**Table 347: show (ospf | ospf3) backup neighbor Output Fields**

| Field Name              | Field Description                                 | Level of Output |
|-------------------------|---------------------------------------------------|-----------------|
| Neighbor to Self Metric | Metric from the backup neighbor to the OSPF node. | All levels      |

Table 347: show (ospf |ospf3) backup neighbor Output Fields (*continued*)

| Field Name                     | Field Description                                 | Level of Output |
|--------------------------------|---------------------------------------------------|-----------------|
| <b>Self to Neighbor Metric</b> | Metric from the OSPF node to the backup neighbor. | All levels      |
| <b>Direct next-hop</b>         | Interface and address of the direct next hop.     | All levels      |

## Sample Output

### show ospf backup neighbor

```
user@host> show ospf backup neighbor
Topology default backup neighbors:

Area 0.0.0.5 backup neighbors:

10.0.0.5
 Neighbor to Self Metric: 5
 Self to Neighbor Metric: 5
 Direct next-hop: ge-4/0/0.111 via 10.0.175.5

10.0.0.6
 Neighbor to Self Metric: 5
 Self to Neighbor Metric: 5
 Direct next-hop: ge-4/1/0.110 via 10.0.176.6
```

## show ospf context-identifier

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Table 348: show ospf context-identifier Output Fields

| Field Name                  | Field Description                                                                                                                                                                                                                                                                                                                                                                                  | Level of Output |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Context</b>              | IPv4 address that defines a protection pair. The context is manually configured on both primary and protector provider edge (PE) devices.                                                                                                                                                                                                                                                          | All levels      |
| <b>Status</b>               | State of the path: <b>active</b> or <b>inactive</b> .                                                                                                                                                                                                                                                                                                                                              | All levels      |
| <b>Metric</b>               | Advertised OSPF metric.                                                                                                                                                                                                                                                                                                                                                                            | All levels      |
| <b>Area</b>                 | OSPF area number.                                                                                                                                                                                                                                                                                                                                                                                  | All levels      |
| <b>Other Advertisements</b> | Other advertisements received by the OSPF node: <ul style="list-style-type: none"> <li>• <b>Advertising router</b>—Address of the device that sent the advertisement.</li> <li>• <b>Type</b>—Type of OSPF path: <b>inter-area</b> and <b>stub</b>.</li> <li>• <b>Metric</b>—Advertised OSPF metric.</li> <li>• <b>None</b>—No additional advertisements were received by the OSPF node.</li> </ul> | <b>detail</b>   |

## Sample Output

### show ospf context-identifier

```
user@host> show ospf context-identifier
Context-id: 2.2.4.3
Status: active, Metric: 65534, PE role: protector, Area: 0.0.0.0
```

### show ospf context-identifier detail

```
user@host> show ospf context-identifier detail
Context-id: 88.24.13.1
Status: inactive, Metric: 0, PE role: protector, Area: 0.0.0.13
Other Advertisements:
Advertising router: 8.8.8.103
Type: stub link
Metric: 65534
```

## show ospf database

**Release Information**    Command introduced before Junos OS Release 7.4.  
                                   Command introduced in Junos OS Release 9.0 for EX Series switches.  
                                   **advertising-router self (*address* | self)** option introduced in Junos OS Release 9.5.  
                                   **advertising-router self (*address* | self)** option introduced in Junos OS Release 9.5 for EX Series switches.  
                                   Command introduced in Junos OS Release 11.3 for the QFX Series.

**Description**    Display the entries in the Open Shortest Path First version 2 (OSPFv2) link-state database, which contains data about link-state advertisement (LSA) packets.

**Options**    **none**—Display standard information about entries in the OSPFv2 link-state database for all routing instances.

**brief | detail | extensive | summary**—(Optional) Display the specified level of output.

**advertising-router (*address* | self)**—(Optional) Display the LSAs advertised either by a particular routing device or by this routing device.

**area** *area-id*—(Optional) Display the LSAs in a particular area.

**asbrsummary**—(Optional) Display summary AS boundary router LSA entries.

**external**—(Optional) Display external LSAs.

**instance** *instance-name*—(Optional) Display all OSPF database information under the named routing instance.

**link-local**—(Optional) Display information about link-local LSAs.

**logical-system** (**all** | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on a particular logical system.

**lsa-id** *lsa-id*—(Optional) Display the LSA with the specified LSA identifier.

**netsummary**—(Optional) Display summary network LSAs.

**network**—(Optional) Display information about network LSAs.

**nssa**—(Optional) Display information about not-so-stubby area (NSSA) LSAs.

**opaque-area**—(Optional) Display opaque area-scope LSAs.

**router**—(Optional) Display information about router LSAs.

**Output Fields**

[Table 349](#) describes the output fields for the **show ospf database** command. Output fields are listed in the approximate order in which they appear.

