}, \text{ where } 0 \leq a \leq 1)$$

When the **New-Aggr-Bw** value is less than or equal to  $[1+a]$  multiplied by the **Current-Aggr-Bw** value, the ingress routing device does not perform normalization, but instead LSP merging is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

### Node and Link Protection

---

Junos OS supports the following mechanisms for node and link protection:

- Fast-reroute
- Link protection
- Node-link protection

Only one of the above-mentioned modes of protection can be configured on an ingress routing device at any given time. All member LSPs (nominal and supplementary) use the same mode of protection that is configured.

### Naming Convention

---

While configuring a container LSP, a name is assigned to the LSP. The name of a nominal and a supplementary LSP is formed by adding the configured-name suffix and an auto-generated suffix to the name of the container LSP. The name of the container LSP is unique and is checked for accuracy during the configuration parsing. The container LSP name should uniquely identify parameters, such as the ingress and egress router names.

**NOTE:** A container LSP member LSP and a point-to-point LSP on an ingress routing device cannot have the same LSP name.

The container LSPs follow a number-based LSP naming convention. For example, if the nominal LSP's configured name is **bob** and the number of member LSPs is  $N$ , the member LSPs are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-N***.

After a normalization event, the number of member LSPs can change. For example, if the number of member LSPs increases from six to eight, then the ingress routing device keeps the first six LSPs named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***. The two additional LSPs are named **bob-7** and **bob-8**. The original LSPs might need to be re-optimized if their signaled bandwidth changes.

Similarly, if the number of member LSPs reduces from eight to six, the ingress routing device re-signals the member LSPs in such a way that the remaining active LSPs in the system are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***.

In the process of creating new LSPs, an RSVP LSP named **bob-*<configured-suffix>-7*** can be configured.

## Normalization

- [Operational Overview on page 5285](#)
- [Operational Constraints on page 5285](#)
- [Inter-Operation with Autobandwidth on page 5286](#)

### Operational Overview

Normalization is an event that happens periodically. When it happens, a decision is made on the number of member LSPs that should remain active and their respective bandwidths in a container LSP. More specifically, the decision is made on whether new supplementary LSPs are to be created, or any existing LSPs are required to be re-signaled or deleted during the normalization event.

Between two normalization events, a member LSP can undergo several autobandwidth adjustments. A normalization timer, similar to re-optimization timer, is configured. The normalization timer interval should be no less than the adjustment interval or optimization timer.

**NOTE:** Normalization is not triggered based on network events, such as topology changes.

### Operational Constraints

Normalization has the following operational constraints:

- Normalization happens only when none of the member LSPs are undergoing re-optimization or make-before-break. Normalization starts when all the member LSPs complete their ongoing make-before-break. If normalization is pending, new optimization should not be attempted until the normalization is complete.
- After normalization, an ingress routing device first computes a set of bandwidth-feasible paths using constraint-based routing computations. If enough constraint-based routing computed paths are not brought up with an aggregate bandwidth value that exceeds the desired bandwidth, several failover actions are taken.
- After a set of bandwidth-feasible paths are available, the ingress routing device signals those paths while keeping the original set of paths up with the old bandwidth values. The make-before-break is done with shared explicit (SE) sharing style, and when some of the LSPs do not get successfully re-signaled, a bounded number of retries is attempted for a specified duration. Only when all the LSPs are successfully signaled does the ingress router switch from the old instance of the container LSP to the newer instance. If all LSPs could not be successfully signaled, the ingress router keeps those instances of members that are up with higher bandwidth values.

For example, if the bandwidth of an old instance of a member LSP (LSP-1) is 1G, the LSP is split into LSP-1 with bandwidth 2G and LSP-2 with bandwidth 2G. If the signaling of LSP-1 with bandwidth 2G fails, the ingress router keeps LSP-1 with bandwidth 1G and LSP-2 with bandwidth 2G.

When there is a signaling failure, the ingress routing device stays in the error state, where some LSPs have updated bandwidth values only if the aggregate bandwidth has increased. The ingress router makes an attempt to bring up those LSPs that could not be successfully signaled, resulting in minimum traffic loss.

- If an LSP goes down between two normalization events, it can increase the load on other LSPs that are up. In order to prevent overuse of other LSPs, premature normalization can be configured in case of LSP failure. LSPs can go down because of pre-emption or lack of node or link protection. It might not be necessary to bring up the LSPs that are down because the normalization process re-runs the constraint-based routing path computations.

### ***Inter-Operation with Autobandwidth***

Taking as an example, there is one nominal LSP named LSP-1 configured with the following parameters:

- Splitting-bandwidth and maximum-signaling-bandwidth of 1G
- Merging-bandwidth and minimum-signaling-bandwidth of 0.8G
- Autobandwidth

Normalization is performed differently in the following scenarios:

- [Changes in Per-LSP Autobandwidth Adjustments on page 5286](#)
- [Changes in Traffic Growth on page 5288](#)
- [Computed Range and Configured Feasible Ranges on page 5288](#)

### ***Changes in Per-LSP Autobandwidth Adjustments***

[Table 421](#) illustrates how normalization splits and merges member LSPs as autobandwidth adjustments change per-LSP bandwidth with unconditional normalization.

**Table 421: Normalization with Per-LSP Autobandwidth Adjustment Changes**

| Normalization Time | Current State                                                               | Events                                                                                                                                                                                                                     | Adjusted State                           |
|--------------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| T0                 | No state.                                                                   | Initialization                                                                                                                                                                                                             | LSP-1 is signaled with bandwidth of 0.8G |
| T1                 | LSP-1 usage increases to 1.5G                                               | <ul style="list-style-type: none"> <li>• Multiple autobandwidth adjustments since T0 is possible.</li> <li>• The ingress router decides to split LSP-1 into two LSPs, and creates LSP-2.</li> </ul>                        | LSP-1 = 0.8G<br>LSP-2 = 0.8G             |
| T2                 | LSP-1 usage increase to 2G<br>LSP-2 usage increases to 0.9G (within limits) | <ul style="list-style-type: none"> <li>• Aggregate bandwidth is 2.9G, which exceeds aggregate splitting maximum of 2G.</li> <li>• The ingress router decides to split LSP-1 into three LSPs, and creates LSP-3.</li> </ul> | LSP-1 = 1G<br>LSP-2 = 1G<br>LSP-3 = 1G   |

Table 421: Normalization with Per-LSP Autobandwidth Adjustment Changes (*continued*)

| Normalization Time | Current State                 | Events                                                                                                                                                                                                        | Adjusted State                                       |
|--------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| T3                 | LSP-3 usage increases to 1.5G | <ul style="list-style-type: none"> <li>Aggregate bandwidth is 3.5G with a maximum aggregate splitting of 3G.</li> <li>The ingress router decides to split LSP-1 into four LSPs, and creates LSP-4.</li> </ul> | LSP-1 = 1G<br>LSP-2 = 1G<br>LSP-3 = 1G<br>LSP-4 = 1G |
| T4                 | LSP-2 usage drops to 0.5G     | <ul style="list-style-type: none"> <li>Aggregate bandwidth is 3G.</li> <li>The ingress router decides to merge LSP-1 and removes LSP-4.</li> </ul>                                                            | LSP-1 = 1G<br>LSP-2 = 1G<br>LSP-3 = 1G               |

Because autobandwidth is configured on a per-LSP basis, every time there is an autobandwidth adjustment, the ingress router re-signals each LSP with **Max Avg Bw**.

Another approach to handling the changes in per-LSP autobandwidth adjustments is to not allow individual LSPs to run autobandwidth on the ingress router, but to run autobandwidth in passive (monitor) mode. This way, sampling is done at every statistics interval for member LSPs only, and normalization is performed for the container LSP alone instead of acting on individual LSPs adjustment timer expiry.

As a result, the number of re-signaling attempts and bandwidth fluctuations for a given member LSP is reduced. Only the computed bandwidth-values per-member LSP is used by the ingress router to find an aggregate bandwidth to be used during normalization. Configuring autobandwidth adjustment followed by normalization (adjustments and normalization intervals are comparable) can lead to considerable overhead because of re-signaling.

Taking the same example, and applying the second approach, LSP-1 goes from 0.8G to 1.5G and then back to 0.8G. If the normalization timer is of the same order as the adjustment interval, the ingress router leaves LSP-1 alone with its original 0.8G and only signals LSP-2 with 0.8G. This helps achieve the final result of normalization, thus avoiding the extra signaling attempt on LSP-1 with 1.5G at adjustment timer expiry.

Because member LSPs always use equal bandwidth, any adjustment done on member LSPs is undone. The member LSPs are re-signaled with reduced bandwidth when compared to the reserved capacity in adjustment trigger with normalization trigger. Therefore, avoiding adjustment trigger for member LSPs might be useful assuming that normalization and adjustment intervals are of the same order.

**NOTE:** We recommend that the normalization timer be higher than the autobandwidth adjustment interval and regular optimization duration, as the traffic trends are observed at a longer time scale and normalization is performed one-to-three times per day. An LSP can undergo optimization for the following reasons:

- Normal optimization
- Autobandwidth adjustment
- Normalization

### *Changes in Traffic Growth*

Table 422 illustrates how normalization is performed when traffic grows in large factor.

**Table 422: Normalization with Traffic Growth**

| Normalization Time | Current State              | Events                                                                                                                                                                                                | Adjusted State                           |
|--------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| T0                 | No state                   |                                                                                                                                                                                                       | LSP-1 is signaled with bandwidth of 0.8G |
| T1                 | LSP-1 usage increase to 3G | <ul style="list-style-type: none"> <li>• Aggregate usage exceeds maximum splitting bandwidth</li> <li>• The ingress router decides to split LSP-1, and creates two more supplementary LSPs</li> </ul> | LSP-1 = 1G<br>LSP-2 = 1G<br>LSP-3 = 1G   |

Having fewer LSPs is preferred over signaling four LSPs each with 0.8G bandwidth, unless there is a constraint on the minimum number of LSPs.

### *Computed Range and Configured Feasible Ranges*

When an ingress router is configured with the minimum and maximum number of LSPs, and per LSP splitting-bandwidth and merging-bandwidth values, the bandwidth thresholds are used for splitting and merging. For this, the number of LSPs (N) should satisfy the following constraints:

$$\text{minimum-member-lsps} \leq N \leq \text{maximum-member-lsps}$$

At the time of normalization, based on the aggregate demand X:

$$\lceil X/\text{splitting-bandwidth} \rceil \leq N \leq \lfloor X/\text{merging-bandwidth} \rfloor$$

The above-mentioned constraints provide two ranges for N to work from. If the two ranges for N are overlapping, N will be selected from the overlapping interval (lowest possible N) to keep the number of LSPs small in the network.

Otherwise, if maximum-member-lsps is less than  $\lceil X/\text{splitting-bandwidth} \rceil$ , the ingress router keeps (at maximum) the maximum-member-lsps in the system, and the bandwidth of each LSP is  $\lceil X/\text{maximum-member-lsps} \rceil$  or the maximum-signaling-bandwidth, whichever is less. It is possible that some LSPs might not get signaled successfully.

Similarly, if minimum-member-lsps is greater than  $[X/\text{merging-bandwidth}]$ , the ingress router keeps (at minimum) the minimum-member-lsps in the system, and the bandwidth of each LSP is  $[X/\text{minimum-member-lsps}]$  or the minimum-signaling-bandwidth, whichever is less.

Taking as an example, normalization is performed as following in these cases:

- Case 1
  - minimum-member-lsps = 2
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 1G
  - splitting-bandwidth = 2.5G

In this case, the ingress routing device signals four member LSPs each with a bandwidth of 2G.

- Case 2
  - minimum-member-lsps = 5
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 2.5G
  - splitting-bandwidth = 10G

In this case, the ingress routing device signals five member LSPs each with a bandwidth of 2G. Here, the static configuration on the number of member LSPs takes precedence.

- Case 3
  - minimum-signaling-bandwidth = 5G
  - maximum-signaling-bandwidth = 40G
  - merging-bandwidth = 10G
  - splitting-bandwidth = 50G

When a container LSP comes up, the nominal LSP is signaled with minimum-signaling-bandwidth. At the time of normalization, the new-aggregate-bandwidth is 100G. To find N and the bandwidth of each LSP, N should satisfy the following constraint:

$$100/50 \leq N \leq 100/10, \text{ which gives } 2 \leq N \leq 10$$

Therefore, N is equal to:

- N = 2, bandwidth =  $\min \{100/2G, 40G\} = 40G$

This option does not satisfy the new aggregate of 100G.

- N = 3, bandwidth =  $\min \{100/3G, 40G\} = 33.3G$

This option makes the aggregate bandwidth equal to 100G.

In this case, the ingress routing device signals three LSPs each with a bandwidth of 33.3G.

**NOTE:** The ingress router does not signal an LSP smaller than the minimum-signaling-bandwidth.

---

### Constraint-Based Routing Path Computation

---

Although there are no changes in the general constraint-based routing path computation, with a container LSP, there is a separate module that oversees the normalization process, schedules constraint-based routing events, and schedules switchover from an old instance to a new instance, when appropriate. An ingress routing device has to handle the constraint-based routing path computation periodically. When normalization occurs, an ingress router has to compute constraint-based routing paths, if the number of LSPs or the bandwidth of the LSPs needs to be changed.

For example, there are K LSPs at the ingress router with bandwidth values X-1, X-2, ..., and X-K. The current aggregate bandwidth value is Y, which is the sum of X-1 plus X-2 plus X-K. If there is a new demand of W, the ingress router first computes how many LSPs are required. If the ingress router only needs N LSPs (LSP-1, LSP-2, ..., and LSP-N) each with bandwidth value B, the task of the constraint-based routing module is to provide a set of bandwidth-feasible LSPs that can accommodate the new aggregate demand which is not less than Y.

The ingress router then tries to see if the constraint-based routing paths can be computed successfully for all N LSPs. If the paths for all the LSPs are found successfully, the constraint-based routing module returns the set to the normalization module.

It is possible that the constraint-based routing computation is not successful for some LSPs. In this case, the ingress routing device takes the following action:

- If the configuration allows for incremental-normalization, implying if the ingress router has enough LSPs whose aggregate exceeds Y, the constraint-based routing module returns that set of paths.
- Whether increment-normalization is configured or not, if constraint-based routing paths could not be computed for a sufficient number of LSPs, the ingress router has to repeat the process of finding a new set of LSPs. Initially, the ingress router starts with the lowest value of N from the feasible region. Every time, the ingress router has to revise the number, it linearly increases it by 1. As a result, per LSP bandwidth becomes less and therefore, there is a greater chance of successful signaling. The process is repeated for all feasible values of N (or some bounded number of times or duration as configured).

The ingress router signals the LSPs after successful computations of the constraint-based routing path computation. It might happen that when the LSPs are signaled, signaling of many LSPs fail. In addition to the constraint-based routing path

computations to be successful, the RSVP signaling should also succeed, such that the new aggregate is not less than the old aggregate bandwidth.

### Sampling

Sampling is important for normalization to function. With sampling configured, an ingress routing device is able to make a statistical estimate of the aggregate traffic demands. Every time the sampling timer fires, the ingress routing device can consider traffic rates on different LSPs and compute an aggregate bandwidth sample. This sampling timer is different from the statistics sampling done periodically by RSVP on all LSPs. The aggregate bandwidth is a sample to be used at the time of normalization. An ingress routing device can save past samples to compute an average (or some other statistical measure) and use it the next time normalization happens.

To remove any outlier samples, a sampling token is configured. In other words, from all the aggregate samples collected during the configured time, the bottom and top outliers are ignored before computing a statistical measure from the remaining samples.

The following two methods of computing an aggregate bandwidth value are supported:

- **Average**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The average bandwidth value is computed from the remaining samples to be used during normalization.
- **Max**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The maximum bandwidth value is picked from the remaining samples to be used during normalization.

The time duration, the number of past aggregate samples to store, the percentile value to determine, and the ignore outliers are user-configurable parameters.

### Support for NSR, IPG-FA, and Static Routes

Starting with Junos OS Release 15.1, container label-switched paths (LSPs) provide support for nonstop active routing (NSR), IGP forwarding adjacency (FA), and static routes to address the requirements of wider business cases.

- [NSR Support on page 5291](#)
- [IPG-FA Support on page 5293](#)
- [Static Route Support on page 5294](#)

#### **NSR Support**

A container LSP has the characteristics of ECMP and RSVP traffic engineering. Because a container LSP consists of several member LSPs between an ingress and an egress router, with each member LSP taking a different path to the same destination, the ingress router is configured with all the parameters necessary to compute an RSVP ECMP LSP. These parameters along with the forwarding state information have to be synchronized between the master and backup Routing Engines to enable the support for nonstop active routing (NSR) for container LSPs. While some of the forwarding state information on the backup Routing Engine is locally built based on the configuration, most of it is built

based on periodic updates from the master Routing Engine. The container LSPs are created dynamically using the replicated states on the backup Routing Engine.

By default, normalization occurs once in every 6 hours and during this time, a number of autobandwidth adjustments happen over each member LSP. A member LSP is resized according to the traffic it carries and the configured autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by summing up the bandwidth across all the member LSPs.

For RSVP point-to-point LSPs, a Routing Engine switchover can be under any one of the following:

- **Steady state**

In the steady state, the LSP state is up and forwards traffic; however, no other event, such as the make-before-break (MBB), occurs on the LSP. At this stage, the RPD runs on both the Routing Engines, and the switchover event toggles between the master and backup Routing Engine. The backup Routing Engine has the LSP information replicated already. After the switchover, the new master uses the information of the replicated structure to construct the container LSP and en-queues the path (ERO) of LSP in the retrace mode. RSVP signals and checks if the path mentioned in the ERO is reachable. If the RSVP checks fail, then the LSP is restarted. If the RSVP checks succeed, the LSP state remains up.

- **Action leading to make-before-break (MBB)**

A container LSP can be optimized with updated bandwidth, and this change is done in a MBB fashion. During an MBB process, there are two path instances for a given LSP, and the LSP switches from one instance to another. For every Routing Engine switchover, the path is checked to find out where in the MBB process the path is. If the path is in the middle of the MBB process, with the main instance being down and the re-optimized path being up, then MBB can switch over to the new instance. The **show mpls lsp extensive** command output, in this case, is as follows:

```
13 Dec 3 01:33:38.941 Make-before-break: Switched to new instance
12 Dec 3 01:33:37.943 Record Route: 10.1.1.1
11 Dec 3 01:33:37.942 Up
10 Dec 3 01:33:37.942 Automatic Autobw adjustment succeeded: BW changes
from 100 bps to 281669 bps

```

A similar behavior is retained for member LSPs during bandwidth optimization.

A Routing Engine switchover under the steady state (when normalization is not in progress), keeps the container LSPs up and running without any traffic loss. Events, such as an MBB due to autobandwidth adjustments, link status being down, or double failure, in the steady state are similar to a normal RSVP point-to-point LSP.

If the container LSP is in the process of normalization, and the normalization event is triggered either manually or periodically, it goes through the computation and execution phase. In either of the cases, zero percent traffic loss is not guaranteed.

- Normalization in the computation phase

During the computation phase, the master Routing Engine calculates the targeted member LSP count and bandwidth with which each member LSP should be re-signaled. The backup Routing Engine has limited information about the container LSP, such as the LSP name, LSP ID, current bandwidth of its member LSP, member LSP count, and the normalization retry count. If the switchover happens during the computation phase, then the backup Routing Engine is not aware of the targeted member LSP count and the bandwidth to be signaled. Since traffic statistics are not copied to the backup Routing Engine, it cannot compute the targeted member count and bandwidth. In this case, the new master Routing Engine uses the old data stored in the targeted member LSP count and the targeted bandwidth to signal the LSPs.

- Normalization in the execution phase

During the execution phase, RSVP of the master Routing Engine tries to signal the LSPs with the newly calculated bandwidth. If the switchover occurs during the signaling of LSPs with greater bandwidth or during LSP splitting or merging, then the new master Routing Engine uses the information of the targeted member count and bandwidth value to be signaled with, to bring up the LSPs.

### ***IPG-FA Support***

A forwarding adjacency (FA) is a traffic engineering label-switched path (LSP) that is configured between two nodes and used by an interior gateway protocol (IGP) to forward traffic. By default, an IGP does not consider MPLS traffic-engineering tunnels between sites, for traffic forwarding. Forwarding adjacency treats a traffic engineering LSP tunnel as a link in an IGP topology, thus allowing the nodes in the network also to forward the IP traffic to reach the destination over this FA LSP. A forwarding adjacency can be created between routing devices regardless of their location in the network.

To advertise a container LSP as an IGP-FA, the LSP name needs to be configured either under IS-IS or OSPF. For example:

```
IS-IS [edit]
 protocols {
 isis {
 label-switched-path container-lsp-name;
 }
 }

OSPF [edit]
 protocols {
 ospf {
 area 0.0.0.0 {
 label-switched-path container-lsp-name;
 }
 }
 }
```

**NOTE:** The IGP-FA is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for FA.

### Static Route Support

Static routes often include only one or very few paths to a destination and generally do not change. These routes are used for stitching services when policies and other protocols are not configured.

To advertise a container LSP as a static route, the LSP name needs to be configured under the static route configuration. For example:

```
Static Route [edit]
 routing-options {
 static {
 route destination {
 lsp-next-hop container-lsp-name;
 }
 }
 }
```

**NOTE:** The static route support is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for static routing.

## Configuration Statements Supported for Container LSPs

Table 423 lists the MPLS LSP configuration statements that apply to RSVP LSP and a container LSP (nominal and supplementary).

The configuration support is defined using the following terms:

- Yes—The configuration statement is supported for this type of LSP.
- No—The configuration statement is not supported for this type of LSP.
- N/A—The configuration statement is not applicable for this type of LSP.

**Table 423: Applicability of RSVP LSPs Configuration to a Container LSP**

| Configuration Statement             | RSVP LSP (Ingress) | Member LSP (Ingress) |
|-------------------------------------|--------------------|----------------------|
| adaptive<br>(Default: non-adaptive) | Yes                | Yes                  |
| admin-down                          | Yes                | Yes                  |
| admin-group                         | Yes                | Yes                  |

Table 423: Applicability of RSVP LSPs Configuration to a Container LSP (*continued*)

| Configuration Statement                                      | RSVP LSP (Ingress) | Member LSP (Ingress) |
|--------------------------------------------------------------|--------------------|----------------------|
| admin-groups-except                                          | Yes                | Yes                  |
| apply-groups                                                 | Yes                | Yes                  |
| apply-groups-except                                          | Yes                | Yes                  |
| associate-backup-pe-groups                                   | Yes                | No                   |
| associate-lsp<br>(No bidirectional support)                  | Yes                | No                   |
| auto-bandwidth                                               | Yes                | Yes                  |
| backup                                                       | Yes                | No                   |
| bandwidth                                                    | Yes                | Yes                  |
| class-of-service                                             | Yes                | Yes                  |
| corouted-bidirectional<br>(No bidirectional support)         | Yes                | No                   |
| corouted-bidirectional-passive<br>(No bidirectional support) | Yes                | No                   |
| description                                                  | Yes                | Yes                  |

## Impact of Configuring Container LSPs on Network Performance

A container LSP is a container LSP that allows multiple member LSPs to co-exist and be managed as a bundle. The member LSPs are similar to independent point-to-point RSVP LSPs. As a result, resource consumption is similar to the sum of resources consumed by each point-to-point RSVP LSP. However, provisioning a container LSP is more efficient, as under-utilized member LSPs are dynamically removed, thus saving memory and CPU resources.

The container LSP features are dependent on the presence of a functional base MPLS RSVP implementation. As a result, a container LSP does not introduce any security considerations beyond the existing considerations for the base MPLS RSVP functionality. The categories of possible attacks and countermeasures are as follows:

- Interaction with processes and router configuration

No new communication mechanisms with external hosts are required for a container LSP. Data arrives at the RSVP module through local software processes and router configuration, other than RSVP neighbor adjacency. Junos OS provides security controls on access to the router and router configuration.

- Communication with external RSVP neighbors

RSVP signaled MPLS LSPs depend on the services of RSVP and IGP to communicate RSVP messages among neighboring routers across the network. Because the RSVP sessions involve communication outside of the local router, they are subject to many forms of attack, such as spoofing of peers, injection of falsified RSVP messages and route updates, and attacks on the underlying TCP/UDP transport for sessions. Junos OS provides countermeasures for such attack vectors.

- Resource limits and denial of service

Junos OS provides several mechanisms through policers and filters to protect against denial-of-service attacks based on injecting higher than the expected traffic demands. At the MPLS LSP level, Junos OS allows operators to configure limits on the LSP bandwidth and the number of LSPs. However, like point-to-point RSVP LSPs, container LSPs do not enforce limits on the volume of traffic forwarded over these LSPs.

## Supported and Unsupported Features

Junos OS supports the following container LSP features:

- Equal-bandwidth-based LSP splitting mechanism
- Aggregate-bandwidth-based LSP splitting and merging in a make-before-break way

- LSP-number-based naming mechanism for dynamically created member LSPs
- Periodic sampling mechanisms to estimate aggregate bandwidth
- Interoperability with auto-bandwidth feature
- ECMP using the dynamically created LSPs
- LDP-tunneling on the dynamically created LSP
- Configuring container LSP using IGP shortcuts
- Aggregated Ethernet links
- Logical systems

Junos OS does **not** support the following container LSP functionality:

- Node and link disjoint paths for different LSPs between an ingress and an egress routing device
- Bandwidth allocation policy different from equal bandwidth policy at the normalization event
- Constraint-based routing path computation to find equal IGP cost paths for different LSPs
- RSVP objects, such as **MLSP\_TUNNEL Sender Template**, and **MLSP\_TUNNEL Filter Specification** defined in [KOMPELLA-MLSP]
- Change in topology as a trigger for LSP splitting and merging
- Change in topology and link failure as a trigger for normalization, unless member LSPs go down
- Egress protection on container LSP
- Container LSP as a backup LSP for IGP interface
- Container LSP configured as IGP interface as forwarding address
- Container LSP as provider tunnel for multicast VPNs
- Dynamic LSPs for normalization
- CCC using container LSP
- Secondary paths for container LSP
- Bidirectional container LSP
- Policing
- Static routes using container LSPs as next hops on a best-effort basis
- External path computing entity, such as PCE
- Graceful Routing Engine switchover
- Nonstop active routing
- Unified ISSU

- Multichassis
- IPv6

## **[edit protocols rsvp] Hierarchy Level**

This topic lists the supported configuration statements at the **[edit protocols rsvp]** hierarchy level on the QFX Series. For more information about these statements, see the *Junos OS MPLS Applications Library for Routing Devices*.

```
protocols {
 rsvp {
 disable;
 fast-reroute

## admin-group

**Syntax**

```
admin-group {
 exclude [group-names];
 include-all [group-names];
 include-any [group-names];
}
```

**Hierarchy Level**

[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection],  
[edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *bypass-name*],  
[edit protocols rsvp interface *interface-name* link-protection],  
[edit protocols rsvp interface *interface-name* link-protection bypass *bypass-name*]

**Release Information** Statement introduced in Junos OS Release 9.2.

**Description** Enable you to configure administrative groups for bypass label-switched paths (LSPs). You can configure administrative groups either globally for all bypass LSPs traversing an interface or for just a specific bypass LSP.

**Options**

**exclude *group-names***—Specify the administrative groups to exclude for a bypass LSP.

**include-all *group-names***—Specify the administrative groups whose links the bypass LSP must traverse.

**include-any *group-names***—Specify the administrative groups whose links the bypass LSP can traverse.

**Required Privilege Level**

routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>For certain logical interfaces (such as Asynchronous Transfer Mode [ATM], Permanent Virtual Circuit [PVC], or Frame Relay), you cannot determine the correct bandwidth from the hardware. This statement enables you to specify the actual available bandwidth.</p> <p>This statement also enables you to specify the bandwidth for a bypass label switched path (LSP). If you have configured multiple bypasses, this statement is mandatory and is applied to all of the bypass LSPs.</p>                                                                                                                                |
| <b>Default</b>                  | The hardware raw bandwidth is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <p><b><i>bps</i></b>—Bandwidth in bits per second. You can specify this as an integer value. If you do so, count your zeros carefully, or you can use the abbreviations <b>k</b> (for a thousand), <b>m</b> (for a million), or <b>g</b> (for a billion [also called a thousand million]).</p> <p><b>Range:</b> Any positive integer</p> <p><b>Default:</b> 0 (no bandwidth is reserved)</p>                                                                                                                                                                                                                                  |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Release Information      | Statement introduced before Junos OS Release 7.4.<br>The <b>description</b> option was added in Junos OS Release 10.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description              | <p>Enables you to configure specific bandwidth and path constraints for a bypass LSP. It is possible to individually configure multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.</p> <p>If you specify the <b>bandwidth</b>, <b>hop-limit</b>, and <b>path</b> statements for the bypass LSP, these values take precedence over the values configured at the [edit protocols rsvp interface <i>interface-name</i> link-protection] hierarchy level. The other attributes (<b>subscription</b>, <b>no-node-protection</b>, and <b>optimize-timer</b>) are inherited from the general constraints.</p>                                                                                                                                                                                                                                                                                                           |
| Options                  | <p><b>bypass-name</b>—(Required) Specify a name for the bypass LSP. The name can be up to 64 characters.</p> <p><b>description</b>—Provides a textual description of the bypass LSP. Enclose any descriptive text that includes spaces in quotation marks (" "). Any descriptive text you include is displayed in the output of the <b>show mpls lsp bypass detail</b> command and has no effect on the operation of the bypass LSP. The description text can be no more than 80 characters in length.</p> <p><b>to address</b>—(Required) Specify the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.</p> <p>The remaining statements are explained separately.</p> |
| Required Privilege Level | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | Disable helper mode for graceful restart. When helper mode is disabled, a router or switch cannot help a neighboring router that is attempting to restart.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>                  | Helper mode is enabled by default for these supported protocols: IS-IS, LDP, OSPF/OSPFv3, and RSVP.                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | <p>Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:</p> <ul style="list-style-type: none"> <li>• LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.</li> <li>• Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.</li> <li>• Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>                  | <p><b><i>number</i></b>—Maximum number of hops.</p> <p><b>Range:</b> 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)</p> <p><b>Default:</b> 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Description         | Enable link protection on the specified interface. Using link protection, you can configure a network to reroute traffic quickly around broken links. To fully enable link protection, you also need to configure the <b>link-protection</b> statement at the [edit protocols mpls label-switched-path <i>lsp-name</i> ] hierarchy level. You can configure single or multiple bypasses for protected interface.                                                                                                                                                                                                                                                                                                                                         |
| Default             | Link protection is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Options** **no-node-protection**—Disable node-link protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Specify the maximum number of dynamic bypass LSPs permitted for protecting this interface. When this option is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled. The limit on bypasses configured applies only to dynamically generated bypass LSPs. By default, this option is disabled and only one dynamic bypass LSP is enabled for each interface. If you configure <b>max-bypasses</b> , you must also configure the <b>bandwidth</b> statement. |
| <b>Options</b>                  | <b>number</b> —Configure the maximum number of bypass LSPs. If you configure a value of 0, no dynamic bypass LSPs are allowed to be established for the interface. Only static bypass LSPs can be configured.<br><b>Range:</b> 0 through 99<br><b>Default:</b> 1                                                                                                                                                                                                                                                  |

| <b>Description</b>              | Allows you to explicitly disable RSVP interface hellos globally on the router. This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the <a href="#">hello-interval (Protocols RSVP)</a> statement. This configuration disables RSVP interface hellos globally but enables RSVP interface hellos on the specified interface. This configuration might be necessary in a heterogeneous network where some devices support RSVP node ID hellos and other devices support RSVP interface hellos. |

| <b>Description</b>              | <p>Disables RSVP local revertive mode as specified in RFC 4090, <i>Fast Reroute Extensions to RSVP-TE for LSP Tunnels</i>. RSVP local revertive mode is supported on all Juniper Networks routers running the Junos OS. It is the default behavior. If you include this statement, the Juniper Networks router uses global revertive mode instead. You might need to disable RSVP local revertive mode on Juniper Networks routers if your network includes equipment that does not support this mode.</p> <p>The following information can also be found in RFC 4090. Refer to the full RFC for additional information. When an LSP fails, the connection can be repaired locally using a traffic protection mechanism such as fast reroute. To restore the LSP to a full working path, RFC 4090 specifies the following strategies:</p> <ul style="list-style-type: none"><li>• Local revertive mode—Upon detecting that the path is restored, the point of local repair (PLR) resignals each of the LSPs that were formerly routed over the restored path. Every LSP successfully resingaled along the restored path is switched back.</li><li>• Global revertive mode—The ingress router of each tunnel is responsible for reoptimizing the LSPs that used the failed path. There are several potential reoptimization triggers: RSVP error messages, inspection of OSPF LSAs or IS-IS LSPs, and timers. This re-optimization process can proceed as soon as the failure is detected. It is not tied to the restoration of the failed path.</li></ul> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.2.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | Reject Resv messages that include the S2L_SUB_LSP object. By default, Resv messages that include the S2L_SUB_LSP object are accepted. However, in a network which includes Juniper Networks devices running both Junos OS Release 9.2 and later and Junos OS Release 9.1 and earlier, it is necessary to configure the <b>no-p2mp-sublsp</b> statement on devices running Junos OS Release 9.2 and later to ensure that point-to-multipoint LSPs function properly. |
| <b>Default</b>                  | Resv messages that include the S2L_SUB_LSP object are accepted.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                 |

| <b>Release Information</b>      | Statement introduced in JUNOS Release 10.0.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | Enables node-ID based RSVP hellos globally on all of the RSVP interfaces on the router to allow Juniper Networks routers to interoperate with the equipment of other vendors. By default, the JUNOS Software uses interface-based RSVP hellos and node-ID based RSVP hellos are disabled. If you have not enabled RSVP node IDs on the router, the JUNOS software does not accept any node-ID hello packets. |

| <b>Description</b>              | Configure an optimize timer for a bypass LSP. The optimize timer initiates a periodic optimization process that reshuffles data LSPs among bypass LSPs to achieve the most efficient use of network resources. The optimization process attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all bypasses, or both. |
| <b>Options</b>                  | <b><i>seconds</i></b> —Specify the number of seconds between optimizations.<br><b>Range:</b> 0 through 65,535 seconds<br><b>Default:</b> 0 (disabled)                                                                                                                                                                                                                                   |

| <b>Description</b>              | Configure an explicit path (a sequence of strict or loose routes) to control where and how a bypass LSP is established. If multiple bypasses are configured, they all will use the same explicit path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>                  | No path is configured. CSPF automatically calculates the path the bypass LSP takes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>                  | <p><b>address</b>—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is <b>loose</b>. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.</p> <p><b>Default:</b> If you do not specify any routers explicitly, no routing limitations are imposed on the bypass LSP.</p> <p><b>loose</b>—(Optional) The next address in the <b>path</b> statement is loose. The LSP can traverse other routers before reaching this router.</p> <p><b>Default:</b> <b>strict</b></p> <p><b>strict</b>—(Optional) The LSP must go to the next address specified in the <b>path</b> statement without traversing other nodes. This is the default.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | Configure the setup priority and reservation priority for a bypass LSP. If insufficient link bandwidth is available during session establishment, the setup priority is compared with other setup priorities for established sessions on the link to determine whether some of them should be preempted to accommodate the new session. The session with the lower-hold priority is preempted.                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <p><b>reservation-priority</b>—Reservation priority, used to keep a reservation after it has been set up. A smaller number has a higher priority. The priority must be greater than or equal to the setup priority to prevent preemption loops.</p> <p><b>Range:</b> 0 through 7, where 0 is the highest and 7 is the lowest priority.</p> <p><b>Default:</b> 0 (Once the session is set up, no other session can preempt it.)</p> <p><b>setup-priority</b>—Setup priority.</p> <p><b>Range:</b> 0 through 7, where 0 is the highest and 7 is the lowest priority.</p> <p><b>Default:</b> 7 (The session cannot preempt any existing sessions.)</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b>              | The facility-backup fast reroute mechanism can provide setup protection for LSPs which are in the process of being signaled. Both point-to-point LSPs and point-to-multipoint LSPs are supported. You should configure the <b>setup-protection</b> statement on each of the routers along the LSP path on which you want to enable LSP setup protection. You should also configure IGP traffic engineering on all of the routers on the LSP path. |

| Description         | Perform splitting and merging.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Options             | <p><b>maximum-member-lsps <i>number</i></b>—Number of label-switched paths (LSPs) that a container LSP can have as member LSPs at maximum.<br/><b>Default:</b> 1</p> <p><b>maximum-signaling-bandwidth <i>bandwidth</i></b>—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at maximum after normalization. When <b>maximum-signaling-bandwidth</b> is not configured, the value is derived from the <b>splitting-bandwidth</b>.<br/>When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the <b>splitting-bandwidth</b>.<br/><b>Default:</b> 1 bps</p> <p><b>merging-bandwidth <i>bandwidth</i></b>—Amount of bandwidth in bits per second (bps) that is used for merging during normalization.<br/><b>Default:</b> 1 bps</p> <p><b>minimum-member-lsps <i>number</i></b>—Number of LSPd that a container LSP can have as member LSPs at minimum.<br/><b>Default:</b> 64</p> <p><b>minimum-signaling-bandwidth <i>bandwidth</i></b>—Amount of bandwidth in bits per second (bps) that can be signaled for an LSP at minimum after normalization. When <b>minimum-signaling-bandwidth</b> is not configured, the value is derived from the <b>merging-bandwidth</b>.<br/>When auto-bandwidth adjustment is done between two normalization events, per LSP auto-bandwidth configuration and thresholds are used instead of the <b>merging-bandwidth</b>.<br/><b>Default:</b> 1 bps</p> |

**splitting-bandwidth *bandwidth***—Amount of bandwidth in bits per second (bps) that can be used for splitting during normalization.

**Default:** 1 bps

**splitting-merging-threshold *percent***—Percentage changes in aggregate bandwidth relevant for splitting and merging.

**Default:** 0%

The remaining statements are explained separately.

| <b>Description</b>         | Enable RSVP-level trace options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>             | The default RSVP-level trace options are those inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>filename</b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place RSVP tracing output in the file <b>rsvp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 2 files</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <ul style="list-style-type: none"><li>• <b>all</b>—All tracing operations</li><li>• <b>error</b>—All detected error conditions</li><li>• <b>event</b>—RSVP-related events</li><li>• <b>lmp</b>—RSVP-LMP interactions</li><li>• <b>packets</b>—All RSVP packets</li><li>• <b>path</b>—All path messages</li><li>• <b>pathtear</b>—PathTear messages</li></ul> |

- **resv**—Resv messages
- **resvtear**—ResvTear messages
- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-world-readable**—(Optional) Enable only certain users to read the log file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

**world-readable**—(Optional) Enable any user to read the log file.

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>Required Privilege</b> | routing and trace—To view this statement in the configuration.                |
| <b>Level</b>              | routing-control and trace-control—To add this statement to the configuration. |

## Monitoring Commands for RSVP

---

- `clear mpls container-lsp`
- `clear rsvp session`
- `clear rsvp statistics`
- `ping mpls rsvp`
- `request mpls container-lsp`
- `clear mpls container-lsp`
- `show rsvp interface`
- `show rsvp neighbor`
- `show rsvp session`
- `show rsvp statistics`
- `show rsvp version`
- `traceroute mpls rsvp`

## clear mpls container-lsp

| <b>Description</b>              | Release the routes and states associated with MPLS container label-switched paths (LSPs), and start new LSPs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>none</b>—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.</p> <p><b>autobandwidth</b>—(Optional) Clear LSP autobandwidth counters.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>name <i>name</i></b>—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the <i>Junos Network Interfaces Configuration Guide</i>.</p> <p><b>optimize   optimize-aggressive</b>—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.</p> <p><b>statistics</b>—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (<b>name</b> and <b>path</b> options) on transit routers.</p> |
| <b>Required Privilege Level</b> | clear                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>                         | Reset and restart Resource Reservation Protocol (RSVP) sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>                             | <p><b>none</b>—Reset and restart all RSVP sessions for which this routing device is the ingress, transit, or egress routing device.</p> <p><b>connection-source address</b>—(Optional) Source address for GMPLS and MPLS LSPs from the RSVP sender template.</p> <p><b>connection-destination address</b>—(Optional) Destination address for GMPLS and MPLS LSPs from the RSVP sender template.</p> <p><b>gracefully</b>—(Optional) Gracefully reset an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin-Status object is signaled along the path to the other endpoint of the RSVP session. In the second pass, the path used by the RSVP session is torn down. This option can only be used on the ingress or egress routing device of the RSVP session and is only valid for nonpacket LSPs.</p> <p><b>logical-system (all   logical-system-name)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>lsp-id identifier</b>—(Optional) LSP identifier (source port) for the RSVP sender template.</p> <p><b>name name</b>—(Optional) Reset and restart the specified RSVP session.</p> <p><b>optimize-fast-reroute</b>—(Optional) Begin fast reroute optimization.</p> |

**tunnel-id** *identifier*—(Optional) Tunnel identifier (destination port) for the RSVP session.

**Required Privilege Level** clear

**Release Information** Command introduced before Junos OS Release 7.4.  
 The **egress** and **multipoint** options were introduced in Junos OS Release 9.2.  
 The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
 The **dynamic-bypass** and **manual-bypass** options were introduced in Junos OS Release 10.2.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Check the operability of MPLS RSVP-signaled label-switched path (LSP) connections. Type Ctrl+c to interrupt a **ping mpls** command.

**Options** **count count**—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination address**—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**NOTE:** When using the **detail** option, the reported time is based on the system time configured on the local and remote routers. Differences in these system times can result in inaccurate one way ping trip times being reported.

In practice, it is difficult to synchronize the system times of independent Juniper Networks routers with sufficient accuracy to provide a meaningful time value for the **detail** option (even when synchronized using NTP).

**dynamic-bypass**—(Optional) Ping dynamically generated bypass LSPs, used for protecting other LSPs.

**egress *egress-address***—(Optional) Only the specified egress router or switch responds to the ping request.

**exp *forwarding-class***—(Optional) Value of the forwarding class for the MPLS ping packets.

**interface**—(Optional) Specify the name of the interface protected by the manual bypass LSP. This option is only available when you have also used the **manual-bypass** option.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on the specified logical system.

***lsp-name***—Ping an RSVP-signaled LSP using an LSP name.

**manual-bypass**—(Optional) Ping manually configured bypass LSPs, used for protecting other LSPs. For this option, you must also specify the interface protected by the manual bypass LSP using the **interface** option.

**multipoint**—(Optional) Send ping requests to each of the egress routers or switches participating in a point-to-multipoint LSP. You can also include the **egress** option to ping a specific egress router or switch participating in a point-to-multipoint LSP.

**size *bytes***—(Optional) Size of the LSP ping request packet (100 through 65468 bytes). Packets are 4-byte aligned. For example, if you enter a size of 101, 102, 103, or 104, the router or switch uses a size value of 104 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 100-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface.

**standby *standby-path-name***—(Optional) Name of the standby path.

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls rsvp \(Echo Reply Received\) on page 5349](#)  
[ping mpls rsvp \(Echo Reply with Error Code\) on page 5349](#)

[ping mpls rsvp detail on page 5349](#)

[ping mpls rsvp multipoint egress detail count on page 5349](#)

[ping mpls rsvp multipoint detail count on page 5349](#)

[ping mpls rsvp destination detail count size on page 5350](#)

[ping mpls rsvp destination detail sweep size on page 5350](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with an error code are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls rsvp (Echo Reply Received)

```
user@host> ping mpls rsvp test1
!!!!!--- lsping statistics ---5 packets transmitted, 5 packets received, 0% packet
loss
```

### ping mpls rsvp (Echo Reply with Error Code)

```
user@host> ping mpls rsvp test2
!!xxx--- lsping statistics ---5 packets transmitted, 2 packets received, 60%
packet loss3 packets received with error status, not counted as received.
```

### ping mpls rsvp detail

```
user@host> ping mpls rsvp to-green detail
Request for seq 1, to interface 67, labels <100095, 0, 0>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 67, labels <100095, 0, 0>
Reply for seq 2, return code: Egress-ok
```

### ping mpls rsvp multipoint egress detail count

```
user@host>ping mpls rsvp sample-lsp multipoint egress 192.168.1.3 detail count 1
Request for seq 1, to interface 70, label 299952
Request for seq 1, to interface 70, no label stack.
Request for seq 1, to interface 67, no label stack.