**Table 349: show ospf database Output Fields**

| Field Name     | Field Description                                                                                                                                        | Level of Output |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>area</b>    | Area number. Area 0.0.0.0 is the backbone area.                                                                                                          | All levels      |
| <b>Type</b>    | Type of link advertisement: <b>ASBRSum</b> , <b>Extern</b> , <b>Network</b> , <b>NSSA</b> , <b>OpaqArea</b> , <b>Router</b> , or <b>Summary</b> .        | All levels      |
| <b>ID</b>      | LSA identifier included in the advertisement. An asterisk preceding the identifier marks database entries that originated from the local routing device. | All levels      |
| <b>Adv Rtr</b> | Address of the routing device that sent the advertisement.                                                                                               | All levels      |

**Output Fields** Table 350 lists the output fields for the **show (ospf | ospf3) interface** command. Output fields are listed in the approximate order in which they appear.

**Table 350: show (ospf | ospf3) interface Output Fields**

| Field Name              | Field Description                                                                                                                                                                                    | Level of Output         |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>Interface</b>        | Name of the interface running OSPF version 2 or OSPF version 3.                                                                                                                                      | All levels              |
| <b>State</b>            | State of the interface: <b>BDR</b> , <b>Down</b> , <b>DR</b> , <b>DRother</b> , <b>Loop</b> , <b>PtToPt</b> , or <b>Waiting</b> .                                                                    | All levels              |
| <b>Area</b>             | Number of the area that the interface is in.                                                                                                                                                         | All levels              |
| <b>DR ID</b>            | Address of the area's designated router.                                                                                                                                                             | All levels              |
| <b>BDR ID</b>           | Backup designated router for a particular subnet.                                                                                                                                                    | All levels              |
| <b>Nbrs</b>             | Number of neighbors on this interface.                                                                                                                                                               | All levels              |
| <b>Type</b>             | Type of interface: <b>LAN</b> , <b>NBMA</b> , <b>P2MP</b> , <b>P2P</b> , or <b>Virtual</b> .                                                                                                         | <b>detail extensive</b> |
| <b>Address</b>          | IP address of the neighbor.                                                                                                                                                                          | <b>detail extensive</b> |
| <b>Mask</b>             | Netmask of the neighbor.                                                                                                                                                                             | <b>detail extensive</b> |
| <b>Prefix-length</b>    | (OSPFv3) IPv6 prefix length, in bits.                                                                                                                                                                | <b>detail extensive</b> |
| <b>OSPF3-Intf-Index</b> | (OSPFv3) OSPF version 3 interface index.                                                                                                                                                             | <b>detail extensive</b> |
| <b>MTU</b>              | Interface maximum transmission unit (MTU).                                                                                                                                                           | <b>detail extensive</b> |
| <b>Cost</b>             | Interface cost (metric).                                                                                                                                                                             | <b>detail extensive</b> |
| <b>DR addr</b>          | Address of the designated router.                                                                                                                                                                    | <b>detail extensive</b> |
| <b>BDR addr</b>         | Address of the backup designated router.                                                                                                                                                             | <b>detail extensive</b> |
| <b>Adj count</b>        | Number of adjacent neighbors.                                                                                                                                                                        | <b>detail extensive</b> |
| <b>Secondary</b>        | Indicates that this interface is configured as a secondary interface for this area. This interface can belong to more than one area, but can be designated as a primary interface for only one area. | <b>detail extensive</b> |

Table 350: show (ospf | ospf3) interface Output Fields (*continued*)

| Field Name             | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Level of Output         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>Flood Reduction</b> | Indicates that this interface is configured with flooding reduction. All self-originated LSAs from this interface are initially sent with the <b>DoNotAge</b> bit set. As a result, LSAs are refreshed only when a change occurs.                                                                                                                                                                                                                                   | <b>extensive</b>        |
| <b>Priority</b>        | Router priority used in designated router (DR) election on this interface.                                                                                                                                                                                                                                                                                                                                                                                          | <b>detail extensive</b> |
| <b>Flood list</b>      | List of link-state advertisements (LSAs) that might be about to flood this interface.                                                                                                                                                                                                                                                                                                                                                                               | <b>extensive</b>        |
| <b>Ack list</b>        | Acknowledgment list. List of pending acknowledgments on this interface.                                                                                                                                                                                                                                                                                                                                                                                             | <b>extensive</b>        |
| <b>Descriptor list</b> | List of packet descriptors.                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>        |
| <b>Hello</b>           | Configured value for the hello timer.                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>detail extensive</b> |
| <b>Dead</b>            | Configured value for the dead timer.                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>detail extensive</b> |

| <b>Output Fields</b>                            | Table 351 lists the output fields for the <b>show ospf io-statistics</b> command. Output fields are listed in the approximate order in which they appear.                                                           |

**Table 351: show (ospf | ospf3) io-statistics Output Fields**

| Field Name      | Field Description                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| Packets read    | Number of OSPF packets read since the last time the routing protocol was started.                         |
| average per run | Total number of packets divided by the total number of times the OSPF read operation is scheduled to run. |
| max run         | Maximum number of packets for a given run among all scheduled runs.                                       |
| Receive errors  | Number of faulty packets received with errors.                                                            |

## Sample Output

### show ospf io-statistics

```
user@host> show ospf io-statistics
```

```
Packets read: 7361, average per run: 1.00, max run: 1
Receive errors:
None
```

## show (ospf | ospf3) log

| <b>Output Fields</b>                            | Table 352 lists the output fields for the <b>show (ospf   ospf3) log</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 352: show (ospf | ospf3) log Output Fields**

| Field Name  | Field Description                                                                      |
|-------------|----------------------------------------------------------------------------------------|
| <b>When</b> | Time, in weeks ( <b>w</b> ) and days ( <b>d</b> ), since the SPF calculation was made. |

Table 352: show (ospf | ospf3) log Output Fields (*continued*)

| Field Name | Field Description                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type       | Type of calculation: Cleanup, External, Interarea, NSSA, Redist, SPF, Stub, Total, or Virtuallink.                                                                           |
| Elapsed    | Amount of time, in seconds, that elapsed during the operation, or the time required to complete the SPF calculation. The start time is the time displayed in the When field. |