Reply for seq 1, egress 192.168.1.3, return code: Egress-ok, time: 0.242 ms

## Sample Output

### request mpls container-lsp

```
user@host> request mpls container-lsp lsp-name normalize
```

### request mpls container-lsp

```
user@host> request mpls container-lsp normalize bandwidth bps
```

## clear mpls container-lsp

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b>              | Release the routes and states associated with MPLS container label-switched paths (LSPs), and start new LSPs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>none</b>—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.</p> <p><b>autobandwidth</b>—(Optional) Clear LSP autobandwidth counters.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>name <i>name</i></b>—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the <i>Junos Network Interfaces Configuration Guide</i>.</p> <p><b>optimize   optimize-aggressive</b>—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.</p> <p><b>statistics</b>—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (<b>name</b> and <b>path</b> options) on transit routers.</p> |
| <b>Required Privilege Level</b> | clear                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Output Fields</b>               | Table 424 lists the output fields for the <b>show rsvp interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 424: show rsvp interface Output Fields

| Field Name                    | Field Description                                                                                                                                                                                                                                                                                                    | Level of Output  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>RSVP interface</b>         | Number of interfaces on which RSVP is active. Each interface has one line of output.                                                                                                                                                                                                                                 | All levels       |
| <b>Interface</b>              | Name of the interface.                                                                                                                                                                                                                                                                                               | All levels       |
| <b>Index</b>                  | Index of the interface.                                                                                                                                                                                                                                                                                              | <b>detail</b>    |
| <b>State</b>                  | State of the interface. <ul style="list-style-type: none"> <li>• <b>Disabled</b>—No traffic engineering information is displayed.</li> <li>• <b>Down</b>—Interface is not operational.</li> <li>• <b>Enabled</b>—Displays traffic engineering information.</li> <li>• <b>Up</b>—Interface is operational.</li> </ul> | All levels       |
| <b>NoAuthentication</b>       | Interface does not support RSVP authentication.                                                                                                                                                                                                                                                                      | <b>detail</b>    |
| <b>NoAggregate</b>            | Interface does not support refresh reduction.                                                                                                                                                                                                                                                                        | <b>detail</b>    |
| <b>NoReliable</b>             | Interface does not support refresh reduction message ID extension.                                                                                                                                                                                                                                                   | <b>detail</b>    |
| <b>NoLinkProtection</b>       | Interface does not support link protection.                                                                                                                                                                                                                                                                          | <b>detail</b>    |
| <b>HelloInterval</b>          | Frequency at which RSVP hellos are sent on this interface (in seconds).                                                                                                                                                                                                                                              | <b>detail</b>    |
| <b>Address</b>                | IP address of the local interface.                                                                                                                                                                                                                                                                                   | <b>detail</b>    |
| <b>Active control channel</b> | Next-hop link address to transmit messages.                                                                                                                                                                                                                                                                          | None specified   |
| <b>TELink</b>                 | Traffic-engineered links that are managed by the peer they are associated with.                                                                                                                                                                                                                                      | None specified   |
| <b>Active resv</b>            | Number of reservations that are actively reserving bandwidth on the interface.                                                                                                                                                                                                                                       | All levels       |
| <b>PreemptionCnt</b>          | Number of times an RSVP session was preempted on this interface.                                                                                                                                                                                                                                                     | <b>detail</b>    |
| <b>Update threshold</b>       | Percentage change in reserved bandwidth to trigger an IGP update.                                                                                                                                                                                                                                                    | <b>detail</b>    |
| <b>Subscription</b>           | User-configured subscription factor.                                                                                                                                                                                                                                                                                 | All levels       |
| <b>bc number</b>              | Bandwidth allocated for the specified bandwidth constraint.                                                                                                                                                                                                                                                          | <b>extensive</b> |
| <b>ct number</b>              | Bandwidth allocated for the specified class type.                                                                                                                                                                                                                                                                    | <b>extensive</b> |
| <b>Static BW</b>              | Total interface bandwidth, in bps.                                                                                                                                                                                                                                                                                   | All levels       |
| <b>Available BW</b>           | Amount of bandwidth that RSVP is allowed to reserve, in bps. It is equal to (static bandwidth * subscription factor).                                                                                                                                                                                                | al levels        |

Table 424: show rsvp interface Output Fields (*continued*)

| Field Name                     | Field Description                                                                                                                                               | Level of Output |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Reserved BW</b>             | Currently reserved bandwidth, in bps.                                                                                                                           | All levels      |
| <b>SoftPreemptionCnt</b>       | Number of times a soft preemption occurred on this interface. This number is not included in the <b>PreemptionCnt</b> value.                                    | detail          |
| <b>Overbooked BW</b>           | Currently overbooked bandwidth, in bps, by class type (ct0 through ct3).                                                                                        | detail          |
| <b>Highwater mark</b>          | Highest bandwidth that has ever been reserved on this interface, in bps.                                                                                        | brief           |
| <b>PacketType</b>              | Type of RSVP packet.                                                                                                                                            | detail          |
| <b>Total Sent</b>              | Total number of packets sent.                                                                                                                                   | detail          |
| <b>Total Received</b>          | Total number of packets received since RSVP was enabled.                                                                                                        | detail          |
| <b>Last 5 seconds Sent</b>     | Number of packets sent in the last 5 seconds.                                                                                                                   | detail          |
| <b>Last 5 seconds Received</b> | Number of packets received in the last 5 seconds.                                                                                                               | detail          |
| <b>Path</b>                    | Statistics about Path messages, which are sent from the RSVP sender along the data paths and store path state information in each node along the path.          | detail          |
| <b>PathErr</b>                 | Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.                                                            | detail          |
| <b>PathTear</b>                | Statistics about PathTear messages, which remove path states and dependent reservation states in any routers along a path.                                      | detail          |
| <b>Resv</b>                    | Statistics about Resv messages, which are sent from the RSVP receiver along the data paths and store reservation state information in each node along the path. | detail          |
| <b>ResvErr</b>                 | Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.                                  | detail          |
| <b>ResvTear</b>                | Statistics about ResvTear messages, which remove reservation states along a path.                                                                               | detail          |
| <b>Hello</b>                   | Number of RSVP hello packets that have been sent to and received from the neighbor.                                                                             | detail          |
| <b>Ack</b>                     | Acknowledge message for refresh reductions.                                                                                                                     | detail          |
| <b>Srefresh</b>                | Summary refresh messages.                                                                                                                                       | detail          |
| <b>EndtoEnd RSVP</b>           | Statistics for the number of end-to-end RSVP messages sent.                                                                                                     | detail          |
| <b>Queue</b>                   | CoS transmit queue number and its associated forwarding class designation.                                                                                      | extensive       |

Table 424: show rsvp interface Output Fields (*continued*)

| Field Name                  | Field Description                                                                                                                                 | Level of Output  |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>TxRate</b>               | Configured bandwidth in Mbps and configured bandwidth as a percentage of the specified queue.                                                     | <b>extensive</b> |
| <b>Priority</b>             | Weight of the queue relative to other configured queues, in percentage.                                                                           | <b>extensive</b> |
| <i>queue-priority-value</i> | <b>Low, High, None, or Exact.</b> <b>None</b> indicates no rate limiting. <b>Exact</b> indicates the queue transmits at the configured rate only. | <b>extensive</b> |

| <b>Output Fields</b>               | Table 425 lists the output fields for the <b>show rsvp neighbor</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 425: show rsvp neighbor Output Fields**

| Field Name           | Field Description                                                                                                                                                    | Level of Output |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>RSVP neighbor</b> | Number of neighbors that the routing device has learned of. Each neighbor has one line of output.                                                                    | All levels      |
| <b>via</b>           | Name of the interface where the neighbor has been detected. In the case of generalized MPLS (GMPLS) LSPs, the name of the peer where the neighbor has been detected. | <b>detail</b>   |
| <b>Address</b>       | Address of a learned neighbor.                                                                                                                                       | All levels      |

Table 425: show rsvp neighbor Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Level of Output |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Idle</b>                | Length of time the neighbor has been idle, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | All levels      |
| <b>Up/Dn</b>               | Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | All levels      |
| <b>Up cnt and Down cnt</b> | Number of neighbor up or down transitions detected by RSVP hello packets. If the up count is 1 greater than the down count, the neighbor is currently up. Otherwise, the neighbor is down. Neighbors that do not support RSVP hello packets, such as routers running Junos OS Release 3.2 or earlier, are not reported as up or down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>detail</b>   |
| <b>status</b>              | State of the RSVP neighbor: <ul style="list-style-type: none"> <li>• <b>Up</b>—Routing device can detect RSVP Hello messages from the neighbor.</li> <li>• <b>Down</b>—Routing device has received one of the following indications:               <ul style="list-style-type: none"> <li>• Communication failure from the neighbor.</li> <li>• Communication from IGP that the neighbor is unavailable.</li> <li>• Change in the sequence numbers in the RSVP Hello messages sent by the neighbor.</li> </ul> </li> <li>• <b>Restarting</b>—RSVP neighbor is unavailable and might be restarting. The neighbor remains in this state until it has restarted or is declared dead. This state is possible only when graceful restart is enabled.</li> <li>• <b>Restarted</b>—RSVP neighbor has restarted and is undergoing state recovery (graceful restart) procedures.</li> <li>• <b>Dead</b>—Routing device has lost all communication with the RSVP neighbor. Any RSVP sessions with that neighbor are torn down.</li> </ul> | <b>detail</b>   |
| <b>LastChange</b>          | Time elapsed since the neighbor state changed either from up to down or from down to up. The format is <b>hh:mm:ss</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | All levels      |
| <b>Last changed time</b>   | Time elapsed since the neighbor state changed either from up to down or from down to up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <b>detail</b>   |

| <b>Remote Instance</b>     | Identification provided by the remote routing device during Hello message exchange.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <b>detail</b>   |

Table 425: show rsvp neighbor Output Fields (*continued*)

| Field Name               | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Local Instance</b>    | Identification sent to the remote routing device during Hello message exchange.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>   |
| <b>Refresh reduction</b> | <p>Measure of processing overhead requests of refresh messages. Refresh reduction extensions improve routing device performance by reducing the process overhead, thus increasing the number of LSPs a routing device can support. <b>Refresh reduction</b> can have the following values:</p> <ul style="list-style-type: none"> <li>• <b>operational</b>—All four RSVP refresh reduction extensions—message ack, bundling, summary refresh, and staged refresh timer—are functional between the two neighboring routing devices. For a detailed explanation of these extensions, see RFC 2961.</li> <li>• <b>incomplete</b>—Some RSVP refresh reduction extensions are functional between the two neighboring routing devices.</li> <li>• <b>no operational</b>—Either the refresh reduction feature has been turned off, or the remote routing device cannot support the refresh reduction extensions.</li> </ul> | <b>detail</b>   |
| <b>Remote end</b>        | <p>Neighboring routing device's status with regard to refresh reduction:</p> <ul style="list-style-type: none"> <li>• <b>enabled</b>—Remote routing device has requested refresh reduction during RSVP message exchanges.</li> <li>• <b>disabled</b>—Remote routing device does not require refresh reduction.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <b>detail</b>   |
| <b>Ack-extension</b>     | <p>An RSVP refresh reduction extension:</p> <ul style="list-style-type: none"> <li>• <b>enabled</b>—Both local and remote routing devices support the ack-extension (RFC 2961).</li> <li>• <b>disabled</b>—Remote routing device does not support the ack-extension.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>   |
| <b>Link protection</b>   | <p>Status of the MPLS fast reroute mechanism that protects traffic from link failure:</p> <ul style="list-style-type: none"> <li>• <b>enabled</b>—Link protection feature has been turned on, protecting the neighbor with a bypass LSP.</li> <li>• <b>disabled</b>—No link protection feature has been enabled for this neighbor.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <b>detail</b>   |
| <b>LSP name</b>          | Name of the bypass LSP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>detail</b>   |
| <b>Bypass LSP</b>        | <p>Status of the bypass LSP. It can have the following values:</p> <ul style="list-style-type: none"> <li>• <b>does not exist</b>—Bypass LSP is not available.</li> <li>• <b>connecting</b>—Routing device is in the process of establishing a bypass LSP, and the LSP is not available for link protection at the moment.</li> <li>• <b>operational</b>—Bypass LSP is up and running.</li> <li>• <b>down</b>—Bypass LSP has gone down, with the most probable cause a node or a link failure on the bypass path.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b>   |
| <b>Backup routes</b>     | Number of user LSPs (or routes) that are being protected by a bypass LSP (before link failure).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>   |
| <b>Backup LSPs</b>       | Number of LSPs that have been temporarily established to maintain traffic by refreshing the downstream LSPs during link failure (not a one-to-one correspondence).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>detail</b>   |

Table 425: show rsvp neighbor Output Fields (*continued*)

| Field Name                   | Field Description                                                                                                                                                                                                                                                                                                              | Level of Output |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Bypass explicit route</b> | Explicit route object's (ERO) path that is taken by the bypass LSP.                                                                                                                                                                                                                                                            | <b>detail</b>   |
| <b>Restart time</b>          | Length of time a neighbor waits to receive a Hello from the restarting node before declaring the node dead and deleting the states (in milliseconds).                                                                                                                                                                          | <b>detail</b>   |
| <b>Recovery time</b>         | Length of time during which the restarting node attempts to recover its lost states with help from its neighbors (in milliseconds). Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed. | <b>detail</b>   |

| <b>Options</b>                             | <p><b>none</b>—Display standard information about all RSVP sessions.</p> <p><b>brief   detail   extensive   terse</b>—(Optional) Display the specified level of output.</p> <p><b>bidirectional   unidirectional</b>—(Optional) Display information about bidirectional or unidirectional RSVP sessions only, respectively.</p> <p><b>bypass</b>—(Optional) Display RSVP sessions for bypass LSPs.</p> <p><b>down   up</b>—(Optional) Display only LSPs that are inactive or active, respectively.</p> |

**externally-provisioned**—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

**instance *instance-name***—(Optional) Display RSVP sessions for the specified instance. If *instance-name* is omitted, RSVP session information is displayed for the master instance.

**interface *interface-name***—(Optional) Display RSVP sessions for the specified interface only.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

***lsp-type***—(Optional) Display information about RSVP sessions with regard to LSPs:

- **bypass**—Sessions used for bypass LSPs.
- **lsp**—Sessions used to set up LSPs.
- **nolsp**—Sessions not used to set up LSPs.

**name *session-name***—(Optional) Display information about the named session.

**p2mp**—(Optional) Display point-to-multipoint information.

***session-type***—(Optional) Display information about a particular session type:

- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that transit through this routing device.

**statistics**—(Optional) Display packet statistics.

**te-link *te-link***—(Optional) Display sessions with reservations on the specified TE link.

**Required Privilege  
Level**

| Ingress RSVP      | Information about ingress RSVP sessions. Each session has one line of output.                                                                                                                                                                                                                            | All levels      |
| Egress RSVP       | Information about egress RSVP sessions.                                                                                                                                                                                                                                                                  | All levels      |
| Transit RSVP      | Information about the transit RSVP sessions.                                                                                                                                                                                                                                                             | All levels      |
| P2MP name         | (Appears only when the <b>p2mp</b> option is specified). Name of the point-to-multipoint LSP path.                                                                                                                                                                                                       | All levels      |
| P2MP branch count | (Appears only when the <b>p2mp</b> option is specified). Number of LSPs receiving packets from the point-to-multipoint LSP.                                                                                                                                                                              | All levels      |
| To                | Destination (egress routing device) of the session.                                                                                                                                                                                                                                                      | All levels      |
| From              | Source (ingress routing device) of the session.                                                                                                                                                                                                                                                          | All levels      |
| State             | State of the path: <b>Up</b> , <b>Down</b> , or <b>AdminDn</b> . <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                                                                                   | All levels      |
| Address           | Destination (egress routing device) of the LSP.                                                                                                                                                                                                                                                          | detail          |
| From              | Source (ingress routing device) of the session.                                                                                                                                                                                                                                                          | detail          |
| LSPstate          | State of the LSP that is being handled by this RSVP session. It can be either <b>Up</b> , <b>Dn</b> (down), or <b>AdminDn</b> . <b>AdminDn</b> indicates that the LSP is being taken down gracefully.                                                                                                    | brief detail    |
| Rt                | Number of active routes (prefixes) that have been installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and egress RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ).                         | brief           |
| Active Route      | Number of active routes (prefixes) that have been installed in the forwarding table. For ingress RSVP sessions, the forwarding table is the primary IPv4 table ( <b>inet.0</b> ). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table ( <b>mpls.0</b> ).                | detail          |
| LSPname           | Name of the LSP.                                                                                                                                                                                                                                                                                         | brief detail    |
| LSPpath           | Indicates whether the RSVP session is for the primary or secondary LSP path. <b>LSPpath</b> can be either <b>primary</b> or <b>secondary</b> and can be displayed on the ingress, egress, and transit routing devices. <b>LSPpath</b> can also indicate when a graceful LSP deletion has been triggered. | detail          |

Table 426: show rsvp session Output Fields (*continued*)

| Field Name                      | Field Description                                                                                                                                                                                                                                  | Level of Output     |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| <b>Bypass</b>                   | (Egress routing device) Destination address for the bypass LSP.                                                                                                                                                                                    | <b>detail</b>       |
| <b>Bidir</b>                    | (When LSP is bidirectional) LSP will allow data to travel in both directions between GMPLS devices.                                                                                                                                                | <b>detail</b>       |
| <b>Bidirectional</b>            | (When LSP is bidirectional) LSP will allow data to travel both ways between GMPLS devices.                                                                                                                                                         | <b>detail</b>       |
| <b>Upstream label in</b>        | (When LSP is bidirectional) Incoming label for reverse direction traffic for this LSP.                                                                                                                                                             | <b>detail</b>       |
| <b>Upstream label out</b>       | (When LSP is bidirectional) Outgoing label for reverse direction traffic for this LSP.                                                                                                                                                             | <b>detail</b>       |
| <b>Recovery label received</b>  | (When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.                                                                                                                                             | <b>detail</b>       |
| <b>Recovery label sent</b>      | (When LSP is bidirectional) Label the downstream node suggests for use in its Resv messages that is returned.                                                                                                                                      | <b>detail</b>       |
| <b>Suggested label received</b> | (When LSP is bidirectional) Label the upstream node suggests for use in the Resv message that is sent.                                                                                                                                             | <b>detail</b>       |
| <b>Suggested label sent</b>     | (When LSP is bidirectional) Label the downstream node suggests for use in its Resv message that is returned.                                                                                                                                       | <b>detail</b>       |
| <b>Resv style or Style</b>      | RSVP reservation style. This field consists of two parts. The first is the number of active reservations. The second is the reservation style, which can be <b>FF</b> (fixed filter), <b>SE</b> (shared explicit), or <b>WF</b> (wildcard filter). | <b>brief detail</b> |
| <b>Label in</b>                 | Incoming label for this LSP.                                                                                                                                                                                                                       | <b>brief detail</b> |
| <b>Label out</b>                | Outgoing label for this LSP.                                                                                                                                                                                                                       | <b>brief detail</b> |
| <b>Time left</b>                | Number of seconds remaining in the lifetime of the reservation.                                                                                                                                                                                    | <b>brief detail</b> |
| <b>Since</b>                    | Date and time when the RSVP session was initiated.                                                                                                                                                                                                 | <b>detail</b>       |
| <b>Tspec</b>                    | Sender's traffic specification, which describes the sender's traffic parameters.                                                                                                                                                                   | <b>detail</b>       |
| <b>DiffServ info</b>            | Indicates whether the LSP is a multiclass LSP ( <b>multiclass diffServ-TE LSP</b> ) or a Differentiated-Services-aware traffic engineering LSP ( <b>diffServ-TE LSP</b> ).                                                                         | <b>detail</b>       |
| <b>bandwidth</b>                | Bandwidth for each class type ( <b>ct0</b> , <b>ct1</b> , <b>ct2</b> , or <b>ct3</b> ).                                                                                                                                                            | <b>detail</b>       |
| <b>Port number</b>              | Protocol ID and sender/receiver port used in this RSVP session.                                                                                                                                                                                    | <b>detail</b>       |
| <b>Attrib flags</b>             | <b>Non-PHP</b> indicates that ultimate hop popping has been requested by the LSP using this RSVP session                                                                                                                                           | <b>extensive</b>    |

Table 426: show rsvp session Output Fields (*continued*)

| Field Name                                          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Level of Output         |

| <b>Deleting backup LSP, protected LSP restored</b>  | Link has come back up and the LSP has been restored. Because the backup LSP is no longer needed, it is deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <b>extensive</b>        |
| <b>Path mtu</b>                                     | Displays the value of the path MTU received from the network (through signaling) and the value used for forwarding. This value is only displayed on ingress routing devices with the <b>allow-fragmentation</b> statement configured at the <b>[edit protocols mpls path-mtu]</b> hierarchy level. If there is a detour LSP, the path MTU for the detour is also displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>detail</b>           |

Table 426: show rsvp session Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                   | Level of Output |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Egress protection<br>PLR as protector | RSVP state on the Protector or the point-of-local-repair (PLR) routing device: <ul style="list-style-type: none"> <li><b>Active</b>— Egress protection is available at the Protector or the PLR routing device.</li> <li><b>In Use</b>— Local repair has been completed.</li> </ul> | detail          |
| PATH rcvfrom                          | Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor.                                                                                               | detail          |
| Adspec                                | MTU signaled from the ingress routing device to the egress routing device by means of the adspec object.                                                                                                                                                                            | detail          |
| PATH sentto                           | Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor (or peer-name in the GMPLS LSP case), and number of packets sent to the downstream routing device.                                                                             | detail          |
| Explct route                          | Explicit route for the session. Normally this value will be the same as that of record route. Differences indicate that path rerouting has occurred, typically during fast reroute.                                                                                                 | detail          |
| Record route                          | Recorded route for the session, taken from the record route object. Normally this value will be the same as that of explct route. Differences indicate that path rerouting has occurred, typically during fast reroute.                                                             | detail          |

| <b>List of Sample Output</b>       | <a href="#">show rsvp statistics on page 5378</a>                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Output Fields</b>               | Table 427 describes the output fields for the <b>show rsvp statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                            |

**Table 427: show rsvp statistics Output Fields**

| Field Name                     | Field Description                                        |
|--------------------------------|----------------------------------------------------------|
| <b>Packet Type</b>             | Statistics about different RSVP messages.                |
| <b>Total Sent</b>              | Total number of packets sent since RSVP was enabled.     |
| <b>Total Received</b>          | Total number of packets received since RSVP was enabled. |
| <b>Last 5 seconds Sent</b>     | Total number of packets sent in the last 5 seconds.      |
| <b>Last 5 seconds Received</b> | Number of packets received in the last 5 seconds.        |

Table 427: show rsvp statistics Output Fields (*continued*)

| Field Name                    | Field Description                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Path</b>                   | Statistics about Path messages, which are sent from the RSVP sender along the data paths and which store path state information in each node along the path. |
| <b>PathErr</b>                | Statistics about PathErr messages, which are advisory messages that are sent upstream to the sender.                                                         |
| <b>PathTear</b>               | Statistics about PathTear messages, which remove path states and dependent reservation states in any routing devices along a path.                           |
| <b>Resv FF</b>                | Statistics about fixed-filter reservation style messages, which consist of distinct reservations among explicit senders.                                     |
| <b>Resv WF</b>                | Statistics about wildcard-filter reservation style messages, which consist of shared reservations among wildcard senders.                                    |
| <b>Res SE</b>                 | Statistics about shared-explicit reservation style messages, which consist of shared reservations among explicit senders.                                    |
| <b>ResvErr</b>                | Statistics about ResvErr messages, which are advisory messages that are sent when an attempt to establish a reservation fails.                               |
| <b>ResvTear</b>               | Statistics about ResvTear messages, which remove reservation states along a path.                                                                            |
| <b>ResvConf</b>               | Statistics about ResvConfirm messages, which are responses to confirm a reservation request.                                                                 |
| <b>Ack</b>                    | Acknowledge message for refresh reductions.                                                                                                                  |
| <b>SRefresh</b>               | Summary refresh messages.                                                                                                                                    |
| <b>Hello</b>                  | Number of RSVP hello packets that have been sent to and received from the neighbor.                                                                          |
| <b>EndtoEnd RSVP</b>          | Statistics for the number of End-to-end RSVP messages.                                                                                                       |
| <b>Errors</b>                 | Statistics about errored RSVP packets.                                                                                                                       |
| <b>Rcv pkt bad length</b>     | The packet was not processed because its length is inappropriate.                                                                                            |
| <b>Rcv pkt unknown type</b>   | The packet is not one of the well-known RSVP types, as defined in RFC 2205, <i>Resource ReSerVation Protocol (RSVP)</i> .                                    |
| <b>Rcv pkt bad version</b>    | The packet is not an RSVP version 1 packet.                                                                                                                  |
| <b>Rcv pkt auth fail</b>      | The packet failed authentication checks.                                                                                                                     |
| <b>Rcv pkt bad checksum</b>   | The RSVP checksum check failed.                                                                                                                              |
| <b>Rcv pkt bad format</b>     | General packet processing failed because the packet was badly formed.                                                                                        |
| <b>Memory allocation fail</b> | An internal resource failure occurred.                                                                                                                       |

Table 427: show rsvp statistics Output Fields (*continued*)

| Field Name                  | Field Description                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No path information         | A reservation was received, but no sender is active.                                                                                                                                                                                                                                                                                  |
| Resv style conflict         | The same session contains inconsistent reservation styles.                                                                                                                                                                                                                                                                            |
| Port conflict               | There were inconsistent port numbers for the same session.                                                                                                                                                                                                                                                                            |
| Resv no interface           | An interface for the receive reservation packets cannot be located.                                                                                                                                                                                                                                                                   |
| PathErr to client           | Number of PathErr packets delivered to the local client.                                                                                                                                                                                                                                                                              |
| ResvErr to client           | Number of ResvErr packets delivered to the local client.                                                                                                                                                                                                                                                                              |
| Path timeout                | Number of times the sender timed out because the path was removed.                                                                                                                                                                                                                                                                    |
| Resv timeout                | Number of times the receiver timed out because the reservation was removed.                                                                                                                                                                                                                                                           |
| Message out-of-order        | Records the number of RSVP incoming messages that are considered out of order. This is detected from the message ID object's sequence number.                                                                                                                                                                                         |
| Unknown ack msg             | A neighboring routing device replies with an ACK object that contains an unknown message ID. This can indicate a message ID handshake problem. For example, a router receives an ACK for message IDs 1, 2, and 3. However, it only has state for message IDs 1 and 3. The router increments the unknown ack counter by 1.             |
| Recv nack                   | If a neighboring router receives an unknown message ID in an RSVP refresh message, the router sends a Resv nack message back to the sender. This can happen if that neighbor has been rebooted. For this case, the router sends a regular RSVP refresh message to recover the state and start the message-ID handshake process again. |
| Recv duplicated msg-id      | Number of times the same message ID is used by two different RSVP messages. This duplication is usually caused when a neighboring routing device restarts.                                                                                                                                                                            |
| No TE-link to rcv Hop       | Counter of packets discarded because a TE link was not found.                                                                                                                                                                                                                                                                         |
| Rcv pkt disabled interface  | Number of RSVP packets received on an interface that is not enabled for RSVP.                                                                                                                                                                                                                                                         |
| Transmit buffer full        | Number of times the buffer for assembling an outgoing RSVP message was not large enough.                                                                                                                                                                                                                                              |
| Transmit failure            | Number of times the RSVP task failed to send out a packet.                                                                                                                                                                                                                                                                            |
| Receive failure             | Number of times the RSVP task failed to read an incoming packet.                                                                                                                                                                                                                                                                      |
| P2MP RESV discarded by appl | Number of Resv messages discarded because the MPLS label is not valid for the P2MP LSP application.                                                                                                                                                                                                                                   |
| Rate limit                  | Number of RSVP packets dropped due to rate limiting.                                                                                                                                                                                                                                                                                  |

Table 427: show rsvp statistics Output Fields (*continued*)

| Field Name                   | Field Description                                                                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Err msg loop detected</b> | Number of RSVP error messages that have looped back to their originator. This is detected by checking the error node address in the ERROR_SPEC object. |

| Field Name                             | Field Description                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resource ReSerVation Protocol, version | RSVP software version.                                                                                                                                                                                                                                                                                                                          |
| RSVP protocol                          | Status of RSVP: <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                                                                                                                             |
| R(refresh timer)                       | Configured time interval used to generate periodic RSVP messages.                                                                                                                                                                                                                                                                               |
| K(keep multiplier)                     | Number of RSVP messages that can be lost before an RSVP state is declared stale.                                                                                                                                                                                                                                                                |
| Preemption                             | Currently configured preemption capability: <b>Aggressive</b> , <b>Disabled</b> , or <b>Normal</b> . The default is <b>Normal</b> .                                                                                                                                                                                                             |
| Soft-preemption cleanup                | Time, in seconds, that an LSP is kept after it has been soft preempted. This is a global property of the RSVP protocol.                                                                                                                                                                                                                         |
| Graceful deleting timeout              | Currently configured value for the <b>graceful-deletion-timeout</b> statement. The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down. |

Table 428: show rsvp version Output Fields (*continued*)

| Field Name                           | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NSR Mode</b>                      | Status of the nonstop active routing feature for RSVP on the restarting device: <b>Disabled</b> , <b>Enabled/Master</b> , or <b>Enabled/Standby</b> .                                                                                                                                                                                                                                                                                |
| <b>NSR State</b>                     | <p>State of the nonstop active routing feature for RSVP on the restarting device.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>Idle</b></li> <li>• <b>TE-link sync complete</b></li> <li>• <b>Neighbor sync complete</b></li> <li>• <b>Path state sync complete</b></li> <li>• <b>Resv state sync complete</b></li> <li>• <b>Bypass sync complete</b></li> <li>• <b>Init sync complete</b></li> </ul> |
| <b>Setup protection</b>              | Status of point-to-point and point-to-multipoint LSP setup protection configuration on the device: <b>Enabled</b> or <b>Disabled</b>                                                                                                                                                                                                                                                                                                 |
| <b>Graceful restart</b>              | Status of the graceful restart feature for RSVP on the restarting routing device: <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                                                                                                                                                |
| <b>Restart helper mode</b>           | Status of the helper mode feature: <b>Enabled</b> or <b>Disabled</b> . When this feature is enabled, the restarting routing device can help the neighbor with its RSVP restart procedures.                                                                                                                                                                                                                                           |
| <b>Maximum helper restart time</b>   | Number of milliseconds (ms) configured for the maximum helper restart time. The maximum helper restart time is the length of time the routing device waits before declaring that an RSVP neighbor attempting to restart gracefully is down.                                                                                                                                                                                          |
| <b>Maximum helper recovery time</b>  | Number of milliseconds configured for the maximum helper recovery time. The maximum helper recovery time is the amount of time the routing device maintains the state of an RSVP neighbor attempting to restart gracefully.                                                                                                                                                                                                          |
| <b>Restart time</b>                  | Number of milliseconds that a neighbor waits to receive a Hello message from the restarting node before declaring the node dead and deleting the states.                                                                                                                                                                                                                                                                             |
| <b>Recovery time</b>                 | Number of milliseconds during which the restarting node attempts to recover its lost states with help from its neighbors. Recovery time is advertised by the restarting node to its neighbors, and applies to nodal faults. The restarting node considers its graceful restart complete after this time has elapsed.                                                                                                                 |
| <b>P2p transit LSP nexthop mode</b>  | Point-to-point transit LSP nexthop mode on PTX Series devices. The possible values are <b>Chained</b> or <b>Unchained</b>                                                                                                                                                                                                                                                                                                            |
| <b>P2mp transit LSP nexthop mode</b> | Point-to-multipoint transit LSP nexthop mode on PTX Series devices. The possible values are <b>Chained</b> or <b>Unchained</b>                                                                                                                                                                                                                                                                                                       |

## Sample Output

### show rsvp version

```
user@host> show rsvp version
```

```
Resource ReSerVation Protocol, version 1. rfc2205
 RSVP protocol: Enabled
 R(refresh timer): 30 seconds
 K(keep multiplier): 3
 Preemption: Normal
 Soft-preemption cleanup: 30 seconds
 Graceful deletion timeout: 30 seconds
 NSR mode: Enabled/Master
 NSR state: Init sync complete
 Setup protection: Disabled
 Graceful restart: Disabled
 Restart helper mode: Enabled
 Maximum helper restart time: 20000 msec
 Maximum helper recovery time: 180000 msec
 Restart time: 0 msec
 P2p transit LSP nexthop mode: Unchained
 P2mp transit LSP nexthop mode: Unchained
```

| <b>Release Information</b>      | Command introduced in Junos OS Release 9.2.<br><code>egress</code> , <code>multipoint</code> , and <code>ttl</code> options added in Junos OS Release 11.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | Trace route to a remote host for an MPLS LSP signaled by RSVP. Use <b>traceroute mpls rsvp</b> as a debugging tool to locate MPLS label-switched path (LSP) forwarding issues in a network. (Currently supported for IPv4 packets only.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>                  | <p><b><i>lsp-name</i></b>—Specify the name of the LSP to be traced.</p> <p><b><code>detail</code></b>—(Optional) Display detailed output.</p> <p><b><code>egress</code></b>—(Optional) Request that a specific point-to-multipoint egress node reply to the trace route. The trace route would follow the associated sub-LSP to the egress node.</p> <p><b><code>exp</code></b>—(Optional) Specify the class of service to use when sending probes. The range of values is 0 through 7. The default value is 7.</p> <p><b><code>logical-system</code></b>—(Optional) Specify the name of the logical system for the traceroute attempt.</p> <p><b><code>multipoint</code></b>—(Optional) Perform a trace route on a point-to-multipoint LSP.</p> <p><b><code>no-resolve</code></b>—(Optional) Specify not to resolve the hostname that corresponds to the IP address.</p> <p><b><code>retries</code></b>—(Optional) Specify the number of times to resend probe. The range of values is 1 through 9. The default value is 3.</p> <p><b><code>source <i>source-address</i></code></b>—(Optional) Specify the source address of the outgoing traceroute packets.</p> <p><b><code>ttl</code></b>—(Optional) Specify the number of hops to follow before forcing the trace route to quit.</p> |
| <b>Required Privilege Level</b> | network                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Output Fields** Table 429 describes the output fields for the **traceroute mpls rsvp *lsp-name*** and **traceroute mpls rsvp *lsp-name* detail** commands. Output fields are listed in the approximate order in which they appear.

**Table 429: traceroute mpls rsvp Output Fields**

| Field Name         | Field Description                                                                                                                                                                                                                                          | Level of Output |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Probe options      | Probe options specified in the <b>traceroute mpls rsvp <i>lsp-name</i></b> command.                                                                                                                                                                        | all levels      |
| ttl                | Time-to-live value of the labeled packet.                                                                                                                                                                                                                  | none specified  |
| Label              | MPLS label used to forward the packets along the LSP.                                                                                                                                                                                                      | none specified  |
| Protocol           | Signaling protocol used. For this command, it is RSVP-TE.                                                                                                                                                                                                  | none specified  |
| Address            | Address of the next hop.                                                                                                                                                                                                                                   | none specified  |
| Previous Hop       | Address of the previous hop. Previous hop address of the first hop is null.                                                                                                                                                                                | none specified  |
| Probe status       | Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths). Displays <b>Success</b> if the trace to a hop is successful or <b>Egress</b> if the trace has reached the last router on the path. | none specified  |
| Hop                | Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop.                                                                                                                                   | <b>detail</b>   |
| Parent             | Address of the previous hop. Parent value for the first hop is null.                                                                                                                                                                                       | <b>detail</b>   |
| Return Code        | Return code for reporting the result of processing the echo request by the receiver.                                                                                                                                                                       | <b>detail</b>   |
| Sender timestamp   | Displays the timestamp when the MPLS echo request is sent to the next hop.                                                                                                                                                                                 | <b>detail</b>   |
| Receiver timestamp | Timestamp when the echo request from the previous hop is received and acknowledged with an echo response by the next hop.                                                                                                                                  | <b>detail</b>   |
| Response time      | Time for the echo request to reach the receiver.                                                                                                                                                                                                           | <b>detail</b>   |
| MTU                | Size of the largest packet that includes the label stack forwarded to the next hop.                                                                                                                                                                        | <b>detail</b>   |

Table 429: traceroute mpls rsvp Output Fields (*continued*)

| Field Name     | Field Description                                                                                        | Level of Output |
|----------------|----------------------------------------------------------------------------------------------------------|-----------------|
| Multipath type | Labels or addresses used by the specified multipath type. If multipaths are not used, the value is none. | <b>detail</b>   |
| Label stack    | Label stack used to forward the packet.                                                                  | <b>detail</b>   |
| Path           | Displays the sub-lsp path number for this traceroute, the interface used, and the destination address.   | all levels      |

## Sample Output

### traceroute mpls rsvp

```
user@host> traceroute mpls rsvp lsp-chicago-atlanta
```

```
Probe options: retries 3, exp 7
```

| ttl | Label  | Protocol | Address     | Previous Hop | Probe Status |
|-----|--------|----------|-------------|--------------|--------------|
| 1   | 299792 | RSVP-TE  | 192.168.1.2 | (null)       | Success      |
| 2   | 299803 | RSVP-TE  | 192.168.2.3 | 192.168.1.2  | Success      |
| 3   | 3      | RSVP-TE  | 192.168.3.4 | 192.168.2.3  | Egress       |

```
Path 1 via ge-0/0/0.1 destination 127.0.0.64
```

### traceroute mpls rsvp detail

```

# Multicast Protocols Feature Guide for QFX10000 Switches

# Overview

- [Multicast Overview on page 5389](#)

## Multicast Overview

---

IP has three fundamental types of addresses: unicast, broadcast, and multicast. A *unicast address* is used to send a packet to a single destination. A *broadcast address* is used to send a datagram to an entire subnetwork. A *multicast address* is used to send a datagram to a set of hosts that can be on different subnetworks and that are configured as members of a multicast group.

A multicast datagram is delivered to destination group members with the same best-effort reliability as a standard unicast IP datagram. This means that multicast datagrams are not guaranteed to reach all members of a group or to arrive in the same order in which they were transmitted. The only difference between a multicast IP packet and a unicast IP packet is the presence of a group address in the IP header destination address field. Multicast addresses use the Class D address format.

**NOTE:** On all SRX Series devices, reordering is not supported for multicast fragments. Reordering of unicast fragments is supported.

Individual hosts can join or leave a multicast group at any time. There are no restrictions on the physical location or the number of members in a multicast group. A host can be a member of more than one multicast group at any time. A host does not have to belong to a group to send packets to members of a group.

Routers use a group membership protocol to learn about the presence of group members on directly attached subnetworks. When a host joins a multicast group, it transmits a group membership protocol message for the group or groups that it wants to receive and sets its IP process and network interface card to receive frames addressed to the multicast group.

## Comparing Multicast to Unicast

The Junos<sup>®</sup> operating system (Junos OS) routing protocol process supports a wide variety of routing protocols. These routing protocols carry network information among routing devices not only for *unicast* traffic streams sent between one pair of clients and servers,

but also for *multicast* traffic streams containing video, audio, or both, between a single server source and many client receivers. The routing protocols used for multicast differ in many key ways from unicast routing protocols.

Information is delivered over a network by three basic methods: unicast, broadcast, and multicast.

The differences among unicast, broadcast, and multicast can be summarized as follows:

- Unicast: One-to-one, from one source to one destination.
- Broadcast: One-to-all, from one source to all possible destinations.
- Multicast: One-to-many, from one source to multiple destinations expressing an interest in receiving the traffic.

**NOTE:** This list does not include a special category for many-to-many applications, such as online gaming or videoconferencing, where there are many sources for the same receiver and where receivers often double as sources. Many-to-many is a service model that repeatedly employs one-to-many multicast and therefore requires no unique protocol. The original multicast specification, RFC 1112, supports both the any-source multicast (ASM) many-to-many model and the source-specific multicast (SSM) one-to-many model.

---

With unicast traffic, many streams of IP packets that travel across networks flow from a single source, such as a website server, to a single destination such as a client PC. Unicast traffic is still the most common form of information transfer on networks.

Broadcast traffic flows from a single source to all possible destinations reachable on the network, which is usually a LAN. Broadcasting is the easiest way to make sure traffic reaches its destinations.

Television networks use broadcasting to distribute video and audio. Even if the television network is a cable television (CATV) system, the source signal reaches all possible destinations, which is the main reason that some channels' content is scrambled. Broadcasting is not feasible on the Internet because of the enormous amount of unnecessary information that would constantly arrive at each end user's device, the complexities and impact of scrambling, and related privacy issues.

Multicast traffic lies between the extremes of unicast (one source, one destination) and broadcast (one source, all destinations). Multicast is a "one source, many destinations" method of traffic distribution, meaning only the destinations that explicitly indicate their need to receive the information from a particular source receive the traffic stream.

On an IP network, because destinations (clients) do not often communicate directly with sources (servers), the routing devices between source and destination must be able to determine the topology of the network from the unicast or multicast perspective to avoid routing traffic haphazardly. Multicast routing devices replicate packets received on one input interface and send the copies out on multiple output interfaces.

In IP multicast, the source and destination are almost always hosts and not routing devices. Multicast routing devices distribute the multicast traffic across the network from source to destinations. The multicast routing device must find multicast sources on the network, send out copies of packets on several interfaces, prevent routing loops, connect interested destinations with the proper source, and keep the flow of unwanted packets to a minimum. Standard multicast routing protocols provide most of these capabilities, but some router architectures cannot send multiple copies of packets and so do not support multicasting directly.

## IP Multicast Uses

Multicast allows an IP network to support more than just the unicast model of data delivery that prevailed in the early stages of the Internet. Multicast, originally defined as a host extension in RFC 1112 in 1989, provides an efficient method for delivering traffic flows that can be characterized as one-to-many or many-to-many.

Unicast traffic is not strictly limited to data applications. Telephone conversations, wireless or not, contain digital audio samples and might contain digital photographs or even video and still flow from a single source to a single destination. In the same way, multicast traffic is not strictly limited to multimedia applications. In some data applications, the flow of traffic is from a single source to many destinations that require the packets, as in a news or stock ticker service delivered to many PCs. For this reason, the term *receiver* is preferred to *listener* for multicast destinations, although both terms are common.

Network applications that can function with unicast but are better suited for multicast include collaborative groupware, teleconferencing, periodic or “push” data delivery (stock quotes, sports scores, magazines, newspapers, and advertisements), server or website replication, and distributed interactive simulation (DIS) such as war simulations or virtual reality. Any IP network concerned with reducing network resource overhead for one-to-many or many-to-many data or multimedia applications with multiple receivers benefits from multicast.

If unicast were employed by radio or news ticker services, each radio or PC would have to have a separate traffic session for each listener or viewer at a PC (this is actually the method for some Web-based services). The processing load and bandwidth consumed by the server would increase linearly as more people “tune in” to the server. This is extremely inefficient when dealing with the global scale of the Internet. Unicast places the burden of packet duplication on the server and consumes more and more backbone bandwidth as the number of users grows.

If broadcast were employed instead, the source could generate a single IP packet stream using a broadcast destination address. Although broadcast eliminates the server packet duplication issue, this is not a good solution for IP because IP broadcasts can be sent only to a single subnetwork, and IP routing devices normally isolate IP subnetworks on separate interfaces. Even if an IP packet stream could be addressed to literally go everywhere, and there were no need to “tune” to any source at all, broadcast would be extremely inefficient because of the bandwidth strain and need for uninterested hosts to discard large numbers of packets. Broadcast places the burden of packet rejection on each host and consumes the maximum amount of backbone bandwidth.

For radio station or news ticker traffic, multicast provides the most efficient and effective outcome, with none of the drawbacks and all of the advantages of the other methods. A single source of multicast packets finds its way to every *interested* receiver. As with broadcast, the transmitting host generates only a single stream of IP packets, so the load remains constant whether there is one receiver or one million. The network routing devices replicate the packets and deliver the packets to the proper receivers, but only the replication role is a new one for routing devices. The links leading to subnets consisting of entirely uninterested receivers carry no multicast traffic. Multicast minimizes the burden placed on sender, network, and receiver.

## IP Multicast Terminology

Multicast has its own particular set of terms and acronyms that apply to IP multicast routing devices and networks. [Figure 152](#) depicts some of the terms commonly used in an IP multicast network.

In a multicast network, the key component is the *routing device*, which is able to replicate packets and is therefore multicast-capable. The routing devices in the IP multicast network, which has exactly the same topology as the unicast network it is based on, use a *multicast routing protocol* to build a *distribution tree* that connects receivers (preferred to the multimedia implications of listeners, but listeners is also used) to *sources*. In multicast terminology, the distribution tree is *rooted at the source* (the root of the distribution tree is the source). The interface on the routing device leading toward the source is the *upstream* interface, although the less precise terms *incoming* or *inbound* interface are used as well. To keep bandwidth use to a minimum, it is best for only one upstream interface on the routing device to receive multicast packets. The interface on the routing device leading toward the receivers is the *downstream* interface, although the less precise terms *outgoing* or *outbound* interface are used as well. There can be 0 to  $N-1$  downstream interfaces on a routing device, where  $N$  is the number of logical interfaces on the routing device. To prevent looping, the upstream interface must never receive copies of downstream multicast packets.

Figure 152: Multicast Terminology in an IP Network

Routing loops are disastrous in multicast networks because of the risk of repeatedly replicated packets. One of the complexities of modern multicast routing protocols is the need to avoid routing loops, packet by packet, much more rigorously than in unicast routing protocols.

### Reverse-Path Forwarding for Loop Prevention

The routing device's multicast forwarding state runs more logically based on the reverse path, from the receiver back to the root of the distribution tree. In RPF, every multicast packet received must pass an RPF check before it can be replicated or forwarded on any interface. When it receives a multicast packet on an interface, the routing device verifies that the *source* address in the multicast IP packet is the *destination* address for a unicast IP packet back to the source.

If the outgoing interface found in the unicast routing table is the same interface that the multicast packet was received on, the packet passes the RPF check. Multicast packets that fail the RPF check are dropped, because the incoming interface is not on the shortest path back to the source. routing devices can build and maintain separate tables for RPF purposes.

### Shortest-Path Tree for Loop Prevention

The distribution tree used for multicast is rooted at the source and is the shortest-path tree (SPT), but this path can be long if the source is at the periphery of the network. Providing a *shared tree* on the backbone as the distribution tree locates the multicast source more centrally in the network. Shared distribution trees with roots in the core network are created and maintained by a multicast routing device operating as a rendezvous point (RP), a feature of sparse mode multicast protocols.

## Administrative Scoping for Loop Prevention

Scoping limits the routing devices and interfaces that can forward a multicast packet. Multicast scoping is *administrative* in the sense that a range of multicast addresses is reserved for scoping purposes, as described in RFC 2365, *Administratively Scoped IP Multicast*. routing devices at the boundary must filter multicast packets and ensure that packets do not stray beyond the established limit.

## Multicast Leaf and Branch Terminology

Each subnetwork with hosts on the routing device that has at least one interested receiver is a *leaf* on the distribution tree. routing devices can have multiple leaves on different interfaces and must send a copy of the IP multicast packet out on each interface with a leaf. When a new leaf subnetwork is added to the tree (that is, the interface to the host subnetwork previously received no copies of the multicast packets), a new *branch* is built, the leaf is joined to the tree, and replicated packets are sent out on the interface. The number of leaves on a particular interface does not affect the routing device. The action is the same for one leaf or a hundred.

**NOTE:** On Juniper Networks security devices, if the maximum number of leaves on a multicast distribution tree is exceeded, multicast sessions are created up to the maximum number of leaves, and any multicast sessions that exceed the maximum number of leaves are ignored. The maximum number of leaves on a multicast distribution tree is device specific.

When a branch contains no leaves because there are no interested hosts on the routing device interface leading to that IP subnetwork, the branch is *pruned* from the distribution tree, and no multicast packets are sent out that interface. Packets are replicated and sent out multiple interfaces only where the distribution tree branches at a routing device, and no link ever carries a duplicate flow of packets.

Collections of hosts all receiving the same stream of IP packets, usually from the same multicast source, are called *groups*. In IP multicast networks, traffic is delivered to multicast groups based on an IP multicast address, or *group address*. The groups determine the location of the leaves, and the leaves determine the branches on the multicast network.

## IP Multicast Addressing

Multicast uses the Class D IP address range (224.0.0.0 through 239.255.255.255). Class D addresses are commonly referred to as *multicast addresses* because the entire classful address concept is obsolete. Multicast addresses can never appear as the source address in an IP packet and can only be the destination of a packet.

Multicast addresses usually have a prefix length of /32, although other prefix lengths are allowed. Multicast addresses represent logical groupings of receivers and not physical collections of devices. Blocks of multicast addresses can still be described in terms of prefix length in traditional notation, but only for convenience. For example, the multicast

address range from 232.0.0.0 through 232.255.255.255 can be written as 232.0.0.0/8 or 232/8.

Internet service providers (ISPs) do not typically allocate multicast addresses to their customers because multicast addresses relate to content, not to physical devices. Receivers are not assigned their own multicast addresses, but need to know the multicast address of the content. Sources need to be assigned multicast addresses only to produce the content, not to identify their place in the network. Every source and receiver still needs an ordinary, unicast IP address.

Multicast addressing most often references the receivers, and the source of multicast content is usually not even a member of the multicast group for which it produces content. If the source needs to monitor the packets it produces, monitoring can be done locally, and there is no need to make the packets traverse the network.

Many applications have been assigned a range of multicast addresses for their own use. These applications assign multicast addresses to sessions created by that application. You do not usually need to statically assign a multicast address, but you can do so.

## Multicast Addresses

Multicast host group addresses are defined to be the IP addresses whose high-order four bits are 1110, giving an address range from 224.0.0.0 through 239.255.255.255, or simply 224.0.0.0/4. (These addresses also are referred to as Class D addresses.)

The Internet Assigned Numbers Authority (IANA) maintains a list of registered IP multicast groups. The base address 224.0.0.0 is reserved and cannot be assigned to any group. The block of multicast addresses from 224.0.0.1 through 224.0.0.255 is reserved for local wire use. Groups in this range are assigned for various uses, including routing protocols and local discovery mechanisms.

The range from 239.0.0.0 through 239.255.255.255 is reserved for administratively scoped addresses. Because packets addressed to administratively scoped multicast addresses do not cross configured administrative boundaries, and because administratively scoped multicast addresses are locally assigned, these addresses do not need to be unique across administrative boundaries.

## Layer 2 Frames and IPv4 Multicast Addresses

Multicasting on a LAN is a good place to start an investigation of multicasting at Layer 2. At Layer 2, multicast deals with media access control (MAC) frames and addresses instead of IPv4 or IPv6 packets and addresses. Consider a single LAN, without routing devices, with a multicast source sending to a certain group. The rest of the hosts are receivers interested in the multicast group's content. So the multicast source host generates packets with its unicast IP address as the source, and the multicast group address as the destination.

Which MAC addresses are used on the frame containing this packet? The packet source address—the unicast IP address of the host originating the multicast content—translates easily and directly to the MAC address of the source. But what about the packet's destination address? This is the IP multicast group address. Which destination MAC address for the frame corresponds to the packet's multicast group address?

One option is for LANs simply to use the LAN broadcast MAC address, which guarantees that the frame is processed by every station on the LAN. However, this procedure defeats the whole purpose of multicast, which is to limit the circulation of packets and frames to interested hosts. Also, hosts might have access to many multicast groups, which multiplies the amount of traffic to noninterested destinations. Broadcasting frames at the LAN level to support multicast groups makes no sense.

However, there is an easy way to effectively use Layer 2 frames for multicast purposes. The MAC address has a bit that is set to 0 for unicast (the LAN term is *individual address*) and set to 1 to indicate that this is a multicast address. Some of these addresses are reserved for multicast groups of specific vendors or MAC-level protocols. Internet multicast applications use the range 0x01-00-5E-00-00-00 to 0x01-00-5E-FF-FF-FF. Multicast receivers (hosts running TCP/IP) listen for frames with one of these addresses when the application joins a multicast group. The host stops listening when the application terminates or the host leaves the group at the packet layer (Layer 3).

This means that 3 bytes, or 24 bits, are available to map IPv4 multicast addresses at Layer 3 to MAC multicast addresses at Layer 2. However, all IPv4 addresses, including multicast addresses, are 32 bits long, leaving 8 IP address bits left over. Which method of mapping IPv4 multicast addresses to MAC multicast addresses minimizes the chance of “collisions” (that is, two different IP multicast groups at the packet layer mapping to the same MAC multicast address at the frame layer)?

First, it is important to realize that all IPv4 multicast addresses begin with the same 4 bits (**1110**), so there are really only 4 bits of concern, not 8. A LAN must not drop the last bits of the IPv4 address because these are almost guaranteed to be host bits, depending on the subnet mask. But the high-order bits, the leftmost address bits, are almost always network bits, and there is only one LAN (for now).

One other bit of the remaining 24 MAC address bits is reserved (an initial **0** indicates an Internet multicast address), so the 5 bits following the initial **1110** in the IPv4 address are dropped. The 23 remaining bits are mapped, one for one, into the last 23 bits of the MAC address. An example of this process is shown in [Figure 153](#).

Figure 153: Converting MAC Addresses to Multicast Addresses

|   |                                                                                                       |                             |          |           |           |
|---|-------------------------------------------------------------------------------------------------------|-----------------------------|----------|-----------|-----------|
| 1 | IPv4 header multicast destination address                                                             | 232.                        | 224.     | 202.      | 181       |
|   | Written in hexadecimal                                                                                | E8                          | E0       | CA        | B5        |
|   | Written in binary                                                                                     | 1110 1000 1                 | 110 0000 | 1100 1010 | 1011 0101 |
| 2 | Ignore the first 9 bits and copy the remaining 23 bits                                                | X                           | 110 0000 | 1100 1010 | 1011 0101 |
| 3 | First bit X = 0 for Internet; X = 1 for other                                                         | 0                           | 110 0000 | 1100 1010 | 1011 0101 |
| 4 | Written in hexadecimal                                                                                |                             | 60       | CA        | B5        |
| 5 | MAC address in hexadecimal                                                                            | 01 : 00 : 5E : E0 : CA : B5 |          |           |           |
| 6 | Drop last 24 bits                                                                                     | 01 : 00 : 5E :              |          |           |           |
| 7 | Copy the multicast bits                                                                               | 01 : 00 : 5E : 60 : CA : B5 |          |           |           |
| 8 | MAC frame destination address 01:00:5E:60:CA:B5 corresponds to multicast IPv4 address 232.224.202.181 |                             |          |           |           |

658108

Note that this process means that there are 32 ( $2^5$ ) IPv4 multicast addresses that could map to the same MAC multicast addresses. For example, multicast IPv4 addresses 224.8.7.6 and 229.136.7.6 translate to the same MAC address (0x01-00-5E-08-07-06). This is a real concern, and because the host could be interested in frames sent to both of those multicast groups, the IP software must reject one or the other.

**NOTE:** This “collision” problem does not exist in IPv6 because of the way IPv6 handles multicast groups, but it is always a concern in IPv4. The procedure for placing IPv6 multicast packets inside multicast frames is nearly identical to that for IPv4, except for the MAC destination address 0x3333 prefix (and the lack of “collisions”).

Once the MAC address for the multicast group is determined, the host's operating system essentially orders the LAN interface card to join or leave the multicast group. Once joined to a multicast group, the host accepts frames sent to the multicast address as well as the host's unicast address and ignores other multicast group's frames. It is possible for a host to join and receive multicast content from more than one group at the same time, of course.

## Multicast Interface Lists

To avoid multicast routing loops, every multicast routing device must always be aware of the interface that leads to the source of that multicast group content by the shortest path. This is the upstream (incoming) interface, and packets are never to be forwarded back toward a multicast source. All other interfaces are potential downstream (outgoing) interfaces, depending on the number of branches on the distribution tree.

routing devices closely monitor the status of the incoming and outgoing interfaces, a process that determines the *multicast forwarding state*. A routing device with a multicast forwarding state for a particular multicast group is essentially “turned on” for that group's

content. Interfaces on the routing device's outgoing interface list send copies of the group's packets received on the incoming interface list for that group. The incoming and outgoing interface lists might be different for different multicast groups.

The multicast forwarding state in a routing device is usually written in either (S,G) or (\*,G) notation. These are pronounced “ess comma gee” and “star comma gee,” respectively. In (S,G), the S refers to the unicast IP address of the source for the multicast traffic, and the G refers to the particular multicast group IP address for which S is the source. All multicast packets sent from this source have S as the source address and G as the destination address.

The asterisk (\*) in the (\*,G) notation is a wildcard indicating that the state applies to any multicast application source sending to group G. So, if two sources are originating exactly the same content for multicast group 224.1.1.2, a routing device could use (\*,224.1.1.2) to represent the state of a routing device forwarding traffic from both sources to the group.

## Multicast Routing Protocols

Multicast routing protocols enable a collection of multicast routing devices to build (join) distribution trees when a host on a directly attached subnet, typically a LAN, wants to receive traffic from a certain multicast group, prune branches, locate sources and groups, and prevent routing loops.

There are several multicast routing protocols:

- **Distance Vector Multicast Routing Protocol (DVMRP)**—The first of the multicast routing protocols and hampered by a number of limitations that make this method unattractive for large-scale Internet use. DVMRP is a dense-mode-only protocol, and uses the flood-and-prune or implicit join method to deliver traffic everywhere and then determine where the uninterested receivers are. DVMRP uses source-based distribution trees in the form (S,G), and builds its own multicast routing tables for RPF checks.
- **Multicast OSPF (MOSPF)**—Extends OSPF for multicast use, but only for dense mode. However, MOSPF has an explicit join message, so routing devices do not have to flood their entire domain with multicast traffic from every source. MOSPF uses source-based distribution trees in the form (S,G).
- ***Bidirectional PIM mode***—A variation of PIM. Bidirectional PIM builds bidirectional shared trees that are rooted at a rendezvous point (RP) address. Bidirectional traffic does not switch to shortest path trees as in PIM-SM and is therefore optimized for routing state size instead of path length. This means that the end-to-end latency might be longer compared to PIM sparse mode. Bidirectional PIM routes are always wildcard-source (\*,G) routes. The protocol eliminates the need for (S,G) routes and data-triggered events. The bidirectional (\*,G) group trees carry traffic both upstream from senders toward the RP, and downstream from the RP to receivers. As a consequence, the strict reverse path forwarding (RPF)-based rules found in other PIM modes do not apply to bidirectional PIM. Instead, bidirectional PIM (\*,G) routes forward traffic from all sources and the RP. Bidirectional PIM routing devices must have the ability to accept traffic on many potential incoming interfaces. Bidirectional PIM scales well because it needs no source-specific (S,G) state. Bidirectional PIM is recommended in deployments with many dispersed sources and many dispersed receivers.

- *PIM dense mode*—In this mode of PIM, the assumption is that almost all possible subnets have at least one receiver wanting to receive the multicast traffic from a source, so the network is *flooded* with traffic on all possible branches, then pruned back when branches do not express an interest in receiving the packets, explicitly (by message) or implicitly (time-out silence). This is the *dense mode* of multicast operation. LANs are appropriate networks for dense-mode operation. Some multicast routing protocols, especially older ones, support only dense-mode operation, which makes them inappropriate for use on the Internet. In contrast to DVMRP and MOSPF, PIM dense mode allows a routing device to use any unicast routing protocol and performs RPF checks using the unicast routing table. PIM dense mode has an implicit join message, so routing devices use the flood-and-prune method to deliver traffic everywhere and then determine where the uninterested receivers are. PIM dense mode uses source-based distribution trees in the form (S,G), as do all dense-mode protocols. PIM also supports sparse-dense mode, with mixed sparse and dense groups, but there is no special notation for that operational mode. If *sparse-dense mode* is supported, the multicast routing protocol allows some multicast groups to be sparse and other groups to be dense.
- *PIM sparse mode*—In this mode of PIM, the assumption is that very few of the possible receivers want packets from each source, so the network establishes and sends packets only on branches that have at least one leaf indicating (by message) an interest in the traffic. This multicast protocol allows a routing device to use any unicast routing protocol and performs reverse-path forwarding (RPF) checks using the unicast routing table. PIM sparse mode has an *explicit* join message, so routing devices determine where the interested receivers are and send join messages upstream to their neighbors, building trees from receivers to the rendezvous point (RP). PIM sparse mode uses an RP routing device as the initial source of multicast group traffic and therefore builds distribution trees in the form (\*,G), as do all sparse-mode protocols. PIM sparse mode migrates to an (S,G) source-based tree if that path is shorter than through the RP for a particular multicast group's traffic. WANs are appropriate networks for sparse-mode operation, and indeed a common multicast guideline is not to run dense mode on a WAN under any circumstances.
- *Core Based Trees (CBT)*—Shares all of the characteristics of PIM sparse mode (sparse mode, explicit join, and shared (\*,G) trees), but is said to be more efficient at finding sources than PIM sparse mode. CBT is rarely encountered outside academic discussions. There are no large-scale deployments of CBT, commercial or otherwise.
- *PIM source-specific multicast (SSM)*—Enhancement to PIM sparse mode that allows a client to receive multicast traffic directly from the source, without the help of an RP. Used with IGMPv3 to create a shortest-path tree between receiver and source.
- *IGMPv1*—The original protocol defined in RFC 1112, *Host Extensions for IP Multicasting*. IGMPv1 sends an explicit join message to the routing device, but uses a timeout to determine when hosts leave a group. Three versions of the Internet Group Management Protocol (IGMP) run between receiver hosts and routing devices.
- *IGMPv2*—Defined in RFC 2236, *Internet Group Management Protocol, Version 2*. Among other features, IGMPv2 adds an explicit leave message to the join message.
- *IGMPv3*—Defined in RFC 3376, *Internet Group Management Protocol, Version 3*. Among other features, IGMPv3 optimizes support for a single source of content for a multicast

group, or source-specific multicast (SSM). Used with PIM SSM to create a shortest-path tree between receiver and source.

- Bootstrap Router (BSR) and Auto-Rendezvous Point (RP)—Allow sparse-mode routing protocols to find RPs within the routing domain (autonomous system, or AS). RP addresses can also be statically configured.
- Multicast Source Discovery Protocol (MSDP)—Allows groups located in one multicast routing domain to find RPs in other routing domains. MSDP is not used on an RP if all receivers and sources are located in the same routing domain. Typically runs on the same routing device as PIM sparse mode RP. Not appropriate if all receivers and sources are located in the same routing domain.
- Session Announcement Protocol (SAP) and Session Description Protocol (SDP)—Display multicast session names and correlate the names with multicast traffic. SDP is a session directory protocol that advertises multimedia conference sessions and communicates setup information to participants who want to join the session. A client commonly uses SDP to announce a conference session by periodically multicasting an announcement packet to a well-known multicast address and port using SAP.
- Pragmatic General Multicast (PGM)—Special protocol layer for multicast traffic that can be used between the IP layer and the multicast application to add reliability to multicast traffic. PGM allows a receiver to detect missing information in all cases and request replacement information if the receiver application requires it.

The differences among the multicast routing protocols are summarized in [Table 430](#).

**Table 430: Multicast Routing Protocols Compared**

| Multicast Routing Protocol | Dense Mode | Sparse Mode | Implicit Join | Explicit Join | (S,G) SBT  | (*G) Shared Tree |
|----------------------------|------------|-------------|---------------|---------------|------------|------------------|
| DVMRP                      | Yes        | No          | Yes           | No            | Yes        | No               |
| MOSPF                      | Yes        | No          | No            | Yes           | Yes        | No               |
| PIM dense mode             | Yes        | No          | Yes           | No            | Yes        | No               |
| PIM sparse mode            | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |
| Bidirectional PIM          | No         | No          | No            | Yes           | No         | Yes              |
| CBT                        | No         | Yes         | No            | Yes           | No         | Yes              |
| SSM                        | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |
| IGMPv1                     | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |
| IGMPv2                     | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |
| IGMPv3                     | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |

Table 430: Multicast Routing Protocols Compared (*continued*)

| Multicast Routing Protocol | Dense Mode | Sparse Mode | Implicit Join | Explicit Join | (S,G) SBT  | (*G) Shared Tree |
|----------------------------|------------|-------------|---------------|---------------|------------|------------------|
| BSR and Auto-RP            | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |
| MSDP                       | No         | Yes         | No            | Yes           | Yes, maybe | Yes, initially   |

It is important to realize that retransmissions due to a high bit-error rate on a link or overloaded routing device can make multicast as inefficient as repeated unicast. Therefore, there is a trade-off in many multicast applications regarding the session support provided by the Transmission Control Protocol (TCP) (but TCP always resends missing segments), or the simple drop-and-continue strategy of the User Datagram Protocol (UDP) datagram service (but reordering can become an issue). Modern multicast uses UDP almost exclusively.

### T Series Router Multicast Performance

The Juniper Networks T Series Core Routers handle extreme multicast packet replication requirements with a minimum of router load. Each memory component replicates a multicast packet twice at most. Even in the worst-case scenario involving maximum fan-out, when 1 input port and 63 output ports need a copy of the packet, the T Series routing platform copies a multicast packet only six times. Most multicast distribution trees are much sparser, so in many cases only two or three replications are necessary. In no case does the T Series architecture have an impact on multicast performance, even with the largest multicast fan-out requirements.

## Understanding Group Membership Protocols

---

There is a big difference between the multicast protocols used between host and routing device and between the multicast routing devices themselves. Hosts on a given subnetwork need to inform their routing device only whether or not they are interested in receiving packets from a certain multicast group. The source host needs to inform its routing devices only that it is the source of traffic for a particular multicast group. In other words, no detailed knowledge of the distribution tree is needed by any hosts; only a group membership protocol is needed to inform routing devices of their participation in a multicast group. Between adjacent routing devices, on the other hand, the multicast routing protocols must avoid loops as they build a detailed sense of the network topology

and distribution tree from source to leaf. So, different multicast protocols are used for the host-router portion and the router-router portion of the multicast network.

Multicast group membership protocols enable a routing device to detect when a host on a directly attached subnet, typically a LAN, wants to receive traffic from a certain multicast group. Even if more than one host on the LAN wants to receive traffic for that multicast group, the routing device sends only one copy of each packet for that multicast group out on that interface, because of the inherent broadcast nature of LANs. When the multicast group membership protocol informs the routing device that there are no interested hosts on the subnet, the packets are withheld and that leaf is pruned from the distribution tree.

The Internet Group Management Protocol (IGMP) and the Multicast Listener Discovery (MLD) Protocol are the standard IP multicast group membership protocols: IGMP and MLD have several versions that are supported by hosts and routing devices:

- IGMPv1—The original protocol defined in RFC 1112. An explicit join message is sent to the routing device, but a timeout is used to determine when hosts leave a group. This process wastes processing cycles on the routing device, especially on older or smaller routing devices.
- IGMPv2—Defined in RFC 2236. Among other features, IGMPv2 adds an explicit leave message to the join message so that routing devices can more easily determine when a group has no interested listeners on a LAN.
- IGMPv3—Defined in RFC 3376. Among other features, IGMPv3 optimizes support for a single source of content for a multicast group, or *source-specific multicast (SSM)*.
- MLDv1—Defined in RFC 2710. MLDv1 is similar to IGMPv2.
- MLDv2—Defined in RFC 3810. MLDv2 similar to IGMPv3.

The various versions of IGMP and MLD are backward compatible. It is common for a routing device to run multiple versions of IGMP and MLD on LAN interfaces. Backward compatibility is achieved by dropping back to the most basic of all versions run on a LAN. For example, if one host is running IGMPv1, any routing device attached to the LAN running IGMPv2 can drop back to IGMPv1 operation, effectively eliminating the IGMPv2 advantages. Running multiple IGMP versions ensures that both IGMPv1 and IGMPv2 hosts find peers for their versions on the routing device.

---

## Understanding IGMP

The Internet Group Management Protocol (IGMP) manages the membership of hosts and routing devices in multicast groups. IP hosts use IGMP to report their multicast group memberships to any immediately neighboring multicast routing devices. Multicast routing devices use IGMP to learn, for each of their attached physical networks, which groups have members.

IGMP is also used as the transport for several related multicast protocols (for example, Distance Vector Multicast Routing Protocol [DVMRP] and Protocol Independent Multicast version 1 [PIMv1]).

A routing device receives explicit join and prune messages from those neighboring routing devices that have downstream group members. When PIM is the multicast protocol in use, IGMP begins the process as follows:

1. To join a multicast group, G, a host conveys its membership information through IGMP.
2. The routing device then forwards data packets addressed to a multicast group G to only those interfaces on which explicit join messages have been received.
3. A designated router (DR) sends periodic join and prune messages toward a group-specific rendezvous point (RP) for each group for which it has active members. One or more routing devices are automatically or statically designated as the RP, and all routing devices must explicitly join through the RP.
4. Each routing device along the path toward the RP builds a wildcard (any-source) state for the group and sends join and prune messages toward the RP.

The term *route entry* is used to refer to the state maintained in a routing device to represent the distribution tree.

A route entry can include such fields as:

- source address
- group address
- incoming interface from which packets are accepted
- list of outgoing interfaces to which packets are sent
- timers
- flag bits

The wildcard route entry's incoming interface points toward the RP.

The outgoing interfaces point to the neighboring downstream routing devices that have sent join and prune messages toward the RP as well as the directly connected hosts that have requested membership to group G.

5. This state creates a shared, RP-centered, distribution tree that reaches all group members.

IGMP is an integral part of IP and must be enabled on all routing devices and hosts that need to receive IP multicast traffic.

For each attached network, a multicast routing device can be either a querier or a nonquerier. The querier routing device periodically sends general query messages to solicit group membership information. Hosts on the network that are members of a multicast group send report messages. When a host leaves a group, it sends a leave group message.

IGMP version 3 (IGMPv3) supports inclusion and exclusion lists. Inclusion lists enable you to specify which sources can send to a multicast group. This type of multicast group is called a source-specific multicast (SSM) group, and its multicast address is 232/8.

IGMPv3 provides support for source filtering. For example, a routing device can specify particular routing devices from which it accepts or rejects traffic. With IGMPv3, a multicast routing device can learn which sources are of interest to neighboring routing devices.

Exclusion mode works the opposite of an inclusion list. It allows any source but the ones listed to send to the SSM group.

IGMPv3 interoperates with versions 1 and 2 of the protocol. However, to remain compatible with older IGMP hosts and routing devices, IGMPv3 routing devices must also implement versions 1 and 2 of the protocol. IGMPv3 supports the following membership-report record types: mode is allowed, allow new sources, and block old sources.

- *Configuring IGMP*

---

## Configuring IGMP

---

Before you begin:

1. Determine whether the router is directly attached to any multicast sources. Receivers must be able to locate these sources.
2. Determine whether the router is directly attached to any multicast group receivers. If receivers are present, IGMP is needed.
3. Determine whether to configure multicast to use sparse, dense, or sparse-dense mode. Each mode has different configuration considerations.
4. Determine the address of the RP if sparse or sparse-dense mode is used.
5. Determine whether to locate the RP with the static configuration, BSR, or auto-RP method.
6. Determine whether to configure multicast to use its own RPF routing table when configuring PIM in sparse, dense, or sparse-dense mode.
7. Configure the SAP and SDP protocols to listen for multicast session announcements. See *Configuring the Session Announcement Protocol*.

To configure the Internet Group Management Protocol (IGMP), include the **igmp** statement:

```
igmp {
 accounting;
 interface interface-name {
 disable;
 (accounting | no-accounting);
 group-policy [policy-names];
 immediate-leave;
 oif-map map-name;
```

```

promiscuous-mode;
ssm-map ssm-map-name;
static {
 group multicast-group-address {
 exclude;
 group-count number;
 group-increment increment;
 source ip-address {
 source-count number;
 source-increment increment;
 }
 }
}
version version;
}
query-interval seconds;
query-last-member-interval seconds;
query-response-interval seconds;
robust-count number;
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

By default, IGMP is enabled on all interfaces on which you configure Protocol Independent Multicast (PIM), and on all broadcast interfaces on which you configure the Distance Vector Multicast Routing Protocol (DVMRP).

**NOTE:** You can configure IGMP on an interface without configuring PIM. PIM is generally not needed on IGMP downstream interfaces. Therefore, only one “pseudo PIM interface” is created to represent all IGMP downstream (IGMP-only) interfaces on the router. This reduces the amount of router resources, such as memory, that are consumed. You must configure PIM on upstream IGMP interfaces to enable multicast routing, perform reverse-path forwarding for multicast data packets, populate the multicast forwarding table for upstream interfaces, and in the case of bidirectional PIM and PIM sparse mode, to distribute IGMP group memberships into the multicast routing domain.

## Enabling IGMP

The Internet Group Management Protocol (IGMP) manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use IGMP to learn which groups have members on each of their attached physical

networks. IGMP must be enabled for the router to receive IPv4 multicast packets. IGMP is only needed for IPv4 networks, because multicast is handled differently in IPv6 networks. IGMP is automatically enabled on all IPv4 interfaces on which you configure PIM and on all IPv4 broadcast interfaces when you configure DVMRP.

If IGMP is not running on an interface—either because PIM and DVMRP are not configured on the interface or because IGMP is explicitly disabled on the interface—you can explicitly enable IGMP.

To explicitly enable IGMP:

1. If PIM and DVMRP are not running on the interface, explicitly enable IGMP by including the interface name.

```
[edit protocols igmp]
user@host# set interface fe-0/0/0.0
```

2. See if IGMP is disabled on any interfaces. In the following example, IGMP is disabled on a Gigabit Ethernet interface.

```
[edit protocols igmp]
user@host# show
interface fe-0/0/0.0;
interface ge-1/0/0.0 {
 disable;
}
```

3. Enable IGMP on the interface by deleting the **disable** statement.

```
[edit protocols igmp]
delete interface ge-1/0/0.0 disable
```

4. Verify the configuration.

```
[edit protocols igmp]
user@host# show
interface fe-0/0/0.0;
interface ge-1/0/0.0;
```

5. Verify the operation of IGMP on the interfaces by checking the output of the **show igmp interface** command.

---

## Changing the IGMP Version

By default, the routing device runs IGMPv2. Routing devices running different versions of IGMP determine the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version.

To enable source-specific multicast (SSM) functionality, you must configure version 3 on the host and the host's directly connected routing device. If a source address is specified in a multicast group that is statically configured, the version must be set to IGMPv3.

If a static multicast group is configured with the source address defined, and the IGMP version is configured to be version 2, the source is ignored and only the group is added. In this case, the join is treated as an IGMPv2 group join.

If you configure the IGMP version setting at the individual interface hierarchy level, it overrides the **interface all** statement.

If you have already configured the routing device to use IGMP version 1 (IGMPv1) and then configure it to use IGMPv2, the routing device continues to use IGMPv1 for up to 6 minutes and then uses IGMPv2.

To change to IGMPv3 for SSM functionality:

1. Configure the IGMP interface.

```
[edit protocols igmp]
user@host# set interface ge-0/0/0 version 3
```

2. Verify the configuration by checking the version field in the output of the **show igmp interfaces** command. The **show igmp statistics** command has version-specific output fields, such as V1 Membership Report, V2 Membership Report, and V3 Membership Report.

**CAUTION:** On MX Series platforms, IGMPv2 and IGMPv3 cannot be configured together on the same interface. Configuring both together causes unexpected behavior in multicast traffic forwarding.

## Modifying the IGMP Host-Query Message Interval

The objective of IGMP is to keep routers up to date with group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The IGMP querier router periodically sends general host-query messages on each attached network to solicit membership information. The messages are sent to the all-systems multicast group address, 224.0.0.1.

The query interval, the response interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the group membership timeout has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of IGMP messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

```
[edit protocols igmp]
user@host# set query-interval 200
```

The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the IGMP Query Interval field in the output of the **show igmp interface** command.
3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

## Modifying the IGMP Last-Member Query Interval

The last-member query interval is the maximum amount of time between group-specific query messages, including those sent in response to leave-group messages. You can configure this interval to change the amount of time it takes a routing device to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group message from a host, the routing device sends multiple group-specific queries to the group being left. The querier sends a specific number of these queries at a specific interval. The number of queries sent is called the last-member query count. The interval at which the queries are sent is called the last-member query interval. Because both settings are configurable, you can adjust the leave latency. The IGMP leave latency is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-member query count x (times) the last-member query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-member query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

```
[edit protocols igmp]
user@host# set query-last-member-interval 0.1
```

2. Verify the configuration by checking the IGMP Last Member Query Interval field in the output of the **show igmp interfaces** command.

**NOTE:** You can configure the last-member query count by configuring the robustness variable. The two are always equal.

Documentation**

- [Modifying the IGMP Robustness Variable on page 5417](#)
- [show pim interfaces on page 5883](#)

## Specifying Immediate-Leave Host Removal for IGMP

The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.

**NOTE:** Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave on an interface:

1. Configure immediate leave on the IGMP interface.

```
[edit protocols IGMP]
user@host# set interface ge-0/0/0.1 immediate-leave
```

2. Verify the configuration by checking the Immediate Leave field in the output of the `show igmp interface` command.

## Filtering Unwanted IGMP Reports at the IGMP Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted IGMP reports at the interface level. When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), after the router receives an IGMP report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only IGMP group addresses (for IGMPv2) by using the policy's **route-filter** statement to match the group address. You define the policy to match IGMP (source, group) addresses (for IGMPv3) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

**CAUTION:** On MX Series platforms, IGMPv2 and IGMPv3 cannot be configured together on the same interface. Configuring both together causes unexpected behavior in multicast traffic forwarding.

To filter unwanted IGMP reports:

1. Configure an IGMPv2 policy.

```
[edit policy-statement reject_policy_v2]
```

```

user@host# set from route-filter 224.1.1.1/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set then reject

```

2. Configure an IGMPv3 policy.

```

[edit policy-statement reject_policy_v3]
user@host# set from route-filter 224.1.1.1/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set from source-address-filter 10.0.0.0/8 orlonger
user@host# set from source-address-filter 127.0.0.0/8 orlonger
user@host# set then reject

```

3. Apply the policies to the IGMP interfaces on which you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running IGMPv2, and **ge-0/1/1.0** is running IGMPv3.

```

[edit protocols igmp]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v2
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v3

```

4. Verify the operation of the filter by checking the Rejected Report field in the output of the **show igmp statistics** command.

## Accepting IGMP Messages from Remote Subnetworks

By default, IGMP interfaces accept IGMP messages only from the same subnet. Including the **promiscuous-mode** statement enables the routing device to accept IGMP messages from indirectly connected subnets.

**NOTE:** When you enable IGMP on an unnumbered Ethernet interface that uses a /32 loopback address as a donor address, you must configure IGMP promiscuous mode to accept the IGMP packets received on this interface.

**NOTE:** When enabling promiscuous-mode, all routers on the ethernet segment must be configured with the promiscuous mode statement. Otherwise, only the interface configured with lowest IPv4 address acts as the querier for IGMP for this Ethernet segment.

To enable IGMP promiscuous mode on an interface:

1. Configure the IGMP interface.

```

[edit protocols igmp]
user@host# set interface ge-0/1/1.0 promiscuous-mode

```

2. Verify the configuration by checking the Promiscuous Mode field in the output of the **show igmp interface** command.
3. Verify the operation of the filter by checking the Rx non-local field in the output of the **show igmp statistics** command.

---

## Modifying the IGMP Query Response Interval

---

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. Configuring this interval allows you to adjust the burst peaks of IGMP messages on the subnet. Set a larger interval to make the traffic less bursty. Bursty traffic refers to an uneven pattern of data transmission: sometimes a very high data transmission rate, whereas at other times a very low data transmission rate.

The query response interval, the host-query interval, and the robustness variable are related in that they are all variables that are used to calculate the group membership timeout. The group membership timeout is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The group membership timeout is calculated as the (robustness variable x query-interval) + (query-response-interval). If no reports are received for a particular group before the group membership timeout has expired, the routing device stops forwarding remotely originated multicast packets for that group onto the attached network.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.  

```
[edit protocols igmp]
user@host# set query-response-interval 0.4
```
2. Verify the configuration by checking the IGMP Query Response Interval field in the output of the **show igmp interface** command.
3. Verify the operation of the query interval by checking the Membership Query field in the output of the **show igmp statistics** command.

**Related  
Documentation**

- [Modifying the IGMP Robustness Variable on page 5417](#)
- [show igmp interface on page 5801](#)
- [show igmp statistics on page 5805](#)

## Modifying the IGMP Robustness Variable

Fine-tune the IGMP robustness variable to allow for expected packet loss on a subnet. The robust count automatically changes certain IGMP message intervals for IGMPv2 and IGMPv3. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

When the query router receives an IGMP leave message on a shared network running IGMPv2, the query router must send an IGMP group query message a specified number of times. The number of IGMP group query messages sent is determined by the robust count.

The value of the robustness variable is also used in calculating the following IGMP message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is calculated as follows:  $(\text{robustness variable} \times \text{query-interval}) + (1 \times \text{query-response-interval})$ .
- Other querier present interval—The robust count is used to calculate the amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows:  $(\text{robustness variable} \times \text{query-interval}) + (0.5 \times \text{query-response-interval})$ .
- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The number of queries is equal to the value of the robustness variable.

In IGMPv3, a change of interface state causes the system to immediately transmit a state-change report from that interface. In case the state-change report is missed by one or more multicast routers, it is retransmitted. The number of times it is retransmitted is the robust count minus one. In IGMPv3, the robust count is also a factor in determining the group membership interval, the older version querier interval, and the other querier present interval.

By default, the robustness variable is set to 2. You might want to increase this value if you expect a subnet to lose packets.

The number can be from 2 through 10.

To change the value of the robustness variable:

1. Configure the robust count.

When you set the robust count, you are in effect configuring the number of times the querier retries queries on the connected subnets.

```
[edit protocols igmp]
user@host# set robust-count 5
```

2. Verify the configuration by checking the IGMP Robustness Count field in the output of the **show igmp interfaces** command.

## Limiting the Maximum IGMP Message Rate

This section describes how to change the limit for the maximum number of IGMP packets transmitted in 1 second by the router.

Increasing the maximum number of IGMP packets transmitted per second might be useful on a router with a large number of interfaces participating in IGMP.

To change the limit for the maximum number of IGMP packets the router can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

**Related Documentation**

---

## Enabling IGMP Static Group Membership

You can create IGMP static group membership to test multicast forwarding without a receiver host. When you enable IGMP static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts. The router on which you enable static IGMP group membership must be the designated router (DR) for the subnet. Otherwise, traffic does not flow downstream.

When enabling IGMP static group membership, you cannot configure multiple groups using the **group-count**, **group-increment**, **source-count**, and **source-increment** statements if the **all** option is specified as the IGMP interface.

Class-of-service (CoS) adjustment is not supported with IGMP static group membership.

In this example, you create static group 225.1.1.1.

1. On the DR, configure the static groups to be created by including the **static** statement and **group** statement and specifying which IP multicast address of the group to be created. When creating groups individually, you must specify a unique address for each group.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 static {
 group 225.1.1.1;
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created.

```
user@host> show igmp group
Interface: fe-0/1/2
Group: 225.1.1.1
Source: 10.0.0.2
Last reported by: Local
Timeout: 0 Type: Static
```

**NOTE:** When you configure static IGMP group entries on point-to-point links that connect routing devices to a rendezvous point (RP), the static IGMP group entries do not generate join messages toward the RP.

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. On the DR, configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 static {
 group 225.1.1.1 {
 group-count 3;
 }
 }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.2, and 225.1.1.3 have been created.

```
user@host> show igmp group
Interface: fe-0/1/2
 Group: 225.1.1.1
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.2
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.3
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can also configure the group address to be automatically incremented for each group created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and when you do not want the group addresses to be sequential.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. On the DR, configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented for each group. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 group-count 3 group-increment 0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 version 3;
 static {
 group 225.1.1.1 {
 group-increment 0.0.0.2;
 group-count 3;
 }
 }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static groups 225.1.1.1, 225.1.1.3, and 225.1.1.5 have been created.

```
user@host> show igmp group
```

```

Interface: fe-0/1/2
 Group: 225.1.1.1
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.3
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.5
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static

```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, and your network is operating in source-specific multicast (SSM) mode, you can also specify that the multicast source address be accepted. This is useful when you want to test forwarding to multicast receivers from a specific multicast source.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you create group 225.1.1.1 and accept IP address 10.0.0.2 as the only source.

1. On the DR, configure the source address by including the **source** statement and specifying the IPv4 address of the source host.

```

[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2

```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```

user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 version 3;
 static {
 group 225.1.1.1 {
 source 10.0.0.2;
 }
 }
}

```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that source 10.0.0.2 has been accepted.

```

user@host> show igmp group
Interface: fe-0/1/2
 Group: 225.1.1.1
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static

```

When you create IGMP static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of multicast sources be automatically accepted. This is useful when you want to test forwarding to multicast receivers from more than one specified multicast source.

In this example, you create group 255.1.1.1 and accept addresses 10.0.0.2, 10.0.0.3, and 10.0.0.4 as the sources.

1. On the DR, configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count
3
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 version 3;
 static {
 group 225.1.1.1 {
 source 10.0.0.2 {
 source-count 3;
 }
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.3, and 10.0.0.4 have been accepted.

```
user@host> show igmp group
Interface: fe-0/1/2
 Group: 225.1.1.1
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.1
 Source: 10.0.0.3
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.1
 Source: 10.0.0.4
 Last reported by: Local
 Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic, and specify that a number of multicast sources be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately and you do not want the source addresses to be sequential.

In this example, you create group 225.1.1.1 and accept addresses 10.0.0.2, 10.0.0.4, and 10.0.0.6 as the sources.

1. Configure the multicast source address increment by including the **source-increment** statement and specifying the number by which the address should be incremented for each source. The increment is specified in dotted decimal notation similar to an IPv4 address.

```
[edit protocols igmp]
```

```
user@host# set interface fe-0/1/2 static group 225.1.1.1 source 10.0.0.2 source-count 3 source-increment 0.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp
```

```
interface fe-0/1/2.0 {
 version 3;
 static {
 group 225.1.1.1 {
 source 10.0.0.2 {
 source-count 3;
 source-increment 0.0.0.2;
 }
 }
 }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show igmp group** command to verify that static group 225.1.1.1 has been created and that sources 10.0.0.2, 10.0.0.4, and 10.0.0.6 have been accepted.

```
user@host> show igmp group
```

```
Interface: fe-0/1/2
 Group: 225.1.1.1
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.1
 Source: 10.0.0.4
 Last reported by: Local
 Timeout: 0 Type: Static
 Group: 225.1.1.1
 Source: 10.0.0.6
 Last reported by: Local
 Timeout: 0 Type: Static
```

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the source address configured. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the source address configured.

If a source address is specified in a multicast group that is statically configured, the IGMP version on the interface must be set to IGMPv3. IGMPv2 is the default value.

In this example, you exclude address 10.0.0.2 as a source for group 225.1.1.1.

1. On the DR, configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv4 source address to exclude.

```
[edit protocols igmp]
user@host# set interface fe-0/1/2 static group 225.1.1.1 exclude source 10.0.0.2
```

2. After you commit the configuration, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```
user@host> show configuration protocol igmp

interface fe-0/1/2.0 {
 version 3;
 static {
 group 225.1.1.1 {
 exclude;
 source 10.0.0.2;
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show igmp group detail** command to verify that static group 225.1.1.1 has been created and that the static group is operating in exclude mode.

```
user@host> show igmp group detail
Interface: fe-0/1/2
 Group: 225.1.1.1
 Group mode: Exclude
 Source: 10.0.0.2
 Last reported by: Local
 Timeout: 0 Type: Static
```

## Recording IGMP Join and Leave Events

To determine whether IGMP tuning is needed in a network, you can configure the routing device to record IGMP join and leave events. You can record events globally for the routing device or for individual interfaces.

[Table 431](#) describes the recordable IGMP events.

**Table 431: IGMP Event Messages**

| ERRMSG Tag                  | Definition                                                     |
|-----------------------------|----------------------------------------------------------------|
| RPD_IGMP_JOIN               | Records IGMP join events.                                      |
| RPD_IGMP_LEAVE              | Records IGMP leave events.                                     |
| RPD_IGMP_ACCOUNTING_ON      | Records when IGMP accounting is enabled on an IGMP interface.  |
| RPD_IGMP_ACCOUNTING_OFF     | Records when IGMP accounting is disabled on an IGMP interface. |
| RPD_IGMP_MEMBERSHIP_TIMEOUT | Records IGMP membership timeout events.                        |

To enable IGMP accounting:

1. Enable accounting globally or on an IGMP interface. This example shows both options.

```
[edit protocols igmp]
user@host# set accounting
user@host# set interface fe-0/1/0.2 accounting
```

2. Configure the events to be recorded and filter the events to a system log file with a descriptive filename, such as `igmp-events`.

```
[edit system syslog file igmp-events]
user@host# set any info
user@host# set match ".*RPD_IGMP_JOIN.* | .*RPD_IGMP_LEAVE.* |
.*RPD_IGMP_ACCOUNTING.* | .*RPD_IGMP_MEMBERSHIP_TIMEOUT.*"
```

3. Periodically archive the log file.

This example rotates the file size when it reaches 100 KB and keeps three files.

```
[edit system syslog file igmp-events]
user@host# set archive size 100000
user@host# set archive files 3
user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
"anonymous"
user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
user@host# set archive transfer-interval 24
user@host# set archive start-time 2011-01-07:12:30
```

4. You can monitor the system log file as entries are added to the file by running the **monitor start** and **monitor stop** commands.

```
user@host> monitor start igmp-events
```

```
*** igmp-events ***
```

```
Apr 16 13:08:23 host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command
'run monitor start igmp-events '
monitor
```

## Limiting the Number of IGMP Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of IGMP multicast group joins for logical interfaces. When this statement is enabled on a router running IGMP version 2 (IGMPv2) or version 3 (IGMPv3), the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for IGMP multicast groups, keep the following in mind:

- Each any-source group (\*G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in IGMPv3 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.
- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (\*, G1) and (S, G1) would count as two groups toward the configured limit.
- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The groups must then request to rejoin the network (up to the newly configured group limit).
- You can dynamically limit multicast groups on IGMP logical interfaces using dynamic profiles.

Beginning with Junos OS 12.2, you can optionally configure a system log warning threshold for IGMP multicast group joins received on the logical interface. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of IGMP multicast group joins have been received on the interface. These log messages convey when the configured group limit has been exceeded, when the configured threshold has been exceeded, and when the number of groups drop below the configured threshold.

The **group-threshold** statement enables you to configure the threshold at which a warning message is logged. The range is 1 through 100 percent. The warning threshold is a

percentage of the group limit, so you must configure the **group-limit** statement to configure a warning threshold. For instance, when the number of groups exceed the configured warning threshold, but remain below the configured group limit, multicast groups continue to be accepted, and the device logs the warning message. In addition, the device logs a warning message after the number of groups drop below the configured warning threshold. You can further specify the amount of time (in seconds) between the log messages by configuring the **log-interval** statement. The range is 6 through 32,767 seconds.

You might consider throttling log messages because every entry added after the configured threshold and every entry rejected after the configured limit causes a warning message to be logged. By configuring a log interval, you can throttle the amount of system log warning messages generated for IGMP multicast group joins.

To limit multicast group joins on an IGMP logical interface:

1. Access the logical interface at the IGMP protocol hierarchy level.

```
[edit]
user@host# edit protocols igmp interface interface-name
```

2. Specify the group limit for the interface.

```
[edit protocols igmp interface interface-name]
user@host# set group-limit limit
```

3. (Optional) Configure the threshold at which a warning message is logged.

```
[edit protocols igmp interface interface-name]
user@host# set group-threshold value
```

4. (Optional) Configure the amount of time between log messages.

```
[edit protocols igmp interface interface-name]
user@host# set log-interval seconds
```

To confirm your configuration, use the **show protocols igmp** command. To verify the operation of IGMP on the interface, including the configured group limit and the optional warning threshold and interval between log messages, use the **show igmp interface** command.

## Tracing IGMP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag                       | Description           |
|----------------------------|-----------------------|
| <b>all</b>                 | Trace all operations. |
| <b>client-notification</b> | Trace notifications.  |

| Flag                     | Description                                                                         |
|--------------------------|-------------------------------------------------------------------------------------|
| <b>general</b>           | Trace general flow.                                                                 |
| <b>group</b>             | Trace group operations.                                                             |
| <b>host-notification</b> | Trace host notifications.                                                           |
| <b>leave</b>             | Trace leave group messages (IGMPv2 only).                                           |
| <b>mtrace</b>            | Trace mtrace packets. Use the <b>mtrace</b> command to troubleshoot the software.   |
| <b>normal</b>            | Trace normal events.                                                                |
| <b>packets</b>           | Trace all IGMP packets.                                                             |
| <b>policy</b>            | Trace policy processing.                                                            |
| <b>query</b>             | Trace IGMP membership query messages, including general and group-specific queries. |
| <b>report</b>            | Trace membership report messages.                                                   |
| <b>route</b>             | Trace routing information.                                                          |
| <b>state</b>             | Trace state transitions.                                                            |
| <b>task</b>              | Trace task processing.                                                              |
| <b>timer</b>             | Trace timer processing.                                                             |

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on IGMP packets of a particular type. To configure tracing operations for IGMP:

1. (Optional) Configure tracing at the routing options level to trace all protocol packets.

```
[edit routing-options traceoptions]
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the IGMP trace file.

```
[edit protocols igmp traceoptions]
user@host# set file igmp-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols igmp traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols igmp traceoptions]
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols igmp traceoptions]
user@host# set file world-readable
```

6. Configure tracing flags. Suppose you are troubleshooting issues with a particular multicast group. The following example shows how to flag all events for packets associated with the group IP address.

```
[edit protocols igmp traceoptions]
user@host# set flag group | match 232.1.1.2
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/igmp-trace
```

## Disabling IGMP

To disable IGMP on an interface, include the **disable** statement:

```
disable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols igmp interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols igmp interface *interface-name*]

- Related Documentation**

## IGMP Snooping Overview

---

With IGMP snooping enabled, a switch monitors the IGMP (Internet Group Management Protocol) traffic between hosts and multicast routers and uses what it learns to forward multicast traffic to only the downstream interfaces that are connected to interested receivers. This conserves bandwidth by allowing the switch to send multicast traffic to only those interfaces that are connected to devices that want to receive the traffic (instead of flooding the traffic to all the downstream VLAN interfaces).

This IGMP snooping topic includes:

- [How IGMP Snooping Works on page 5431](#)
- [How IGMP Snooping Works with Routed VLAN Interfaces on page 5432](#)
- [How Hosts Join and Leave Multicast Groups on page 5432](#)
- [IGMP Snooping and Forwarding Interfaces on page 5433](#)
- [General Forwarding Rules on page 5433](#)

## How IGMP Snooping Works

A switch usually learns unicast MAC addresses by checking the source address field of the frames it receives and then sends any traffic for that unicast address only to the appropriate interface. However, a multicast MAC address can never be the source address for a packet. As a result, when a switch receives traffic for a multicast destination address, it floods the traffic on the relevant VLAN, which can cause a significant amount of traffic to be sent unnecessarily.

IGMP snooping prevents this flooding. When you enable IGMP snooping, the switch monitors IGMP packets between receivers and multicast routers and uses the content

of the packets to build a multicast cache table—a database of multicast groups and the interfaces that are connected to members of the groups. When the switch receives multicast packets, it uses the cache table to selectively forward the traffic to only the interfaces that are connected to members of the appropriate multicast groups.

**NOTE:** IGMP snooping is enabled by default on the default VLAN only. With versions of Junos OS for the QFX Series previous to 13.2, IGMP snooping is enabled by default on all VLANs.

**NOTE:** You cannot configure IGMP snooping on a secondary (private) VLAN.

## How IGMP Snooping Works with Routed VLAN Interfaces

A switch can use a routed VLAN interface (RVI) to forward traffic between VLANs that connect to it. IGMP snooping works with Layer 2 interfaces and RVIs to forward multicast traffic in a switched network.

When a switch receives a multicast packet, its Packet Forwarding Engines perform a multicast lookup on the packet to determine how to forward the packet to its local interfaces. From the results of the lookup, each Packet Forwarding Engine extracts a list of Layer 3 interfaces that have ports local to the Packet Forwarding Engine. If the list includes an RVI, the switch provides a bridge multicast group ID for the RVI to the Packet Forwarding Engine.

For VLANs that include multicast receivers, the bridge multicast ID includes a sub-next-hop ID, which identifies the Layer 2 interfaces in the VLAN that are interested in receiving the multicast stream. The Packet Forwarding Engine then forwards multicast traffic to bridge multicast IDs that have multicast receivers for a given multicast group.

## How Hosts Join and Leave Multicast Groups

Hosts can join multicast groups in two ways:

- By sending an unsolicited IGMP join message to a multicast router that specifies the IP multicast group that the host is attempting to join.
- By sending an IGMP join message in response to a general query from a multicast router.

A multicast router continues to forward multicast traffic to a VLAN provided that at least one host on that VLAN responds to the periodic general IGMP queries. For a host to remain a member of a multicast group, therefore, it must continue to respond to the periodic general IGMP queries.

To leave a multicast group, either a host cannot respond to the periodic general IGMP queries, which results in a “silent leave” (the only leave option for IGMPv1), or a host can send a group-specific IGMPv2 leave message.

## IGMP Snooping and Forwarding Interfaces

To determine how to forward multicast traffic, a switch with IGMP snooping enabled maintains information about the following interfaces in its multicast forwarding table:

- Multicast-router interfaces—These interfaces lead toward multicast routers or IGMP queriers.
- Group-member interfaces—These interfaces lead toward hosts that are members of multicast groups.

The switch learns about these interfaces by monitoring IGMP traffic. If an interface receives IGMP queries or Protocol Independent Multicast (PIM) updates, the switch adds the interface to its multicast forwarding table as a multicast-router interface. If an interface receives membership reports for a multicast group, the switch adds the interface to its multicast forwarding table as a group-member interface.

Table entries for interfaces that the switch learns about are subject to aging. For example, if a learned multicast-router interface does not receive IGMP queries or PIM hellos within a certain interval, the switch removes the entry for that interface from its multicast forwarding table.

**NOTE:** For a switch to learn multicast-router interfaces and group-member interfaces, an IGMP querier must exist in the network. This is often a multicast router, but if there is no multicast router on the local network, you can configure the switch itself to be an IGMP querier.

You can statically configure an interface to be a multicast-router interface or a group-member interface. The switch adds a static interface to its multicast forwarding table without having to learn about the interface, and the entry in the table is not subject to aging. You can have a mix of statically configured and dynamically learned interfaces on a switch.

## General Forwarding Rules

Multicast traffic received on a switch interface in a VLAN on which IGMP snooping is enabled is forwarded according to the following rules.

IGMP traffic is forwarded as follows:

- IGMP general queries received on a multicast-router interface are forwarded to all other interfaces in the VLAN.
- IGMP group-specific queries received on a multicast-router interface are forwarded to only those interfaces in the VLAN that are members of the group.
- IGMP reports received on a host interface are forwarded to multicast-router interfaces in the same VLAN, but not to the other host interfaces in the VLAN.

Multicast traffic that is not IGMP traffic is forwarded as follows:

- A multicast packet with a destination address of 224.0.0.0/24 is flooded to all other interfaces on the VLAN.
- An unregistered multicast packet—that is, a packet for a group that has no current members—is forwarded to all multicast-router interfaces in the VLAN.
- A registered multicast packet is forwarded only to those host interfaces in the VLAN that are members of the multicast group and to all multicast-router interfaces in the VLAN.

## Configuring IGMP Snooping

With IGMP snooping enabled, a switch monitors the IGMP (Internet Group Management Protocol) traffic between hosts and multicast routers and uses what it learns to forward multicast traffic to only the downstream interfaces that are connected to interested receivers. This conserves bandwidth by allowing the switch to send multicast traffic to only those interfaces that are connected to devices that want to receive the traffic (instead of flooding the traffic to all the downstream VLAN interfaces).

**NOTE:** You cannot configure IGMP snooping on a secondary VLAN.

To enable IGMP snooping and configure individual options as needed for your network by using the CLI:

1. Enable IGMP snooping on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan
```

2. Configure the switch to immediately remove group membership from interfaces on a VLAN when it receives a leave message through that VLAN, and have it not forward any membership queries for the multicast group to the VLAN (IGMPv2 only):

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name immediate-leave
```

3. Configure an interface to belong to a multicast group:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name interface interface-name static group
group-address
```

4. Configure an interface to forward IGMP queries received from multicast routers.

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name interface interface-name
multicast-router-interface
```

5. Configure the switch to wait for four timeout intervals before timing out a multicast group on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name robust-count 4
```

6. If you want a standalone switch to act as an IGMP querier, enter the following:

```
[edit protocols]
user@switch# set igmp-snooping vlan vlan-name l2-querier source-address source address
```

The switch uses the address that you configure as the source address in the IGMP queries that it sends. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is greater (a higher number) than the IP addresses for those routers on the network. This ensures that switch is always the IGMP querier on the network.

## Configuring VLAN-Specific IGMP Snooping Parameters

All of the IGMP snooping statements configured with the **igmp-snooping** statement, with the exception of the **traceoptions** statement, can be qualified with the same statement at the VLAN level. To configure IGMP snooping parameters at the VLAN level, include the **vlan** statement:

```
vlan vlan-id;
 immediate-leave;
 interface interface-name {
 group-limit limit;
 host-only-interface;
 multicast-router-interface;
 static {
 group ip-address {
 source ip-address;
 }
 }
 }
 proxy {
 source-address ip-address;
 }
 query-interval seconds;
 query-last-member-interval seconds;
 query-response-interval seconds;
 robust-count number;
```

```
}
```

You can include this statement at the following hierarchy levels:

- [edit bridge-domains *bridge-domain-name* protocols igmp-snooping]
- [edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping]

## Example: Configuring IGMP Snooping

With IGMP snooping enabled, a switch monitors the IGMP (Internet Group Management Protocol) traffic between hosts and multicast routers and uses what it learns to forward multicast traffic to only the downstream interfaces that are connected to interested receivers. This conserves bandwidth by allowing the switch to send multicast traffic to only those interfaces that are connected to devices that want to receive the traffic (instead of flooding the traffic to all the downstream VLAN interfaces).

This example describes how to configure IGMP snooping:

- [Requirements on page 5436](#)
- [Overview and Topology on page 5436](#)
- [Configuration on page 5437](#)

### Requirements

This example requires Junos OS Release 11.1 or later on a QFX Series product.

Before you configure IGMP snooping, be sure you have:

- Configured the **employee-vlan** VLAN
- Assigned interfaces **ge-0/0/1**, **ge-0/0/2**, and **ge-0/0/3** to **employee-vlan**

### Overview and Topology

In this example you configure an interface to receive multicast traffic from a source and configure some multicast-related behavior for downstream interfaces. The example assumes that IGMP snooping was previously disabled for the VLAN.

[Table 432](#) shows the components of the topology for this example.

**Table 432: Components of the IGMP Snooping Topology**

| Components                         | Settings                                            |
|------------------------------------|-----------------------------------------------------|
| VLAN name                          | <b>employee-vlan</b> , tag 20                       |
| Interfaces in <b>employee-vlan</b> | <b>ge-0/0/1</b> , <b>ge-0/0/2</b> , <b>ge-0/0/3</b> |

Table 432: Components of the IGMP Snooping Topology (*continued*)

| Components                                    | Settings        |
|-----------------------------------------------|-----------------|
| Multicast IP address for <b>employee-vlan</b> | 225.100.100.100 |

## Configuration

To configure basic IGMP snooping on a switch:

### CLI Quick Configuration

To quickly configure IGMP snooping, copy the following commands and paste them into a terminal window:

```
[edit protocols]
set igmp-snooping vlan employee-vlan
set igmp-snooping vlan employee-vlan interface ge-0/0/3 static group 225.100.100.100
set igmp-snooping vlan employee-vlan interface ge-0/0/2 multicast-router-interface
set igmp-snooping vlan employee-vlan robust-count 4
```

### Step-by-Step Procedure

Configure IGMP snooping:

1. Enable and configure IGMP snooping on the VLAN **employee-vlan**:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan
```

2. Configure an interface to belong to a multicast group:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan interface ge-0/0/3 static group
225.100.100.100
```

3. Configure an interface to forward IGMP queries received from multicast routers.

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan interface ge-0/0/2
multicast-router-interface
```

4. Configure the switch to wait for four timeout intervals before timing out a multicast group on a VLAN:

```
[edit protocols]
user@switch# set igmp-snooping vlan employee-vlan robust-count 4
```

### Results

Check the results of the configuration:

```
user@switch# show protocols igmp-snooping
vlan employee-vlan {
 robust-count 4;
}
interface ge-0/0/2 {
 multicast-router-interface;
}
interface ge-0/0/3 {
 static {
 group 225.100.100.100;
 }
}
```

## Monitoring IGMP Snooping

**Purpose** Use the monitoring feature to view status and information about the IGMP snooping configuration.

**Action** To display IGMP snooping details in the CLI, enter the following commands:

- **show igmp-snooping vlans**
- **show igmp-snooping statistics**
- **show igmp-snooping route**
- **show igmp-snooping membership**

**Meaning** [Table 433](#) summarizes the IGMP snooping details displayed.

**Table 433: Summary of IGMP Snooping Output Fields**

| Field                  | Values                                                             |
|------------------------|--------------------------------------------------------------------|
| IGMP Snooping Monitor  |                                                                    |
| VLAN                   | VLAN for which IGMP snooping is enabled.                           |
| Interfaces             | Interface connected to a multicast router.                         |
| Groups                 | Number of the multicast groups learned by the VLAN.                |
| MRouters               | Multicast router.                                                  |
| Receivers              | Multicast receiver.                                                |
| IGMP Route Information |                                                                    |
| VLAN                   | VLAN for which IGMP snooping is enabled.                           |
| Next-Hop               | Next hop assigned by the switch after performing the route lookup. |
| Group                  | Multicast groups learned by the VLAN.                              |

- Related Documentation**
- [IGMP Snooping Overview on page 5431](#)

- [Example: Configuring IGMP Snooping on page 5436](#)
- [Configuring IGMP Snooping on page 5434](#)

---

## Verifying the IGMP Snooping Group Timeout Value

---

**Purpose** Verify that the IGMP snooping group timeout value has been changed correctly from its default value.

**Action** Display the IGMP snooping membership information, which contains the group timeout value that was derived from the IGMP configuration:

```
user@switch> show igmp-snooping membership detail
VLAN: v43 Tag: 43 (Index: 4)
Group: 225.0.0.1
Receiver count: 1, Flags: <v2-hosts>
ge-0/0/15.0 Uptime: 00:00:05 timeout: 510
```

**Meaning** The IGMP snooping group timeout value determines how long a switch waits to receive an IGMP query from a multicast router before removing a multicast group from its multicast cache table. When you enable IGMP snooping, the default IGMP snooping group timeout value of 260 seconds is applied to all VLANs, which means that the switch waits 260 seconds to receive an IGMP query before removing a multicast group from its multicast cache table. You can change the timeout value by using the **robust-count** option.

# Using MLD

- [Understanding MLD on page 5441](#)
- [Examples: Configuring MLD on page 5444](#)

## Understanding MLD

---

The Multicast Listener Discovery (MLD) Protocol manages the membership of hosts and routers in multicast groups. IP version 6 (IPv6) multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. Each routing device maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the routing device does not need to know the address of each listener—just the address of each host. The routing device provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol.

MLD is an integral part of IPv6 and must be enabled on all IPv6 routing devices and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

In include mode, the receiver specifies the source or sources it is interested in receiving the multicast group traffic from. Exclude mode works the opposite of include mode. It allows the receiver to specify the source or sources it is not interested in receiving the multicast group traffic from.

For each attached network, a multicast routing device can be either a querier or a nonquerier. A querier routing device, usually one per subnet, solicits group membership information by transmitting MLD queries. When a host reports to the querier routing device that it has interested listeners, the querier routing device forwards the membership information to the rendezvous point (RP) routing device by means of the receiver's (host's) designated router (DR). This builds the rendezvous-point tree (RPT) connecting the host with interested listeners to the RP routing device. The RPT is the initial path used by the sender to transmit information to the interested listeners. Nonquerier routing devices do not transmit MLD queries on a subnet but can do so if the querier routing device fails.

All MLD-configured routing devices start as querier routing devices on each attached subnet (see [Figure 154](#)). The querier routing device on the right is the receiver's DR.

Figure 154: Routing Devices Start Up on a Subnet

To elect the querier routing device, the routing devices exchange query messages containing their IPv6 source addresses. If a routing device hears a query message whose IPv6 source address is numerically lower than its own selected address, it becomes a nonquerier. In Figure 155, the routing device on the left has a source address numerically lower than the one on the right and therefore becomes the querier routing device.

**NOTE:** In the practical application of MLD, several routing devices on a subnet are nonqueriers. If the elected querier routing device fails, query messages are exchanged among the remaining routing devices. The routing device with the lowest IPv6 source address becomes the new querier routing device. The IPv6 Neighbor Discovery Protocol (NDP) implementation drops incoming Neighbor Announcement (NA) messages that have a broadcast or multicast address in the target link-layer address option. This behavior is recommended by RFC 2461.

Figure 155: Querier Routing Device Is Determined

The querier routing device sends general MLD queries on the **link-scope all-nodes** multicast address FF02::1 at short intervals to all attached subnets to solicit group membership information (see Figure 156). Within the query message is the *maximum response delay* value, specifying the maximum allowed delay for the host to respond with a report message.

Figure 156: General Query Message Is Issued

If interested listeners are attached to the host receiving the query, the host sends a report containing the host's IPv6 address to the routing device (see [Figure 157](#)). If the reported address is not yet in the routing device's list of multicast addresses with interested listeners, the address is added to the list and a timer is set for the address. If the address is already on the list, the timer is reset. The host's address is transmitted to the RP in the PIM domain.

**Figure 157: Reports Are Received by the Querier Routing Device**

If the host has no interested multicast listeners, it sends a done message to the querier routing device. On receipt, the querier routing device issues a multicast address-specific query containing the last **listener query interval** value to the multicast address of the host. If the routing device does not receive a report from the multicast address, it removes the multicast address from the list and notifies the RP in the PIM domain of its removal (see [Figure 158](#)).

**Figure 158: Host Has No Interested Receivers and Sends a Done Message to Routing Device**

If a done message is not received by the querier routing device, the querier routing device continues to send multicast address-specific queries. If the timer set for the address on receipt of the last report expires, the querier routing device assumes there are no longer interested listeners on that subnet, removes the multicast address from the list, and notifies the RP in the PIM domain of its removal (see [Figure 159](#)).

**Figure 159: Host Address Timer Expires and Address Is Removed from Multicast Address List**

## Understanding MLD

The Multicast Listener Discovery (MLD) Protocol manages the membership of hosts and routers in multicast groups. IP version 6 (IPv6) multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. Each routing device maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the routing device does not need to know the address of each listener—just the address of each host. The routing device provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol.

MLD is an integral part of IPv6 and must be enabled on all IPv6 routing devices and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

In include mode, the receiver specifies the source or sources it is interested in receiving the multicast group traffic from. Exclude mode works the opposite of include mode. It allows the receiver to specify the source or sources it is not interested in receiving the multicast group traffic from.

For each attached network, a multicast routing device can be either a querier or a nonquerier. A querier routing device, usually one per subnet, solicits group membership information by transmitting MLD queries. When a host reports to the querier routing

device that it has interested listeners, the querier routing device forwards the membership information to the rendezvous point (RP) routing device by means of the receiver's (host's) designated router (DR). This builds the rendezvous-point tree (RPT) connecting the host with interested listeners to the RP routing device. The RPT is the initial path used by the sender to transmit information to the interested listeners. Nonquerier routing devices do not transmit MLD queries on a subnet but can do so if the querier routing device fails.

All MLD-configured routing devices start as querier routing devices on each attached subnet (see Figure 154). The querier routing device on the right is the receiver's DR.

**Figure 160: Routing Devices Start Up on a Subnet**

To elect the querier routing device, the routing devices exchange query messages containing their IPv6 source addresses. If a routing device hears a query message whose IPv6 source address is numerically lower than its own selected address, it becomes a nonquerier. In Figure 155, the routing device on the left has a source address numerically lower than the one on the right and therefore becomes the querier routing device.

**NOTE:** In the practical application of MLD, several routing devices on a subnet are nonqueriers. If the elected querier routing device fails, query messages are exchanged among the remaining routing devices. The routing device with the lowest IPv6 source address becomes the new querier routing device. The IPv6 Neighbor Discovery Protocol (NDP) implementation drops incoming Neighbor Announcement (NA) messages that have a broadcast or multicast address in the target link-layer address option. This behavior is recommended by RFC 2461.

**Figure 161: Querier Routing Device Is Determined**

The querier routing device sends general MLD queries on the **link-scope all-nodes** multicast address FF02::1 at short intervals to all attached subnets to solicit group membership information (see Figure 156). Within the query message is the *maximum response delay* value, specifying the maximum allowed delay for the host to respond with a report message.

Figure 162: General Query Message Is Issued

If interested listeners are attached to the host receiving the query, the host sends a report containing the host's IPv6 address to the routing device (see [Figure 157](#)). If the reported address is not yet in the routing device's list of multicast addresses with interested listeners, the address is added to the list and a timer is set for the address. If the address is already on the list, the timer is reset. The host's address is transmitted to the RP in the PIM domain.

Figure 163: Reports Are Received by the Querier Routing Device

If the host has no interested multicast listeners, it sends a done message to the querier routing device. On receipt, the querier routing device issues a multicast address-specific query containing the last **listener query interval** value to the multicast address of the host. If the routing device does not receive a report from the multicast address, it removes the multicast address from the list and notifies the RP in the PIM domain of its removal (see [Figure 158](#)).

Figure 164: Host Has No Interested Receivers and Sends a Done Message to Routing Device

If a done message is not received by the querier routing device, the querier routing device continues to send multicast address-specific queries. If the timer set for the address on receipt of the last report expires, the querier routing device assumes there are no longer interested listeners on that subnet, removes the multicast address from the list, and notifies the RP in the PIM domain of its removal (see [Figure 159](#)).

Figure 165: Host Address Timer Expires and Address Is Removed from Multicast Address List

## Configuring MLD

To configure the Multicast Listener Discovery (MLD) Protocol, include the **mld** statement:

```
mld {
 accounting;
 interface interface-name {
 disable;
 (accounting | no-accounting);
 group-policy [policy-names];
 immediate-leave;
 oif-map [map-names];
 passive;
 ssm-map ssm-map-name;
 static (Protocols MLD) {
 group mcast-group-address {
 exclude;
 group-count number;
 group-increment increment;
 source ip-address {
 source-count number;
 source-increment increment;
 }
 }
 }
 version version;
 }
 maximum-transmit-rate packets-per-second;
 query-interval seconds;
 query-last-member-interval seconds;
 query-response-interval seconds;
 robust-count number;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

By default, MLD is enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or the Distance Vector Multicast Routing Protocol (DVMRP).

## Enabling MLD

The Multicast Listener Discovery (MLD) Protocol manages multicast groups by establishing, maintaining, and removing groups on a subnet. Multicast routing devices use MLD to learn which groups have members on each of their attached physical networks. MLD must be enabled for the router to receive IPv6 multicast packets. MLD is only needed for IPv6 networks, because multicast is handled differently in IPv4 networks. MLD is enabled on all IPv6 interfaces on which you configure PIM and on all IPv6 broadcast interfaces when you configure DVMRP.

MLD specifies different behaviors for multicast listeners and for routers. When a router is also a listener, the router responds to its own messages. If a router has more than one interface to the same link, it needs to perform the router behavior over only one of those interfaces. Listeners, on the other hand, must perform the listener behavior on all interfaces connected to potential receivers of multicast traffic.

If MLD is not running on an interface—either because PIM and DVMRP are not configured on the interface or because MLD is explicitly disabled on the interface—you can explicitly enable MLD.

To explicitly enable MLD:

1. If PIM and DVMRP are not running on the interface, explicitly enable MLD by including the interface name.

```
[edit protocols mld]
user@host# set interface fe-0/0/0.0
```

2. Check to see if MLD is disabled on any interfaces. In the following example, MLD is disabled on a Gigabit Ethernet interface.

```
[edit protocols mld]
user@host# show

interface fe-0/0/0.0;
interface ge-0/0/0.0 {
 disable;
}
```

3. Enable MLD on the interface by deleting the **disable** statement.

```
[edit protocols mld]
delete interface ge-0/0/0.0 disable
```

4. Verify the configuration.

```
[edit protocols mld]
user@host# show

interface fe-0/0/0.0;
interface ge-0/0/0.0;
```

5. Verify the operation of MLD by checking the output of the **show mld interface** command.

## Modifying the MLD Version

By default, the router supports MLD version 1 (MLDv1). To enable the router to use MLD version 2 (MLDv2) for source-specific multicast (SSM) only, include the **version 2** statement.

If you configure the MLD version setting at the individual interface hierarchy level, it overrides configuring the IGMP version using the **interface all** statement.

If a source address is specified in a multicast group that is statically configured, the version must be set to MLDv2.

To change an MLD interface to version 2:

1. Configure the MLD interface.

```
[edit protocols mld]
user@host# set interface fe-0/0/0.0 version 2
```

2. Verify the configuration by checking the **version** field in the output of the **show mld interface** command. The **show mld statistics** command has version-specific output fields, such as the counters in the **MLD Message type** field.

## Modifying the MLD Host-Query Message Interval

The objective of MLD is to keep routers up to date with IPv6 group membership of the entire subnet. Routers need not know who all the members are, only that members exist. Each host keeps track of which multicast groups are subscribed to. On each link, one router is elected the querier. The MLD querier router periodically sends general host-query messages on each attached network to solicit membership information. These messages solicit group membership information and are sent to the **link-scope all-nodes** address **FF02::1**. A general host-query message has a maximum response time that you can set by configuring the query response interval.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

By default, host-query messages are sent every 125 seconds. You can change this interval to change the number of MLD messages sent on the subnet.

To modify the query interval:

1. Configure the interval.

```
[edit protocols mld]
user@host# set query-interval 200
```

The value can be from 1 through 1024 seconds.

2. Verify the configuration by checking the **MLD Query Interval** field in the output of the **show mld interface** command.
3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

## Modifying the MLD Query Response Interval

The query response interval is the maximum amount of time that can elapse between when the querier router sends a host-query message and when it receives a response from a host. You can change this interval to adjust the burst peaks of MLD messages on the subnet. Set a larger interval to make the traffic less bursty.

The query response timeout, the query interval, and the robustness variable are related in that they are all variables that are used to calculate the multicast listener interval. The multicast listener interval is the number of seconds that must pass before a multicast router determines that no more members of a host group exist on a subnet. The multicast listener interval is calculated as the (robustness variable x query-interval) + (1 x query-response-interval). If no reports are received for a particular group before the multicast listener interval has expired, the routing device stops forwarding remotely-originated multicast packets for that group onto the attached network.

The default query response interval is 10 seconds. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify the query response interval:

1. Configure the interval.  

```
[edit protocols mld]
user@host# set query-response-interval 0.5
```
2. Verify the configuration by checking the **MLD Query Response Interval** field in the output of the **show mld interface** command.
3. Verify the operation of the query interval by checking the **Listener Query** field in the output of the **show mld statistics** command.

## Modifying the MLD Last-Member Query Interval

The last-member query interval (also called the last-listener query interval) is the maximum amount of time between group-specific query messages, including those sent in response to done messages sent on the **link-scope-all-routers** address FF02::2. You can lower this interval to reduce the amount of time it takes a router to detect the loss of the last member of a group.

When the routing device that is serving as the querier receives a leave-group (done) message from a host, the routing device sends multiple group-specific queries to the group. The querier sends a specific number of these queries, and it sends them at a specific interval. The number of queries sent is called the last-listener query count. The

interval at which the queries are sent is called the last-listener query interval. Both settings are configurable, thus allowing you to adjust the leave latency. The IGMP leave latency is the time between a request to leave a multicast group and the receipt of the last byte of data for the multicast group.

The last-listener query count  $\times$  (times) the last-listener query interval = (equals) the amount of time it takes a routing device to determine that the last member of a group has left the group and to stop forwarding group traffic.

The default last-listener query interval is 1 second. You can configure a subsecond interval up to one digit to the right of the decimal point. The configurable range is 0.1 through 0.9, then in 1-second intervals 1 through 999,999.

To modify this interval:

1. Configure the time (in seconds) that the routing device waits for a report in response to a group-specific query.

```
[edit protocols mld]
```

```
user@host# set query-last-member-interval 0.1
```

2. Verify the configuration by checking the **MLD Last Member Query Interval** field in the output of the **show igmp interfaces** command.

**NOTE:** You can configure the last-member query count by configuring the robustness variable. The two are always equal.

## Specifying Immediate-Leave Host Removal for MLD

The immediate leave setting is useful for minimizing the leave latency of MLD memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.

The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows MLD to determine when the last host sends a leave message for the multicast group.

When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending MLD group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the MLD leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both MLD version 1 and MLD version 2.

NOTE: Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

To enable immediate leave:

1. Configure immediate leave on the MLD interface.

```
[edit protocols mld]
user@host# set interface ge-0/0/0.1 immediate-leave
```

2. Verify the configuration by checking the **Immediate Leave** field in the output of the `show mld interface` command.

## Filtering Unwanted MLD Reports at the MLD Interface Level

Suppose you need to limit the subnets that can join a certain multicast group. The **group-policy** statement enables you to filter unwanted MLD reports at the interface level.

When the **group-policy** statement is enabled on a router, after the router receives an MLD report, the router compares the group against the specified group policy and performs the action configured in that policy (for example, rejects the report if the policy matches the defined address or network).

You define the policy to match only MLD group addresses (for MLDv1) by using the policy's **route-filter** statement to match the group address. You define the policy to match MLD (source, group) addresses (for MLDv2) by using the policy's **route-filter** statement to match the group address and the policy's **source-address-filter** statement to match the source address.

To filter unwanted MLD reports:

1. Configure an MLDv1 policy.

```
[edit policy-statement reject_policy_v1]
user@host# set from route-filter fec0:1:1:4::/64 exact
user@host# set then reject
```

2. Configure an MLDv2 policy.

```
[edit policy-statement reject_policy_v2]
user@host# set from route-filter fec0:1:1:4::/64 exact
user@host# set from source-address-filter fe80::2e0:81ff:fe05:1a8d/32 orlonger
user@host# set then reject
```

3. Apply the policies to the MLD interfaces where you prefer not to receive specific group or (source, group) reports. In this example, **ge-0/0/0.1** is running MLDv1 and **ge-0/1/1.0** is running MLDv2.

```
[edit protocols mld]
user@host# set interface ge-0/0/0.1 group-policy reject_policy_v1
user@host# set interface ge-0/1/1.0 group-policy reject_policy_v2
```

4. Verify the operation of the filter by checking the **Rejected Report** field in the output of the **show mld statistics** command.

## Example: Modifying the MLD Robustness Variable

This example shows how to configure and verify the MLD robustness variable in a multicast domain.

- [Requirements on page 5453](#)
- [Overview on page 5453](#)
- [Configuration on page 5454](#)
- [Verification on page 5454](#)

### Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM. See [“PIM Overview” on page 5491](#).

### Overview

The MLD robustness variable can be fine-tuned to allow for expected packet loss on a subnet. Increasing the robust count allows for more packet loss but increases the leave latency of the subnetwork.

The value of the robustness variable is used in calculating the following MLD message intervals:

- Group member interval—Amount of time that must pass before a multicast router determines that there are no more members of a group on a network. This interval is calculated as follows: (robustness variable x query-interval) + (1 x query-response-interval).
- Other querier present interval—Amount of time that must pass before a multicast router determines that there is no longer another multicast router that is the querier. This interval is calculated as follows: (robustness variable x query-interval) + (0.5 x query-response-interval).

- Last-member query count—Number of group-specific queries sent before the router assumes there are no local members of a group. The default number is the value of the robustness variable.

By default, the robustness variable is set to 2. The number can be from 2 through 10. You might want to increase this value if you expect a subnet to lose packets.

---

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols mld robust-count 5
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To change the value of the robustness variable:

1. Configure the robust count.

```
[edit protocols mld]
user@host# set robust-count 5
```

2. If you are done configuring the device, commit the configuration.

```
[edit protocols mld]
user@host# commit
```

---

### Verification

To verify the configuration is working properly, check the **MLD Robustness Count** field in the output of the **show mld interfaces** command.

## Limiting the Maximum MLD Message Rate

You can change the limit for the maximum number of MLD packets transmitted in 1 second by the router.

Increasing the maximum number of MLD packets transmitted per second might be useful on a router with a large number of interfaces participating in MLD.

To change the limit for the maximum number of MLD packets the router can transmit in 1 second, include the **maximum-transmit-rate** statement and specify the maximum number of packets per second to be transmitted.

## Enabling MLD Static Group Membership

- [Create a MLD Static Group Member on page 5455](#)
- [Automatically create static groups on page 5456](#)

- [Automatically increment group addresses on page 5457](#)
- [Specify multicast source address \(in SSM mode\) on page 5458](#)
- [Automatically specify multicast sources on page 5459](#)
- [Automatically increment source addresses on page 5460](#)
- [Exclude multicast source addresses \(in SSM mode\) on page 5461](#)

### Create a MLD Static Group Member

You can create MLD static group membership to test multicast forwarding without a receiver host. When you enable MLD static group membership, data is forwarded to an interface without that interface receiving membership reports from downstream hosts.

Class-of-service (CoS) adjustment is not supported with MLD static group membership.

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify the number of static groups to be automatically created.

In this example, you create static group ff0e::1:ff05:1a8d.

1. Configure the static groups to be created by including the **static** statement and **group** statement and specifying which IPv6 multicast address of the group to be created.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d;
 }
}
```

3. After you have committed the configuration and after the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created.

```
user@host> show mld group
Interface: fe-0/1/2
Group: ff0e::1:ff05:1a8d
Group mode: Include
Source: fe80::2e0:81ff:fe05:1a8d
Last reported by: Local
Timeout: 0 Type: Static
```

**NOTE:** You must specify a unique address for each group.

### Automatically create static groups

---

When you create MLD static group membership to test multicast forwarding on an interface on which you want to receive multicast traffic, you can specify that a number of static groups be automatically created. This is useful when you want to test forwarding to multiple receivers without having to configure each receiver separately.

In this example, you create three groups.

1. Configure the number of static groups to be created by including the **group-count** statement and specifying the number of groups to be created.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
group-count 3
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 group-count 3;
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff0e::1:ff05:1a8d, ff0e::1:ff05:1a8e, and ff0e::1:ff05:1a8f have been created.

```
user@host> show mld group

Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8e
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8f
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
```

### Automatically increment group addresses

When you configure static groups on an interface on which you want to receive multicast traffic and you specify the number of static groups to be automatically created, you can also configure the group address to be automatically incremented by some number of addresses.

In this example, you create three groups and increase the group address by an increment of two for each group.

1. Configure the group address increment by including the **group-increment** statement and specifying the number by which the address should be incremented for each group. The increment is specified in a format similar to an IPv6 address.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
group-count 3 group-increment ::2
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 group-increment ::2;
 group-count 3;
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static groups ff0e::1:ff05:1a8d, ff0e::1:ff05:1a8f, and ff0e::1:ff05:1a91 have been created.

```
user@host> show mld group

Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8f
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a91
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
```

### Specify multicast source address (in SSM mode)

---

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify the multicast source address to be accepted.

If you specify a group address in the SSM range, you must also specify a source.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you create group ff0e::1:ff05:1a8d and accept IPv6 address fe80::2e0:81ff:fe05:1a8d as the only source.

1. Configure the source address by including the **source** statement and specifying the IPv6 address of the source host.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
source fe80::2e0:81ff:fe05:1a8d
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 source fe80::2e0:81ff:fe05:1a8d;
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that source fe80::2e0:81ff:fe05:1a8d has been accepted.

```
user@host> show mld group

Interface: fe-0/1/2
Group: ff0e::1:ff05:1a8d
Source: fe80::2e0:81ff:fe05:1a8d
Last reported by: Local
Timeout: 0 Type: Static
```

### Automatically specify multicast sources

When you configure static groups on an interface on which you want to receive multicast traffic, you can specify a number of multicast sources to be automatically accepted.

In this example, you create static group ff0e::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f as the source addresses.

1. Configure the number of multicast source addresses to be accepted by including the **source-count** statement and specifying the number of sources to be accepted.

```
[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
source fe80::2e0:81ff:fe05:1a8d source-count 3
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 source fe80::2e0:81ff:fe05:1a8d {
 source-count 3;
 }
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8e, and fe80::2e0:81ff:fe05:1a8f have been accepted.

```
user@host> show mld group

Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8e
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8f
 Last reported by: Local
 Timeout: 0 Type: Static
```

### Automatically increment source addresses

---

When you configure static groups on an interface on which you want to receive multicast traffic, and specify a number of multicast sources to be automatically accepted, you can also specify the number by which the address should be incremented for each source accepted.

In this example, you create static group ff0e::1:ff05:1a8d and accept fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 as the sources.

1. Configure the number of multicast source addresses to be accepted by including the **source-increment** statement and specifying the number of sources to be accepted.

```
[edit protocols mld]
```

```
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
source fe80::2e0:81ff:fe05:1a8d source-count 3 source-increment ::2
```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```
user@host> show configuration protocol mld
```

```
interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 source fe80::2e0:81ff:fe05:1a8d {
 source-count 3;
 source-increment ::2;
 }
 }
 }
}
```

3. After you have committed the configuration and the source is sending traffic, use the **show mld group** command to verify that static group ff0e::1:ff05:1a8d has been created and that sources fe80::2e0:81ff:fe05:1a8d, fe80::2e0:81ff:fe05:1a8f, and fe80::2e0:81ff:fe05:1a91 have been accepted.

```
user@host> show mld group
```

```
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a8f
 Last reported by: Local
 Timeout: 0 Type: Static
Interface: fe-0/1/2
 Group: ff0e2::1:ff05:1a8d
 Source: fe80::2e0:81ff:fe05:1a91
 Last reported by: Local
 Timeout: 0 Type: Static
```

```

Interface: fe-0/1/2

```

### Exclude multicast source addresses (in SSM mode)

When you configure static groups on an interface on which you want to receive multicast traffic and your network is operating in source-specific multicast (SSM) mode, you can specify that certain multicast source addresses be excluded.

By default the multicast source address configured in a static group operates in include mode. In include mode the multicast traffic for the group is accepted from the configured source address. You can also configure the static group to operate in exclude mode. In exclude mode the multicast traffic for the group is accepted from any address other than the configured source address.

If a source address is specified in a multicast group that is statically configured, the MLD version must be set to MLDv2 on the interface. MLDv1 is the default value.

In this example, you exclude address fe80::2e0:81ff:fe05:1a8d as a source for group ff0e::1:ff05:1a8d.

1. Configure a multicast static group to operate in exclude mode by including the **exclude** statement and specifying which IPv6 source address to be excluded.

```

[edit protocols mld]
user@host# set interface fe-0/1/2 static (Protocols MLD) group ff0e::1:ff05:1a8d
exclude source fe80::2e0:81ff:fe05:1a8d

```

2. After you commit the configuration, use the **show configuration protocol mld** command to verify the MLD protocol configuration.

```

user@host> show configuration protocol mld

interface fe-0/1/2.0 {
 static {
 group ff0e::1:ff05:1a8d {
 exclude;
 source fe80::2e0:81ff:fe05:1a8d;
 }
 }
}

```

- After you have committed the configuration and the source is sending traffic, use the **show mld group detail** command to verify that static group ff0e::1:ff05:1a8d has been created and that the static group is operating in exclude mode.

```
user@host> show mld group detail
Interface: fe-0/1/2
 Group: ff0e::1:ff05:1a8d
 Group mode: Exclude
 Source: fe80::2e0:81ff:fe05:1a8d
 Last reported by: Local
 Timeout: 0 Type: Static
```

Similar configuration is available for IPv4 multicast traffic using the IGMP protocol.

### Example: Recording MLD Join and Leave Events

This example shows how to determine whether MLD tuning is needed in a network by configuring the routing device to record MLD join and leave events.

- [Requirements on page 5462](#)
- [Overview on page 5462](#)
- [Configuration on page 5463](#)
- [Verification on page 5464](#)

#### Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable IPv6 unicast routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM. See [“PIM Overview” on page 5491](#).

#### Overview

[Table 434](#) describes the recordable MLD join and leave events.

**Table 434: MLD Event Messages**

| ERRMSG Tag             | Definition                                                   |
|------------------------|--------------------------------------------------------------|
| RPD_MLD_JOIN           | Records MLD join events.                                     |
| RPD_MLD_LEAVE          | Records MLD leave events.                                    |
| RPD_MLD_ACCOUNTING_ON  | Records when MLD accounting is enabled on an MLD interface.  |
| RPD_MLD_ACCOUNTING_OFF | Records when MLD accounting is disabled on an MLD interface. |

Table 434: MLD Event Messages (*continued*)

| ERRMSG Tag                 | Definition                             |
|----------------------------|----------------------------------------|
| RPD_MLD_MEMBERSHIP_TIMEOUT | Records MLD membership timeout events. |

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols mld interface fe-0/1/0.2 accounting
set system syslog file mld-events any info
set system syslog file mld-events match ".*RPD_MLD_JOIN.* | .*RPD_MLD_LEAVE.* |
.*RPD_MLD_ACCOUNTING.* | .*RPD_MLD_MEMBERSHIP_TIMEOUT.*"
set system syslog file mld-events archive size 100000
set system syslog file mld-events archive files 3
set system syslog file mld-events archive transfer-interval 1440
set system syslog file mld-events archive archive-sites "ftp://user@host1//var/tmp"
password "anonymous"
set system syslog file mld-events archive archive-sites "ftp://user@host2//var/tmp"
password "test"
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure recording of MLD join and leave events:

1. Enable accounting globally or on an MLD interface. This example shows the interface configuration.

```
[edit protocols mld]
user@host# set interface fe-0/1/0.2 accounting
```

2. Configure the events to be recorded, and filter the events to a system log file with a descriptive filename, such as **mld-events**.

```
[edit system syslog file mld-events]
user@host# set any info
[edit system syslog file mld-events]
user@host# set match ".*RPD_MLD_JOIN.* | .*RPD_MLD_LEAVE.* |
.*RPD_MLD_ACCOUNTING.* | .*RPD_MLD_MEMBERSHIP_TIMEOUT.*"
```

3. Periodically archive the log file.

This example rotates the file every 24 hours (1440 minutes) when it reaches 100 KB and keeps three files.

```
[edit system syslog file mld-events]
user@host# set archive size 100000
[edit system syslog file mld-events]
user@host# set archive files 3
[edit system syslog file mld-events]
```

```
user@host# set archive archive-sites "ftp://user@host1//var/tmp" password
"anonymous"
[edit system syslog file mld-events]
user@host# set archive archive-sites "ftp://user@host2//var/tmp" password "test"
[edit system syslog file mld-events]
user@host# set archive transfer-interval 1440
[edit system syslog file mld-events]
user@host# set archive start-time 2011-01-07:12:30
```

4. If you are done configuring the device, commit the configuration.

```
[edit system syslog file mld-events]]
user@host# commit
```

---

### Verification

You can view the system log file by running the **file show** command.

```
user@host> file show mld-events
```

You can monitor the system log file as entries are added to the file by running the **monitor start** and **monitor stop** commands.

```
user@host> monitor start mld-events
```

```
*** mld-events ***
Apr 16 13:08:23 host mgd[16416]: UI_CMDLINE_READ_LINE: User 'user', command 'run
monitor start mld-events '
monitor
```

## Configuring the Number of MLD Multicast Group Joins on Logical Interfaces

The **group-limit** statement enables you to limit the number of MLD multicast group joins for logical interfaces. When this statement is enabled on a router running MLD version 2, the limit is applied upon receipt of the group report. Once the group limit is reached, subsequent join requests are rejected.

When configuring limits for MLD multicast groups, keep the following in mind:

- Each any-source group (\*G) counts as one group toward the limit.
- Each source-specific group (S,G) counts as one group toward the limit.
- Groups in MLDv2 exclude mode are counted toward the limit.
- Multiple source-specific groups count individually toward the group limit, even if they are for the same group. For example, (S1, G1) and (S2, G1) would count as two groups toward the configured limit.
- Combinations of any-source groups and source-specific groups count individually toward the group limit, even if they are for the same group. For example, (\*, G1) and (S, G1) would count as two groups toward the configured limit.
- Configuring and committing a group limit on a network that is lower than what already exists on the network results in the removal of all groups from the configuration. The

groups must then request to rejoin the network (up to the newly configured group limit).

- You can dynamically limit multicast groups on MLD logical interfaces by using dynamic profiles. For detailed information about creating dynamic profiles, see the *Junos OS Broadband Subscriber Management and Services Library*.

Beginning with Junos OS 12.2, you can optionally configure a system log warning threshold for MLD multicast group joins received on the logical interface. It is helpful to review the system log messages for troubleshooting purposes and to detect if an excessive amount of MLD multicast group joins have been received on the interface. These log messages convey when the configured group limit has been exceeded, when the configured threshold has been exceeded, and when the number of groups drop below the configured threshold.

The **group-threshold** statement enables you to configure the threshold at which a warning message is logged. The range is 1 through 100 percent. The warning threshold is a percentage of the group limit, so you must configure the **group-limit** statement to configure a warning threshold. For instance, when the number of groups exceed the configured warning threshold, but remain below the configured group limit, multicast groups continue to be accepted, and the device logs a warning message. In addition, the device logs a warning message after the number of groups drop below the configured warning threshold. You can further specify the amount of time (in seconds) between the log messages by configuring the **log-interval** statement. The range is 6 through 32,767 seconds.

You might consider throttling log messages because every entry added after the configured threshold and every entry rejected after the configured limit causes a warning message to be logged. By configuring a log interval, you can throttle the amount of system log warning messages generated for MLD multicast group joins.

To limit multicast group joins on an MLD logical interface:

1. Access the logical interface at the MLD protocol hierarchy level.

```
[edit]
user@host# edit protocols mld interface interface-name
```

2. Specify the group limit for the interface.

```
[edit protocols mld interface interface-name]
user@host# set group-limit limit
```

3. (Optional) Configure the threshold at which a warning message is logged.

```
[edit protocols mld interface interface-name]
user@host# set group-threshold value
```

4. (Optional) Configure the amount of time between log messages.

```
[edit protocols mld interface interface-name]
user@host# set log-interval seconds
```

To confirm your configuration, use the **show protocols mld** command. To verify the operation of MLD on the interface, including the configured group limit and the optional warning threshold and interval between log messages, use the **show mld interface** command.

## Disabling MLD

To disable MLD on an interface, include the **disable** statement:

```
interface interface-name {
 disable;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mld]
- [edit logical-systems *logical-system-name* protocols mld]

## Understanding MLD Snooping

---

**NOTE:** This overview uses Junos OS for switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Understanding MLD Snooping*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

Multicast Listener Discovery (MLD) snooping constrains the flooding of IPv6 multicast traffic on VLANs. When MLD snooping is enabled on a VLAN, a Juniper Networks EX switch examines MLD messages between hosts and multicast routers and learns which hosts are interested in receiving traffic for a multicast group. On the basis of what it learns, the switch then forwards multicast traffic only to those interfaces in the VLAN that are connected to interested receivers instead of flooding the traffic to all interfaces.

MLD snooping supports MLD version 1 (MLDv1) and MLDv2. For details on MLDv1 and MLDv2, see the following standards:

- MLDv1—See RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*.
- MLDv2—See RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*.

This topic covers:

- [How MLD Snooping Works on page 5468](#)
- [MLD Message Types on page 5469](#)

- [MLD Snooping and Forwarding Interfaces on page 5470](#)

- [General Forwarding Rules on page 5471](#)
- [Examples of MLD Snooping Multicast Forwarding on page 5471](#)

## How MLD Snooping Works

By default, a switch floods Layer 2 multicast traffic on all of the interfaces belonging to that VLAN on a switch, except for the interface that is the source of the multicast traffic. This behavior can consume significant amounts of bandwidth.

You can enable MLD snooping to avoid this flooding. When you enable MLD snooping, the switch monitors MLD messages between receivers (hosts) and multicast routers and uses the content of the messages to build an IPv6 multicast forwarding table—a database of IPv6 multicast groups and the interfaces that are connected to the interested members of each group. When the switch receives multicast traffic for a multicast group, it uses the forwarding table to forward the traffic only to interfaces that are connected to receivers that belong to the multicast group.

Figure 166 shows an example of multicast traffic flow with MLD snooping enabled.

**Figure 166: Multicast Traffic Flow with MLD Snooping Enabled**

## MLD Message Types

Multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. In any given subnet, one multicast router is elected to act as an MLD querier. The MLD querier sends out the following types of queries to hosts:

- General query—Asks whether any host is listening to any group.
- Group-specific query—Asks whether any host is listening to a specific multicast group. This query is sent in response to a host leaving the multicast group and allows the router to quickly determine if any remaining hosts are interested in the group.
- Group-and-source-specific query—(MLD version 2 only) Asks whether any host is listening to group multicast traffic from a specific multicast source. This query is sent in response to a host indicating that it is no longer interested in receiving group multicast traffic from the multicast source and allows the router to quickly determine any remaining hosts are interested in receiving group multicast traffic from that source.

Hosts that are multicast listeners send the following kinds of messages:

- Membership report—Indicates that the host wants to join a particular multicast group.
- Leave report—Indicates that the host wants to leave a particular multicast group.

Strictly speaking, only MLDv1 hosts use two different kinds of reports to indicate whether they want to join or leave a group. MLDv2 hosts send only one kind of report, the contents of which indicate whether they want to join or leave a group. However, for simplicity's sake, the MLD snooping documentation uses the term *membership report* for a report that indicates that a host wants to join a group and uses the term *leave report* for a report that indicates a host wants to leave a group.

## How Hosts Join and Leave Multicast Groups

Hosts can join multicast groups in either of two ways:

- By sending an unsolicited membership report that specifies the multicast group that the host is attempting to join.
- By sending a membership report in response to a query from a multicast router.

A multicast router continues to forward multicast traffic to an interface provided that at least one host on that interface responds to the periodic general queries indicating its membership. For a host to remain a member of a multicast group, therefore, it must continue to respond to the periodic general queries.

Hosts can leave multicast groups in either of two ways:

- By not responding to periodic queries within a set interval of time. This results in what is known as a “silent leave.”
- By sending a leave report.

**NOTE:** If a host is connected to the switch through a hub, the host does not automatically leave the multicast group if it disconnects from the hub. The host remains a member of the group until group membership times out and a silent leave occurs. If another host connects to the hub port before the silent leave occurs, the new host might receive the group multicast traffic until the silent leave, even though it never sent an membership report.

---

## Support for MLDv2 Multicast Sources

In MLDv2, a host can send a membership report that includes a list of source addresses. When the host sends a membership report in INCLUDE mode, the host is interested in group multicast traffic only from those sources in the source address list. If host sends a membership report in EXCLUDE mode, the host is interested in group multicast traffic from any source *except* the sources in the source address list. A host can also send an EXCLUDE report in which the source-list parameter is empty, which is known as an EXCLUDE NULL report. An EXCLUDE NULL report indicates that the host wants to join the multicast group and receive packets from all sources.

## MLD Snooping and Forwarding Interfaces

To determine how to forward multicast traffic, a switch with MLD snooping enabled maintains information about the following interfaces in its multicast forwarding table:

- Multicast-router interfaces—These interfaces lead toward multicast routers or MLD queriers.
- Group-member interfaces—These interfaces lead toward hosts that are members of multicast groups.

The switch learns about these interfaces by monitoring MLD traffic. If an interface receives MLD queries, the switch adds the interface to its multicast forwarding table as a multicast-router interface. If an interface receives membership reports for a multicast group, the switch adds the interface to its multicast forwarding table as a group-member interface.

Table entries for interfaces that the switch learns about are subject to aging. For example, if a learned multicast-router interface does not receive MLD queries within a certain interval, the switch removes the entry for that interface from its multicast forwarding table.

**NOTE:** For a switch to learn multicast-router interfaces and group-member interfaces, an MLD querier must exist in the network. For the switch itself to function as an MLD querier, MLD must be enabled on the switch.

You can statically configure an interface to be a multicast-router interface or a group-member interface. The switch adds a static interface to its multicast forwarding table without having to learn about the interface, and the entry in the table is not subject

to aging. You can have a mix of statically configured and dynamically learned interfaces on a switch.

## General Forwarding Rules

Multicast traffic received on a switch interface in a VLAN on which MLD snooping is enabled is forwarded according to the following rules.

MLD protocol traffic is forwarded as follows:

- MLD general queries received on a multicast-router interface are forwarded to all other interfaces in the VLAN.
- MLD group-specific queries received on a multicast-router interface are forwarded to only those interfaces in the VLAN that are members of the group.
- MLD reports received on a host interface are forwarded to multicast-router interfaces in the same VLAN, but not to the other host interfaces in the VLAN.

Multicast traffic that is not MLD protocol traffic is forwarded as follows:

- An unregistered multicast packet—that is, a packet for a group that has no current members—is forwarded to all multicast-router interfaces in the VLAN.
- A registered multicast packet is forwarded only to those host interfaces in the VLAN that are members of the multicast group and to all multicast-router interfaces in the VLAN.

## Examples of MLD Snooping Multicast Forwarding

The following examples are provided to illustrate how MLD snooping forwards multicast traffic in different topologies:

- [Scenario 1: Switch Forwarding Multicast Traffic to a Multicast Router and Hosts on page 5471](#)
- [Scenario 2: Switch Forwarding Multicast Traffic to Another Switch on page 5472](#)
- [Scenario 3: Switch Connected to Hosts Only \(No MLD Querier\) on page 5473](#)
- [Scenario 4: Layer 2/Layer 3 Switch Forwarding Multicast Traffic Between VLANs on page 5474](#)

### Scenario 1: Switch Forwarding Multicast Traffic to a Multicast Router and Hosts

In the topology shown in [Figure 167](#), a switch acting as a Layer 2 device receives multicast traffic belonging to multicast group **ff1e::2010** from Source A, which is connected to the multicast router. It also receives multicast traffic belonging to multicast group **ff15::2** from Source B, which is connected directly to the switch. All interfaces on the switch belong to the same VLAN.

Because the switch receives MLD queries from the multicast router on interface P1, MLD snooping learns that interface P1 is a multicast-router interface and adds the interface to its multicast forwarding table. It forwards any MLD general queries it receives on this

interface to all host interfaces on the switch, and, in turn, forwards membership reports it receives from hosts to the multicast-router interface.

In the example, Hosts A and C have responded to the general queries with membership reports for group **ff1e::2010**. MLD snooping adds interfaces P2 and P4 to its multicast forwarding table as member interfaces for group **ff1e::2010**. It forwards the group multicast traffic received from Source A to Hosts A and C, but not to Hosts B and D.

Host B has responded to the general queries with a membership report for group **ff15::2**. The switch adds interface P3 to its multicast forwarding table as a member interface for group **ff15::2** and forwards multicast traffic it receives from Source B to Host B. The switch also forwards the multicast traffic it receives from Source B to the multicast-router interface P1.

**Figure 167: Scenario 1: Switch Forwarding Multicast Traffic to a Multicast Router and Hosts**

### Scenario 2: Switch Forwarding Multicast Traffic to Another Switch

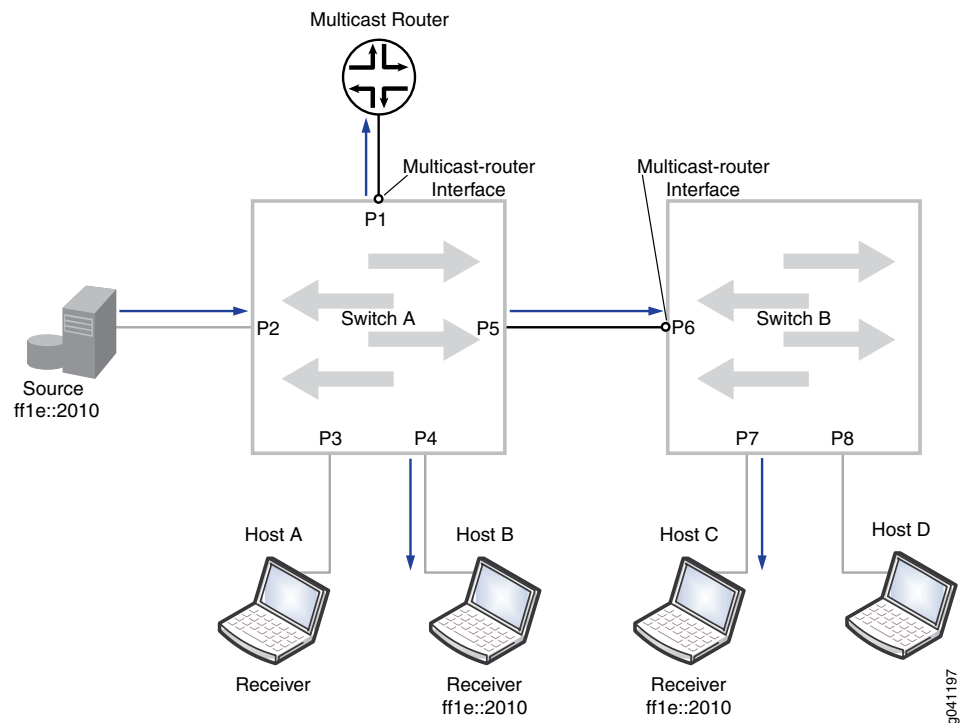

In the topology shown in Figure 168, a multicast source is connected to Switch A. Switch A in turn is connected to another switch, Switch B. Hosts on both Switch A and B are potential members of the multicast group. Both switches are acting as Layer 2 devices, and all interfaces on the switches are members of the same VLAN.

Switch A receives MLD queries from the multicast router on interface P1, making interface P1 a multicast-router interface for Switch A. Switch A forwards all general queries it receives on this interface to the other interfaces on the switch, including the interface connecting Switch B. Because Switch B receives the forwarded MLD queries on interface P6, P6 is the multicast-router interface for Switch B. Switch B forwards the membership

report it receives from Host C to Switch A through its multicast-router interface. Switch A forwards the membership report to its multicast-router interface, includes interface P5 in its multicast forwarding table as a group-member interface, and forwards multicast traffic from the source to Switch B.

**Figure 168: Scenario 2: Switch Forwarding Multicast Traffic to Another Switch**

In certain implementations, you might have to configure P6 on Switch B as a static multicast-router interface to avoid a delay in a host receiving multicast traffic. For example, if Switch B receives unsolicited membership reports from its hosts before it learns which interface is its multicast-router interface, it does not forward those reports to Switch A. If Switch A then receives multicast traffic, it does not forward the traffic to Switch B, because it has not received any membership reports on interface P5. This issue will resolve when the multicast router sends out its next general query; however, it can cause a delay in the host receiving multicast traffic. You can statically configure interface P6 as a multicast-router interface to solve this issue.

### Scenario 3: Switch Connected to Hosts Only (No MLD Querier)

In the topology shown in Figure 169, a switch is connected to a multicast source and to hosts. There is no multicast router in this topology—hence there is no MLD querier. Without an MLD querier to respond to, a host does not send periodic membership reports. As a result, even if the host sends an unsolicited membership report to join a multicast group, its membership in the multicast group will time out.

For MLD snooping to work correctly in this network so that the switch forwards multicast traffic to Hosts A and C only, you can either:

- Configure interfaces P2 and P4 as static group-member interfaces.
- Configure a routed VLAN interface (RVI) on the VLAN and enable MLD on it. In this case, the switch itself acts as an MLD querier, and the hosts can dynamically join the multicast group and refresh their group membership by responding to the queries.

**Figure 169: Scenario 3: Switch Connected to Hosts Only (No MLD Querier)**

#### Scenario 4: Layer 2/Layer 3 Switch Forwarding Multicast Traffic Between VLANs

In the topology shown in [Figure 170](#), a multicast source, Multicast Router A, and Hosts A and B are connected to the switch and are in VLAN 10. Multicast Router B and Hosts C and D are also connected to the switch and are in VLAN 20.

In a pure Layer 2 environment, traffic is not forwarded between VLANs. For Host C to receive the multicast traffic from the source on VLAN 10, RVIs must be created on VLAN 10 and VLAN 20 to permit routing of the multicast traffic between the VLANs.

Figure 170: Scenario 4: Layer 2/Layer 3 Switch Forwarding Multicast Traffic Between VLANs

## Configuring MLD Snooping on a VLAN (CLI Procedure)

**NOTE:** This task uses Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring MLD Snooping on a VLAN (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on [page 41](#).

You can enable MLD snooping on a VLAN to constrain the flooding of IPv6 multicast traffic on the VLAN. When MLD snooping is enabled, a switch examines MLD messages between hosts and multicast routers and learns which hosts are interested in receiving multicast traffic for a multicast group. Based on what it learns, the switch then forwards IPv6 multicast traffic only to those interfaces connected to interested receivers instead of flooding the traffic to all interfaces.

You can perform the following configurations for each VLAN:

- Selectively enable MLD snooping on specific VLANs.
- Specify the MLD version for the general query that the switch sends on an interface when the interface comes up.
- Enable immediate leave to reduce the length of time it takes the switch to stop forwarding multicast traffic when the last member host on the interface leaves the group.
- Configure an interface as a static multicast-router interface so that the switch does not need to dynamically learn that the interface is a multicast-router interface.
- Configure an interface as a static member of a multicast group so that the switch does not need to dynamically learn the interface's membership.
- Change the value for certain timers and counters to match the values configured on the multicast router serving as the MLD querier.

This topic covers:

- [Enabling or Disabling MLD Snooping on VLANs on page 5476](#)
- [Configuring the MLD Version on page 5477](#)
- [Enabling Immediate Leave on page 5477](#)
- [Configuring an Interface as a Multicast-Router Interface on page 5478](#)
- [Configuring Static Group Membership on an Interface on page 5479](#)
- [Changing the Timer and Counter Values on page 5480](#)

## Enabling or Disabling MLD Snooping on VLANs

MLD snooping is not enabled on any VLAN by default. You must explicitly enable MLD snooping on specific interfaces.

- To enable MLD snooping on a specific VLAN:

```
[edit protocols mld-snooping]
user@switch# set vlan vlan-name
```

**NOTE:** You cannot enable MLD snooping on a secondary VLAN.

For example, to enable MLD snooping on VLAN education:

```
[edit protocols mld-snooping]
user@switch# set vlan education
```

- To disable MLD snooping on a specific VLAN:

```
[edit protocols mld-snooping]
user@switch# delete vlan vlan-name
```

You can also deactivate the MLD snooping protocol on the switch without changing the MLD snooping VLAN configurations:

```
[edit]
user@switch# deactivate protocols mld-snooping
```

## Configuring the MLD Version

You can configure the version of MLD queries sent by a switch when MLD snooping is enabled. By default, the switch uses MLD version 1 (MLDv1). If you are using Protocol-Independent Multicast source-specific multicast (PIM-SSM), we recommend that you configure the switch to use MLDv2.

Typically, a switch passively monitors MLD messages sent between multicast routers and hosts and does not send MLD queries. The exception is when a switch detects that an interface has come up. When an interface comes up, the switch sends an immediate general membership query to all hosts on the interface. By doing so, the switch enables the multicast routers to learn group memberships more quickly than they would if they had to wait until the MLD querier sent its next general query.

The MLD version of the general query determines the MLD version of the host membership reports as follows:

- MLD version 1 (MLDv1) general query—Both MLDv1 and MLDv2 hosts respond with an MLDv1 membership report.
- MLDv2 general query—MLDv2 hosts respond with an MLDv2 membership report, while MLDv1 hosts are unable to respond to the query.

By default, the switch sends MLDv1 queries. This ensures compatibility with hosts and multicast routers that support MLDv1 only and cannot process MLDv2 reports. However, if your VLAN contains MLDv2 multicast routers and hosts and the routers are running PIM-SSM, we recommend that you configure MLD snooping for MLDv2. Doing so enables the routers to quickly learn which multicast sources the hosts on the interface want to receive traffic from.

**NOTE:** Configuring the MLD version does not limit the version of MLD messages that the switch can snoop. A switch can snoop both MLDv1 and MLDv2 messages regardless of the MLD version configured.

To configure the MLD version on an interface:

```
[edit protocols]
user@switch# set mld interface interface-name version number
```

For example, to set the MLD version to version 2 on interface ge-0/0/2:

```
[edit protocols]
user@switch# set mld interface ge-0/0/2 version 2
```

## Enabling Immediate Leave

By default, when a switch with MLD snooping enabled receives an MLD leave report on a member interface, it waits for hosts on the interface to respond to MLD group-specific queries to determine whether there still are hosts on the interface interested in receiving

the group multicast traffic. If the switch does not see any membership reports for the group within a set interval of time, it removes the interface's group membership from the multicast forwarding table and stops forwarding multicast traffic for the group to the interface.

You can decrease the leave latency created by this default behavior by enabling immediate leave on a VLAN.

When you enable immediate leave on a VLAN, host tracking is also enabled, allowing the switch to keep track of the hosts on a interface that have joined a multicast group. When the switch receives a leave report from the last member of the group, it immediately stops forwarding traffic to the interface and does not wait for the interface group membership to time out.

Immediate leave is supported for both MLD version 1 (MLDv1) and MLDv2. However, with MLDv1, we recommend that you configure immediate leave only when there is only one MLD host on an interface. In MLDv1, only one host on a interface sends a membership report in response to a group-specific query—any other interested hosts suppress their reports. This report-suppression feature means that the switch only knows about one interested host at any given time.

To enable immediate leave on a VLAN:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name immediate-leave
```

## Configuring an Interface as a Multicast-Router Interface

When MLD snooping is enabled on a switch, the switch determines which interfaces face a multicast router by monitoring interfaces for MLD queries or Protocol Independent Multicast (PIM) updates. If the switch receives these messages on an interface, it adds the interface to its multicast forwarding table as a multicast-router interface.

In addition to dynamically learned interfaces, the multicast forwarding table can include interfaces that you explicitly configure to be multicast router interfaces. Unlike the table entries for dynamically learned interfaces, table entries for statically configured interfaces are not subject to aging and deletion from the forwarding table.

Examples of when you might want to configure a static multicast-router interface include:

- You have an unusual network configuration that prevents MLD snooping from reliably learning about a multicast-router interface through monitoring MLD queries or PIM updates.
- Your implementation does not require an MLD querier.
- You have a stable topology and want to avoid the delay the dynamic learning process entails.

To configure an interface as a static multicast-router interface:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name interface interface-name
multicast-router-interface
```

For example, to configure ge-0/0/5.0 as a multicast-router interface for VLAN employee:

```
[edit protocols]
user@switch# set mld-snooping vlan employee interface ge-0/0/5.0
multicast-router-interface
```

## Configuring Static Group Membership on an Interface

To determine how to forward multicast packets, a switch with MLD snooping enabled maintains a multicast forwarding table containing a list of host interfaces that have interested listeners for a specific multicast group. The switch learns which host interfaces to add or delete from this table by examining MLD membership reports as they arrive on interfaces on which MLD snooping is enabled.

In addition to such dynamically learned interfaces, the multicast forwarding table can include interfaces that you statically configure to be members of multicast groups. When you configure a static group interface, the switch adds the interface to the forwarding table as a host interface for the group. Unlike an entry for a dynamically learned interface, a static interface entry is not subject to aging and deletion from the forwarding table.

Examples of when you might want to configure static group membership on an interface include:

- You want to simulate an attached multicast receiver for testing purposes.
- The interface has receivers that cannot send MLD membership reports.
- You want the multicast traffic for a specific group to be immediately available to a receiver without any delay imposed by the dynamic join process.

You cannot configure multicast source addresses for a static group interface. The MLD version of a static group interface is always MLD version 1.

**NOTE:** The switch does not simulate MLD membership reports on behalf of a statically configured interface. Thus a multicast router might be unaware that the switch has an interface that is a member of the multicast group. You can configure a static group interface on the router to ensure that the switch receives the group multicast traffic.

To configure a host interface as a static member of a multicast group:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name interface interface-name static group
ip-address
```

For example, to configure interface ge-0/0/11.0 in VLAN employee as a static member of multicast group ff1e::1:

```
[edit protocols]
user@switch# set mld-snooping vlan ip-camera-vlan interface ge-0/0/11.0 static group
ff1e::1
```

## Changing the Timer and Counter Values

MLD uses various timers and counters to determine how often an MLD querier sends out membership queries and when group memberships time out. On Juniper Networks switches, the MLD and MLD snooping timers and counters default values are set to the values recommended in RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*. These values work well for most IPv6 multicast deployments.

There might be cases, however, where you might want to adjust the timer and counter values—for example, to reduce burstiness, to reduce leave latency, or to adjust for expected packet loss on a subnet. If you change a timer or counter value for the MLD querier on a VLAN, we recommend that you change the value for all multicast routers and switches on the VLAN so that all devices time out group memberships at approximately the same time.

The following timers and counters are configurable on a switch:

- **query-interval**—The length of time in seconds the MLD querier waits between sending general queries (the default is 125 seconds). You can change this interval to tune the number of MLD messages on the subnet; larger values cause general queries to be sent less often.

To configure the MLD query interval:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name query-interval seconds
```

- **query-response-interval**—The maximum length of time in seconds the host waits before it responds (the default is 10 seconds). You can change this interval to accommodate the burst peaks of MLD messages on the subnet. Set a larger interval to make the traffic less bursty.

To configure the MLD query response interval:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name query-response-interval seconds
```

- **query-last-member-interval**—The length of time the MLD querier waits between sending group-specific membership queries (the default is 1 second). The MLD querier sends a group-specific query after receiving a leave report from a host. You can decrease this interval to reduce the amount of time it takes for multicast traffic to stop forwarding after the last member leaves a group.

To configure the MLD query last member interval:

```
[edit protocols]
user@switch# set mld-snooping vlan vlan-name query-last-member-interval seconds
```

- **robust-count**—The number of times the querier resends a general membership query or a group-specific membership query (the default is 2 times). You can increase this count to tune for higher anticipated packet loss.

For MLD snooping, you can configure **robust-count** for a specific VLAN. If a VLAN does not have **robust-count** configured, the value is inherited from the value configured for MLD.

To configure **robust-count** for MLD snooping on a VLAN:

[edit protocols]

user@switch# **set mld-snooping vlan *vlan-name* robust-count *number***

The values configured for **query-interval**, **query-response-interval**, and **robust-count** determine the multicast listener interval—the length of time the switch waits for a group membership report after a general query before removing a multicast group from its multicast forwarding table. The switch calculates the multicast listener interval by multiplying **query-interval** value by the **robust-count** value and then adding the **query-response-interval** to the product:

$(\text{query-interval} \times \text{robust-count}) + \text{query-response-interval} = \text{multicast listener interval}$

For example, the multicast listener interval is 260 seconds when the default settings for **query-interval**, **query-response-interval**, and **robust-count** are used:

$(125 \times 2) + 10 = 260$

To display the time remaining in the multicast listener interval before a group times out, use the **show mld-snooping membership** command.

## Example: Configuring MLD Snooping

**NOTE:** This example uses Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

You can enable MLD snooping on a VLAN to constrain the flooding of IPv6 multicast traffic on a VLAN. When MLD snooping is enabled, a switch examines MLD messages between hosts and multicast routers and learns which hosts are interested in receiving multicast traffic for a multicast group. On the basis of what it learns, the switch then forwards IPv6 multicast traffic only to those interfaces connected to interested receivers instead of flooding the traffic to all interfaces.

This example describes how to configure MLD snooping:

- [Requirements on page 5482](#)
- [Overview and Topology on page 5482](#)
- [Configuration on page 5483](#)
- [Verifying MLD Snooping Configuration on page 5484](#)

## Requirements

This example uses the following software and hardware components:

- One switch running Junos OS with ELS
- Junos OS Release 13.3 or later for EX Series switches or Junos OS Release 15.1X53-D10 or later for QFX10000 switches

Before you configure MLD snooping, be sure you have:

- Configured the vlan 100 VLAN on the switch.
- Assigned interfaces ge-0/0/0, ge-0/0/1, ge-0/0/2, and ge-0/0/12 to vlan100.
- Configured ge-0/0/12 as a trunk interface.

See *Configuring VLANs for EX Series Switches (CLI Procedure)* or “[Configuring VLANs](#)” on [page 2120](#).

## Overview and Topology

In this example, interfaces ge-0/0/0, ge-0/0/1, and ge-0/0/2 on the switch are in vlan100 and are connected to hosts that are potential multicast receivers. Interface ge-0/0/12, a trunk interface also in vlan100, is connected to a multicast router. The router acts as the MLD querier and forwards multicast traffic for group ff1e::2010 to the switch from a multicast source.

The topology for this example is illustrated in [Figure 171](#).

**Figure 171: MLD Snooping Topology Example**

In this sample topology, the multicast router forwards multicast traffic to the switch from the source when it receives a membership report for group ff1e::2010 from one of the

hosts—for example, Host B. If MLD snooping is not enabled on vlan100, the switch floods the multicast traffic on all interfaces in vlan100 (except for interface ge-0/0/12). If MLD snooping is enabled on vlan100, the switch monitors the MLD messages between the hosts and router, allowing it to determine that only Host B is interested in receiving the multicast traffic. The switch then forwards the multicast traffic only to interface ge-0/0/1.

This example shows how to enable MLD snooping on vlan100. It also shows how to perform the following optional configurations, which can reduce group join and leave latency:

- Configure immediate leave on the VLAN. When immediate leave is configured, the switch stops forwarding multicast traffic on an interface when it detects that the last member of the multicast group has left the group. If immediate leave is not configured, the switch waits until the group-specific membership queries time out before it stops forwarding traffic.
- Configure ge-0/0/12 as a static multicast-router interface. In this topology, ge-0/0/12 always leads to the multicast router. By statically configuring ge-0/0/12 as a multicast-router interface, you avoid any delay imposed by the switch having to learn that ge-0/0/12 is a multicast-router interface.

## Configuration

To configure MLD snooping on a switch:

### CLI Quick Configuration

To quickly configure MLD snooping, copy the following commands and paste them into the switch terminal window:

```
[edit]
set protocols mld-snooping vlan vlan100
set protocols mld-snooping vlan vlan100 immediate-leave
set protocols mld-snooping vlan vlan100 interface ge-0/0/12 multicast-router-interface
```

### Step-by-Step Procedure

To configure MLD snooping:

1. Enable MLD snooping on the VLAN vlan100:
 

```
[edit protocols]
user@switch# set mld-snooping vlan vlan100
```
2. Configure the switch to immediately remove a group membership from an interface when it receives a leave report from the last member of the group on the interface:
 

```
[edit protocols]
user@switch# set mld-snooping vlan vlan100 immediate-leave
```
3. Statically configure interface ge-0/0/12 as a multicast-router interface:
 

```
[edit protocols]
user@switch# set mld-snooping vlan vlan100 interface ge-0/0/12 multicast-router-interface
```

### Results

Check the results of the configuration:

```
[edit protocols]
user@switch# show mld-snooping
vlan vlan100 {
 immediate-leave;
 interface ge-0/0/12.0 {
 multicast-router-interface;
```

```
 }
}
```

## Verifying MLD Snooping Configuration

To verify that MLD snooping is enabled on the VLAN and the MLD snooping forwarding interfaces are correct, perform the following task:

- [Verifying MLD Snooping Interface Membership on VLAN vlan100 on page 5484](#)

---

### Verifying MLD Snooping Interface Membership on VLAN vlan100

**Purpose** Verify that MLD snooping is enabled on the VLAN vlan 100 and that the multicast-router interface is statically configured:

**Action** Show the MLD snooping information for ge-0/0/12.0:

```
user@switch> show mld snooping interface
Instance: default-switch
```

```
Vlan: vlan100
```

```
Learning-Domain: default
Interface: ge-0/0/12.0
 State: Up Groups: 3
 Immediate leave: On
 Router interface: yes
```

```
Configured Parameters:
MLD Query Interval: 125.0
MLD Query Response Interval: 10.0
MLD Last Member Query Interval: 1.0
MLD Robustness Count: 2
```

**Meaning** MLD snooping is running on **vlan100**, and interface **ge-0/0/12.0** is a statically configured multicast-router interface. Immediate leave is enabled on the interface.

**Related Documentation**

- [Configuring MLD Snooping on a VLAN \(CLI Procedure\) on page 5475](#)
- [Verifying MLD Snooping on page 5484](#)
- [Understanding MLD Snooping on page 5467](#)

---

## Verifying MLD Snooping

**NOTE:** This topic uses Junos OS with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Verifying MLD Snooping (CLI Procedure)*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 41.

Multicast Listener Discovery (MLD) snooping constrains the flooding of IPv6 multicast traffic on VLANs. This topic describes how to verify MLD snooping operation on a VLAN.

It covers:

- [Verifying MLD Snooping Memberships on page 5485](#)
- [Verifying MLD Snooping Interfaces on page 5485](#)
- [Viewing MLD Snooping Statistics on page 5486](#)
- [Viewing MLD Snooping Routing Information on page 5487](#)

## Verifying MLD Snooping Memberships

**Purpose** Verify that MLD snooping is enabled on a VLAN and determine group memberships.

**Action** Enter the following command:

```
user@switch> show mld snooping membership detail
Instance: default-switch
```

```
Vlan: v1
```

```
Learning-Domain: default
Interface: ge-0/0/1.0, Groups: 1
 Group: ff05::1
 Group mode: Exclude
 Source: ::
 Last reported by: fe80::
 Group timeout: 259 Type: Dynamic
Interface: ge-0/0/2.0, Groups: 0
```

**Meaning** The switch has multicast membership information for one VLAN on the switch, **v1**. MLD snooping might be enabled on other VLANs, but the switch does not have any multicast membership information for them.

- The following information is provided about the group memberships for the VLAN:
  - Currently, the VLAN has membership in only one multicast group, **ff05::1**.
  - The host or hosts that have reported membership in the group are on interface **ge-0/0/1.0**.
  - The last host that reported membership in the group has address **fe80::**.
  - The interface group membership will time out in **259** seconds if no hosts respond to membership queries during this interval.
  - The group membership has been learned by MLD snooping, as indicated by **Dynamic**.

## Verifying MLD Snooping Interfaces

**Purpose** Display MLD snooping information for each interface on which MLD snooping is enabled.

**Action** Enter the following command:

```
user@switch> show mld snooping interface
Instance: default-switch
```

```
Vlan: v100
```

```

Learning-Domain: default
Interface: ge-0/0/1.0
 State: Up Groups: 1
 Immediate leave: Off
 Router interface: no
Interface: ge-0/0/2.0
 State: Up Groups: 0
 Immediate leave: Off
 Router interface: no

Configured Parameters:
MLD Query Interval: 125.0
MLD Query Response Interval: 10.0
MLD Last Member Query Interval: 1.0
MLD Robustness Count: 2

```

**Meaning** MLD snooping is configured on one VLAN on the switch, **v100**. Each interface in each VLAN is listed and the following information is provided:

- How many multicast groups the interface belongs to.
- Whether immediate leave has been configured for the interface.
- Whether the interface is a multicast-router interface.

The output also shows the configured parameters for the MLD querier.

## Viewing MLD Snooping Statistics

**Purpose** Display MLD snooping statistics, such as number of MLD queries, reports, and leaves received and how many of these MLD messages contained errors.

**Action** Enter the following command:

```

user@switch>show mld snooping statistics
Vlan: v1
MLD Message type Received Sent Rx errors
Listener Query (v1/v2) 0 4 0
Listener Report (v1) 447 0 0
Listener Done (v1/v2) 0 0 0
Listener Report (v2) 0 0 0
Other Unknown types 0 0
Vlan: v2
MLD Message type Received Sent Rx errors
Listener Query (v1/v2) 0 4 0
Listener Report (v1) 154 0 0
Listener Done (v1/v2) 0 0 0
Listener Report (v2) 0 0 0
Other Unknown types 0 0
Instance: default-switch
MLD Message type Received Sent Rx errors
Listener Query (v1/v2) 0 8 0
Listener Report (v1) 601 0 0
Listener Done (v1/v2) 0 0 0
Listener Report (v2) 0 0 0
Other Unknown types 0 0

```

```

MLD Global Statistics
Bad Length 0
Bad Checksum 0
Bad Receive If 0
Rx non-local 0
Timed out 0

```

**Meaning** The output shows how many MLD messages of each type—**Queries**, **Done**, **Report**—the switch received or transmitted on interfaces on which MLD snooping is enabled. For each message type, it also shows the number of MLD packets the switch received that had errors—for example, packets that do not conform to the MLDv1 or MLDv2 standards. If the **Rx errors** count increases, verify that the hosts are compliant with MLDv1 or MLDv2 standards. If the switch is unable to recognize the MLD message type for a packet, it counts the packet under **Other Unknown types**.

## Viewing MLD Snooping Routing Information

**Purpose** Display the next-hop information maintained in the multicast snooping forwarding table.

**Action** Enter the following command:

```

user@switch>show multicast snooping route
Nexthop Bulking: OFF

```

```

Family: INET6

```

```

Group: ff00::/8
Source: ::/128
Vlan: v1

Group: ff02::1/128
Source: ::/128
Vlan: v1
Downstream interface list:
ge-1/0/16.0

```

```

Group: ff05::1/128
Source: ::/128
Vlan: v1
Downstream interface list:
ge-1/0/16.0

```

```

Group: ff06::1/128
Source: ::/128
Vlan: v1
Downstream interface list:
ge-1/0/16.0

```

**Meaning** The output shows the next-hop interfaces for a given multicast group on a VLAN. For example, route **ff02::1/128** on VLAN **v1** has the next-hop interface **ge-1/0/16.0**.

## PIM Overview

---

The predominant multicast routing protocol in use on the Internet today is Protocol Independent Multicast, or PIM. The type of PIM used on the Internet is PIM sparse mode. PIM sparse mode is so accepted that when the simple term “PIM” is used in an Internet context, some form of sparse mode operation is assumed.

PIM emerged as an algorithm to overcome the limitations of dense-mode protocols such as the Distance Vector Multicast Routing Protocol (DVMRP), which was efficient for dense clusters of multicast receivers, but did not scale well for the larger, sparser, groups encountered on the Internet. The Core Based Trees (CBT) Protocol was intended to support sparse mode as well, but CBT, with its all-powerful core approach, made placement of the core critical, and large conference-type applications (many-to-many) resulted in bottlenecks in the core. PIM was designed to avoid the dense-mode scaling issues of DVMRP and the potential performance issues of CBT at the same time.

PIM is one of the most rapidly evolving specifications on the Internet today. Since its introduction in 1995, PIM has already seen two major revisions to its packet structure (PIM version 1 [PIMv1] and PIM version 2 [PIMv2]), two major RFCs (RFC 2362 obsoleted RFC 2117), and numerous drafts describing major components of PIM, such as many-to-many trees and source-specific multicast (SSM). Long-lasting RFCs are not a feature of PIM, and virtually all of PIM must be researched, understood, and implemented

directly from Internet drafts. In fact, no current RFC describes PIMv1 at all. The drafts have all expired, and PIMv1 was never issued as an official RFC.

PIM itself is not nonstandard or unstable, however. PIM has been a promising multicast routing protocol since its inception, especially PIM sparse mode, the first real sparse-mode multicast routing protocol. Work continues on PIM in a number of areas, from bidirectional trees to network management, and the rapid pace of development makes drafts essential for PIM.

PIMv1 and PIMv2 can coexist on the same router and even on the same interface. The main difference between PIMv1 and PIMv2 is the packet format. PIMv1 messages use Internet Group Management Protocol (IGMP) packets, whereas PIMv2 has its own IP protocol number (103) and packet structure. All routers connecting to an IP subnet such as a LAN must use the same PIM version. Some PIM implementations can recognize PIMv1 packets and automatically switch the router interface to PIMv1. Because the difference between PIMv1 and PIMv2 involves the message format, but not the meaning of the message or how the router processes the PIM message, a router can easily mix PIMv1 and PIMv2 interfaces.

PIM is used for efficient routing to multicast groups that might span wide-area and interdomain internetworks. It is called “protocol independent” because it does not depend on a particular unicast routing protocol. Junos OS supports bidirectional mode, sparse mode, dense mode, and sparse-dense mode.

PIM operates in several modes: bidirectional mode, sparse mode, dense mode, and sparse-dense mode. In sparse-dense mode, some multicast groups are configured as dense mode (flood-and-prune, [S,G] state) and others are configured as sparse mode (explicit join to rendezvous point [RP], [\*G] state).

PIM drafts also establish a mode known as PIM source-specific mode, or PIM SSM. In PIM SSM there is only one specific source for the content of a multicast group within a given domain.

Because the PIM mode you choose determines the PIM configuration properties, you first must decide whether PIM operates in bidirectional, sparse, dense, or sparse-dense mode in your network. Each mode has distinct operating advantages in different network environments.

- In sparse mode, routers must join and leave multicast groups explicitly. Upstream routers do not forward multicast traffic to a downstream router unless the downstream router has sent an explicit request (by means of a join message) to the rendezvous point (RP) router to receive this traffic. The RP serves as the root of the shared multicast delivery tree and is responsible for forwarding multicast data from different sources to the receivers.

Sparse mode is well suited to the Internet, where frequent interdomain join messages and prune messages are common.

- Bidirectional PIM is similar to sparse mode, and is especially suited to applications that must scale to support a large number of dispersed sources and receivers. In bidirectional PIM, routers build shared bidirectional trees and do not switch to a source-based tree.

Bidirectional PIM scales well because it needs no source-specific (S,G) state. Instead, it builds only group-specific (\*G) state.

- Unlike sparse mode and bidirectional mode, in which data is forwarded only to routers sending an explicit PIM join request, dense mode implements a *flood-and-prune* mechanism, similar to the Distance Vector Multicast Routing Protocol (DVMRP). In dense mode, a router receives the multicast data on the incoming interface, then forwards the traffic to the outgoing interface list. Flooding occurs periodically and is used to refresh state information, such as the source IP address and multicast group pair. If the router has no interested receivers for the data, and the outgoing interface list becomes empty, the router sends a PIM prune message upstream.

Dense mode works best in networks where few or no prunes occur. In such instances, dense mode is actually more efficient than sparse mode.

- Sparse-dense mode, as the name implies, allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as “dense” is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense mode rules. A group specified as “sparse” is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules. Sparse-dense mode is useful in networks implementing auto-RP for PIM sparse mode.

**NOTE:** On SRX Series devices, PIM does not support upstream and downstream interfaces across different virtual routers in flow mode.

## Basic PIM Network Components

PIM dense mode requires only a multicast source and series of multicast-enabled routers running PIM dense mode to allow receivers to obtain multicast content. Dense mode makes sure that all multicast traffic gets everywhere by periodically flooding the network with multicast traffic, and relies on prune messages to make sure that subnets where all receivers are uninterested in that particular multicast group stop receiving packets.

PIM sparse mode is more complicated and requires the establishment of special routers called *rendezvous points (RPs)* in the network core. These routers are where upstream join messages from interested receivers meet downstream traffic from the source of the multicast group content. A network can have many RPs, but PIM sparse mode allows only one RP to be active for any multicast group.

If there is only one RP in a routing domain, the RP and adjacent links might become congested and form a single point of failure for all multicast traffic. Thus, multiple RPs are the rule, but the issue then becomes how other multicast routers find the RP that is the source of the multicast group the receiver is trying to join. This RP-to-group mapping is controlled by a special *bootstrap router (BSR)* running the PIM BSR mechanism. There can be more than one bootstrap router as well, also for single-point-of-failure reasons.

The bootstrap router does not have to be an RP itself, although this is a common implementation. The bootstrap router's main function is to manage the collection of RPs and allow interested receivers to find the source of their group's multicast traffic.

PIM SSM can be seen as a subset of a special case of PIM sparse mode and requires no specialized equipment other than that used for PIM sparse mode (and IGMP version 3).

Bidirectional PIM RPs, unlike RPs for PIM sparse mode, do not need to perform PIM Register tunneling or other specific protocol action. Bidirectional PIM RPs implement no specific functionality. RP addresses are simply a location in the network to rendezvous toward. In fact, for bidirectional PIM, RP addresses need not be loopback interface addresses or even be addresses configured on any router, as long as they are covered by a subnet that is connected to a bidirectional PIM-capable router and advertised to the network.

---

## PIM on Aggregated Interfaces

If you configure PIM on an aggregated (**ae-** or **as-**) interface, each of the interfaces in the aggregate is included in the multicast output interface list and carries the single stream of replicated packets in a load-sharing fashion. The multicast aggregate interface is “expanded” into its constituent interfaces in the next-hop database.

**Related Documentation**

- [PIM Overview on page 5491](#)
- [interface on page 5719](#)

---

## Changing the PIM Version

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default for rendezvous point (RP) mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults.

To configure the PIM version, include the **version** statement:

```
version (1 | 2);
```

---

## Modifying the PIM Hello Interval

Routing devices send hello messages at a fixed interval on all PIM-enabled interfaces. By using hello messages, routing devices advertise their existence as PIM routing devices on the subnet. With all PIM-enabled routing devices advertised, a single designated router for the subnet is established.

When a routing device is configured for PIM, it sends a hello message at a 30-second default interval. The interval range is from 0 through 255. When the interval counts down to 0, the routing device sends another hello message, and the timer is reset. A routing device that receives no response from a neighbor in 3.5 times the interval value drops

the neighbor. In the case of a 30-second interval, the amount of time a routing device waits for a response is 105 seconds.

If a PIM hello message contains the hold-time option, the neighbor timeout is set to the hold-time sent in the message. If a PIM hello message does not contain the hold-time option, the neighbor timeout is set to the default hello hold time.

To modify how often the routing device sends hello messages out of an interface:

1. This example shows the configuration for the routing instance. Configure the interface globally or in the routing instance.

```
[edit routing-instances PIM.master protocols pim interface fe-3/0/2.0]
user@host# set hello-interval 255
```

2. Verify the configuration by checking the **Hello Option Holdtime** field in the output of the **show pim neighbors detail** command.

```
user@host> show pim neighbors detail
Instance: PIM.master
Interface: fe-3/0/2.0
Address: 192.168.195.37, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 255 seconds
Hello Option DR Priority: 1
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
Rx Join: Group Source Timeout
225.1.1.1 192.168.195.78 0
225.1.1.1 0

Interface: lo0.0
Address: 10.255.245.91, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 255 seconds
Hello Option DR Priority: 1
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported

Interface: pd-6/0/0.32768
Address: 0.0.0.0, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 255 seconds
Hello Option DR Priority: 0
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
```

## Preserving Multicast Performance by Disabling Response to the ping Utility

The ping utility uses ICMP Echo messages to verify connectivity to any device with an IP address. However, in the case of multicast applications, a single ping sent to a multicast address can degrade the performance of routers because the stream of packets is replicated multiple times.

You can disable the router's response to ping (ICMP Echo) packets sent to multicast addresses. The system responds normally to unicast ping packets.

To disable the router's response to ping packets sent to multicast addresses:

1. Include the **no-multicast-echo** statement:

```
[edit system]
user@host# set no-multicast-echo
```

2. Verify the configuration by checking the **echo drops with broadcast or multicast destination address** field in the output of the **show system statistics icmp** command.

```
user@host> show system statistics icmp

icmp:
0 drops due to rate limit
0 calls to icmp_error
0 errors not generated because old message was icmp
Output histogram:
echo reply: 21
0 messages with bad code fields
0 messages less than the minimum length
0 messages with bad checksum
0 messages with bad source address
0 messages with bad length
100 echo drops with broadcast or multicast destination address
0 timestamp drops with broadcast or multicast destination address
Input histogram:
echo: 21
21 message responses generated
```

## Configuring PIM Trace Options

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag                             | Description                                                                                                                                                     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>                       | Trace all operations.                                                                                                                                           |
| <b>assert</b>                    | Trace assert messages, which are used to resolve which of the parallel routers connected to a multiaccess LAN is responsible for forwarding packets to the LAN. |
| <b>autorp</b>                    | Trace bootstrap, RP, and auto-RP messages.                                                                                                                      |
| <b>bidirectional-df-election</b> | Trace bidirectional PIM designated-forwarder (DF) election events.                                                                                              |

| Flag                       | Description                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bootstrap</b>           | Trace bootstrap messages, which are sent periodically by the PIM domain's bootstrap router and are forwarded, hop by hop, to all routers in that domain. |
| <b>general</b>             | Trace general events.                                                                                                                                    |
| <b>graft</b>               | Trace graft and graft acknowledgment messages.                                                                                                           |
| <b>hello</b>               | Trace hello packets, which are sent so that neighboring routers can discover one another.                                                                |
| <b>join</b>                | Trace join messages, which are sent to join a branch onto the multicast distribution tree.                                                               |
| <b>mdt</b>                 | Trace messages related to multicast data tunnels.                                                                                                        |
| <b>normal</b>              | Trace normal events.                                                                                                                                     |
| <b>nsr-synchronization</b> | Trace nonstop routing synchronization events                                                                                                             |
| <b>packets</b>             | Trace all PIM packets.                                                                                                                                   |
| <b>policy</b>              | Trace poison-route-reverse packets.                                                                                                                      |
| <b>prune</b>               | Trace prune messages, which are sent to prune a branch off the multicast distribution tree.                                                              |
| <b>register</b>            | Trace register and register-stop messages. Register messages are sent to the RP when a multicast source first starts sending to a group.                 |
| <b>route</b>               | Trace routing information.                                                                                                                               |
| <b>rp</b>                  | Trace candidate RP advertisements.                                                                                                                       |
| <b>state</b>               | Trace state transitions.                                                                                                                                 |
| <b>task</b>                | Trace task processing.                                                                                                                                   |
| <b>timer</b>               | Trace timer processing.                                                                                                                                  |

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on PIM packets of a particular type.

To configure tracing operations for PIM:

1. (Optional) Configure tracing at the [**routing-options** hierarchy level to trace all protocol packets.

[edit routing-options [traceoptions](#)]

```
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the PIM trace file.

```
[edit protocols pim traceoptions]
user@host# set file pim-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols pim traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols pim traceoptions]
user@host# set file size 1m
```

5. (Optional) Enable unrestricted file access.

```
[edit protocols pim traceoptions]
user@host# set file world-readable
```

6. Configure tracing flags.

Suppose you are troubleshooting issues with PIM version 1 control packets that are received on an interface configured for PIM version 2. The following example shows how to trace messages associated with this problem.

```
[edit protocols pim traceoptions]
user@host# set flag packets | match "Rx V1 Require V2"
```

7. View the trace file.

```
user@host> file list /var/log
user@host> file show /var/log/pim-trace
```

## Configuring Interface Priority for PIM Designated Router Selection

A designated router (DR) sends periodic join messages and prune messages toward a group-specific rendezvous point (RP) for each group for which it has active members. When a Protocol Independent Multicast (PIM) router learns about a source, it originates a Multicast Source Discovery Protocol (MSDP) source-address message if it is the DR on the upstream interface.

By default, every PIM interface has an equal probability (priority 1) of being selected as the DR. Configuring the interface DR priority helps ensure that changing an IP address does not alter your forwarding model.

To configure the interface designated router priority:

1. This example shows the configuration for the routing instance. Configure the interface globally or in the routing instance.

```
[edit routing-instances PIM.master protocols pim interface ge-0/0/0.0 family inet]
```

```
user@host# set priority 5
```

2. Verify the configuration by checking the **Hello Option DR Priority** field in the output of the **show pim neighbors detail** command.

```
user@host> show pim neighbors detail
```

```
Instance: PIM.master
Interface: ge-0/0/0.0
Address: 192.168.195.37, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 5
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
Rx Join: Group Source Timeout
225.1.1.1 192.168.195.78 0
225.1.1.1 0
```

```
Interface: lo0.0
Address: 10.255.245.91, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 1
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
```

```
Interface: pd-6/0/0.32768
Address: 0.0.0.0, IPv4, PIM v2, Mode: Sparse
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 0
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Join Suppression supported
```

## Configuring PIM Designated Router Election on Point-to-Point Links

To comply with the latest PIM drafts, enable designated router (DR) election on all PIM interfaces, including point-to-point (P2P) interfaces. (DR election is enabled by default on all other interfaces.) One of the two routers might join a multicast group on its P2P link interface. The DR on that link is responsible for initiating the relevant join messages.

To enable DR election on point-to-point interfaces:

1. On both point-to-point link routers, configure the router globally or in the routing instance. This example shows the configuration for the routing instance.

```
[edit routing-instances PIM.master protocols pim]
user@host# set dr-election-on-p2p
```

2. Verify the configuration by checking the **State** field in the output of the **show pim interfaces** command. The possible values for the **State** field are DR, NotDR, and P2P. When a point-to-point link interface is elected to be the DR, the interface state becomes DR instead of P2P.

3. If the **show pim interfaces** command continues to report the P2P state, consider running the **restart routing** command on both routers on the point-to-point link. Then recheck the state.

**CAUTION:** Do not restart a software process unless specifically asked to do so by your Juniper Networks customer support representative. Restarting a software process during normal operation of a routing platform could cause interruption of packet forwarding and loss of data.

[edit]  
user@host# run restart routing

## Configuring BFD for PIM

The Bidirectional Forwarding Detection (BFD) Protocol is a simple hello mechanism that detects failures in a network. BFD works with a wide variety of network environments and topologies. A pair of routing devices exchanges BFD packets. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply after a specified interval. The BFD failure detection timers have shorter time limits than the Protocol Independent Multicast (PIM) hello hold time, so they provide faster detection.

The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

You must specify the minimum transmit and minimum receive intervals to enable BFD on PIM.

To enable failure detection:

1. Configure the interface globally or in a routing instance.

This example shows the global configuration.

[edit protocols pim]

```
user@host# edit interface fe-1/0/0.0 family inet bfd-liveness-detection
```

2. Configure the minimum transmit interval.

This is the minimum interval after which the routing device transmits hello packets to a neighbor with which it has established a BFD session. Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set transmit-interval 350
```

3. Configure the minimum interval after which the routing device expects to receive a reply from a neighbor with which it has established a BFD session.

Specifying an interval smaller than 300 ms can cause undesired BFD flapping.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set minimum-receive-interval 350
```

4. (Optional) Configure other BFD settings.

As an alternative to setting the receive and transmit intervals separately, configure one interval for both.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set minimum-interval 350
```

5. Configure the threshold for the adaptation of the BFD session detection time.

When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set detection-time threshold 800
```

6. Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set multiplier 50
```

7. Configure the BFD version.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set version 1
```

8. Specify that BFD sessions should not adapt to changing network conditions.

We recommend that you not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

```
[edit protocols pim interface fe-1/0/0.0 family inet bfd-liveness-detection]
user@host# set no-adaptation
```

9. Verify the configuration by checking the output of the **show bfd session** command.

## Configuring BFD Authentication for PIM

---

Beginning with Junos OS Release 9.6, you can configure authentication for Bidirectional Forwarding Detection (BFD) sessions running over Protocol Independent Multicast (PIM). Routing instances are also supported. The following steps are needed to configure authentication on a BFD session:

1. Specify the BFD authentication algorithm for the PIM protocol.
2. Associate the authentication keychain with the PIM protocol.
3. Configure the related security authentication keychain.

The following sections provide instructions for configuring and viewing BFD authentication on PIM:

- [Configuring BFD Authentication Parameters on page 5502](#)
- [Viewing Authentication Information for BFD Sessions on page 5503](#)

### Configuring BFD Authentication Parameters

BFD authentication is only supported in the Canada and United States version of the Junos OS image and is not available in the export version.

To configure BFD authentication:

1. Specify the algorithm (**keyed-md5**, **keyed-sha-1**, **meticulous-keyed-md5**, **meticulous-keyed-sha-1**, or **simple-password**) to use for BFD authentication on a PIM route or routing instance.

```
[edit protocols pim]
```

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication
algorithm keyed-sha-1
```

**NOTE:** Nonstop active routing (NSR) is not supported with the **meticulous-keyed-md5** and **meticulous-keyed-sha-1** authentication algorithms. BFD sessions using these algorithms might go down after a switchover.

2. Specify the keychain to be used to associate BFD sessions on the specified PIM route or routing instance with the unique security authentication keychain attributes.

The keychain you specify must match the keychain name configured at the **[edit security authentication key-chains]** hierarchy level.

```
[edit protocols pim]
```

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication
keychain bfd-pim
```

**NOTE:** The algorithm and keychain must be configured on both ends of the BFD session, and they must match. Any mismatch in configuration prevents the BFD session from being created.

3. Specify the unique security authentication information for BFD sessions:

- The matching keychain name as specified in Step 2.
- At least one key, a unique integer between 0 and 63. Creating multiple keys allows multiple clients to use the BFD session.
- The secret data used to allow access to the session.
- The time at which the authentication key becomes active, in the format *yyyy-mm-dd.hh:mm:ss*.

[edit security]

```
user@host# set authentication-key-chains key-chain bfd-pim key 53 secret
9ggaJDmPQ6/tJgF/AtREVsyPsnCtUhm start-time 2009-06-14.10:00:00
```

4. (Optional) Specify loose authentication checking if you are transitioning from nonauthenticated sessions to authenticated sessions.

[edit protocols pim]

```
user@host# set interface ge-0/1/5 family inet bfd-liveness-detection authentication
loose-check
```

5. (Optional) View your configuration by using the **show bfd session detail** or **show bfd session extensive** command.

6. Repeat these steps to configure the other end of the BFD session.

## Viewing Authentication Information for BFD Sessions

You can view the existing BFD authentication configuration by using the **show bfd session detail** and **show bfd session extensive** commands.

The following example shows BFD authentication configured for the **ge-0/1/5** interface. It specifies the keyed SHA-1 authentication algorithm and a keychain name of **bfd-pim**. The authentication keychain is configured with two keys. Key 1 contains the secret data "**\$9\$ggaJDmPQ6/tJgF/AtREVsyPsnCtUhm**" and a start time of June 1, 2009, at 9:46:02 AM PST. Key 2 contains the secret data "**\$9\$a5jiKW9L.reP38ny.TszF2/9**" and a start time of June 1, 2009, at 3:29:20 PM PST.

[edit protocols pim]

```
interface ge-0/1/5 {
 family inet {
 bfd-liveness-detection {
 authentication {
 key-chain bfd-pim;
 algorithm keyed-sha-1;
 }
 }
 }
}
```

```

}
[edit security]
authentication key-chains {
 key-chain bfd-pim {
 key 1 {
 secret "9ggaJDmPQ6/tJgF/AtREVsyPsnCtUHm";
 start-time "2009-6-1.09:46:02 -0700";
 }
 key 2 {
 secret "9a5jiKW9l.reP38ny.TszF2/9";
 start-time "2009-6-1.15:29:20 -0700";
 }
 }
}
}

```

If you commit these updates to your configuration, you see output similar to the following example. In the output for the **show bfd session detail** command, **Authenticate** is displayed to indicate that BFD authentication is configured. For more information about the configuration, use the **show bfd session extensive** command. The output for this command provides the keychain name, the authentication algorithm and mode for each client in the session, and the overall BFD authentication configuration status, keychain name, and authentication algorithm and mode.

#### show bfd session detail

```
user@host# show bfd session detail
```

## Disabling PIM

By default, when configured, the PIM protocol is enabled on all interfaces for all families. If desired, you can disable PIM at the protocol, interface, or family hierarchy levels.

The hierarchy in which you configure PIM is critical. In general, the most specific configuration takes precedence. However, if PIM is disabled at the protocol level, then any disable statements with respect to an interface or family are ignored.

For example, the order of precedence for disabling PIM on a particular interface family is:

1. If PIM is disabled at the **[edit protocols pim interface *interface-name* family]** hierarchy level, then PIM is disabled for that interface family.
2. If PIM is not configured at the **[edit protocols pim interface *interface-name* family]** hierarchy level, but is disabled at the **[edit protocols pim interface *interface-name*]** hierarchy level, then PIM is disabled for all families on the specified interface.
3. If PIM is not configured at either the **[edit protocols pim interface *interface-name* family]** hierarchy level or the **[edit protocols pim interface *interface-name*]** hierarchy level, but is disabled at the **[edit protocols pim]** hierarchy level, then the PIM protocol is disabled globally for all interfaces and all families.

The following sections describe how to disable PIM at the various hierarchy levels.

- [Disabling the PIM Protocol on page 5505](#)
- [Disabling PIM on an Interface on page 5506](#)
- [Disabling PIM for a Family on page 5506](#)
- [Disabling PIM for a Rendezvous Point on page 5507](#)

### Disabling the PIM Protocol

You can explicitly disable the PIM protocol. Disabling the PIM protocol disables the protocol for all interfaces and all families. This is accomplished at the **[edit protocols pim]** hierarchy level:

```
[edit protocols]
pim {
 disable;
}
```

To disable the PIM protocol:

1. Include the **disable** statement.

```
user@host# set protocols pim disable
```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

```
user@host# run show protocols pim
```

## Disabling PIM on an Interface

You can disable the PIM protocol on a per-interface basis. This is accomplished at the **[edit protocols pim interface *interface-name*]** hierarchy level:

```
[edit protocols]
pim {
 interface interface-name {
 disable;
 }
}
```

To disable PIM on an interface:

1. Include the **disable** statement.

```
user@host# set protocols pim interface fe-0/1/0 disable
```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

```
user@host# run show protocols pim
```

## Disabling PIM for a Family

You can disable the PIM protocol on a per-family basis. This is accomplished at the **[edit protocols pim family]** hierarchy level:

```
[edit protocols]
pim {
 family inet {
 disable;
 }
 family inet6 {
 disable;
 }
}
```

To disable PIM for a family:

1. Include the **disable** statement.

```
user@host# set protocols pim family inet disable
```

```
user@host# set protocols pim family inet6 disable
```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

```
user@host# run show protocols pim
```

## Disabling PIM for a Rendezvous Point

You can disable the PIM protocol for a rendezvous point (RP) on a per-family basis. This is accomplished at the **[edit protocols pim rp local family]** hierarchy level:

```
[edit protocols]
pim {
 rp {
 local {
 family inet {
 disable;
 }
 family inet6 {
 disable;
 }
 }
 }
}
```

To disable PIM for an RP family:

1. Use the **disable** statement.

```
user@host# set protocols pim rp local family inet disable
user@host# set protocols pim rp local family inet6 disable
```

2. (Optional) Verify your configuration settings before committing them by using the **show protocols pim** command.

```
user@host# run show protocols pim
```

# Using PIM Sparse Mode

## Understanding PIM Sparse Mode

---

A Protocol Independent Multicast (PIM) sparse-mode domain uses reverse-path forwarding (RPF) to create a path from a data source to the receiver requesting the data. When a receiver issues an explicit join request, an RPF check is triggered. A (\*,G) PIM join message is sent toward the RP from the receiver's designated router (DR). (By definition, this message is actually called a join/prune message, but for clarity in this description, it is called either join or prune, depending on its context.) The join message is multicast hop by hop upstream to the ALL-PIM-ROUTERS group (224.0.0.13) by means of each router's RPF interface until it reaches the RP. The RP router receives the (\*,G) PIM join message and adds the interface on which it was received to the outgoing interface list (OIL) of the rendezvous-point tree (RPT) forwarding state entry. This builds the RPT connecting the receiver with the RP. The RPT remains in effect, even if no active sources generate traffic.

**NOTE:** State—the (\*,G) or (S,G) entries—is the information used for forwarding unicast or multicast packets. S is the source IP address, G is the multicast group address, and \* represents any source sending to group G. Routers keep track of the multicast forwarding state for the incoming and outgoing interfaces for each group.

When a source becomes active, the source DR encapsulates multicast data packets into a PIM register message and sends them by means of unicast to the RP router.

If the RP router has interested receivers in the PIM sparse-mode domain, it sends a PIM join message toward the source to build a shortest-path tree (SPT) back to the source. The source sends multicast packets out on the LAN, and the source DR encapsulates

the packets in a PIM register message and forwards the message toward the RP router by means of unicast. The RP router receives PIM register messages back from the source, and thus adds a new source to the distribution tree, keeping track of sources in a PIM table. Once an RP router receives packets natively (with S,G), it sends a register stop message to stop receiving the register messages by means of unicast.

In actual application, many receivers with multiple SPTs are involved in a multicast traffic flow. To illustrate the process, we track the multicast traffic from the RP router to one receiver. In such a case, the RP router begins sending multicast packets down the RPT toward the receiver's DR for delivery to the interested receivers. When the receiver's DR receives the first packet from the RPT, the DR sends a PIM join message toward the source DR to start building an SPT back to the source. When the source DR receives the PIM join message from the receiver's DR, it starts sending traffic down all SPTs. When the first multicast packet is received by the receiver's DR, the receiver's DR sends a PIM prune message to the RP router to stop duplicate packets from being sent through the RPT. In turn, the RP router stops sending multicast packets to the receiver's DR, and sends a PIM prune message for this source over the RPT toward the source DR to halt multicast packet delivery to the RP router from that particular source.

If the RP router receives a PIM register message from an active source but has no interested receivers in the PIM sparse-mode domain, it still adds the active source into the PIM table. However, after adding the active source into the PIM table, the RP router sends a register stop message. The RP router discovers the active source's existence and no longer needs to receive advertisement of the source (which utilizes resources).

**NOTE:** If the number of PIM join messages exceeds the configured MTU, the messages are fragmented in IPv6 PIM sparse mode. To avoid the fragmentation of PIM join messages, the multicast traffic receives the interface MTU instead of the path MTU.

---

The major characteristics of PIM sparse mode are as follows:

- Routers with downstream receivers join a PIM sparse-mode tree through an explicit join message.
- PIM sparse-mode RPs are the routers where receivers meet sources.
- Senders announce their existence to one or more RPs, and receivers query RPs to find multicast sessions.
- Once receivers get content from sources through the RP, the last-hop router (the router closest to the receiver) can optionally remove the RP from the shared distribution tree (\*,G) if the new source-based tree (S,G) is shorter. Receivers can then get content directly from the source.

The transitional aspect of PIM sparse mode from shared to source-based tree is one of the major features of PIM, because it prevents overloading the RP or surrounding core links.

There are related issues regarding source, RPs, and receivers when sparse mode multicast is used:

- Sources must be able to send to all RPs.
- RPs must all know one another.
- Receivers must send explicit join messages to a known RP.
- Receivers initially need to know only one RP (they later learn about others).
- Receivers can explicitly prune themselves from a tree.
- Receivers that never transition to a source-based tree are effectively running Core Based Trees (CBT).

PIM sparse mode has standard features for all of these issues.

## Rendezvous Point

The RP router serves as the information exchange point for the other routers. All routers in a PIM domain must provide mapping to an RP router. It is the only router that needs to know the active sources for a domain—the other routers just need to know how to reach the RP. In this way, the RP matches receivers with sources.

The RP router is downstream from the source and forms one end of the shortest-path tree. As shown in [Figure 172](#), the RP router is upstream from the receiver and thus forms one end of the rendezvous-point tree.

**Figure 172: Rendezvous Point As Part of the RPT and SPT**

The benefit of using the RP as the information exchange point is that it reduces the amount of state in non-RP routers. No network flooding is required to provide non-RP routers information about active sources.

## RP Mapping Options

RPs can be learned by one of the following mechanisms:

- Static configuration
- Anycast RP
- Auto-RP
- Bootstrap router

We recommend a static RP mapping with anycast RP and a bootstrap router (BSR) with auto-RP configuration, because static mapping provides all the benefits of a bootstrap router and auto-RP without the complexity of the full BSR and auto-RP mechanisms.

  - [Understanding PIM Auto-RP on page 5561](#)

---

## Designated Router

In a PIM sparse mode (PIM-SM) domain, there are two types of designated routers to consider:

- The receiver DR sends PIM join and PIM prune messages from the receiver network toward the RP.
- The source DR sends PIM register messages from the source network to the RP.

Neighboring PIM routers multicast periodic PIM hello messages to each other every 30 seconds (the default). The PIM hello message usually includes a holdtime value for the neighbor to use, but this is not a requirement. If the PIM hello message does not include a holdtime value, a default timeout value (in Junos OS, 105 seconds) is used. On receipt of a PIM hello message, a router stores the IP address and priority for that neighbor. If the DR priorities match, the router with the highest IP address is selected as the DR.

If a DR fails, a new one is selected using the same process of comparing IP addresses.

**NOTE:** In PIM dense mode (PIM-DM), a DR is elected by the same process that PIM-SM uses. However, the only time that a DR has any effect in PIM-DM is when IGMPv1 is used on the interface. (IGMPv2 is the default.) In this case, the DR also functions as the IGMP Query Router because IGMPv1 does not have a Query Router election mechanism.

---

---

## Enabling PIM Sparse Mode

In PIM sparse mode (PIM-SM), the assumption is that very few of the possible receivers want packets from a source, so the network establishes and sends packets only on branches that have at least one leaf indicating (by message) a desire for the traffic. WANs are appropriate networks for sparse-mode operation.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default. You do not need to configure Internet Group Management Protocol (IGMP) version 2 for a sparse mode configuration. After you enable PIM, by default, IGMP version 2 is also enabled.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default for rendezvous point (RP) mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults. The following example explicitly configures PIMv2 on the interfaces.

You can configure PIM sparse mode globally or for a routing instance. This example shows how to configure PIM sparse mode globally on all interfaces. It also shows how to configure a static RP router and how to configure the non-RP routers.

To configure the router properties for PIM sparse mode:

1. Configure the static RP router.

```
[edit protocols pim]
user@host# set rp local family inet address 192.168.3.253
```

2. Configure the RP router interfaces. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
[edit protocols pim]
user@host# set interface all mode sparse
user@host# set interface all version 2
user@host# set interface fxp0.0 disable
```

3. Configure the non-RP routers. Include the following configuration on all of the non-RP routers.

```
[edit protocols pim]
user@host# set rp static address 192.168.3.253 version 2
user@host# set interface all mode sparse
user@host# set interface all version 2
user@host# set interface fxp0.0 disable
```

4. Monitor the operation of PIM sparse mode.

- [Understanding PIM Sparse Mode on page 5509](#)

## Configuring PIM Join Load Balancing

By default, PIM join messages are sent toward a source based on the RPF routing table check. If there is more than one equal-cost path toward the source, then one upstream interface is chosen to send the join message. This interface is also used for all downstream

traffic, so even though there are alternative interfaces available, the multicast load is concentrated on one upstream interface and routing device.

For PIM sparse mode, you can configure PIM join load balancing to spread join messages and traffic across equal-cost upstream paths (interfaces and routing devices) provided by unicast routing toward a source. PIM join load balancing is only supported for PIM sparse mode configurations.

PIM join load balancing is supported on draft-rosen multicast VPNs (also referred to as dual PIM multicast VPNs). PIM join load balancing is not supported on multiprotocol BGP-based multicast VPNs (also referred to as next-generation Layer 3 VPN multicast). When PIM join load balancing is enabled in a draft-rosen Layer 3 VPN scenario, the load balancing is achieved based on the join counts for the far-end PE routing devices, not for any intermediate P routing devices.

If an internal BGP (IBGP) multipath forwarding VPN route is available, the Junos OS uses the multipath forwarding VPN route to send join messages to the remote PE routers to achieve load balancing over the VPN.

By default, when multiple PIM joins are received for different groups, all joins are sent to the same upstream gateway chosen by the unicast routing protocol. Even if there are multiple equal-cost paths available, these alternative paths are not utilized to distribute multicast traffic from the source to the various groups.

When PIM join load balancing is configured, the PIM joins are distributed equally among all equal-cost upstream interfaces and neighbors. Every new join triggers the selection of the least-loaded upstream interface and neighbor. If there are multiple neighbors on the same interface (for example, on a LAN), join load balancing maintains a value for each of the neighbors and distributes multicast joins (and downstream traffic) among these as well.

Join counts for interfaces and neighbors are maintained globally, not on a per-source basis. Therefore, there is no guarantee that joins for a particular source are load-balanced. However, the joins for all sources and all groups known to the routing device are load-balanced. There is also no way to administratively give preference to one neighbor over another: all equal-cost paths are treated the same way.

You can configure message filtering globally or for a routing instance. This example shows the global configuration.

You configure PIM join load balancing on the non-RP routers in the PIM domain.

1. Determine if there are multiple paths available for a source (for example, an RP) with the output of the **show pim join extensive** or **show pim source** commands.

```
user@host> show pim join extensive
Instance: PIM.master Family: INET

Group: 224.1.1.1
 Source: *
 RP: 10.255.245.6
 Flags: sparse,rptree,wildcard
 Upstream interface: t1-0/2/3.0
 Upstream neighbor: 192.168.38.57
 Upstream state: Join to RP
 Downstream neighbors:
 Interface: t1-0/2/1.0
 192.168.38.16 State: JOIN Flags; SRW Timeout: 164
Group: 224.2.127.254
 Source: *
 RP: 10.255.245.6
 Flags: sparse,rptree,wildcard
 Upstream interface: so-0/3/0.0
 Upstream neighbor: 192.168.38.47
 Upstream state: Join to RP
 Downstream neighbors:
 Interface: t1-0/2/3.0
 192.168.38.16 State: JOIN Flags; SRW Timeout: 164
```

Note that for this router, the RP at IP address 10.255.245.6 is the source for two multicast groups: 224.1.1.1 and 224.2.127.254. This router has two equal-cost paths through two different upstream interfaces (**t1-0/2/3.0** and **so-0/3/0.0**) with two different neighbors (192.168.38.57 and 192.168.38.47). This router is a good candidate for PIM join load balancing.

2. On the non-RP router, configure PIM sparse mode and join load balancing.

```
[edit protocols pim]
user@host# set interface all mode sparse version 2
user@host# set join-load-balance
```

3. Then configure the static address of the RP.

```
[edit protocols pim rp]
user@host# set static address 10.10.10.1
```

4. Monitor the operation.

If load balancing is enabled for this router, the number of PIM joins sent on each interface is shown in the output for the **show pim interfaces** command.

```
user@host> show pim interfaces
Instance: PIM.master
```

| Name           | Stat | Mode   | IP V | State | NbrCnt | JoinCnt | DR address         |
|----------------|------|--------|------|-------|--------|---------|--------------------|
| lo0.0          | Up   | Sparse | 4 2  | DR    | 0      | 0       | 10.255.168.58      |
| pe-1/2/0.32769 | Up   | Sparse | 4 2  | P2P   | 0      | 0       |                    |
| so-0/3/0.0     | Up   | Sparse | 4 2  | P2P   | 1      | 1       |                    |
| t1-0/2/1.0     | Up   | Sparse | 4 2  | P2P   | 1      | 0       |                    |
| t1-0/2/3.0     | Up   | Sparse | 4 2  | P2P   | 1      | 1       |                    |
| lo0.0          | Up   | Sparse | 6 2  | DR    | 0      | 0       | fe80::2a0:a5ff:4b7 |

Note that the two equal-cost paths shown by the **show pim interfaces** command now have nonzero join counts. If the counts differ by more than one and were zero (0) when load balancing commenced, an error occurs (joins before load balancing are not redistributed). The join count also appears in the **show pim neighbors detail** output:

```
user@host> show pim neighbors detail
Interface: so-0/3/0.0
```

```
Address: 192.168.38.46, IPv4, PIM v2, Mode: Sparse, Join Count: 0
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 1
Hello Option Generation ID: 1689116164
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
```

```
Address: 192.168.38.47, IPv4, PIM v2, Join Count: 1
BFD: Disabled
Hello Option Holdtime: 105 seconds 102 remaining
Hello Option DR Priority: 1
Hello Option Generation ID: 792890329
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
```

```
Interface: t1-0/2/3.0
```

```
Address: 192.168.38.56, IPv4, PIM v2, Mode: Sparse, Join Count: 0
Hello Option Holdtime: 65535 seconds
Hello Option DR Priority: 1
Hello Option Generation ID: 678582286
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
```

```
Address: 192.168.38.57, IPv4, PIM v2, Join Count: 1
BFD: Disabled
Hello Option Holdtime: 105 seconds 97 remaining
Hello Option DR Priority: 1
Hello Option Generation ID: 1854475503
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
```

Note that the join count is nonzero on the two load-balanced interfaces toward the upstream neighbors.

PIM join load balancing only takes effect when the feature is configured. Prior joins are not redistributed to achieve perfect load balancing. In addition, if an interface or neighbor fails, the new joins are redistributed among remaining active interfaces and neighbors. However, when the interface or neighbor is restored, prior joins are not redistributed. The **clear pim join-distribution** command redistributes the existing flows to new or restored upstream neighbors. Redistributing the existing flows causes traffic to be disrupted, so we recommend that you perform PIM join redistribution during a maintenance window.

---

## Modifying the Join State Timeout

---

This section describes how to configure the join state timeout.

A downstream router periodically sends join messages to refresh the join state on the upstream router. If the join state is not refreshed before the timeout expires, the join state is removed.

By default, the join state timeout is 210 seconds. You can change this timeout to allow additional time to receive the join messages. Because the messages are called join-prune messages, the name used is the **join-prune-timeout** statement.

To modify the timeout, include the **join-prune-timeout** statement:

```
user@host# set protocols pim join-prune-timeout 230
```

The join timeout value can be from 210 through 420 seconds.

## Example: Enabling Join Suppression

---

This example describes how to enable PIM join suppression.

- [Requirements on page 5517](#)
- [Overview on page 5517](#)
- [Configuration on page 5520](#)
- [Verification on page 5521](#)

### Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 5512](#).

### Overview

PIM join suppression enables a router on a multiaccess network to defer sending join messages to an upstream router when it sees identical join messages on the same network. Eventually, only one router sends these join messages, and the other routers suppress identical messages. Limiting the number of join messages improves scalability and efficiency by reducing the number of messages sent to the same router.

This example includes the following statements:

- **override-interval**—Sets the maximum time in milliseconds to delay sending override join messages. When a router sees a prune message for a join it is currently suppressing, it waits before it sends an override join message. Waiting helps avoid multiple downstream routers sending override join messages at the same time. The override interval is a random timer with a value of 0 through the maximum override value.
- **propagation-delay**—Sets a value in milliseconds for a prune pending timer, which specifies how long to wait before executing a prune on an upstream router. During this period, the router waits for any prune override join messages that might be currently suppressed. The period for the prune pending timer is the sum of the **override-interval** value and the value specified for **propagation-delay**.
- **reset-tracking-bit**—Enables PIM join suppression on each multiaccess downstream interface. This statement resets a tracking bit field (T-bit) on the LAN prune delay hello option from the default of 1 (join suppression disabled) to 0 (join suppression enabled).

When multiple identical join messages are received, a random join suppression timer is activated, with a range of 66 through 84 milliseconds. The timer is reset each time join suppression is triggered.

[Figure 173](#) shows the topology used in this example.

Figure 173: Join Suppression

The items in [Figure 173](#) represent the following functions:

- Host 0 is the multicast source.
- Host 1, Host 2, Host 3, and Host 4 are receivers.
- Router R0 is the first-hop router and the RP.
- Router R1 is an upstream router.
- Routers R2, R3, R4, and R5 are downstream routers in the multicast LAN.

This example shows the configuration of the downstream devices: Routers R2, R3, R4, and R5.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit]
set protocols pim traceoptions file pim.log
set protocols pim traceoptions file size 5m
set protocols pim traceoptions file world-readable
set protocols pim traceoptions flag join detail
set protocols pim traceoptions flag prune detail
set protocols pim traceoptions flag normal detail
set protocols pim traceoptions flag register detail
set protocols pim rp static address 10.255.112.160
set protocols pim interface all mode sparse
set protocols pim interface all version 2
set protocols pim interface fxp0.0 disable
set protocols pim reset-tracking-bit
set protocols pim propagation-delay 500
set protocols pim override-interval 4000
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PIM join suppression on a non-RP downstream router in the multicast LAN:

1. Configure PIM sparse mode on the interfaces.

```
[edit]
user@host# edit protocols pim
[edit protocols pim]
user@host# set rp static address 10.255.112.160
[edit protocols pim]
user@host# set interface all mode sparse version 2
[edit protocols pim]
user@host# set interface all version 2
[edit protocols pim]
user@host# set interface fxp0.0 disable
```

2. Enable the join suppression timer.

```
[edit protocols pim]
user@host# set reset-tracking-bit
```

3. Configure the prune override interval value.

```
[edit protocols pim]
user@host# set override-interval 4000
```

4. Configure the propagation delay of the link.

```
[edit protocols pim]
user@host# set propagation-delay 500
```

5. (Optional) Configure PIM tracing operations.

```
[edit protocols pim]
user@host# set traceoptions file pim.log size 5m world-readable
[edit protocols pim]
user@host# set traceoptions flag join detail
[edit protocols pim]
user@host# set traceoptions flag normal detail
[edit protocols pim]
user@host# set traceoptions flag register detail
```

6. If you are done configuring the device, commit the configuration.

```
[edit protocols pim]
user@host# commit
```

## Results

From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show protocols
pim {
 traceoptions {
 file pim.log size 5m world-readable;
 flag join detail;
 flag prune detail;
 flag normal detail;
 flag register detail;
 }
 rp {
 static {
 address 10.255.112.160;
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 reset-tracking-bit;
 propagation-delay 500;
 override-interval 4000;
}
```

## Verification

To verify the configuration, run the following commands on the upstream and downstream routers:

- **show pim join extensive**

- [show multicast route extensive](#)

## Understanding PIM Dense Mode

---

PIM dense mode is less sophisticated than PIM sparse mode. PIM dense mode is useful for multicast LAN applications, the main environment for all dense mode protocols.

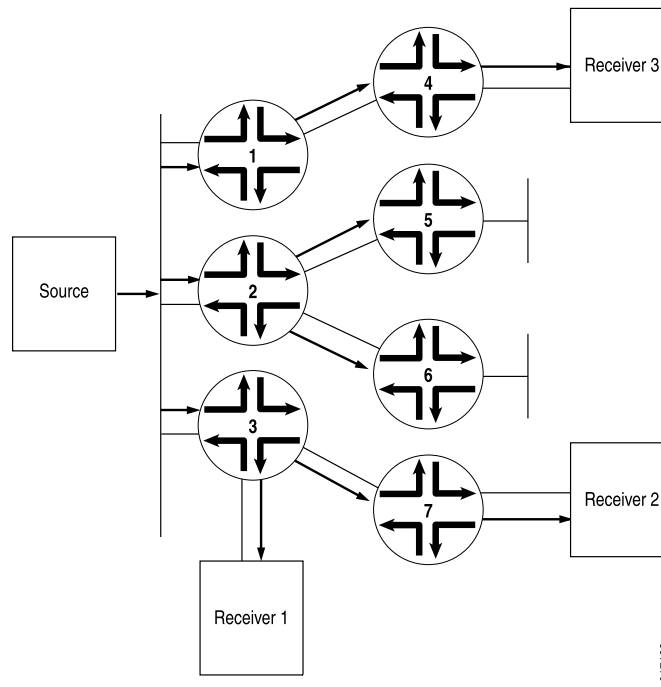

PIM dense mode implements the same flood-and-prune mechanism that DVMRP and other dense mode routing protocols employ. The main difference between DVMRP and PIM dense mode is that PIM dense mode introduces the concept of protocol independence. PIM dense mode can use the routing table populated by any underlying unicast routing protocol to perform reverse-path-forwarding (RPF) checks.

Internet service providers (ISPs) typically appreciate the ability to use any underlying unicast routing protocol with PIM dense mode because they do not need to introduce and manage a separate routing protocol just for RPF checks. While unicast routing protocols extended as multiprotocol BGP (MBGP) and Multitopology Routing in IS-IS (M-IS-IS) were later employed to build special tables to perform RPF checks, PIM dense mode does not require them.

PIM dense mode can use the unicast routing table populated by OSPF, IS-IS, BGP, and so on, or PIM dense mode can be configured to use a special multicast RPF table populated by MBGP or M-IS-IS when performing RPF checks.

Unlike sparse mode, in which data is forwarded only to routers sending an explicit request, dense mode implements a *flood-and-prune* mechanism, similar to DVMRP. In PIM dense mode, there is no RP. A router receives the multicast data on the interface closest to the source, then forwards the traffic to all other interfaces (see [Figure 174](#)).

**Figure 174: Multicast Traffic Flooded from the Source Using PIM Dense Mode**

Flooding occurs periodically. It is used to refresh state information, such as the source IP address and multicast group pair. If the router has no interested receivers for the data, and the OIL becomes empty, the router sends a prune message upstream to stop delivery of multicast traffic (see [Figure 175](#)).

**Figure 175: Prune Messages Sent Back to the Source to Stop Unwanted Multicast Traffic**

## Understanding PIM Sparse-Dense Mode

Sparse-dense mode, as the name implies, allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as dense is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense-mode rules. A group specified as sparse is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules.

For information about PIM sparse-mode and PIM dense-mode rules, see [“Understanding PIM Sparse Mode” on page 5509](#) and [“Understanding PIM Dense Mode” on page 5523](#).

- Related Documentation**
- [Understanding PIM Sparse Mode on page 5509](#)
  - [Understanding PIM Dense Mode on page 5523](#)

## Mixing PIM Sparse and Dense Modes

It is possible to mix PIM dense mode, PIM sparse mode, and PIM source-specific multicast (SSM) on the same network, the same router, and even the same interface. This is because modes are effectively tied to multicast groups, an IP multicast group address must be unique for a particular group's traffic, and scoping limits enforce the division between potential or actual overlaps.

**NOTE:** PIM sparse mode was capable of forming shortest-path trees (SPTs) already. Changes to PIM sparse mode to support PIM SSM mainly involved defining behavior in the SSM address range, because shared-tree behavior is prohibited for groups in the SSM address range.

A multicast router employing sparse-dense mode is a good example of mixing PIM modes on the same network or router or interface. Dense modes are easy to support because of the flooding, but scaling issues make dense modes inappropriate for Internet use beyond very restricted uses.

---

## Configuring PIM Dense Mode Properties

---

In PIM dense mode (PIM-DM), the assumption is that almost all possible subnets have at least one receiver wanting to receive the multicast traffic from a source, so the network is flooded with traffic on all possible branches, then pruned back when branches do not express an interest in receiving the packets, explicitly (by message) or implicitly (time-out silence). LANs are appropriate networks for dense-mode operation.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default.

You can configure PIM dense mode globally or for a routing instance. This example shows how to configure the routing instance and how to specify that PIM dense mode use **inet.2** as its RPF routing table instead of **inet.0**.

To configure the router properties for PIM dense mode:

1. (Optional) Create an IPv4 routing table group so that interface routes are installed into two routing tables, **inet.0** and **inet.2**.

```
[edit routing-options rib-groups]
user@host# set pim-rg export-rib inet.0
user@host# set pim-rg import-rib [inet.0 inet.2]
```

2. (Optional) Associate the routing table group with a PIM routing instance.

```
[edit routing-instances PIM.dense protocols pim]
user@host# set rib-group inet pim-rg
```

3. Configure the PIM interface. If you do not specify any interfaces, PIM is enabled on all router interfaces. Generally, you specify interface names only if you are disabling PIM on certain interfaces.

```
[edit routing-instances PIM.dense protocols pim]
user@host# set interface fe-0/0/1.0 mode dense
```

**NOTE:** You cannot configure both PIM and Distance Vector Multicast Routing Protocol (DVMRP) in forwarding mode on the same interface. You can configure PIM on the same interface only if you configured DVMRP in unicast-routing mode.

4. Monitor the operation of PIM dense mode by running the **show pim interfaces**, **show pim join**, **show pim neighbors**, and **show pim statistics** commands.

**Related Documentation**

## Configuring PIM Sparse-Dense Mode Properties

Sparse-dense mode allows the interface to operate on a per-group basis in either sparse or dense mode. A group specified as “dense” is not mapped to an RP. Instead, data packets destined for that group are forwarded by means of PIM dense mode rules. A group specified as “sparse” is mapped to an RP, and data packets are forwarded by means of PIM sparse-mode rules. Sparse-dense mode is useful in networks implementing auto-RP for PIM sparse mode.

By default, PIM is disabled. When you enable PIM, it operates in sparse mode by default.

You can configure PIM sparse-dense mode globally or for a routing instance. This example shows how to configure PIM sparse-dense mode globally on all interfaces, specifying that the groups 224.0.1.39 and 224.0.1.40 are using dense mode.

To configure the router properties for PIM sparse-dense mode:

1. Configure the dense-mode groups.

```
[protocols pim]
user@host# set dense-groups 224.0.1.39
user@host# set dense-groups 224.0.1.40
```

2. Configure all interfaces on the routing device to use sparse-dense mode. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
[edit protocols pim]
user@host# set interface all mode sparse-dense
user@host# set interface fxp0.0 disable
```

3. Monitor the operation of PIM sparse-dense mode by running the **show pim interfaces**, **show pim join**, **show pim neighbors**, and **show pim statistics** commands.

## Source-Specific Multicast Groups Overview

---

Source-specific multicast (SSM) is a service model that identifies session traffic by both source and group address. SSM implemented in Junos OS has the efficient explicit join procedures of Protocol Independent Multicast (PIM) sparse mode but eliminates the immediate shared tree and rendezvous point (RP) procedures using (\*,G) pairs. The (\*) is a wildcard referring to any source sending to group G, and "G" refers to the IP multicast group. SSM builds shortest-path trees (SPTs) directly represented by (S,G) pairs. The "S" refers to the source's unicast IP address, and the "G" refers to the specific multicast group address. The SSM (S,G) pairs are called channels to differentiate them from any-source multicast (ASM) groups. Although ASM supports both one-to-many and many-to-many communications, ASM's complexity is in its method of source discovery. For example, if you click a link in a browser, the receiver is notified about the group information, but not the source information. With SSM, the client receives both source and group information.

SSM is ideal for one-to-many multicast services such as network entertainment channels. However, many-to-many multicast services might require ASM.

To deploy SSM successfully, you need an end-to-end multicast-enabled network and applications that use an Internet Group Management Protocol version 3 (IGMPv3) or Multicast Listener Discovery version 2 (MLDv2) stack, or you need to configure SSM mapping from IGMPv1 or IGMPv2 to IGMPv3. An IGMPv3 stack provides the capability of a host operating system to use the IGMPv3 protocol. IGMPv3 is available for Windows XP, Windows Vista, and most UNIX operating systems.

SSM mapping allows operators to support an SSM network without requiring all hosts to support IGMPv3. This support exists in static (S,G) configurations, but SSM mapping also supports dynamic per-source group state information, which changes as hosts join and leave the group using IGMP.

SSM is typically supported with a subset of IGMPv3 and PIM sparse mode known as *PIM SSM*. Using SSM, a client can receive multicast traffic directly from the source. PIM SSM uses the PIM sparse-mode functionality to create an SPT between the client and the source, but builds the SPT without the help of an RP.

An SSM-configured network has distinct advantages over a traditionally configured PIM sparse-mode network. There is no need for shared trees or RP mapping (no RP is required), or for RP-to-RP source discovery through the Multicast Source Discovery Protocol (MSDP).

---

## Understanding PIM SSM

RFC 1112, the original multicast RFC, supported both many-to-many and one-to-many models. These came to be known collectively as any-source multicast (ASM) because ASM allowed one or many sources for a multicast group's traffic. However, an ASM network must be able to determine the locations of all sources for a particular multicast group whenever there are interested listeners, no matter where the sources might be located in the network. In ASM, the key function of *source discovery* is a required function of the network itself.

Multicast source discovery appears to be an easy process, but in sparse mode it is not. In dense mode, it is simple enough to flood traffic to every router in the whole network so that every router learns the source address of the content for that multicast group. However, the flooding presents scalability and network resource use issues and is not a viable option in sparse mode.

PIM sparse mode (like any sparse mode protocol) achieves the required source discovery functionality without flooding at the cost of a considerable amount of complexity. The RP routers must be added and must know all multicast sources, and complicated shared distribution trees must be built to the RPs.

In an environment where many sources come and go, such as for a videoconferencing service, ASM is appropriate. However, by ignoring the many-to-many model and focusing attention on the one-to-many source-specific multicast (SSM) model, several commercially promising multicast applications, such as television channel distribution over the Internet, might be brought to the Internet much more quickly and efficiently than if full ASM functionality were required of the network.

PIM SSM is simpler than PIM sparse mode because only the one-to-many model is supported. Initial commercial multicast Internet applications are likely to be available to *subscribers* (that is, receivers that issue join messages) from only a single source (a special case of SSM covers the need for a backup source). PIM SSM therefore forms a subset of PIM sparse mode. PIM SSM builds shortest-path trees (SPTs) rooted at the source immediately because in SSM, the router closest to the interested receiver host is informed of the unicast IP address of the source for the multicast traffic. That is, PIM SSM bypasses the RP connection stage through shared distribution trees, as in PIM sparse mode, and goes directly to the source-based distribution tree.

PIM SSM introduces new terms for many of the concepts in PIM sparse mode. PIM SSM can technically be used in the entire 224/4 multicast address range, although PIM SSM operation is guaranteed only in the 232/8 range (232.0.0/24 is reserved). The new SSM terms are appropriate for Internet video applications and are summarized in [Table 435](#).

**Table 435: ASM and SSM Terminology**

| Term                | Any-Source Multicast  | Source-Specific Multicast         |
|---------------------|-----------------------|-----------------------------------|
| Address identifier  | G                     | S,G                               |
| Address designation | group                 | channel                           |
| Receiver operations | join, leave           | subscribe, unsubscribe            |
| Group address range | 224/4 excluding 232/8 | 224/4 (guaranteed only for 232/8) |

Although PIM SSM describes receiver operations as *subscribe* and *unsubscribe*, the same PIM sparse mode join and leave messages are used by both forms of the protocol. The terminology change distinguishes ASM from SSM even though the receiver messages are identical.

## PIM SSM

PIM source-specific multicast (SSM) uses a subset of PIM sparse mode and IGMP version 3 (IGMPv3) to allow a client to receive multicast traffic directly from the source. PIM SSM uses the PIM sparse-mode functionality to create an SPT between the receiver and the source, but builds the SPT without the help of an RP.

By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the **ssm-groups** statement at the **[edit routing-options multicast]** hierarchy level. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the **ssm-groups** statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.

You can also configure Junos OS to accept any-source multicast (ASM) join messages (\*G) for group addresses that are within the default or configured range of source-specific multicast (SSM) groups. This allows you to support a mix of any-source and source-specific multicast groups simultaneously.

An SSM-configured network has distinct advantages over a traditionally configured PIM sparse-mode network. There is no need for shared trees or RP mapping (no RP is required), or for RP-to-RP source discovery through MSDP.

Deploying SSM is easy. You need to configure PIM sparse mode on all router interfaces and issue the necessary SSM commands, including specifying IGMPv3 on the receiver's LAN. If PIM sparse mode is not explicitly configured on both the source and group member interfaces, multicast packets are not forwarded. Source lists, supported in IGMPv3, are

used in PIM SSM. As sources become active and start sending multicast packets, interested receivers in the SSM group receive the multicast packets.

In a PIM SSM-configured network, a host subscribes to an SSM channel (by means of IGMPv3), announcing a desire to join group G and source S (see [Figure 176](#)). The directly connected PIM sparse-mode router, the receiver's DR, sends an (S,G) join message to its RPF neighbor for the source. Notice in [Figure 176](#) that the RP is not contacted in this process by the receiver, as would be the case in normal PIM sparse-mode operations.

**Figure 176: Receiver Announces Desire to Join Group G and Source S**

The (S,G) join message initiates the source tree and then builds it out hop by hop until it reaches the source. In [Figure 177](#), the source tree is built across the network to Router 3, the last-hop router connected to the source.

**Figure 177: Router 3 (Last-Hop Router) Joins the Source Tree**

Using the source tree, multicast traffic is delivered to the subscribing host (see [Figure 178](#)).

**Figure 178: (S,G) State Is Built Between the Source and the Receiver**

To configure additional SSM groups, include the **ssm-groups** statement at the **[edit routing-options multicast]** hierarchy level.

## Example: Configuring PIM SSM on a Network

The following example shows how PIM SSM is configured between a receiver and a source in the network illustrated in [Figure 179](#).

Figure 179: Network on Which to Configure PIM SSM

This example shows how to configure the IGMP version to IGMPv3 on all receiving host interfaces.

1. Enable IGMPv3 on all host-facing interfaces, and disable IGMP on the **fxp0.0** interface on Router 1.

```

user@router1# set protocols igmp interface all version 3
user@router1# set protocols igmp interface fxp0.0 disable

```

**NOTE:** When you configure IGMPv3 on a router, hosts on interfaces configured with IGMPv2 cannot join the source tree.

2. After the configuration is committed, use the **show configuration protocol igmp** command to verify the IGMP protocol configuration.

```

user@router1> show configuration protocol igmp

[edit protocols igmp]
interface all {
 version 3;
}
interface fxp0.0 {
 disable;
}

```

3. Use the **show igmp interface** command to verify that IGMP interfaces are configured.

```

user@router1> show igmp interface
Interface State Querier Timeout Version Groups
fe-0/0/0.0 Up 198.58.3.245 213 3 0
fe-0/0/1.0 Up 198.58.3.241 220 3 0
fe-0/0/2.0 Up 198.58.3.237 218 3 0
Configured Parameters:
IGMP Query Interval (1/10 secs): 1250
IGMP Query Response Interval (1/10 secs): 100
IGMP Last Member Query Interval (1/10 secs): 10
IGMP Robustness Count: 2
Derived Parameters:
IGMP Membership Timeout (1/10 secs): 2600
IGMP Other Querier Present Timeout (1/10 secs): 2550

```

4. Use the **show pim join extensive** command to verify the PIM join state on Router 2 and Router 3 (the upstream routers).

```
user@router2> show pim join extensive
232.1.1.1 10.4.1.2 sparse
 Upstream interface: fe-1/1/3.0
 Upstream State: Local Source
 Keepalive timeout: 209
 Downstream Neighbors:
 Interface: so-1/0/2.0
 10.10.71.1 State: Join Flags: S Timeout: 209
```

5. Use the **show pim join extensive** command to verify the PIM join state on Router 1 (the router connected to the receiver).

```
user@router1> show pim join extensive
232.1.1.1 10.4.1.2 sparse
 Upstream interface: so-1/0/2.0
 Upstream State: Join to Source
 Keepalive timeout: 209
 Downstream Neighbors:
 Interface: fe-0/2/3.0
 10.3.1.1 State: Join Flags: S Timeout: Infinity
```

**NOTE:** IP version 6 (IPv6) multicast routers use the Multicast Listener Discovery (MLD) Protocol to manage the membership of hosts and routers in multicast groups and to learn which groups have interested listeners for each attached physical networks. Each routing device maintains a list of host multicast addresses that have listeners for each subnetwork, as well as a timer for each address. However, the routing device does not need to know the address of each listener—just the address of each host. The routing device provides addresses to the multicast routing protocol it uses, which ensures that multicast packets are delivered to all subnetworks where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) Protocol. MLD is an integral part of IPv6 and must be enabled on all IPv6 routing devices and hosts that need to receive IP multicast traffic. The Junos OS supports MLD versions 1 and 2. Version 2 is supported for source-specific multicast (SSM) include and exclude modes.

## Example: Configuring an SSM-Only Domain

Deploying an SSM-only domain is much simpler than deploying an ASM domain because it only requires a few configuration steps. Enable PIM sparse mode on all interfaces by adding the **mode** statement at the **[edit protocols pim interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface. Then configure IGMPv3 on all host-facing interfaces by adding the **version** statement at the **[edit protocols igmp interface interface-name]** hierarchy level.

In the following example, the host-facing interface is **fe-0/1/2**:

```
[edit]
protocols {
 pim {
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
 igmp {
 interface fe-0/1/2 {
 version 3;
 }
 }
}
```

## Example: Configuring SSM Mapping

SSM mapping does not require that all hosts support IGMPv3. SSM mapping translates IGMPv1 or IGMPv2 membership reports to an IGMPv3 report. This enables hosts running IGMPv1 or IGMPv2 to participate in SSM until the hosts transition to IGMPv3.

SSM mapping applies to all group addresses that match the policy, not just those that conform to SSM addressing conventions (232.1.1.1/32 for IPv4, ff30::/32 through ff3F::/32 for IPv6).

We recommend separate SSM maps for IPv4 and IPv6 if both address families require SSM support. If you apply an SSM map containing both IPv4 and IPv6 addresses to an interface in an IPv4 context (using IGMP), only the IPv4 addresses in the list are used. If there are no such addresses, no action is taken. Similarly, if you apply an SSM map containing both IPv4 and IPv6 addresses to an interface in an IPv6 context (using MLD), only the IPv6 addresses in the list are used. If there are no such addresses, no action is taken.

In this example, you create a policy to match the group addresses that you want to translate to IGMPv3. Then you define the SSM map that associates the policy with the source addresses where these group addresses are found. Finally, you apply the SSM map to one or more IGMP (for IPv4) or MLD (for IPv6) interfaces.

1. Create an SSM policy named **ssm-policy-example**. The policy terms match the IPv4 SSM group address 232.1.1.1/32 and the IPv6 SSM group address ff35::1/128. All other addresses are rejected.

```
user@router1# set policy-options policy-statement ssm-policy-example term A from
route-filter 232.1.1.1/32 exact
user@router1# set policy-options policy-statement ssm-policy-example term A then
accept
user@router1# set policy-options policy-statement ssm-policy-example term B from
route-filter ff35::1/128 exact
```

```
user@router1# set policy-options policy-statement ssm-policy-example term B then
accept
```

2. After the configuration is committed, use the **show configuration policy-options** command to verify the policy configuration.

```
user@host> show configuration policy-options

[edit policy-options]
policy-statement ssm-policy-example {
 term A {
 from {
 route-filter 232.1.1.1/32 exact;
 }
 then accept;
 }
 term B {
 from {
 route-filter ff35::1/128 exact;
 }
 then accept;
 }
 then reject;
}
```

The group addresses must match the configured policy for SSM mapping to occur.

3. Define two SSM maps, one called **ssm-map-ipv6-example** and one called **ssm-map-ipv4-example**, by applying the policy and configuring the source addresses as a multicast routing option.

```
user@host# set routing-options multicast ssm-map ssm-map-ipv6-example policy
ssm-policy-example
user@host# set routing-options multicast ssm-map ssm-map-ipv6-example source
fec0::1 fec0::12
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example policy
ssm-policy-example
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
10.10.10.4
user@host# set routing-options multicast ssm-map ssm-map-ipv4-example source
192.168.43.66
```

4. After the configuration is committed, use the **show configuration routing-options** command to verify the policy configuration.

```
user@host> show configuration routing-options

[edit routing-options]
multicast {
 ssm-map ssm-map-ipv6-example {
 policy ssm-policy-example;
 source [fec0::1 fec0::12];
 }
 ssm-map ssm-map-ipv4-example {
 policy ssm-policy-example;
 source [10.10.10.4 192.168.43.66];
 }
}
```

We recommend separate SSM maps for IPv4 and IPv6.

5. Apply SSM maps for IPv4-to-IGMP interfaces and SSM maps for IPv6-to-MLD interfaces:

```
user@host# set protocols igmp interface fe-0/1/0.0 ssm-map ssm-map-ipv4-example
user@host# set protocols mld interface fe-0/1/1.0 ssm-map ssm-map-ipv6-example
```

6. After the configuration is committed, use the **show configuration protocol** command to verify the IGMP and MLD protocol configuration.

```
user@router1> show configuration protocol

[edit protocols]
igmp {
 interface fe-0/1/0.0 {
 ssm-map ssm-map-ipv4-example;
 }
}
mld {
 interface fe-0/1/1.0 {
 ssm-map ssm-map-ipv6-example;
 }
}
```

7. Use the **show igmp interface** and the **show mld interface** commands to verify that the SSM maps are applied to the interfaces.

```
user@host> show igmp interface fe-0/1/0.0
Interface: fe-0/1/0.0
 Querier: 192.168.224.28
 State: Up Timeout: None Version: 2 Groups: 2
 SSM Map: ssm-map-ipv4-example

user@host> show mld interface fe-0/1/1.0
Interface: fe-0/1/1.0
 Querier: fec0:0:0:0:1::12
 State: Up Timeout: None Version: 2 Groups: 2
 SSM Map: ssm-map-ipv6-example
```

## Example: Configuring Source-Specific Multicast Groups with Any-Source Override

This example shows how to extend source-specific multicast (SSM) group operations beyond the default IP address range of 232.0.0.0 through 232.255.255.255. This example also shows how to accept any-source multicast (ASM) join messages (\*G) for group addresses that are within the default or configured range of SSM groups. This allows you to support a mix of any-source and source-specific multicast groups simultaneously.

- [Requirements on page 5538](#)
- [Overview on page 5538](#)
- [Configuration on page 5539](#)
- [Verification on page 5541](#)

## Requirements

Before you begin, configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.

## Overview

To deploy SSM, configure PIM sparse mode on all routing device interfaces and issue the necessary SSM commands, including specifying IGMPv3 or MLDv2 on the receiver's LAN. If PIM sparse mode is not explicitly configured on both the source and group members interfaces, multicast packets are not forwarded. Source lists, supported in IGMPv3 and MLDv2, are used in PIM SSM. Only sources that are specified send traffic to the SSM group.

In a PIM SSM-configured network, a host subscribes to an SSM channel (by means of IGMPv3 or MLDv2) to join group G and source S (see [Figure 180](#)). The directly connected PIM sparse-mode router, the receiver's designated router (DR), sends an (S,G) join message to its reverse-path forwarding (RPF) neighbor for the source. Notice in [Figure 180](#) that the RP is not contacted in this process by the receiver, as would be the case in normal PIM sparse-mode operations.

**Figure 180: Receiver Sends Messages to Join Group G and Source S**

The (S,G) join message initiates the source tree and then builds it out hop by hop until it reaches the source. In [Figure 181](#), the source tree is built across the network to Router 3, the last-hop router connected to the source.

**Figure 181: Router 3 (Last-Hop Router) Joins the Source Tree**

Using the source tree, multicast traffic is delivered to the subscribing host (see [Figure 182](#)).

Figure 182: (S,G) State Is Built Between the Source and the Receiver

SSM can operate in include mode or in exclude mode. In exclude mode the receiver specifies a list of sources that it does not want to receive the multicast group traffic from. The routing device forwards traffic to the receiver from any source except the sources specified in the exclusion list. The receiver accepts traffic from any sources except the sources specified in the exclusion list.

This example works with the simple RPF topology shown in [Figure 183](#).

Figure 183: Simple RPF Topology

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ospf area 0.0.0.0 interface all
set protocols pim rp local address 10.255.72.46
set protocols pim rp local group-ranges 239.0.0.0/24
set protocols pim interface fe-1/0/0.0 mode sparse
set protocols pim interface lo0.0 mode sparse
set routing-options multicast ssm-groups 232.0.0.0/8
set routing-options multicast ssm-groups 239.0.0.0/8
set routing-options multicast asm-override-ssm
```

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an RPF policy:

1. Configure OSPF.

```
[edit protocols ospf]
user@host# set area 0.0.0.0 interface fxp0.0 disable
user@host# set area 0.0.0.0 interface all
```

2. Configure PIM sparse mode.

```
[edit protocols pim]
user@host# set rp local address 10.255.72.46
user@host# set rp local group-ranges 239.0.0.0/24
user@host# set interface fe-1/0/0.0 mode sparse
user@host# set interface lo0.0 mode sparse
```

3. Configure additional SSM groups.

```
[edit routing-options]
user@host# set ssm-groups [232.0.0.0/8 239.0.0.0/8]
```

4. Configure the RP to accept ASM join messages for groups within the SSM address range.

```
[edit routing-options]
user@host# set multicast asm-override-ssm
```

5. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

---

## Results

Confirm your configuration by entering the **show protocols** and **show routing-options** commands.

```
user@host# show protocols
ospf {
 area 0.0.0.0 {
 interface fxp0.0 {
 disable;
 }
 interface all;
 }
}
pim {
 rp {
 local {
 address 10.255.72.46;
 group-ranges {
 239.0.0.0/24;
 }
 }
 }
}
interface fe-1/0/0.0 {
 mode sparse;
}
interface lo0.0 {
 mode sparse;
}
}

user@host# show routing-options
multicast {
 ssm-groups [232.0.0.0/8 239.0.0.0/8];
```

```
asm-override-ssm;
}
```

Verification

To verify the configuration, run the following commands:

- `show igmp group`
- `show igmp statistics`
- `show pim join`

Related Documentation

Example: Configuring SSM Maps for Different Groups to Different Sources

- [Multiple SSM Maps and Groups for Interfaces on page 5541](#)
- [Example: Configuring Multiple SSM Maps Per Interface on page 5541](#)

Multiple SSM Maps and Groups for Interfaces

You can configure multiple source-specific multicast (SSM) maps so that different groups map to different sources, which enables a single multicast group to map to different sources for different interfaces.

Example: Configuring Multiple SSM Maps Per Interface

This example shows how to assign more than one SSM map to an IGMP interface.

- [Requirements on page 5541](#)
- [Overview on page 5541](#)
- [Configuration on page 5542](#)
- [Verification on page 5543](#)

Requirements

This example requires Junos OS Release 11.4 or later.

Overview

In this example, you configure a routing policy, POLICY-ipv4-example1, that maps multicast group join messages over an IGMP logical interface to IPv4 multicast source addresses based on destination IP address as follows:

| Routing Policy Name         | Multicast Group Join Messages for a Route Filter at This Destination Address | Multicast Source Addresses   |
|-----------------------------|------------------------------------------------------------------------------|------------------------------|
| POLICY-ipv4-example1 term 1 | 232.1.1.1                                                                    | 10.10.10.4,<br>192.168.43.66 |

| Routing Policy Name         | Multicast Group Join Messages for a Route Filter at This Destination Address | Multicast Source Addresses   |
|-----------------------------|------------------------------------------------------------------------------|------------------------------|
| POLICY-ipv4-example1 term 2 | 232.1.1.2                                                                    | 10.10.10.5,<br>192.168.43.67 |

You apply routing policy POLICY-ipv4-example1 to IGMP logical interface fe-0/1/0.0.

### Configuration

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure this example, perform the following task:

#### CLI Quick Configuration

To quickly configure this example, copy the following configuration commands into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set policy-options policy-statement POLICY-ipv4-example1 term 1 from route-filter
 232.1.1.1/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
 10.10.10.4
set policy-options policy-statement POLICY-ipv4-example1 term 1 then ssm-source
 192.168.43.66
set policy-options policy-statement POLICY-ipv4-example1 term 1 then accept
set policy-options policy-statement POLICY-ipv4-example1 term 2 from route-filter
 232.1.1.2/32 exact
set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
 10.10.10.5
set policy-options policy-statement POLICY-ipv4-example1 term 2 then ssm-source
 192.168.43.67
set policy-options policy-statement POLICY-ipv4-example1 term 2 then accept
set protocols igmp interface fe-0/1/0.0 ssm-map-policy POLICY-ipv4-example1
```

#### Step-by-Step Procedure

To configure multiple SSM maps per interface:

1. Configure protocol-independent routing options for route filter 232.1.1.1, and specify the multicast source addresses to which matching multicast groups are to be mapped.

```
[edit policy-options policy-statement POLICY-ipv4-example1 term 1]
user@host# set from route-filter 232.1.1.1/32 exact
user@host# set then ssm-source 10.10.10.4
user@host# set then ssm-source 192.168.43.66
user@host# set then accept
```

2. Configure protocol-independent routing options for route filter 232.1.1.2, and specify the multicast source addresses to which matching multicast groups are to be mapped.

```
[edit policy-options policy-statement POLICY-ipv4-example1 term 2]
user@host# set from route-filter 232.1.1.2/32 exact
user@host# set then ssm-source 10.10.10.5
```

```
user@host# set then ssm-source 192.168.43.67
user@host# set then accept
```

3. Apply the policy map POLICY-ipv4-example1 to IGMP logical interface fe-0/1/1/0.

```
[edit protocols igmp interface fe-0/1/0.0]
user@host# set ssm-map-policy POLICY-ipv4-example1
```

**Results** After the configuration is committed, confirm the configuration by entering the **show policy-options** and **show protocols** configuration mode commands. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
user@host# show policy-options
policy-statement POLICY-ipv4-example1 {
 term 1 {
 from {
 route-filter 232.1.1.1/32 exact;
 }
 then {
 ssm-source [10.10.10.4 192.168.43.66];
 accept;
 }
 }
 term 2 {
 from {
 route-filter 232.1.1.2/32 exact;
 }
 then {
 ssm-source [10.10.10.5 192.168.43.67];
 accept;
 }
 }
}

user@host# show protocols
igmp {
 interface fe-0/1/0.0 {
 ssm-map-policy POLICY-ipv4-example1;
 }
}
```

### Verification

Confirm that the configuration is working properly.

- [Displaying Information About IGMP-Enabled Interfaces on page 5543](#)
- [Displaying the PIM Groups on page 5544](#)
- [Displaying the Entries in the IP Multicast Forwarding Table on page 5544](#)

#### *Displaying Information About IGMP-Enabled Interfaces*

**Purpose** Verify that the SSM map policy POLICY-ipv4-example1 is applied to logical interface fe-0/1/0.0.

**Action** Use the `show igmp interface` operational mode command for the IGMP logical interface to which you applied the SSM map policy.

```
user@host> show igmp interface
Interface: fe-0/1/0.0
 Querier: 10.111.30.1
 State: Up Timeout: None Version: 2 Groups: 2
 SSM Map Policy: POLICY-ipv4-example1;
```

```
Configured Parameters:
IGMP Query Interval: 125.0
IGMP Query Response Interval: 10.0
IGMP Last Member Query Interval: 1.0
IGMP Robustness Count: 2
```

```
Derived Parameters:
IGMP Membership Timeout: 260.0
IGMP Other Querier Present Timeout: 255.0
```

The command output displays the name of the IGMP logical interface (fe-0/1/0.0), which is the address of the routing device that has been elected to send membership queries and group information.

#### ***Displaying the PIM Groups***

**Purpose** Verify the Protocol Independent Multicast (PIM) source and group pair (S,G) entries.

**Action** Use the `show pim join extensive 232.1.1.1` operational mode command to display the PIM source and group pair (S,G) entries for the 232.1.1.1 group.

#### ***Displaying the Entries in the IP Multicast Forwarding Table***

**Purpose** Verify that the IP multicast forwarding table displays the multicast route state.

**Action** Use the `show multicast route extensive` operational mode command to display the entries in the IP multicast forwarding table to verify that the **Route state** is active and that the **Forwarding state** is forwarding.

# Using Static RP

- [Understanding Static RP on page 5545](#)
- [Configuring Local PIM RPs on page 5545](#)
- [Configuring the Static PIM RP Address on the Non-RP Routing Device on page 5547](#)

## Understanding Static RP

---

Protocol Independent Multicast (PIM) sparse mode is the most common multicast protocol used on the Internet. PIM sparse mode is the default mode whenever PIM is configured on any interface of the device. However, because PIM must not be configured on the network management interface, you must disable it on that interface.

Each any-source multicast (ASM) group has a shared tree through which receivers learn about new multicast sources and new receivers learn about all multicast sources. The rendezvous point (RP) router is the root of this shared tree and receives the multicast traffic from the source. To receive multicast traffic from the groups served by the RP, the device must determine the IP address of the RP for the source.

You can configure a static rendezvous point (RP) configuration that is similar to static routes. A static configuration has the benefit of operating in PIM version 1 or version 2. When you configure the static RP, the RP address that you select for a particular group must be consistent across all routers in a multicast domain.

One common way for the device to locate RPs is by static configuration of the IP address of the RP. A static configuration is simple and convenient. However, if the statically defined RP router becomes unreachable, there is no automatic failover to another RP router. To remedy this problem, you can use anycast RP.

- [Configuring the Static PIM RP Address on the Non-RP Routing Device on page 5547](#)

## Configuring Local PIM RPs

---

Local RP configuration makes the routing device a statically defined RP. Consider statically defining an RP if the network does not have many different RPs defined or if the RP assignment does not change very often. The Junos IPv6 PIM implementation supports

only static RP configuration. Automatic RP announcement and bootstrap routers are not available with IPv6.

You can configure a local RP globally or for a routing instance. This example shows how to configure a local RP in a routing instance for IPv4 or IPv6.

To configure the routing device's RP properties:

1. Configure the routing instance as the local RP.

```
[routing-instances VPN-A protocols pim]
user@host# set rp local
```

2. Configure the IP protocol family and IP address.

IPv6 PIM hello messages are sent to every interface on which you configure **family inet6**, whether at the PIM level of the hierarchy or not. As a result, if you configure an interface with both **family inet** at the **[edit interface *interface-name*]** hierarchy level and **family inet6** at the **[edit protocols pim interface *interface-name*]** hierarchy level, PIM sends both IPv4 and IPv6 hellos to that interface.

By default, PIM operates in sparse mode on an interface. If you explicitly configure sparse mode, PIM uses this setting for all IPv6 multicast groups. However, if you configure sparse-dense mode, PIM does not accept IPv6 multicast groups as dense groups and operates in sparse mode over them.

```
[edit routing-instances VPN-A protocols pim rp local]
user@host# set family inet6 address 2001:db8:85a3::8a2e:370:7334
user@host# set family inet address 10.1.2.254
```

3. (IPv4 only) Configure the routing device's RP priority.

**NOTE:** The priority statement is not supported for IPv6, but is included here for informational purposes. The routing device's priority value for becoming the RP is included in the bootstrap messages that the routing device sends. Use a smaller number to increase the likelihood that the routing device becomes the RP for local multicast groups. Each PIM routing device uses the priority value and other factors to determine the candidate RPs for a particular group range. After the set of candidate RPs is distributed, each routing device determines algorithmically the RP from the candidate RP set using a hash function. By default, the priority value is set to 1. If this value is set to 0, the bootstrap router can override the group range being advertised by the candidate RP.

```
[edit routing-instances VPN-A protocols pim rp local]
user@host# set priority 5
```

4. Configure the groups for which the routing device is the RP.

By default, a routing device running PIM is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12). The following example limits the groups for which this routing device can be the RP.

```
[edit routing-instances VPN-A protocols pim rp local]
```

```
user@host# set group-ranges fec0::/10
user@host# set group-ranges 10.1.2.0/24
```

5. (IPv4 only) Modify the local RP hold time.

If the local routing device is configured as an RP, it is considered a candidate RP for its local multicast groups. For candidate RPs, the hold time is used by the bootstrap router to time out RPs, and applies to the bootstrap RP-set mechanism. The RP hold time is part of the candidate RP advertisement message sent by the local routing device to the bootstrap router. If the bootstrap router does not receive a candidate RP advertisement from an RP within the hold time, it removes that routing device from its list of candidate RPs. The default hold time is 150 seconds.

```
[edit routing-instances VPN-A protocols pim rp local]
user@host# set hold-time 200
```

6. (Optional) Override dynamic RP for the specified group address range.

If you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for the given static RP group range, and allow dynamic RP mapping for all other groups.

If you exclude this statement from the configuration and you use both static and dynamic RP mechanisms for different group ranges within the same routing instance, the dynamic RP mapping takes precedence over the static RP mapping, even if static RP is defined for a specific group range.

```
[edit routing-instances VPN-A protocols pim rp local]
user@host# set override
```

7. Monitor the operation of PIM by running the **show pim** commands. Run **show pim ?** to display the supported commands.

## Configuring the Static PIM RP Address on the Non-RP Routing Device

Consider statically defining an RP if the network does not have many different RPs defined or if the RP assignment does not change very often. The Junos IPv6 PIM implementation supports only static RP configuration. Automatic RP announcement and bootstrap routers are not available with IPv6.

You configure a static RP address on the non-RP routing device. This enables the non-RP routing device to recognize the local statically defined RP. For example, if R0 is a non-RP router and R1 is the local RP router, you configure R0 with the static RP address of R1. The static IP address is the routable address assigned to the loopback interface on R1. In the following example, the loopback address of the RP is 2001:db8:85a3::8a2e:370:7334.

You can configure a static RP address globally or for a routing instance. This example shows how to configure a static RP address in a routing instance for IPv6.

To configure the static RP address:

1. On a non-RP routing device, configure the routing instance to point to the routable address assigned to the loopback interface of the RP.

```
[routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334
```

**NOTE:** Logical systems are also supported. You can configure a static RP address in a logical system only if the logical system is not directly connected to a source.

2. (Optional) Set the PIM sparse mode version.

For each static RP address, you can optionally specify the PIM version. The default PIM version is version 1.

```
[edit routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334 version 2
```

**NOTE:** The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIM version 1 is the default for RP mode ([edit pim rp static address *address*]). PIM version 2 is the default for interface mode ([edit pim interface *interface-name*]). Explicitly configured versions override the defaults.

3. (Optional) Set the group address range.

By default, a routing device running PIM is eligible to be the RP for all IPv4 or IPv6 groups (224.0.0.0/4 or FF70::/12 to FFF0::/12). The following example limits the groups for which the 2001:db8:85a3::8a2e:370:7334 address can be the RP.

```
[edit routing-instances VPN-A protocols pim rp]
user@host# set static address 2001:db8:85a3::8a2e:370:7334 group-ranges fec0::/10
```

The RP that you select for a particular group must be consistent across all routers in a multicast domain.

4. (Optional) Override dynamic RP for the specified group address range.

If you configure both static RP mapping and dynamic RP mapping (such as auto-RP) in a single routing instance, allow the static mapping to take precedence for the given static RP group range, and allow dynamic RP mapping for all other groups.

If you exclude this statement from the configuration and you use both static and dynamic RP mechanisms for different group ranges within the same routing instance, the dynamic RP mapping takes precedence over the static RP mapping, even if static RP is defined for a specific group range.

```
[edit routing-instances VPN-A protocols pim rp static address
 2001:db8:85a3::8a2e:370:7334]
user@host# set override
```

5. Monitor the operation of PIM by running the **show pim** commands. Run **show pim ?** to display the supported commands.

### Understanding RP Mapping with Anycast RP

---

Having a single active rendezvous point (RP) per multicast group is much the same as having a single server providing any service. All traffic converges on this single point, although other servers are sitting idle, and convergence is slow when the resource fails. In multicast specifically, there might be closer RPs on the shared tree, so the use of a single RP is suboptimal.

For the purposes of load balancing and redundancy, you can configure anycast RP. You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP fails, sources and receivers are taken to a new RP by means of unicast routing. When you configure anycast RP, you bypass the restriction of having one active RP per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

Anycast means that multiple RP routers share the same unicast IP address. Anycast addresses are advertised by the routing protocols. Packets sent to the anycast address are sent to the nearest RP with this address. Anycast addressing is a generic concept and is used in PIM sparse mode to add load balancing and service reliability to RPs.

Anycast RP is defined in RFC3446, *Anycast RP Mechanism Using PIM and MSDP*, and can be found here: <https://www.ietf.org/rfc/rfc3446.txt>.

## Example: Configuring PIM Anycast With or Without MSDP

---

When you configure anycast RP, you bypass the restriction of having one active rendezvous point (RP) per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP stops operating, sources and receivers are taken to a new RP by means of unicast routing.

You can configure anycast RP to use PIM and MSDP for IPv4, or PIM alone for both IPv4 and IPv6 scenarios. Both are discussed in this section.

We recommend a static RP mapping with anycast RP over a bootstrap router and auto-RP configuration because it provides all the benefits of a bootstrap router and auto-RP without the complexity of the BSR and auto-RP mechanisms.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default RP mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults. This example explicitly configures PIMv2 on the interfaces.

The following example shows an anycast RP configuration for the RP routers, first with MSDP and then using PIM alone, and for non-RP routers.

1. For a network using an RP with MSDP, configure the RP using the **lo0** loopback interface, which is always up. Include the **address** statement and specify the unique and routable router ID and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement for the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
 lo0 {
 description "PIM RP";
 unit 0 {
 family inet {
 address 198.58.3.254/32;
 primary;
 address 198.58.3.253/32;
 }
 }
 }
}
```

2. Specify the RP address. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
 pim {
 rp {
 local {
 family inet;
 address 198.58.3.253;
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

3. Configure MSDP peering. Include the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, include the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
 msdp {
 peer 198.58.3.250 {
 local-address 198.58.3.254;
 }
 }
}
```

**NOTE:** If you need to configure a PIM RP for both IPv4 and IPv6 scenarios, perform Step 4 and Step 5. Otherwise, go to Step 6.

4. Configure an RP using the **lo0** loopback interface, which is always up. Include the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement on the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
 lo0 {
 description "PIM RP";
```

```

unit 0 {
 family inet {
 address 198.58.3.254/32 {
 primary;
 }
 address 198.58.3.253/32;
 }
}

```

5. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse**, and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

Include the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

```

protocols {
 pim {
 rp {
 local {
 family inet {
 address 198.58.3.253;
 anycast-pim {
 rp-set {
 address 198.58.3.240;
 address 198.58.3.241 forward-msdp-sa;
 }
 local-address 198.58.3.254; #If not configured, use lo0 primary
 }
 }
 }
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
}

```

6. Configure the non-RP routers. The anycast RP configuration for a non-RP router is the same whether MSDP is used or not. Specify a static RP by adding the address at

the `[edit protocols pim rp static]` hierarchy level. Include the **version** statement at the `[edit protocols pim rp static address]` hierarchy level to specify PIM version 2.

```
protocols {
 pim {
 rp {
 static {
 address 198.58.3.253 {
 version 2;
 }
 }
 }
 }
}
```

7. Include the **mode** statement at the `[edit protocols pim interface all]` hierarchy level to specify sparse mode on all interfaces. Then include the **version** statement at the `[edit protocols pim rp interface all mode]` to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
 pim {
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

## Configuring a PIM Anycast RP Router with MSDP

Add the **address** statement at the `[edit protocols pim rp local]` hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the `[edit protocols pim rp local interface all]` hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
 pim {
 rp {
 local {
 family inet;
 address 198.58.3.253;
 }
 interface all {
 mode sparse;
 version 2;
 }
 }
 }
}
```

```
 interface fxp0.0 {
 disable;
 }
 }
}
```

To configure MSDP peering, add the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, add the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
 msdp {
 peer 198.58.3.250 {
 local-address 198.58.3.254;
 }
 }
}
```

---

## Configuring a PIM Anycast RP Router Using Only PIM

---

In this example, configure an RP using the **lo0** loopback interface, which is always up. Use the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this case, the router ID is 198.58.3.254/32 and the shared RP address is 198.58.3.253/32. Add the flag statement **primary** to the first address. Using this flag selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
 lo0 {
 description "PIM RP";
 unit 0 {
 family inet {
 address 198.58.3.254/32 {
 primary;
 }
 address 198.58.3.253/32;
 }
 }
 }
}
```

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse**, and include the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

Use the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are

configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

```
protocols {
 pim {
 rp {
 local {
 family inet {
 address 198.58.3.253;
 anycast-pim {
 rp-set {
 address 198.58.3.240;
 address 198.58.3.241 forward-msdp-sa;
 }
 local-address 198.58.3.254; #If not configured, use lo0 primary
 }
 }
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

## Configuring All PIM Anycast Non-RP Routers

Use the **mode** statement at the **[edit protocols pim rp interface all]** hierarchy level to specify sparse mode on all interfaces. Then add the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
 pim {
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

## Example: Configuring Multiple RPs in a Domain with Anycast RP

---

This example shows how to configure anycast RP on each RP router in the PIM-SM domain. With this configuration you can deploy more than one RP for a single group range. This enables load balancing and redundancy.

- [Requirements on page 5558](#)
- [Overview on page 5558](#)
- [Configuration on page 5558](#)
- [Verification on page 5560](#)

### Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 5512](#).

### Overview

When you configure anycast RP, the RP routers in the PIM-SM domain use a shared address. In this example, the shared address is 10.1.1.2/32. Anycast RP uses Multicast Source Discovery Protocol (MSDP) to discover and maintain a consistent view of the active sources. Anycast RP also requires an RP selection method, such as static, auto-RP, or bootstrap RP. This example uses static RP and shows only one RP router configuration.

### Configuration

|                                |                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CLI Quick Configuration</b> | To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the <b>[edit]</b> hierarchy level.                                          |
| <b>RP Routers</b>              | <pre>set interfaces lo0 unit 0 family inet address 192.168.132.1/32 primary set interfaces lo0 unit 0 family inet address 10.1.1.2/32 set protocols msdp local-address 192.168.132.1 set protocols msdp peer 192.168.12.1 set protocols pim rp local address 10.1.1.2 set routing-options router-id 192.168.132.1</pre> |
| <b>Non-RP Routers</b>          | <pre>set protocols pim rp static address 10.1.1.2</pre>                                                                                                                                                                                                                                                                 |

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure anycast RP:

1. On each RP router in the domain, configure the shared anycast address on the router's loopback address.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 10.1.1.2/32
```

2. On each RP router in the domain, make sure that the router's regular loopback address is the primary address for the interface, and set the router ID.

```
[edit interfaces]
user@host# set lo0 unit 0 family inet address 192.168.132.1/32 primary
```

```
[edit routing-options]
user@host# set router-id 192.168.132.1
```

3. On each RP router in the domain, configure the local RP address, using the shared address.

```
[edit protocols pim]
user@host# set rp local address 10.1.1.2
```

4. On each RP router in the domain, create MSDP sessions to the other RPs in the domain.

```
[edit protocols msdp]
user@host# set local-address 192.168.132.1
user@host# set peer 192.168.12.1
```

5. On each non-RP router in the domain, configure a static RP address using the shared address.

```
[edit protocols pim]
user@host# set rp static address 10.1.1.2
```

6. If you are done configuring the devices, commit the configuration.

```
user@host# commit
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces
lo0 {
 unit 0 {
 family inet {
 address 192.168.132.1/32 {
 primary;
 }
 }
 }
}
```

```
 address 10.1.1.2/32;
 }
}
```

*On the RP routers:*

```
user@host# show protocols
msdp {
 local-address 192.168.132.1;
 peer 192.168.12.1;
}
pim {
 rp {
 local {
 address 10.1.1.2;
 }
 }
}
```

*On the non-RP routers:*

```
user@host# show protocols
pim {
 rp {
 static {
 address 10.1.1.2;
 }
 }
}

user@host# show routing-options
router-id 192.168.132.1;
```

## Verification

To verify the configuration, run the `show pim rps extensive inet` command.

## Understanding PIM Auto-RP

---

You can configure a more dynamic way of assigning rendezvous points (RPs) in a multicast network by means of auto-RP. When you configure auto-RP for a router, the router learns the address of the RP in the network automatically and has the added advantage of operating in PIM version 1 and version 2.

Although auto-RP is a nonstandard (non-RFC-based) function that typically uses dense mode PIM to advertise control traffic, it provides an important failover advantage that simple static RP assignment does not. You can configure multiple routers as RP candidates. If the elected RP fails, one of the other preconfigured routers takes over the RP functions. This capability is controlled by the auto-RP mapping agent.

## Configuring PIM Auto-RP

---

For correct operation, every multicast router within a PIM domain must be able to map a particular multicast group address to the same rendezvous point (RP). The auto-RP mechanism is one way that a multicast router can learn the set of group-to-RP mappings. Auto-RP automatically distributes mapping information to routing devices. It simplifies use of multiple RPs for different multicast group ranges, thus allowing multiple RPs to act as backups for each other. Auto-RP relies on a router to act as the RP mapping agent. Potential RPs announce themselves to the mapping agent, and the mapping agent resolves any conflicts.

The mapping agent sends the multicast group-RP mapping information to the other routers using PIM dense mode. The specific groups used are 224.0.1.39 and .40. The first (.39) is used to advertise, the second (.40) is used for discovery. Because PIM dense mode is necessary to enable auto-RP to work, which in turns enables PIM sparse mode to work, you must configure PIM sparse-dense mode in the PIM domains that use auto-RP.

Although auto-RP is a nonstandard (non-RFC-based) function requiring dense mode PIM to advertise control traffic, it provides an important failover advantage that static

RP assignment does not. That is, you can configure multiple routing devices as RP candidates. If the elected RP fails, one of the other preconfigured routing devices takes over the RP functions. This capability is controlled by the auto-RP mapping agent.

Auto-RP operates in PIM version 1 and version 2.

In most cases, how the routing device handles auto-RP discovery, announce, or mapping messages depends on whether the routing device is an RP (configured as local RP) or not. [Table 436](#) shows how the routing device behaves depending on the local RP configuration.

**Table 436: Local RP and Auto-RP Message Types**

| Auto-RP Message Type | Local RP? | Routing Device Behavior                                                                                                                                             |
|----------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| discovery            | No        | Listen for auto-RP mapping messages.                                                                                                                                |
| discovery            | Yes       | Listen for auto-RP mapping messages.                                                                                                                                |
| announce             | No        | Listen for auto-RP mapping messages.                                                                                                                                |
| announce             | Yes       | Listen for auto-RP mapping messages. Send auto-RP announce messages.                                                                                                |
| mapping              | No        | Listen for auto-RP mapping messages. Listen for auto-RP announce messages. If elected mapping agent, send auto-RP mapping messages.                                 |
| mapping              | Yes       | Listen for auto-RP mapping messages. Send auto-RP announce messages. Listen for auto-RP announce messages. If elected mapping agent, send auto-RP mapping messages. |

**NOTE:** If the routing device receives auto-RP announcements split across multiple messages, the routing device loses the information in the previous part of the message as soon as the next part of the message is received.

You can configure auto-RP properties globally or for a routing instance. This example shows the global configuration.

To configure auto-RP properties:

1. Configure PIM in sparse-dense mode on all routing devices in the PIM domain.

```
[edit protocols pim]
user@host# edit
user@host# set interface all mode sparse-dense
```

This configuration allows the routing device to operate in sparse mode for most groups and dense mode for others. The default is to operate in sparse mode unless the routing device is specifically informed of a dense mode group.

2. Configure a routable loopback interface address on all routing devices in the PIM domain.

The routing device joins the auto-RP groups on the configured interfaces and on the loopback interface **lo0.0**. For auto-RP to work correctly, configure a routable IP address on the loopback interface. You cannot use the loopback address 127.0.0.1. Also, you must enable PIM sparse-dense mode on the **lo0.0** interface if you do not specify **interface all**.

```
[edit interfaces lo0.0 unit 0 family inet]
user@host# set address 192.168.0.3 preferred
```

3. Configure the two multicast dense groups on all the routing devices.

Auto-RP requires multicast flooding to announce potential RP candidates and to discover the elected RPs in the network. Multicast flooding occurs through a PIM dense mode model, where group 224.0.1.39 is used for **announce** messages and group 224.0.1.40 is used for **discovery** messages.

```
[edit protocols pim]
user@host# set dense-groups 224.0.1.39/32
user@host# set dense-groups 224.0.1.40/32
```

**TIP:** Step 3 is required. When auto-RP is enabled, the auto-RP announce group (224.0.1.39) and auto-RP-discovery group (224.0.1.40) must be configured explicitly as dense groups. When the auto-RP discovery group is not configured as a dense group, auto-RP is not enabled. When the auto-RP announce group is not configured as a dense group, auto-RP is enabled in the discovery mode only, and mapping and announce modes are disabled.

4. Configure the auto-RP **announce** option.

At least one routing device in the PIM domain must announce auto-RP messages and at least one must map them, or you can configure a routing device to perform both functions.

When a routing device sends announce messages in the network, it is advertising itself as a candidate RP. A routing device configured with this option must also be configured as an RP, or announce messages are not sent.

```
[edit protocols pim rp]
user@host# set local address 192.168.0.1
user@host# set auto-rp announce
```

**NOTE:** You cannot include the `auto-rp announce` option at the `[edit logical-systems logical-system-name routing-instances routing-instance-name protocols pim]` hierarchy level.

5. Configure the auto-RP mapping agent.

The mapping agent sends discovery messages to the network, informing all routing devices in a multicast group of which RP to use. If the mapping agent is also an RP, the **mapping** option also allows the routing device to send auto-RP announcements (mapping on an RP allows the routing device to perform both the announcement and mapping functions).

```
[edit protocols pim rp]
user@host# set auto-rp mapping
```

If the mapping agent is also an RP, configure the mapping agent as a local RP.

```
[edit protocols pim rp]
user@host# set local address 192.168.0.2
```

6. Configure mapping agent election.

If you configure the **mapping** option on more than one routing device in the PIM domain, configure mapping agent election on each potential mapping agent.

Auto-RP specifications state that mapping agents do not send mapping messages if they receive messages from a mapping agent with a higher IP address. However, some vendors' mapping agents continue to announce mappings, even in the presence of higher-addressed mapping agents. In other words, some mapping agents will always send mapping messages.

The default auto-RP operation is to perform mapping agent election. To explicitly configure mapping agent election, you can include the **mapping-agent-election** statement. When this option is configured, the mapping agent will stop sending mapping messages if it receives messages from a mapping agent with a higher IP address.

```
[edit protocols pim rp]
user@host# set auto-rp mapping mapping-agent-election
```

Mapping message suppression is disabled with the **no-mapping-agent-election** statement. When this option is configured, the mapping agent will always send mapping messages even in the presence of higher-addressed mapping agents.

To disable mapping agent election for compatibility with other vendors' equipment, include the **no-mapping-agent-election** statement.

```
[edit protocols pim rp]
user@host# set auto-rp mapping no-mapping-agent-election
```

7. Configure the remaining routing devices in the PIM domain to discover the RP.

Discovery enables the routing devices to receive and process discovery messages from the mapping agent. This is the most basic auto-RP option.

```
[edit protocols pim rp]
user@host# set auto-rp discovery
```

8. Monitor the operation of PIM auto-RP routers by running the following commands:

- **show pim interfaces**
- **show pim rps**

- [show pim rps](#)

9. Issue the **show pim rps extensive** command to see information about how an RP is learned, what groups it handles, and the number of groups actively using the RP.

```

user@host> show pim rps extensive
RP: 192.168.5.1
Learned from 192.168.5.1 via: auto-rp
Time Active: 00:34:29
Holdtime: 150 with 108 remaining
Device Index: 6
Subunit: 32769
Interface: pd-0/0/0.32769
Group Ranges:
 224.0.0.0/4
Active groups using RP:
 224.2.2.100
 total 1 groups active
Register State for RP:
Group Source FirstHop RP Address StateRP address Type Holdtime
Timeout

```

In the example, the RP at 192.168.5.1 was learned through auto-RP. The RP is able to support all groups in the 224.0.0.0/4 range (all possible groups). The local router has sent PIM control traffic for the 224.2.2.100 group to the RP.

Additionally, the presence of a Tunnel Physical Interface Card (PIC) in an RP router creates a de-encapsulation interface, which allows the RP to receive multicast traffic from the source. This interface is indicated by **pd-0/0/0.32769**.

## Understanding the PIM Bootstrap Router

---

To determine which router is the rendezvous point (RP), all routers within a PIM sparse-mode domain collect bootstrap messages. A PIM sparse-mode domain is a group of routers that all share the same RP router. The domain bootstrap router initiates bootstrap messages, which are sent hop by hop within the domain. The routers use bootstrap messages to distribute RP information dynamically and to elect a bootstrap router when necessary.

**Related  
Documentation**

- [Configuring PIM Bootstrap Properties for IPv4 or IPv6](#)

## Configuring PIM Bootstrap Properties for IPv4 or IPv6

---

For correct operation, every multicast router within a PIM domain must be able to map a particular multicast group address to the same rendezvous point (RP). The bootstrap router mechanism is one way that a multicast router can learn the set of group-to-RP mappings. Bootstrap routers are supported in IPv4 and IPv6.

To determine which routing device is the RP, all routing devices within a PIM domain collect bootstrap messages. A PIM domain is a contiguous set of routing devices that implement PIM. All devices are configured to operate within a common boundary. The domain's bootstrap router initiates bootstrap messages, which are sent hop by hop within the domain. The routing devices use bootstrap messages to distribute RP information dynamically and to elect a bootstrap router when necessary.

You can configure bootstrap properties globally or for a routing instance. This example shows the global configuration.

To configure the bootstrap router properties:

1. Configure the bootstrap priority.

By default, each routing device has a bootstrap priority of 0, which means the routing device can never be the bootstrap router. The routing device with the highest priority value is elected to be the bootstrap router. In the case of a tie, the routing device with the highest IP address is elected to be the bootstrap router. A simple bootstrap configuration assigns a bootstrap priority value to a routing device.

**NOTE:** In the IPv4-only configuration, specifying a bootstrap priority of 0 disables the bootstrap function and does not cause the routing device to send BSR packets with a 0 in the priority field. In the combined IPv4 and IPv6 configuration, specifying a bootstrap priority of 0 does not disable the function, but causes the routing device to send BSR packets with a 0 in the priority field. To disable the bootstrap function in the IPv4 and IPv6 configuration, delete the `bootstrap` statement.

```
user@host# edit protocols pim rp
user@host# set bootstrap family inet priority 3
```

2. (Optional) Create import and export policies to control the flow of bootstrap messages to and from the RP, and apply the policies to PIM. Import and export policies are useful when some of the routers in your PIM domain have interfaces that connect to other PIM domains. Configuring a policy prevents bootstrap messages from crossing domain boundaries. The **import** statement prevents messages from being imported into the RP. The **export** statement prevents messages from being exported from the RP.

```
[edit protocols pim rp]
user@host# set bootstrap family inet import pim-bootstrap-import
user@host# set bootstrap family inet export pim-bootstrap-export
user@host# exit
```

3. Configure the policies.

```
user@host# edit policy-options policy-statement pim-bootstrap-import
[edit policy-options policy-statement pim-bootstrap-import]
user@host# set from interface se-0/0/0
user@host# set then reject
user@host# exit
user@host# edit policy-options policy-statement pim-bootstrap-export
user@host# set from interface se-0/0/0
user@host# set then reject
user@host# exit
```

4. Monitor the operation of PIM bootstrap routers by running the `show pim bootstrap` command.

**Related Documentation**

- [Understanding PIM Sparse Mode on page 5509](#)

- [Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain on page 5569](#)
- [show pim bootstrap on page 5881](#) in the CLI Explorer

## Example: Rejecting PIM Bootstrap Messages at the Boundary of a PIM Domain

In this example, the **from interface so-0-1/0 then reject** policy statement rejects bootstrap messages from the specified interface (the example is configured for both IPv4 and IPv6 operation):

```
protocols {
 pim {
 rp {
 bootstrap {
 family inet {
 priority 1;
 import pim-import;
 export pim-export;
 }
 family inet6 {
 priority 1;
 import pim-import;
 export pim-export;
 }
 }
 }
 }
}
policy-options {
 policy-statement pim-import {
 from interface so-0/1/0;
 then reject;
 }
 policy-statement pim-export {
 to interface so-0/1/0;
 then reject;
 }
}
```

## Example: Configuring PIM BSR Filters

Configure a filter to prevent BSR messages from entering or leaving your network. Add this configuration to all routers:

```
protocols {
 pim {
 rp {
 bootstrap-import no-bsr;
 bootstrap-export no-bsr;
 }
 }
}
```

```
policy-options {
 policy-statement no-bsr {
 then reject;
 }
}
```

- [Configuring Register Message Filters on a PIM RP and DR on page 5577](#)

## Understanding Multicast Message Filters

---

Multicast sources and routers generate a considerable number of control messages, especially when using PIM sparse mode. These messages form distribution trees, locate rendezvous points (RPs) and designated routers (DRs), and transition from one type of tree to another. In most cases, this multicast messaging system operates transparently and efficiently. However, in some configurations, more control over the sending and receiving of multicast control messages is necessary.

You can configure multicast filtering to control the sending and receiving of multicast control messages.

To prevent unauthorized groups and sources from registering with an RP router, you can define a routing policy to reject PIM register messages from specific groups and sources and configure the policy on the designated router or the RP router.

- If you configure the reject policy on an RP router, it rejects incoming PIM register messages from the specified groups and sources. The RP router also sends a register stop message by means of unicast to the designated router. On receiving the register stop message, the designated router sends periodic null register messages for the specified groups and sources to the RP router.
- If you configure the reject policy on a designated router, it stops sending PIM register messages for the specified groups and sources to the RP router.

**NOTE:** If you have configured the reject policy on an RP router, we recommend that you configure the same policy on all the RP routers in your multicast network.

**NOTE:** If you delete a group and source address from the reject policy configured on an RP router and commit the configuration, the RP router will register the group and source only when the designated router sends a null register message.

---

## Filtering MAC Addresses

When a router is exclusively configured with multicast protocols on an interface, multicast sets the interface media access control (MAC) filter to multicast promiscuous mode, and the number of multicast groups is unlimited. However, when the router is not exclusively used for multicasting and other protocols such as OSPF, Routing Information Protocol version 2 (RIPv2), or Network Time Protocol (NTP) are configured on an interface, each of these protocols individually requests that the interface program the MAC filter to pick up its respective multicast group only. In this case, without multicast configured on the interface, the maximum number of multicast MAC filters is limited to 20. For example, the maximum number of interface MAC filters for protocols such as OSPF (multicast group 224.0.0.5) is 20, unless a multicast protocol is also configured on the interface.

No configuration is necessary for MAC filters.

---

## Filtering RP and DR Register Messages

You can filter Protocol Independent Multicast (PIM) register messages sent from the designated router (DR) or to the rendezvous point (RP). The PIM RP keeps track of all active sources in a single PIM sparse mode domain. In some cases, more control over which sources an RP discovers, or which sources a DR notifies other RPs about, is desired. A high degree of control over PIM register messages is provided by RP and DR register message filtering. Message filtering also prevents unauthorized groups and sources from registering with an RP router.

Register messages that are filtered at a DR are not sent to the RP, but the sources are available to local users. Register messages that are filtered at an RP arrive from source DRs, but are ignored by the router. Sources on multicast group traffic can be limited or directed by using RP or DR register message filtering alone or together.

If the action of the register filter policy is to discard the register message, the router needs to send a register-stop message to the DR. Register-stop messages are throttled to prevent malicious users from triggering them on purpose to disrupt the routing process.

Multicast group and source information is encapsulated inside unicast IP packets. This feature allows the router to inspect the multicast group and source information before sending or accepting the PIM register message.

Incoming register messages to an RP are passed through the configured register message filtering policy before any further processing. If the register message is rejected, the RP router sends a register-stop message to the DR. When the DR receives the register-stop message, the DR stops sending register messages for the filtered groups and sources to the RP. Two fields are used for register message filtering:

- Group multicast address
- Source address

The syntax of the existing policy statements is used to configure the filtering on these two fields. The **route-filter** statement is useful for multicast group address filtering, and the **source-address-filter** statement is useful for source address filtering. In most cases, the action is to **reject** the register messages, but more complex filtering policies are possible.

Filtering cannot be performed on other header fields, such as DR address, protocol, or port. In some configurations, an RP might not send register-stop messages when the policy action is to discard the register messages. This has no effect on the operation of the feature, but the router will continue to receive register messages.

When anycast RP is configured, register messages can be sent or received by the RP. All the RPs in the anycast RP set need to be configured with the same RP register message filtering policies. Otherwise, it might be possible to circumvent the filtering policy.

## Configuring Interface-Level PIM Neighbor Policies

You can configure a policy to filter unwanted PIM neighbors. In the following example, the PIM interface compares neighbor IP addresses with the IP address in the policy statement before any hello processing takes place. If any of the neighbor IP addresses (primary or secondary) match the IP address specified in the prefix list, PIM drops the hello packet and rejects the neighbor.

If you configure a PIM neighbor policy after PIM has already established a neighbor adjacency to an unwanted PIM neighbor, the adjacency remains intact until the neighbor hold time expires. When the unwanted neighbor sends another hello message to update its adjacency, the router recognizes the unwanted address and rejects the neighbor.

To configure a policy to filter unwanted PIM neighbors:

1. Configure the policy. The neighbor policy must be a properly structured policy statement that uses a prefix list (or a route filter) containing the neighbor primary address (or any secondary IP addresses) in a prefix list, and the **reject** option to reject the unwanted address.

```
[edit policy-options]
user@host# set prefix-list nbrGroup 1 20.20.20.1/32
user@host# set policy-statement nbr-policy from prefix-list nbrGroup1
user@host# set policy-statement nbr-policy then reject
```

2. Configure the interface globally or in the routing instance. This example shows the configuration for the routing instance.

```
[edit routing-instances PIM.master protocols pim]
user@host# set neighbor-policy nbr-policy
```

3. Verify the configuration by checking the **Hello dropped on neighbor policy** field in the output of the **show pim statistics** command.

---

## Filtering Outgoing PIM Join Messages

When the core of your network is using MPLS, PIM join and prune messages stop at the customer edge (CE) routers and are not forwarded toward the core, because these routers do not have PIM neighbors on the core-facing interfaces. When the core of your network is using IP, PIM join and prune messages are forwarded to the upstream PIM neighbors in the core of the network.

When the core of your network is using a mix of IP and MPLS, you might want to filter certain PIM join and prune messages at the upstream egress interface of the CE routers.

You can filter PIM sparse mode (PIM-SM) join and prune messages at the egress interfaces for IPv4 and IPv6 in the upstream direction. The messages can be filtered based on the group address, source address, outgoing interface, PIM neighbor, or a combination of these values. If the filter is removed, the join is sent after the PIM periodic join timer expires.

To filter PIM sparse mode join and prune messages at the egress interfaces, create a policy rejecting the group address, source address, outgoing interface, or PIM neighbor, and then apply the policy.

The following example filters PIM join and prune messages for group addresses 224.0.1.2 and 225.1.1.1.

1. In configuration mode, create the policy.

```
user@host# set policy-options policy-statement block-groups term t1 from route-filter
224.0.1.2/32 exact
user@host# set policy-options policy-statement block-groups term t1 from route-filter
225.1.1.1/32 exact
```

```

user@host# set policy-options policy-statement block-groups term t1 then reject
user@host# set policy-options policy-statement block-groups term last then accept

```

2. Verify the policy configuration by running the **show policy-options** command.

```

user@host# show policy-options
policy-statement block-groups {
 term t1 {
 from {
 route-filter 224.0.1.2/32 exact;
 route-filter 225.1.1.1/32 exact;
 then reject;
 }
 term last {
 then accept;
 }
 }
}

```

3. Apply the PIM join and prune message filter.

```

user@host> set protocols pim export block-groups

```

4. After the configuration is committed, use the **show pim statistics** command to verify that outgoing PIM join and prune messages are being filtered.

```

user@host> show pim statistics | grep filtered
RP Filtered Source 0

Rx Joins/Prunes filtered 0

Tx Joins/Prunes filtered 254

```

The egress filter count is shown on the **Tx Joins/Prunes filtered** line.

**Related Documentation**

- [Filtering Incoming PIM Join Messages on page 5575](#)

## Filtering Incoming PIM Join Messages

Multicast scoping controls the propagation of multicast messages. Whereas multicast scoping prevents the actual multicast data packets from flowing in or out of an interface, PIM join filters prevent a state from being created in a router. A state—the (\*,G) or (S,G) entries—is the information used for forwarding unicast or multicast packets. Using PIM join filters prevents the transport of multicast traffic across a network and the dropping of packets at a scope at the edge of the network. Also, PIM join filters reduce the potential for denial-of-service (DoS) attacks and PIM state explosion—large numbers of PIM join messages forwarded to each router on the rendezvous-point tree (RPT), resulting in memory consumption.

To use PIM join filters to efficiently restrict multicast traffic from certain source addresses, create and apply the routing policy across all routers in the network.

See [Table 437](#) for a list of match conditions.

Table 437: PIM Join Filter Match Conditions

| Match Condition              | Matches On                                                                           |
|------------------------------|--------------------------------------------------------------------------------------|
| <b>interface</b>             | Router interface or interfaces specified by name or IP address                       |
| <b>neighbor</b>              | Neighbor address (the source address in the IP header of the join and prune message) |
| <b>route-filter</b>          | Multicast group address embedded in the join and prune message                       |
| <b>source-address-filter</b> | Multicast source address embedded in the join and prune message                      |

The following example shows how to create a PIM join filter. The filter is composed of a route filter and a source address filter—**bad-groups** and **bad-sources**, respectively. the **bad-groups** filter prevents (\*G) or (S,G) join messages from being received for all groups listed. The **bad-sources** filter prevents (S,G) join messages from being received for all sources listed. The **bad-groups** filter and **bad-sources** filter are in two different terms. If route filters and source address filters are in the same term, they are logically ANDed.

To filter incoming PIM join messages:

1. Configure the policy.

```
[edit policy-statement pim-join-filter term bad-groups]
user@host# set from route-filter 224.0.1.2/32 exact
user@host# set from route-filter 239.0.0.0/8 orlonger
user@host# set then reject

[edit policy-statement pim-join-filter term bad-sources]
user@host# set from source-address-filter 10.0.0.0/8 orlonger
user@host# set from source-address-filter 127.0.0.0/8 orlonger
user@host# set then reject

[edit policy-statement pim-join-filter term last]
user@host# set then accept
```

2. Apply one or more policies to routes being imported into the routing table from PIM.

```
[edit protocols pim]
user@host# set import pim-join-filter
```

3. Verify the configuration by checking the output of the **show pim join** and **show policy** commands.

## Configuring Register Message Filters on a PIM RP and DR

PIM register messages are sent to the rendezvous point (RP) by a designated router (DR). When a source for a group starts transmitting, the DR sends unicast PIM register packets to the RP.

Register messages have the following purposes:

- Notify the RP that a source is sending to a group.
- Deliver the initial multicast packets sent by the source to the RP for delivery down the shortest-path tree (SPT).

The PIM RP keeps track of all active sources in a single PIM sparse mode domain. In some cases, you want more control over which sources an RP discovers, or which sources a DR notifies other RPs about. A high degree of control over PIM register messages is provided by RP or DR register message filtering. Message filtering prevents unauthorized groups and sources from registering with an RP router.

You configure RP or DR register message filtering to control the number and location of multicast sources that an RP discovers. You can apply register message filters on a DR to control outgoing register messages, or apply them on an RP to control incoming register messages.

When anycast RP is configured, all RPs in the anycast RP set need to be configured with the same register message filtering policy.

You can configure message filtering globally or for a routing instance. These examples show the global configuration.

To configure an RP filter to drop the register packets for multicast group range 224.1.1.0/24 from source address 10.10.94.2:

1. On the RP, configure the policy.

```
[edit policy-options policy-statement incoming-policy-for-rp from]
user@host# set route-filter 224.1.1.0/24 orlonger
user@host# set source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the RP.

```
[edit protocols pim rp]
user@host# set rp-register-policy incoming-policy-for-rp
user@host# set local address 10.10.10.5
user@host# exit
```

To configure a DR filter to prevent sending register packets for group range 224.1.1.0/24 and source address 10.10.10.1/32:

1. On the DR, configure the policy.

```
[edit policy-options policy-statement outgoing-policy-for-rp]
```

```
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.10.1/32 exact
user@host# set then reject
user@host# exit
```

2. Apply the policy to the DR.

The static address is the address of the RP to which you do not want the DR to send the filtered register messages.

```
[edit protocols pim rp]
user@host# set dr-register-policy outgoing-policy-for-dr
user@host# set static 10.10.10.3
user@host# exit
```

To configure a policy expression to accept register messages for multicast group 224.1.1.5 but reject those for 224.1.1.1:

1. On the RP, configure the policies.

```
[edit policy-options policy-statement reject_224_1_1_1]
user@host# set from route-filter 224.1.1.0/24 orlonger
user@host# set from source-address-filter 10.10.94.2/32 exact
user@host# set then reject
user@host# exit

[edit policy-options policy-statement accept_224_1_1_5]
user@host# set term one from route-filter 224.1.1.5/32 exact
user@host# set term one from source-address-filter 10.10.94.2/32 exact
user@host# set term one then accept
user@host# set term two then reject
user@host# exit
```

2. Apply the policies to the RP.

```
[edit protocols pim rp]
user@host# set rp-register-policy [reject_224_1_1_1 | accept_224_1_1_5]
user@host# set local address 10.10.10.5
```

To monitor the operation of the filters, run the **show pim statistics** command. The command output contains the following fields related to filtering:

- RP Filtered Source
- Rx Joins/Prunes filtered
- Tx Joins/Prunes filtered
- Rx Register msgs filtering drop
- Tx Register msgs filtering drop

### Understanding Multicast Rendezvous Points, Shared Trees, and Rendezvous-Point Trees

---

In a shared tree, the root of the distribution tree is a router, not a host, and is located somewhere in the core of the network. In the primary sparse mode multicast routing protocol, Protocol Independent Multicast sparse mode (PIM SM), the core router at the root of the shared tree is the rendezvous point (RP). Packets from the upstream source and join messages from the downstream routers “rendezvous” at this core router.

In the RP model, other routers do not need to know the addresses of the sources for every multicast group. All they need to know is the IP address of the RP router. The RP router discovers the sources for all multicast groups.

The RP model shifts the burden of finding sources of multicast content from each router (the (S,G) notation) to the network (the (\*,G) notation knows only the RP). Exactly how the RP finds the unicast IP address of the source varies, but there must be some method to determine the proper source for multicast content for a particular group.

Consider a set of multicast routers without any active multicast traffic for a certain group. When a router learns that an interested receiver for that group is on one of its directly connected subnets, the router attempts to join the distribution tree for that group back to the RP, not to the actual source of the content.

To join the shared tree, or *rendezvous-point tree (RPT)* as it is called in PIM sparse mode, the router must do the following:

- Determine the IP address of the RP for that group. Determining the address can be as simple as static configuration in the router, or as complex as a set of nested protocols.
- Build the shared tree for that group. The router executes an RPF check on the RP address in its routing table, which produces the interface closest to the RP. The router now detects that multicast packets from this RP for this group need to flow into the router on this RPF interface.
- Send a join message out on this interface using the proper multicast protocol (probably PIM sparse mode) to inform the upstream router that it wants to join the shared tree for that group. This message is a (\*,G) join message because S is not known. Only the RP is known, and the RP is not actually the source of the multicast packets. The router receiving the (\*,G) join message adds the interface on which the message was received to its outgoing interface list (OIL) for the group and also performs an RPF check on the RP address. The upstream router then sends a (\*,G) join message out from the RPF interface toward the source, informing the upstream router that it also wants to join the group.

Each upstream router repeats this process, propagating join messages from the RPF interface, building the shared tree as it goes. The process stops when the join message reaches one of the following:

- The RP for the group that is being joined
- A router along the RPT that already has a multicast forwarding state for the group that is being joined

In either case, the branch is created, and packets can flow from the source to the RP and from the RP to the receiver. Note that there is no guarantee that the shared tree (RPT) is the shortest path tree to the source. Most likely it is not. However, there are ways to “migrate” a shared tree to an SPT once the flow of packets begins. In other words, the forwarding state can transition from (\*,G) to (S,G). The formation of both types of tree depends heavily on the operation of the RPF check and the RPF table.

Documentation**

- *Understanding Multicast Reverse Path Forwarding*

---

## Building an RPT Between the RP and Receivers

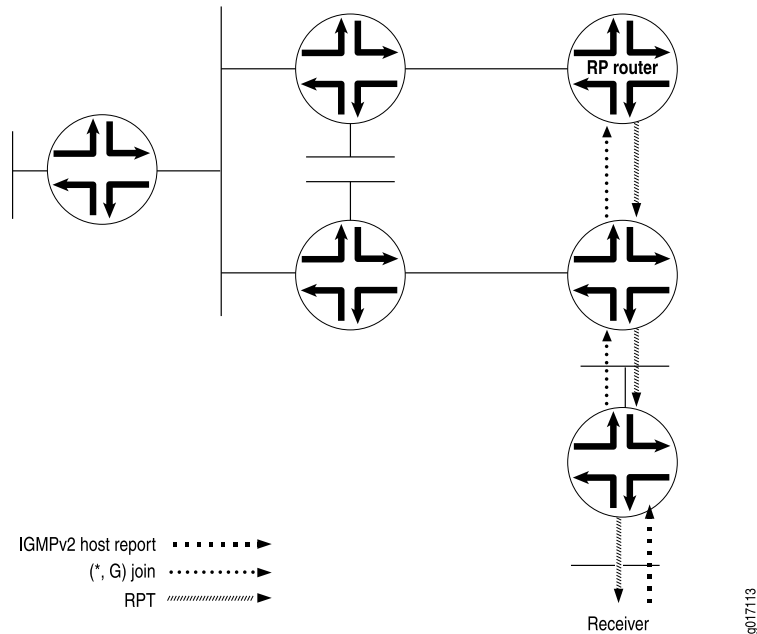

---

The RPT is the path between the RP and receivers (hosts) in a multicast group (see [Figure 184](#)). The RPT is built by means of a PIM join message from a receiver's DR:

1. A receiver sends a request to join group (G) in an Internet Group Management Protocol (IGMP) host membership report. A PIM sparse-mode router, the receiver's DR, receives the report on a directly attached subnet and creates an RPT branch for the multicast group of interest.
2. The receiver's DR sends a PIM join message to its RPF neighbor, the next-hop address in the RPF table, or the unicast routing table.
3. The PIM join message travels up the tree and is multicast to the ALL-PIM-ROUTERS group (224.0.0.13). Each router in the tree finds its RPF neighbor by using either the RPF table or the unicast routing table. This is done until the message reaches the RP

and forms the RPT. Routers along the path set up the multicast forwarding state to forward requested multicast traffic back down the RPT to the receiver.

**Figure 184: Building an RPT Between the RP and the Receiver**

## PIM Sparse Mode Source Registration

The RPT is a unidirectional tree, permitting traffic to flow down from the RP to the receiver in one direction. For multicast traffic to reach the receiver from the source, another branch of the distribution tree, called the shortest-path tree, needs to be built from the source's DR to the RP.

The shortest-path tree is created in the following way:

1. The source becomes active, sending out multicast packets on the LAN to which it is attached. The source's DR receives the packets and encapsulates them in a PIM register message, which it sends to the RP router (see [Figure 185](#)).
2. When the RP router receives the PIM register message from the source, it sends a PIM join message back to the source.

Figure 185: PIM Register Message and PIM Join Message Exchanged

3. The source's DR receives the PIM join message and begins sending traffic down the SPT toward the RP router (see [Figure 186](#)).
4. Once traffic is received by the RP router, it sends a register stop message to the source's DR to stop the register process.

Figure 186: Traffic Sent from the Source to the RP Router

5. The RP router sends the multicast traffic down the RPT toward the receiver (see [Figure 187](#)).

Figure 187: Traffic Sent from the RP Router Toward the Receiver

## Multicast Shortest-Path Tree

---

The distribution tree used for multicast is rooted at the source and is the shortest-path tree (SPT) as well. Consider a set of multicast routers without any active multicast traffic for a certain group (that is, they have no multicast forwarding state for that group). When a router learns that an interested receiver for that group is on one of its directly connected subnets, the router attempts to join the tree for that group.

To join the distribution tree, the router determines the unicast IP address of the source for that group. This address can be a simple static configuration on the router, or as complex as a set of protocols.

To build the SPT for that group, the router executes an a reverse path forwarding (RPF) check on the source address in its routing table. The RPF check produces the interface closest to the source, which is where multicast packets from this source for this group need to flow into the router.

The router next sends a join message out on this interface using the proper multicast protocol to inform the upstream router that it wants to join the distribution tree for that group. This message is an (S,G) join message because both S and G are known. The router receiving the (S,G) join message adds the interface on which the message was received to its output interface list (OIL) for the group and also performs an RPF check on the source address. The upstream router then sends an (S,G) join message out on the RPF interface toward the source, informing the upstream router that it also wants to join the group.

Each upstream router repeats this process, propagating joins out on the RPF interface, building the SPT as it goes. The process stops when the join message does one of two things:

- Reaches the router directly connected to the host that is the source.
- Reaches a router that already has multicast forwarding state for this source-group pair.

In either case, the branch is created, each of the routers has multicast forwarding state for the source-group pair, and packets can flow down the distribution tree from source to receiver. The RPF check at each router makes sure that the tree is an SPT.

SPTs are always the shortest path, but they are not necessarily short. That is, sources and receivers tend to be on the periphery of a router network, not on the backbone, and multicast distribution trees have a tendency to sprawl across almost every router in the network. Because multicast traffic can overwhelm a slow interface, and one packet can easily become a hundred or a thousand on the opposite side of the backbone, it makes sense to provide a shared tree as a distribution tree so that the multicast source can be located more centrally in the network, on the backbone. This sharing of distribution trees with roots in the core network is accomplished by a multicast rendezvous point.

## SPT Cutover

Instead of continuing to use the SPT to the RP and the RPT toward the receiver, a direct SPT is created between the source and the receiver in the following way:

1. Once the receiver's DR receives the first multicast packet from the source, the DR sends a PIM join message to its RPF neighbor (see [Figure 188](#)).
2. The source's DR receives the PIM join message, and an additional (S,G) state is created to form the SPT.
3. Multicast packets from that particular source begin coming from the source's DR and flowing down the new SPT to the receiver's DR. The receiver's DR is now receiving two copies of each multicast packet sent by the source—one from the RPT and one from the new SPT.

**Figure 188: Receiver DR Sends a PIM Join Message to the Source**

4. To stop duplicate multicast packets, the receiver's DR sends a PIM prune message toward the RP router, letting it know that the multicast packets from this particular source coming in from the RPT are no longer needed (see [Figure 189](#)).

**Figure 189: PIM Prune Message Is Sent from the Receiver's DR Toward the RP Router**

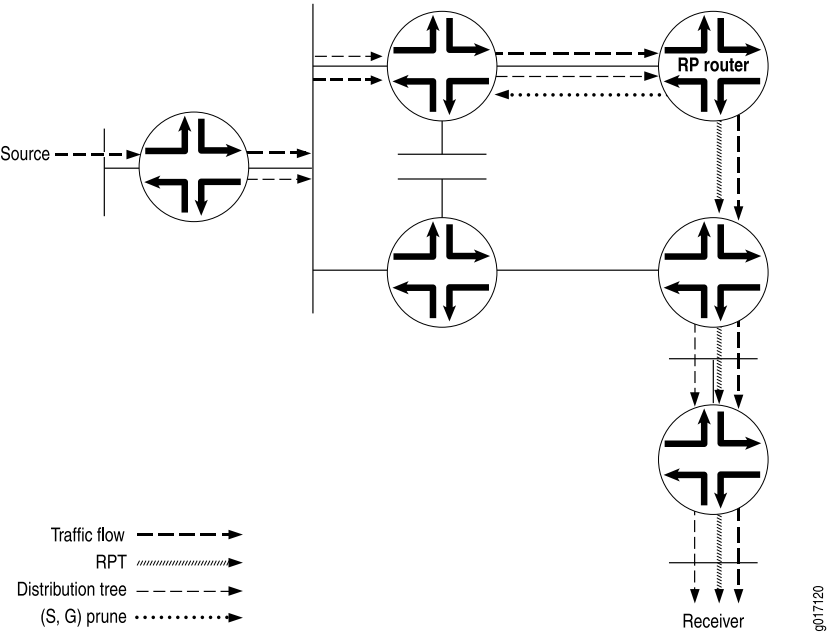

5. The PIM prune message is received by the RP router, and it stops sending multicast packets down to the receiver's DR. The receiver's DR is getting multicast packets only for this particular source over the new SPT. However, multicast packets from the source are still arriving from the source's DR toward the RP router (see [Figure 190](#)).

**Figure 190: RP Router Receives PIM Prune Message**

6. To stop the unneeded multicast packets from this particular source, the RP router sends a PIM prune message to the source's DR (see [Figure 191](#)).

Figure 191: RP Router Sends a PIM Prune Message to the Source DR

7. The receiver's DR now receives multicast packets only for the particular source from the SPT (see Figure 192).

Figure 192: Source's DR Stops Sending Duplicate Multicast Packets Toward the RP Router

## SPT Cutover Control

---

In some cases, the last-hop router needs to stay on the shared tree to the RP and not transition to a direct SPT to the source. You might not want the last-hop router to transition when, for example, a low-bandwidth multicast stream is forwarded from the RP to a last-hop router. All routers between last hop and source must maintain and refresh the SPT state. This can become a resource-intensive activity that does not add much to the network efficiency for a particular pair of source and multicast group addresses.

In these cases, you configure an SPT threshold policy on the last-hop router to control the transition to a direct SPT. An SPT cutover threshold of infinity applied to a source-group address pair means the last-hop router will never transition to a direct SPT. For all other source-group address pairs, the last-hop router transitions immediately to a direct SPT rooted at the source DR.

## Example: Configuring the PIM Assert Timeout

---

This example shows how to configure the timeout period for a PIM assert forwarder.

- [Requirements on page 5588](#)
- [Overview on page 5588](#)
- [Configuration on page 5590](#)

### Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 5512](#).

### Overview

The role of PIM assert messages is to determine the forwarder on a network with multiple routers. The forwarder is the router that forwards multicast packets to a network with multicast group members. The forwarder is generally the same as the PIM DR.

A router sends an assert message when it receives a multicast packet on an interface that is listed in the outgoing interface list of the matching routing entry. Receiving a message on an outgoing interface is an indication that more than one router forwards the same multicast packets to a network.

In [Figure 193](#), both routing devices R1 and R2 forward multicast packets for the same (S,G) entry on a network. Both devices detect this situation and both devices send assert messages on the Ethernet network. An assert message contains, in addition to a source

address and group address, a unicast cost metric for sending packets to the source, and a preference metric for the unicast cost. The preference metric expresses a preference between unicast routing protocols. The routing device with the smallest preference metric becomes the forwarder (also called the assert winner). If the preference metrics are equal, the device that sent the lowest unicast cost metric becomes the forwarder. If the unicast metrics are also equal, the routing device with the highest IP address becomes the forwarder. After the transmission of assert messages, only the forwarder continues to forward messages on the network.

When an assert message is received and the RPF neighbor is changed to the assert winner, the assert timer is set to an assert timeout period. The assert timeout period is restarted every time a subsequent assert message for the route entry is received on the incoming interface. When the assert timer expires, the routing device resets its RPF neighbor according to its unicast routing table. Then, if multiple forwarders still exist, the forwarders reenter the assert message cycle. In effect, the assert timeout period determines how often multicast routing devices enter a PIM assert message cycle.

The range is from 5 through 210 seconds. The default is 180 seconds.

Assert messages are useful for LANs that connect multiple routing devices and no hosts.

Figure 193 shows the topology for this example.

**Figure 193: PIM Assert Topology**

## Configuration

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure an assert timeout:

1. Configure the timeout period, in seconds.

```
[edit protocols pim]
user@host# set assert-timeout 60
```

2. (Optional) Trace assert messages.

```
[edit protocols pim]
user@host# set traceoptions file PIM.log
user@host# set traceoptions flag assert detail
```

3. If you are done configuring the device, commit the configuration.

```
user@host# commit
```

4. To verify the configuration, run the following commands:

- `show pim join`
- `show pim statistics`

## Example: Configuring the PIM SPT Threshold Policy

This example shows how to apply a policy that suppresses the transition from the rendezvous-point tree (RPT) rooted at the RP to the shortest-path tree (SPT) rooted at the source.

- [Requirements on page 5590](#)
- [Overview on page 5591](#)
- [Configuration on page 5592](#)
- [Verification on page 5594](#)

## Requirements

Before you begin:

- Configure the router interfaces. See the *Junos OS Network Interfaces Library for Routing Devices*.

- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Configure PIM Sparse Mode on the interfaces. See [“Enabling PIM Sparse Mode” on page 5512](#).

## Overview

Multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or through an SPT rooted at the source. In some cases, the last-hop routing device needs to stay on the shared RPT to the RP and not transition to a direct SPT to the source. Receiving the multicast data traffic on SPT is optimal but introduces more state in the network, which might not be desirable in some multicast deployments. Ideally, low-bandwidth multicast streams can be forwarded on the SPT, and high-bandwidth streams can use the SPT. This example shows how to configure such a policy.

This example includes the following settings:

- **spt-threshold**—Enables you to configure an SPT threshold policy on the last-hop routing device to control the transition to a direct SPT. When you include this statement in the main PIM instance, the PE router stays on the RPT for control traffic.
- **infinity**—Applies an SPT cutover threshold of infinity to a source-group address pair, so that the last-hop routing device never transitions to a direct SPT. For all other source-group address pairs, the last-hop routing device transitions immediately to a direct SPT rooted at the source DR. This statement must reference a properly configured policy to set the SPT cutover threshold for a particular source-group pair to infinity. The use of values other than infinity for the SPT threshold is not supported. You can configure more than one policy.
- **policy-statement**—Configures the policy. The simplest type of SPT threshold policy uses a route filter and source address filter to specify the multicast group and source addresses and to set the SPT threshold for that pair of addresses to infinity. The policy is applied to the main PIM instance.

This example sets the SPT transition value for the source-group pair 10.10.10.1 and 224.1.1.1 to infinity. When the policy is applied to the last-hop router, multicast traffic from this source-group pair never transitions to a direct SPT to the source. Traffic will continue to arrive through the RP. However, traffic for any other source-group address combination at this router transitions to a direct SPT to the source.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.

Note these points when configuring the SPT threshold policy:

- Configuration changes to the SPT threshold policy affect how the routing device handles the SPT transition.
- When the policy is configured for the first time, the routing device continues to transition to the direct SPT for the source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- If you do not clear the PIM-join state when you apply the infinity policy configuration for the first time, you must apply it before the PE router is brought up.
- When the policy is deleted for a source-group address pair for the first time, the routing device does not transition to the direct SPT for that source-group address pair until the PIM-join state is cleared with the **clear pim join** command.
- When the policy is changed for a source-group address pair for the first time, the routing device does not use the new policy until the PIM-join state is cleared with the **clear pim join** command.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
[edit]
set policy-options policy-statement spt-infinity-policy term one from route-filter
 224.1.1.1/32 exact
set policy-options policy-statement spt-infinity-policy term one from source-address-filter
 10.10.10.1/32 exact
set policy-options policy-statement spt-infinity-policy term one then accept
set policy-options policy-statement spt-infinity-policy term two then reject
set protocols pim spt-threshold infinity spt-infinity-policy
```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure an SPT threshold policy:

1. Apply the policy.

```
[edit]
user@host# edit protocols pim
```

```
[edit protocols pim]
user@host# set spt-threshold infinity spt-infinity-policy
[edit protocols pim]
user@host# exit
```

2. Configure the policy.

```
[edit]
user@host# edit policy-options policy-statement spt-infinity-policy
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from route-filter 224.1.1.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one from source-address-filter 10.10.10.1/32 exact
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term one then accept
[edit policy-options policy-statement spt-infinity-policy]
user@host# set term two then reject
[edit policy-options policy-statement spt-infinity-policy]
user@host# exit
policy-statement {
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@host# commit
```

4. Clear the PIM join cache to force the configuration to take effect.

```
[edit]
user@host# run clear pim join
```

## Results

Confirm your configuration by entering the **show policy-options** command and the **show protocols** command from configuration mode. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show policy-options
policy-statement spt-infinity-policy {
 term one {
 from {
 route-filter 224.1.1.1/32 exact;
 source-address-filter 10.10.10.1/32 exact;
 }
 then accept;
 }
 term two {
 then reject;
 }
}

user@host# show protocols
pim {
 spt-threshold {
 infinity spt-infinity-policy;
 }
}
```

## Verification

To verify the configuration, run the [show pim join](#) command.

## Understanding MSDP

---

The Multicast Source Discovery Protocol (MSDP) is used to connect multicast routing domains. It typically runs on the same router as the Protocol Independent Multicast (PIM) sparse-mode rendezvous point (RP). Each MSDP router establishes adjacencies with internal and external MSDP peers similar to the way BGP establishes peers. These peer routers inform each other about active sources within the domain. When they detect active sources, the routers can send PIM sparse-mode explicit join messages to the active source.

The peer with the higher IP address passively listens to a well-known port number and waits for the side with the lower IP address to establish a Transmission Control Protocol (TCP) connection. When a PIM sparse-mode RP that is running MSDP becomes aware of a new local source, it sends source-active type, length, and values (TLVs) to its MSDP peers. When a source-active TLV is received, a peer-reverse-path-forwarding (peer-RPF) check (not the same as a multicast RPF check) is done to make sure that this peer is in the path that leads back to the originating RP. If not, the source-active TLV is dropped. This TLV is counted as a “rejected” source-active message.

The MSDP peer-RPF check is different from the normal RPF checks done by non-MSDP multicast routers. The goal of the peer-RPF check is to stop source-active messages from looping. Router R accepts source-active messages originated by Router S only from neighbor Router N or an MSDP mesh group member. For more information about configuring MSDP mesh groups, see [“Example: Configuring MSDP with Active Source Limits and Mesh Groups” on page 5604](#).

Router R locates its MSDP peer-RPF neighbor (Router N) deterministically. A series of rules is applied in a particular order to received source-active messages, and the first rule that applies determines the peer-RPF neighbor. All source-active messages from other routers are rejected.

The six rules applied to source-active messages originating at Router S received at Router R from Router X are as follows:

1. If Router X originated the source-active message (Router X is Router S), then Router X is also the peer-RPF neighbor, and its source-active messages are accepted.
2. If Router X is a member of the Router R mesh group, or is the configured peer, then Router X is the peer-RPF neighbor, and its source-active messages are accepted.
3. If Router X is the BGP next hop of the active multicast RPF route toward Router S (Router X installed the route on Router R), then Router X is the peer-RPF neighbor, and its source-active messages are accepted.
4. If Router X is an external BGP (EBGP) or internal BGP (IBGP) peer of Router R, and the last autonomous system (AS) number in the BGP AS-path to Router S is the same as Router X's AS number, then Router X is the peer-RPF neighbor, and its source-active messages are accepted.
5. If Router X uses the same next hop as the next hop to Router S, then Router X is the peer-RPF neighbor, and its source-active messages are accepted.
6. If Router X fits none of these criteria, then Router X is not an MSDP peer-RPF neighbor, and its source-active messages are rejected.

The MSDP peers that receive source-active TLVs can be constrained by BGP reachability information. If the AS path of the network layer reachability information (NLRI) contains the receiving peer's AS number prepended second to last, the sending peer is using the receiving peer as a next hop for this source. If the split horizon information is not being received, the peer can be pruned from the source-active TLV distribution list.

## Configuring MSDP

To configure the Multicast Source Discovery Protocol (MSDP), include the **msdp** statement:

```
msdp {
 disable;
 active-source-limit {
 maximum number;
 threshold number;
 }
 data-encapsulation (disable | enable);
 export [policy-names];
 group group-name {
 ... group-configuration ...
 }
}
```

```

hold-time seconds;
import [policy-names];
local-address address;
keep-alive seconds;
peer address {
 ... peer-configuration ...
}
rib-group group-name;
source ip-prefix </prefix-length> {
 active-source-limit {
 maximum number;
 threshold number;
 }
}
sa-hold-time seconds;
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
group group-name {
 disable;
 export [policy-names];
 import [policy-names];
 local-address address;
 mode (mesh-group | standard);
 peer address {
 ... same statements as at the [edit protocols msdp peer address] hierarchy level shown
 just following ...
 }
 traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
 }
}
peer address {
 disable;
 active-source-limit {
 maximum number;
 threshold number;
 }
 authentication-key peer-key;
 default-peer;
 export [policy-names];
 import [policy-names];
 local-address address;
 traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
 }
}
}

```

You can include this statement at the following hierarchy levels:

- [\[edit protocols\]](#)
- [\[edit routing-instances \*routing-instance-name\* protocols\]](#)
- [\[edit logical-systems \*logical-system-name\* protocols\]](#)
- [\[edit logical-systems \*logical-system-name\* routing-instances \*routing-instance-name\* protocols\]](#)

By default, MSDP is disabled.

  - [Example: Configuring MSDP with Active Source Limits and Mesh Groups on page 5604](#)

## Filtering MSDP SA Messages

Along with applying MSDP source active (SA) filters on all external MSDP sessions (in and out) to prevent SAs for groups and sources from leaking in and out of the network, you need to apply bootstrap router (BSR) filters. Applying a BSR filter to the boundary of a network prevents foreign BSR messages (which announce RP addresses) from leaking into your network. Since the routers in a PIM sparse-mode domain need to know the address of only one RP router, having more than one in the network can create issues.

If you did not use multicast scoping to create boundary filters for all customer-facing interfaces, you might want to use PIM join filters. Multicast scopes prevent the actual multicast data packets from flowing in or out of an interface. PIM join filters prevent PIM sparse-mode state from being created in the first place. Since PIM join filters apply only to the PIM sparse-mode state, it might be more beneficial to use multicast scoping to filter the actual data.

**NOTE:** When you apply firewall filters, firewall action modifiers, such as **log**, **sample**, and **count**, work only when you apply the filter on an inbound interface. The modifiers do not work on an outbound interface.

  - [Example: Configuring PIM BSR Filters on page 5569](#)

## Tracing MSDP Protocol Traffic

Tracing operations record detailed messages about the operation of routing protocols, such as the various types of routing protocol packets sent and received, and routing policy actions. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

| Flag | Description           |
|------|-----------------------|
| all  | Trace all operations. |

| Flag                          | Description                              |
|-------------------------------|------------------------------------------|
| <b>general</b>                | Trace general events.                    |
| <b>keepalive</b>              | Trace keepalive messages.                |
| <b>normal</b>                 | Trace normal events.                     |
| <b>packets</b>                | Trace all MSDP packets.                  |
| <b>policy</b>                 | Trace policy processing.                 |
| <b>route</b>                  | Trace MSDP changes to the routing table. |
| <b>source-active</b>          | Trace source-active packets.             |
| <b>source-active-request</b>  | Trace source-active request packets.     |
| <b>source-active-response</b> | Trace source-active response packets.    |
| <b>state</b>                  | Trace state transitions.                 |
| <b>task</b>                   | Trace task processing.                   |
| <b>timer</b>                  | Trace timer processing.                  |

You can configure MSDP tracing for all peers, for all peers in a particular group, or for a particular peer.

In the following example, tracing is enabled for all routing protocol packets. Then tracing is narrowed to focus only on MSDP peers in a particular group. To configure tracing operations for MSDP:

1. (Optional) Configure tracing by including the **traceoptions** statement at the **[edit routing-options]** hierarchy level and set the **all-packets-trace** and **all** flags to trace all protocol packets.

```
[edit routing-options traceoptions]
user@host# set file all-packets-trace
user@host# set flag all
```

2. Configure the filename for the MSDP trace file.

```
[edit protocols msdp group groupa traceoptions]
user@host# set file msdp-trace
```

3. (Optional) Configure the maximum number of trace files.

```
[edit protocols msdp group groupa traceoptions]
user@host# set file files 5
```

4. (Optional) Configure the maximum size of each trace file.

```
[edit protocols msdp group groupa traceoptions]
```

```
user@host# set file size 1m
```

- (Optional) Enable unrestricted file access.

```
[edit protocols msdp group groupa traceoptions]
```

```
user@host# set file world-readable
```

- Configure tracing flags. Suppose you are troubleshooting issues with the source-active cache for **groupa**. The following example shows how to trace messages associated with the group address.

```
[edit protocols msdp group groupa traceoptions]
```

```
user@host# set flag source-active | match 230.0.0.3
```

- View the trace file.

```
user@host> file list /var/log
```

```
user@host> file show /var/log/msdp-trace
```

## Configuring the Interface to Accept Traffic from a Remote Source

You can configure an incoming interface to accept multicast traffic from a remote source. A remote source is a source that is not on the same subnet as the incoming interface. [Figure 194](#) shows such a topology, where R2 connects to the R1 source on one subnet, and to the incoming interface on R3 (ge-0/3/0.0 in the figure) on another subnet.

**Figure 194: Accepting Multicast Traffic from a Remote Source**

In this topology R2 is a pass-through device not running PIM, so R3 is the first hop router for multicast packets sent from R1. Because R1 and R3 are in different subnets, the default behavior of R3 is to disregard R1 as a remote source. You can have R3 accept multicast traffic from R1, however, by enabling **accept-remote-source** on the target interface.

To accept traffic from a remote source:

- Identify the router and physical interface that you want to receive multicast traffic from the remote source.
- Configure the interface to accept traffic from the remote source.

```
[edit protocols pim interface ge-1/3/0.0]
```

```
user@host# set accept-remote-source
```

**NOTE:** If the interface you identified is not the only path from the remote source, you need to ensure that it is the best path. For example you can configure a static route on the receiver side PE router to the source, or you can prepend the AS path on the other possible routes:

```
[edit policy-options policy-statement as-path-prepend term prepend]
user@host# set from route-filter 192.168.0.0/16 orlonger
user@host# set from route-filter 172.16.0.0/16 orlonger
user@host# set then as-path-prepend "1 1 1"
```

3. Commit the configuration changes.
4. Confirm that the interface you configured accepts traffic from the remote source.

```
user@host# show pim statistics
```

## Example: Configuring MSDP

Configure a router to act as a PIM sparse-mode rendezvous point and an MSDP peer:

```
[edit]
routing-options {
 interface-routes {
 rib-group ifrg;
 }
 rib-groups {
 ifrg {
 import-rib [inet.0 inet.2];
 }
 mcrg {
 export-rib inet.2;
 import-rib inet.2;
 }
 }
}
protocols {
 bgp {
 group lab {
 type internal;
 family any;
 neighbor 192.168.6.18 {
 local-address 192.168.6.17;
 }
 }
 }
}
```

```
pim {
 dense-groups {
 224.0.1.39/32;
 224.0.1.40/32;
 }
 rib-group mcr;
 rp {
 local {
 address 192.168.1.1;
 }
 }
 interface all {
 mode sparse-dense;
 version 1;
 }
}
msdp {
 rib-group mcr;
 group lab {
 peer 192.168.6.18 {
 local-address 192.168.6.17;
 }
 }
}
```

---

## Example: Configuring MSDP with Active Source Limits and Mesh Groups

This example shows how to configure MSDP to filter source-active messages and limit the flooding of source-active messages.

- [Requirements on page 5604](#)
- [Overview on page 5604](#)
- [Configuration on page 5608](#)
- [Verification on page 5609](#)

### Requirements

Before you begin:

- Configure the router interfaces.
- Configure an interior gateway protocol or static routing. See the *Junos OS Routing Protocols Library for Routing Devices*.
- Enable PIM sparse mode. See “[PIM Overview](#)” on [page 5491](#).
- Configure the router as a PIM sparse-mode RP. See “[Configuring Local PIM RPs](#)” on [page 5545](#).

### Overview

A router interested in MSDP messages, such as an RP, might have to process a large number of MSDP messages, especially source-active messages, arriving from other

routers. Because of the potential need for a router to examine, process, and create state tables for many MSDP packets, there is a possibility of an MSDP-based denial-of-service (DoS) attack on a router running MSDP. To minimize this possibility, you can configure the router to limit the number of source active messages the router accepts. Also, you can configure a threshold for applying random early detection (RED) to drop some but not all MSDP active source messages.

By default, the router accepts 25,000 source active messages before ignoring the rest. The limit can be from 1 through 1,000,000. The limit is applied to both the number of messages and the number of MSDP peers.

By default, the router accepts 24,000 source-active messages before applying the RED profile to prevent a possible DoS attack. This number can also range from 1 through 1,000,000. The next 1000 messages are screened by the RED profile and the accepted messages processed. If you configure no drop profiles (as this example does not), RED is still in effect and functions as the primary mechanism for managing congestion. In the default RED drop profile, when the packet queue fill-level is 0 percent, the drop probability is 0 percent. When the fill-level is 100 percent, the drop probability is 100 percent.

**NOTE:** The router ignores source-active messages with encapsulated TCP packets. Multicast does not use TCP; segments inside source-active messages are most likely the result of worm activity.

The number configured for the threshold must be less than the number configured for the maximum number of active MSDP sources.

You can configure an active source limit globally, for a group, or for a peer. If active source limits are configured at multiple levels of the hierarchy (as shown in this example), all are applied.

You can configure an active source limit for an address range as well as for a specific peer. A per-source active source limit uses an IP prefix and prefix length instead of a specific address. You can configure more than one per-source active source limit. The longest match determines the limit.

Per-source active source limits can be combined with active source limits at the peer, group, and global (instance) hierarchy level. Per-source limits are applied before any other type of active source limit. Limits are tested in the following order:

- Per-source
- Per-peer or group
- Per-instance

An active source message must “pass” all limits established before being accepted. For example, if a source is configured with an active source limit of 10,000 active multicast groups and the instance is configured with a limit of 5000 (and there are no other sources or limits configured), only 5000 active source messages are accepted from this source.

MSDP mesh groups are groups of peers configured in a full-mesh topology that limits the flooding of source-active messages to neighboring peers. Every mesh group member must have a peer connection with every other mesh group member. When a source-active message is received from a mesh group member, the source-active message is always accepted but is not flooded to other members of the same mesh group. However, the source-active message is flooded to non-mesh group peers or members of other mesh groups. By default, standard flooding rules apply if **mesh-group** is not specified.

**CAUTION:** When configuring MSDP mesh groups, you must configure all members the same way. If you do not configure a full mesh, excessive flooding of source-active messages can occur.

A common application for MSDP mesh groups is peer-reverse-path-forwarding (peer-RPF) check bypass. For example, if there are two MSDP peers inside an autonomous system (AS), and only one of them has an external MSDP session to another AS, the internal MSDP peer often rejects incoming source-active messages relayed by the peer with the external link. Rejection occurs because the external MSDP peer must be reachable by the internal MSDP peer through the next hop toward the source in another AS, and this next-hop condition is not certain. To prevent rejections, configure an MSDP mesh group on the internal MSDP peer so it always accepts source-active messages.

**NOTE:** An alternative way to bypass the peer-RPF check is to configure a default peer. In networks with only one MSDP peer, especially stub networks, the source-active message always needs to be accepted. An MSDP default peer is an MSDP peer from which all source-active messages are accepted without performing the peer-RPF check. You can establish a default peer at the peer or group level by including the **default-peer** statement.

Table 438 explains how flooding is handled by peers in this example. .

**Table 438: Source-Active Message Flooding Explanation**

| Source-Active Message Received From | Source-Active Message Flooded To                     | Source-Active Message Not Flooded To |
|-------------------------------------|------------------------------------------------------|--------------------------------------|
| Peer 21                             | Peer 11, Peer 12, Peer 13, Peer 31, Peer 32          | Peer 22                              |
| Peer 11                             | Peer 21, Peer 22, Peer 31, Peer 32                   | Peer 12, Peer 13                     |
| Peer 31                             | Peer 21, Peer 22, Peer 11, Peer 12, Peer 13, Peer 32 | —                                    |

Figure 195 illustrates source-active message flooding between different mesh groups and peers within the same mesh group.

Figure 195: Source-Active Message Flooding

This example includes the following settings:

- **active-source-limit maximum 10000**—Applies a limit of 10,000 active sources to all other peers.
- **data-encapsulation disable**—On an RP router using MSDP, disables the default encapsulation of multicast data received in MSDP register messages inside MSDP source-active messages.

MSDP data encapsulation mainly concerns bursty sources of multicast traffic. Sources that send only one packet every few minutes have trouble with the timeout of state relationships between sources and their multicast groups (S,G). Routers lose data while they attempt to reestablish (S,G) state tables. As a result, multicast register messages contain data, and this data encapsulation in MSDP source-active messages can be turned on or off through configuration.

By default, MSDP data encapsulation is enabled. An RP running MSDP takes the data packets arriving in the source's register message and encapsulates the data inside an MSDP source-active message.

However, data encapsulation creates both a multicast forwarding cache entry in the **inet.1** table (this is also the forwarding table) and a routing table entry in the **inet.4** table. Without data encapsulation, MSDP creates only a routing table entry in the **inet.4** table. In some circumstances, such as the presence of Internet worms or other forms of DoS attack, the router's forwarding table might fill up with these entries. To prevent the forwarding table from filling up with MSDP entries, you can configure the router not to use MSDP data encapsulation. However, if you disable data encapsulation, the router ignores and discards the encapsulated data. Without data encapsulation, multicast applications with bursty sources having transmit intervals greater than about 3 minutes might not work well.

- **group MSDP-group local-address 10.1.2.3**—Specifies the address of the local router (this router).
- **group MSDP-group mode mesh-group**—Specifies that all peers belonging to the MSDP-group group are mesh group members.

- **group MSDP-group peer 10.10.10.10**—Prevents the sending of source-active messages to neighboring peer 10.10.10.10.
- **group MSDP-group peer 10.10.10.10 active-source-limit maximum 7500**—Applies a limit of 7500 active sources to MSDP peer 10.10.10.10 in group **MSDP-group**.
- **peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000**—Applies a threshold of 4000 active sources and a limit of 5000 active sources to MSDP peer 10.0.0.1.
- **source 10.1.0.0/16 active-source-limit maximum 500**—Applies a limit of 500 active sources to any source on the 10.1.0.0/16 network.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set protocols msdp data-encapsulation disable
set protocols msdp active-source-limit maximum 10000
set protocols msdp peer 10.0.0.1 active-source-limit maximum 5000
set protocols msdp peer 10.0.0.1 active-source-limit threshold 4000
set protocols msdp source 10.1.0.0/16 active-source-limit maximum 500
set protocols msdp group MSDP-group mode mesh-group
set protocols msdp group MSDP-group local-address 10.1.2.3
set protocols msdp group MSDP-group peer 10.10.10.10 active-source-limit maximum
7500
```

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure MSDP source active routes and mesh groups:

1. (Optional) Disable data encapsulation.

```
[edit protocols msdp]
user@host# set data-encapsulation disable
```

2. Configure the active source limits.

```
[edit protocols msdp]
user@host# set peer 10.0.0.1 active-source-limit maximum 5000 threshold 4000
user@host# set group MSDP-group peer 10.10.10.10 active-source-limit maximum
7500
user@host# set active-source-limit maximum 10000
user@host# set source 10.1.0.0/16 active-source-limit maximum 500
```

3. Configure the mesh group.

```
[edit protocols msdp]
user@host# set group MSDP-group mode mesh-group
user@host# set group MSDP-group peer 10.10.10.10
user@host# set group MSDP-group local-address 10.1.2.3
```

4. If you are done configuring the device, commit the configuration.

```
[edit routing-instances]
user@host# commit
```

## Results

Confirm your configuration by entering the **show protocols** command.

```
user@host# show protocols
msdp {
 data-encapsulation disable;
 active-source-limit {
 maximum 10000;
 }
 peer 10.0.0.1 {
 active-source-limit {
 maximum 5000;
 threshold 4000;
 }
 }
 source 10.1.0.0/16 {
 active-source-limit {
 maximum 500;
 }
 }
 group MSDP-group {
 mode mesh-group;
 local-address 10.1.2.3;
 peer 10.10.10.10 {
 active-source-limit {
 maximum 7500;
 }
 }
 }
}
```

## Verification

To verify the configuration, run the following commands:

- [show msdp source-active](#)
- [show msdp statistics](#)

### Related Documentation

- [Configuring Local PIM RPs on page 5545](#)

## Example: Configuring PIM Anycast With or Without MSDP

---

When you configure anycast RP, you bypass the restriction of having one active rendezvous point (RP) per multicast group, and instead deploy multiple RPs for the same group range. The RP routers share one unicast IP address. Sources from one RP are known to other RPs that use the Multicast Source Discovery Protocol (MSDP). Sources and receivers use the closest RP, as determined by the interior gateway protocol (IGP).

You can use anycast RP within a domain to provide redundancy and RP load sharing. When an RP stops operating, sources and receivers are taken to a new RP by means of unicast routing.

You can configure anycast RP to use PIM and MSDP for IPv4, or PIM alone for both IPv4 and IPv6 scenarios. Both are discussed in this section.

We recommend a static RP mapping with anycast RP over a bootstrap router and auto-RP configuration because it provides all the benefits of a bootstrap router and auto-RP without the complexity of the BSR and auto-RP mechanisms.

All systems on a subnet must run the same version of PIM.

The default PIM version can be version 1 or version 2, depending on the mode you are configuring. PIMv1 is the default RP mode (at the **[edit protocols pim rp static address address]** hierarchy level). However, PIMv2 is the default for interface mode (at the **[edit protocols pim interface interface-name]** hierarchy level). Explicitly configured versions override the defaults. This example explicitly configures PIMv2 on the interfaces.

The following example shows an anycast RP configuration for the RP routers, first with MSDP and then using PIM alone, and for non-RP routers.

1. For a network using an RP with MSDP, configure the RP using the **lo0** loopback interface, which is always up. Include the **address** statement and specify the unique and routable router ID and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement for the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
 lo0 {
 description "PIM RP";
 unit 0 {
 family inet {
 address 198.58.3.254/32;
 primary;
 address 198.58.3.253/32;
 }
 }
 }
}
```

2. Specify the RP address. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
 pim {
 rp {
 local {
 family inet;
 address 198.58.3.253;
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

3. Configure MSDP peering. Include the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, include the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
 msdp {
 peer 198.58.3.250 {
 local-address 198.58.3.254;
 }
 }
}
```

**NOTE:** If you need to configure a PIM RP for both IPv4 and IPv6 scenarios, perform Step 4 and Step 5. Otherwise, go to Step 6.

4. Configure an RP using the **lo0** loopback interface, which is always up. Include the **address** statement to specify the unique and routable router address and the RP address at the **[edit interfaces lo0 unit 0 family inet]** hierarchy level. In this example, the router ID is **198.58.3.254** and the shared RP address is **198.58.3.253**. Include the **primary** statement on the first address. Including the **primary** statement selects the router's primary address from all the preferred addresses on all interfaces.

```
interfaces {
 lo0 {
 description "PIM RP";
```

```

unit 0 {
 family inet {
 address 198.58.3.254/32 {
 primary;
 }
 address 198.58.3.253/32;
 }
}

```

5. Include the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, include the **mode** statement to set the mode to **sparse**, and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

Include the **anycast-pim** statement to configure anycast RP without MSDP (for example, if IPv6 is used for multicasting). The other RP routers that share the same IP address are configured using the **rp-set** statement. There is one entry for each RP, and the maximum that can be configured is 15. For each RP, specify the routable IP address of the router and whether MSDP source active (SA) messages are forwarded to the RP.

MSDP configuration is not necessary for this type of IPv4 anycast RP configuration.

```

protocols {
 pim {
 rp {
 local {
 family inet {
 address 198.58.3.253;
 anycast-pim {
 rp-set {
 address 198.58.3.240;
 address 198.58.3.241 forward-msdp-sa;
 }
 local-address 198.58.3.254; #If not configured, use lo0 primary
 }
 }
 }
 }
 }
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
}

```

6. Configure the non-RP routers. The anycast RP configuration for a non-RP router is the same whether MSDP is used or not. Specify a static RP by adding the address at

the **[edit protocols pim rp static]** hierarchy level. Include the **version** statement at the **[edit protocols pim rp static address]** hierarchy level to specify PIM version 2.

```
protocols {
 pim {
 rp {
 static {
 address 198.58.3.253 {
 version 2;
 }
 }
 }
 }
}
```

7. Include the **mode** statement at the **[edit protocols pim interface all]** hierarchy level to specify sparse mode on all interfaces. Then include the **version** statement at the **[edit protocols pim rp interface all mode]** to configure all interfaces for PIM version 2. When configuring all interfaces, exclude the **fxp0.0** management interface by including the **disable** statement for that interface.

```
protocols {
 pim {
 interface all {
 mode sparse;
 version 2;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

## Configuring a PIM Anycast RP Router with MSDP

Add the **address** statement at the **[edit protocols pim rp local]** hierarchy level to specify the RP address (the same address as the secondary **lo0** interface).

For all interfaces, use the **mode** statement to set the mode to **sparse** and the **version** statement to specify PIM version 2 at the **[edit protocols pim rp local interface all]** hierarchy level. When configuring all interfaces, exclude the **fxp0.0** management interface by adding the **disable** statement for that interface.

```
protocols {
 pim {
 rp {
 local {
 family inet;
 address 198.58.3.253;
 }
 interface all {
 mode sparse;
 version 2;
 }
 }
 }
}
```

```
 interface fxp0.0 {
 disable;
 }
 }
}
```

To configure MSDP peering, add the **peer** statement to configure the address of the MSDP peer at the **[edit protocols msdp]** hierarchy level. For MSDP peering, use the unique, primary addresses instead of the anycast address. To specify the local address for MSDP peering, add the **local-address** statement at the **[edit protocols msdp peer]** hierarchy level.

```
protocols {
 msdp {
 peer 198.58.3.250 {
 local-address 198.58.3.254;
 }
 }
}
```

    }  
}`

**Hierarchy Level**    [edit logical-systems *logical-system-name* protocols],  
                          [edit protocols]

**Release Information**    Statement introduced before Junos OS Release 7.4.  
                              Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description**    Enable IGMP on the router. IGMP must be enabled for the router to receive multicast packets.

The remaining statements are explained separately.

**Default**    IGMP is disabled on the router. IGMP is automatically enabled on all broadcast interfaces when you configure Protocol Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP).

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |
|                                 | <p> <b>NOTE:</b> Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b>              | Specify that the interface accepts IGMP reports from hosts on any subnetwork. Note that when enabling promiscuous-mode, all routing devices on the ethernet segment must be configured with the promiscuous mode statement. Otherwise, only the interface configured with lowest IPv4 address acts as the querier for IGMP for this Ethernet segment. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                   |

| <b>Description</b>              | Configure the number of times the multicast source address should be incremented for each static group created. The increment is specified in dotted decimal notation similar to an IPv4 address.                                                                                |

| <b>Description</b>              | <p>Test multicast forwarding on an interface without a receiver host.</p> <p>The <b>static</b> statement simulates IGMP joins on a routing device statically on an interface without any IGMP hosts. It is supported for both IGMPv2 and IGMPv3 joins. This statement is especially useful for testing multicast forwarding on an interface without a receiver host.</p> |
|                                 | <p> <b>NOTE:</b> To prevent joining too many groups accidentally, the <b>static</b> statement is not supported with the <b>interface all</b> statement.</p>                                                                                                                           |
|                                 | <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                |

| <b>Description</b>         | <p>Configure IGMP tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p>To trace the paths of multicast packets, use the <b>mtrace</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>             | The default IGMP trace options are those inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the file <b>igmp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>IGMP Tracing Flags</b></p> <ul style="list-style-type: none"> <li><b>leave</b>—Leave group messages (for IGMP version 2 only).</li> <li><b>mtrace</b>—Mtrace packets. Use the <b>mtrace</b> command to troubleshoot the software.</li> </ul> |

- **packets**—All IGMP packets.
- **query**—IGMP membership query messages, including general and group-specific queries.
- **report**—Membership report messages.

#### Global Tracing Flags

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>              | Configure a limit for the number of multicast groups (or [S,G] channels in IGMPv3) allowed on an interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>                  | By default, there is no limit to the number of multicast groups joining an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <i>limit</i> —a 32-bit number for the limit on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 14.1X53-D15 for QFabric Systems.                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Configure a QFabric Node device to be an IGMP querier. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is lower (a smaller number) than the IP addresses for those routers on the network. This ensures that Node is always the IGMP querier on the network.     |

| <b>Description</b>         | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |

**NOTE:** Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

## interface (Bridge Domains)

---

**Syntax** `interface interface-name {  
 group-limit limit;  
 host-only-interface;  
 multicast-router-interface;  
 static {  
 group ip-address {  
 source ip-address;  
 }  
 }  
}`

**Hierarchy Level** [edit bridge-domains *bridge-domain-name* protocols igmp-snooping],  
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id*],  
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols igmp-snooping],  
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols vlan *vlan-id* igmp-snooping]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Enable IGMP snooping on an interface and configure interface-specific properties.

**Options** *interface-name*—Name of the interface. Specify the full interface name, including the physical and logical address components. To configure all interfaces, you can specify **all**.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3 for the QFX Series.<br>Statement introduced in Junos OS Release 14.1X53-D15 for QFabric Systems.                                                                                                                                                                                                                              |
| <b>Description</b>              | Configure the address that the switch uses as the source address in the IGMP queries that it sends. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is smaller (a lower number) than the IP addresses for those routers on the network. This ensures that switch is always the IGMP querier on the network. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                         |

| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>         | Define tracing operations for IGMP snooping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>             | The <b>traceoptions</b> feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached (<b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 3 files</p> <p><b>flag <i>flag</i></b> —Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"><li>• <b>all</b>—All tracing operations.</li><li>• <b>general</b>—Trace general IGMP snooping protocol events.</li><li>• <b>krt</b>—Trace communication over routing sockets.</li><li>• <b>nexthop</b>— Trace next-hop related events.</li><li>• <b>normal</b>—Trace normal IGMP snooping protocol events.</li><li>• <b>packets</b>—Trace all IGMP packets.</li><li>• <b>policy</b>—Trace policy processing.</li><li>• <b>query</b>—Trace IGMP membership query messages.</li><li>• <b>report</b>—Trace membership report messages.</li></ul> |

- **route**—Trace routing information.
- **state**—Trace IGMP state transitions.
- **task**—Trace routing protocol task processing.
- **timer**—Trace routing protocol timer processing.
- **vlan**—Trace VLAN related events.

**no-stamp**—(Optional) Do not time stamp trace file.

**no-world-readable**—(Optional) Restrict file access to the user who created the file.

**size size** —(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option. Use **xk** to specify KB, **xm** to specify MB, or **xg** to specify gigabytes.

**Range:** 10 KB through 1 gigabytes

**Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for EX Series switches.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Specify the IGMP version for the IGMP general query that the switch sends to hosts when an interface comes up. The configured IGMP version affects only the version of the general queries sent by a switch. It does not affect the version of IGMP messages that the switch can snoop. For example, If the switch is configured for IGMP version 1 (IGMPv1), it can snoop IGMPv2 and IGMPv3 messages. |
| <b>Default</b>                  | If you do not configure the <b>version</b> statement, the default is IGMPv2.                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <b>version</b> —IGMP version number.<br><b>Range:</b> 1 and 2.                                                                                                                                                                                                                                                                                                                                         |

## vlan (IGMP Snooping)

```
Syntax vlan vlan-name {
 immediate-leave;
 interface interface-name {
 group-limit limit;
 host-only-interface;
 multicast-router-interface;
 static {
 group mcast-group-address {
 source ip-address;
 }
 }
 }
 qualified-vlan ;
 proxy {
 source-address ip-address;
 }
 query-interval seconds;
 query-last-member-interval seconds;
 query-response-interval seconds;
 robust-count number;
 }
```

**Hierarchy Level** [edit protocols igmp-snooping ],

**Release Information** Statement introduced in Junos OS Release 8.5.  
Statement introduced in Junos OS Release 13.2 for the QFX series.

**Description** Configure IGMP snooping parameters for a particular VLAN.

**Default** By default, IGMP snooping options apply to all VLANs.

**Options** *vlan-name*—Apply the parameters to this VLAN.  
  
The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Configure a limit for the number of multicast groups (or [S,G] channels in IGMPv3) allowed on an interface. After this limit is reached, new reports are ignored and all related flows are not flooded on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>                  | By default, there is no limit to the number of multicast groups joining an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <i>limit</i> —a 32-bit number for the limit on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 14.1X53-D15 for QFabric Systems.                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Configure a QFabric Node device to be an IGMP querier. If there are any multicast routers on the same local network, make sure the source address for the IGMP querier is lower (a smaller number) than the IP addresses for those routers on the network. This ensures that Node is always the IGMP querier on the network.     |

| <b>Description</b>         | <p>The immediate leave setting is useful for minimizing the leave latency of IGMP memberships. When this setting is enabled, the routing device leaves the multicast group immediately after the last host leaves the multicast group.</p> <p>The immediate-leave setting enables host tracking, meaning that the device keeps track of the hosts that send join messages. This allows IGMP to determine when the last host sends a leave message for the multicast group.</p> <p>When the immediate leave setting is enabled, the device removes an interface from the forwarding-table entry without first sending IGMP group-specific queries to the interface. The interface is pruned from the multicast tree for the multicast group specified in the IGMP leave message. The immediate leave setting ensures optimal bandwidth management for hosts on a switched network, even when multiple multicast groups are being used simultaneously.</p> <p>When immediate leave is disabled and one host sends a leave group message, the routing device first sends a group query to determine if another receiver responds. If no receiver responds, the routing device removes all hosts on the interface from the multicast group. Immediate leave is disabled by default for both IGMP version 2 and IGMP version 3.</p> |

**NOTE:** Although host tracking is enabled for IGMPv2 and MLDv1 when you enable immediate leave, use immediate leave with these versions only when there is one host on the interface. The reason is that IGMPv2 and MLDv1 use a report suppression mechanism whereby only one host on an interface sends a group join report in response to a membership query. The other interested hosts suppress their reports. The purpose of this mechanism is to avoid a flood of reports for the same group. But it also interferes with host tracking, because the router only knows about the one interested host and does not know about the others.

## interface (Bridge Domains)

---

**Syntax** `interface interface-name {  
 group-limit limit;  
 host-only-interface;  
 multicast-router-interface;  
 static {  
 group ip-address {  
 source ip-address;  
 }  
 }  
}`

**Hierarchy Level** [edit bridge-domains *bridge-domain-name* protocols igmp-snooping],  
[edit bridge-domains *bridge-domain-name* protocols igmp-snooping vlan *vlan-id*],  
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols  
igmp-snooping],  
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* protocols  
vlan *vlan-id* igmp-snooping]

**Release Information** Statement introduced in Junos OS Release 8.5.

**Description** Enable IGMP snooping on an interface and configure interface-specific properties.

**Options** *interface-name*—Name of the interface. Specify the full interface name, including the physical and logical address components. To configure all interfaces, you can specify **all**.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>         | Define tracing operations for IGMP snooping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>             | The <b>traceoptions</b> feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached (<b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify gigabytes), at which point the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 3 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple flag statements. You can include the following flags:</p> <ul style="list-style-type: none"> <li>• <b>all</b>—All tracing operations.</li> <li>• <b>general</b>—Trace general IGMP snooping protocol events.</li> <li>• <b>krt</b>—Trace communication over routing sockets.</li> <li>• <b>nexthop</b>— Trace next-hop related events.</li> <li>• <b>normal</b>—Trace normal IGMP snooping protocol events.</li> <li>• <b>packets</b>—Trace all IGMP packets.</li> <li>• <b>policy</b>—Trace policy processing.</li> <li>• <b>query</b>—Trace IGMP membership query messages.</li> <li>• <b>report</b>—Trace membership report messages.</li> </ul> |

- **route**—Trace routing information.
- **state**—Trace IGMP state transitions.
- **task**—Trace routing protocol task processing.
- **timer**—Trace routing protocol timer processing.
- **vlan**—Trace VLAN related events.

**no-stamp**—(Optional) Do not time stamp trace file.

**no-world-readable**—(Optional) Restrict file access to the user who created the file.

**size size** —(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten. If you specify a maximum number of files, you also must specify a maximum file size with the **files** option. Use **xk** to specify KB, **xm** to specify MB, or **xg** to specify gigabytes.

**Range:** 10 KB through 1 gigabytes

**Default:** 128 KB

**world-readable**—(Optional) Enable unrestricted file access.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for EX Series switches.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.                                                                                                                                                                                                                                                             |
| <b>Description</b>              | Specify the IGMP version for the IGMP general query that the switch sends to hosts when an interface comes up. The configured IGMP version affects only the version of the general queries sent by a switch. It does not affect the version of IGMP messages that the switch can snoop. For example, If the switch is configured for IGMP version 1 (IGMPv1), it can snoop IGMPv2 and IGMPv3 messages. |
| <b>Default</b>                  | If you do not configure the <b>version</b> statement, the default is IGMPv2.                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <b>version</b> —IGMP version number.<br><b>Range:</b> 1 and 2.                                                                                                                                                                                                                                                                                                                                         |

## vlan (IGMP Snooping)

---

**Syntax**    `vlan vlan-name {  
                  immediate-leave;  
                  interface interface-name {  
                    group-limit limit;  
                    host-only-interface;  
                    multicast-router-interface;  
                    static {  
                      group multicast-group-address {  
                        source ip-address;  
                      }  
                    }  
                  }  
                  qualified-vlan ;  
                  proxy {  
                    source-address ip-address;  
                  }  
                  query-interval seconds;  
                  query-last-member-interval seconds;  
                  query-response-interval seconds;  
                  robust-count number;  
                  }`

**Hierarchy Level**    [edit protocols igmp-snooping ],

**Release Information**    Statement introduced in Junos OS Release 8.5.  
                              Statement introduced in Junos OS Release 13.2 for the QFX series.

**Description**    Configure IGMP snooping parameters for a particular VLAN.

**Default**    By default, IGMP snooping options apply to all VLANs.

**Options**    *vlan-name*—Apply the parameters to this VLAN.  
  
              The remaining statements are explained separately.

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration.

| <b>Description</b>              | Multicast routing devices running PIM sparse mode often forward the same stream of multicast packets onto the same LAN through the rendezvous-point tree (RPT) and shortest-path tree (SPT). PIM assert messages help routing devices determine which routing device forwards the traffic and prunes the RPT for this group. By default, routing devices enter an assert cycle every 180 seconds. You can configure this assert timeout to be between 5 and 210 seconds. |
| <b>Options</b>                  | <b><i>seconds</i></b> —Time for routing device to wait before another assert message cycle.<br><b>Range:</b> 5 through 210 seconds<br><b>Default:</b> 180 seconds                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | <p>Enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the <b>clear bfd adaptation</b> command to return BFD interval timers to their configured values. The <b>clear bfd adaptation</b> command is hitless, meaning that the command does not affect traffic flow on the routing device.</p> <p>The remaining statement is explained separately.</p> |

| <b>Description</b>              | <p>Specify loose authentication checking on the BFD session. Use loose authentication for transitional periods only when authentication might not be configured at both ends of the BFD session.</p> <p>By default, strict authentication is enabled and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure <i>loose checking</i>. When loose checking is configured, packets are accepted without authentication being checked at each end of the session.</p> |

| <b>Description</b>              | Set the maximum time in milliseconds to delay sending override join messages for a multicast network that has join suppression enabled. When a router or switch sees a prune message for a join it is currently suppressing, it waits for the interval specified by the override timer before it sends an override join message.                                                                                                                                                                                                                                                               |
| <b>Options</b>                  | This is a random timer with a value in milliseconds.<br><b>Range:</b> 0 through maximum override value<br><b>Default:</b> 2000 milliseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds ( $1.1 \times \text{periodic}$ through $1.4 \times \text{periodic}$ , where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join. |

[edit protocols pim],  
[edit routing-instances *routing-instance-name* protocols pim]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Configure the routing device as an actual or potential RP. A routing device can be an RP  
for more than one group.

The remaining statements are explained separately.

**Default** If you do not include the **rp** statement, the routing device can never become the RP.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## rpf-selection

---

**Syntax**    `rpf-selection {  
              group group-address {  
                  source source-address {  
                      next-hop next-hop-address;  
                  }  
                  wildcard-source {  
                      next-hop next-hop-address;  
                  }  
              }  
              prefix-list prefix-list-addresses {  
                  source source-address {  
                      next-hop next-hop-address;  
                  }  
                  wildcard-source {  
                      next-hop next-hop-address;  
                  }  
              }  
          }`

**Hierarchy Level**    [edit routing-instances *routing-instance-name* protocols pim]

**Release Information**    Statement introduced in JUNOS Release 10.4.  
Statement introduced in Junos OS Release 11.3 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description**    Configure the PIM RPF next-hop neighbor for a specific group and source for a VRF routing instance.

The remaining statements are explained separately.

**Default**    If you omit the **rpf-selection** statement, PIM RPF checks typically choose the best path determined by the unicast protocol for all multicast flows.

**Options**    *source-address*—Specific source address for the PIM group.

**Required Privilege Level**    view-level—To view this statement in the configuration.  
control-level—To add this statement to the configuration.

**Related Documentation**    • *Example: Configuring PIM RPF Selection*

| <b>Description</b>              | <p>Set the SPT threshold to infinity for a source-group address pair. Last-hop multicast routing devices running PIM sparse mode can forward the same stream of multicast packets onto the same LAN through an RPT rooted at the RP or an SPT rooted at the source. By default, last-hop routing devices transition to a direct SPT to the source. You can configure this routing device to set the SPT transition value to infinity to prevent this transition for any source-group address pair.</p> <p>The remaining statements are explained separately.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Description              | <p>Specify the transmit interval for the <b>bfd-liveness-detection</b> statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum interval between receiving packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.</p> <p>The remaining statements are explained separately.</p> |
| Required Privilege Level | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>         | <p>Configure PIM tracing options.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>             | The default PIM trace options are those inherited from the routing protocol's <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place tracing output in the <b>pim-log</b> file.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 2 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>PIM Tracing Flags</b></p> <ul style="list-style-type: none"> <li><b>assert</b>—Assert messages</li> <li><b>bidirectional-df-election</b>—Bidirectional PIM designated-forwarder (DF) election events</li> </ul> |

- **bootstrap**—Bootstrap messages
- **cache**—Packets in the PIM sparse mode routing cache
- **graft**—Graft and graft acknowledgment messages
- **hello**—Hello packets
- **join**—Join messages
- **mt**—Multicast tunnel messages
- **nsr-synchronization**—Nonstop active routing (NSR) synchronization messages
- **packets**—All PIM packets
- **prune**—Prune messages
- **register**—Register and register stop messages
- **rp**—Candidate RP advertisements
- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**no-stamp**—(Optional) Do not place timestamp information at the beginning of each line in the trace file.

**Default:** If you omit this option, timestamp information is placed at the beginning of each line of the tracing output.

**no-world-readable**—(Optional) Do not allow users to read the log file.

**replace**—(Optional) Replace an existing trace file if there is one.

**Default:** If you do not include this option, tracing output is appended to an existing trace file.

**size** *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of trace files.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 0 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>              | <p>Configure source-specific multicast (SSM) groups.</p> <p>By default, the SSM group multicast address is limited to the IP address range from 232.0.0.0 through 232.255.255.255. However, you can extend SSM operations into another Class D range by including the <b>ssm-groups</b> statement in the configuration. The default SSM address range from 232.0.0.0 through 232.255.255.255 cannot be used in the <b>ssm-groups</b> statement. This statement is for adding other multicast addresses to the default SSM group addresses. This statement does not override the default SSM group address range.</p> <p>IGMPv3 supports SSM groups. By utilizing inclusion lists, only sources that are specified send to the SSM group.</p> |
| <b>Options</b>                  | <i>ip-addresses</i> —List of one or more additional SSM group addresses separated by a space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Release Information** Statement introduced before Junos OS Release 7.4.  
 Statement introduced in Junos OS Release 12.1 for the QFX Series.  
 Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Define an MSDP peer group. MSDP peers within groups share common tracing options, if present and not overridden for an individual peer with the **peer** statement. To configure multiple MSDP groups, include multiple **group** statements.

By default, the group's options are identical to the global MSDP options. To override the global options, include group-specific options within the **group** statement.

The group must contain at least one peer.

**Options** **group-name**—Name of the MSDP group.

The remaining statements are explained separately.