## Sample Output

### show ospf log

```

user@host> show ospf log
When Type Elapsed
1w4d 17:25:58 Stub 0.000017
1w4d 17:25:58 SPF 0.000070
1w4d 17:25:58 Stub 0.000019
1w4d 17:25:58 Interarea 0.000054
1w4d 17:25:58 External 0.000005
1w4d 17:25:58 Cleanup 0.000203
1w4d 17:25:58 Total 0.000537
1w4d 17:24:48 SPF 0.000125
1w4d 17:24:48 Stub 0.000017
1w4d 17:24:48 SPF 0.000100
1w4d 17:24:48 Stub 0.000016
1w4d 17:24:48 Interarea 0.000056
1w4d 17:24:48 External 0.000005

Table 353: show (ospf | ospf3) neighbor Output Fields

| Field Name | Field Description                                  | Level of Output |
|------------|----------------------------------------------------|-----------------|
| Address    | Address of the neighbor.                           | All levels      |
| Interface  | Interface through which the neighbor is reachable. | All levels      |

Table 353: show (ospf | ospf3) neighbor Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Level of Output         |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>State</b>                          | <p>State of the neighbor:</p> <ul style="list-style-type: none"> <li>• <b>Attempt</b>—Valid only for neighbors attached to nonbroadcast networks. It indicates that no recent information has been received from the neighbor, but that a more concerted effort must be made to contact the neighbor.</li> <li>• <b>Down</b>—Initial state of a neighbor conversation. It indicates that no recent information has been received from the neighbor. Hello packets might continue to be sent to neighbors in the <b>Down</b> state, although at a reduced frequency.</li> <li>• <b>Exchange</b>—Routing device is describing its entire link-state database by sending database description packets to the neighbor. Each packet has a sequence number and is explicitly acknowledged.</li> <li>• <b>ExStart</b>—First step in creating an adjacency between the two neighboring routing devices. The goal of this step is to determine which routing device is the master, and to determine the initial sequence number.</li> <li>• <b>Full</b>—Neighboring routing devices are fully adjacent. These adjacencies appear in router link and network link advertisements.</li> <li>• <b>Init</b>—A hello packet has recently been sent by the neighbor. However, bidirectional communication has not yet been established with the neighbor. This state may occur, for example, because the routing device itself did not appear in the neighbor's hello packet.</li> <li>• <b>Loading</b>—Link-state request packets are sent to the neighbor to acquire more recent advertisements that have been discovered (but not yet received) in the <b>Exchange</b> state.</li> <li>• <b>2Way</b>—Communication between the two routing devices is bidirectional. This state has been ensured by the operation of the Hello Protocol. This is the most advanced state short of beginning adjacency establishment. The (backup) designated router is selected from the set of neighbors in state <b>2Way</b> or greater.</li> </ul> | All levels              |
| <b>ID</b>                             | Router ID of the neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | All levels              |
| <b>Pri</b>                            | Priority of the neighbor to become the designated router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | All levels              |

| <b>Link state retransmission list</b> | <p>Total number of link-state advertisements retransmitted. For <b>extensive</b> output only, the following information is also displayed:</p> <ul style="list-style-type: none"> <li>• <b>Type</b>—Type of link advertisement: <b>ASBR</b>, <b>Sum</b>, <b>Extern</b>, <b>Network</b>, <b>NSSA</b>, <b>OpaqueArea</b>, <b>Router</b>, or <b>Summary</b>.</li> <li>• <b>LSA ID</b>—LSA identifier included in the advertisement. An asterisk preceding the identifier marks database entries that originated from the local routing device.</li> <li>• <b>Adv rtr</b>—Address of the routing device that sent the advertisement.</li> <li>• <b>Seq</b>—Link sequence number of the advertisement.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>detail extensive</b> |

Table 353: show (ospf | ospf3) neighbor Output Fields (*continued*)

| Field Name              | Field Description                                                                                                                                                                                                                | Level of Output         |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>Neighbor-address</b> | (OSPFv3 only) If the neighbor uses virtual links, the <b>Neighbor-address</b> is the site-local, local, or global address. If the neighbor uses a physical interface, the <b>Neighbor-address</b> is an IPv6 link-local address. | <b>detail extensive</b> |
| <b>area</b>             | Area that the neighbor is in.                                                                                                                                                                                                    | <b>detail extensive</b> |
| <b>OSPF3-Intf-Index</b> | (OSPFv3 only) Displays the OSPFv3 interface index.                                                                                                                                                                               | <b>detail extensive</b> |
| <b>opt</b>              | Option bits received in the hello packets from the neighbor.                                                                                                                                                                     | <b>detail extensive</b> |
| <b>DR or DR-ID</b>      | Address of the designated router.                                                                                                                                                                                                | <b>detail extensive</b> |
| <b>BDR or BDR-ID</b>    | Address of the backup designated router.                                                                                                                                                                                         | <b>detail extensive</b> |
| <b>Up</b>               | Length of time since the neighbor came up.                                                                                                                                                                                       | <b>detail extensive</b> |
| <b>adjacent</b>         | Length of time since the adjacency with the neighbor was established.                                                                                                                                                            | <b>detail extensive</b> |

| <b>Output Fields</b>                            | <a href="#">Table 239</a> lists the output fields for the <b>show ospf overview</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 354: show ospf overview Output Fields

| Field name                       | Field Description                                                                                                                                                                        | Level of Output |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Instance</b>                  | OSPF routing instance.                                                                                                                                                                   | All levels      |
| <b>Router ID</b>                 | Router ID of the routing device.                                                                                                                                                         | All levels      |
| <b>Route table index</b>         | Route table index.                                                                                                                                                                       | All levels      |
| <b>Configured overload</b>       | Overload capability is enabled. If the overload timer is also configured, display the time that remains before it is set to expire. This field is not displayed after the timer expires. | All levels      |
| <b>Topology</b>                  | Topology identifier.                                                                                                                                                                     | All levels      |
| <b>Prefix export count</b>       | Number of prefixes exported into OSPF.                                                                                                                                                   | All levels      |
| <b>Full SPF runs</b>             | Number of complete Shortest Path First calculations.                                                                                                                                     | All levels      |
| <b>SPF delay</b>                 | Delay before performing consecutive Shortest Path First calculations.                                                                                                                    | All levels      |
| <b>SPF holddown</b>              | Delay before performing additional Shortest Path First (SPF) calculations after the maximum number of consecutive SPF calculations is reached.                                           | All levels      |
| <b>SPF rapid runs</b>            | Maximum number of Shortest Path First calculations that can be performed in succession before the hold-down timer begins.                                                                | All levels      |
| <b>LSA refresh time</b>          | Refresh period for link-state advertisement (in minutes).                                                                                                                                | All levels      |
| <b>Database protection state</b> | Current state of database protection.                                                                                                                                                    | All levels      |
| <b>Warning threshold</b>         | Threshold at which a warning message is logged (percentage of maximum LSA count).                                                                                                        | All levels      |
| <b>Non self-generated LSAs</b>   | Number of LSAs whose router ID is not equal to the local router ID: <b>Current</b> , <b>Warning</b> (threshold), and <b>Allowed</b> .                                                    | All levels      |
| <b>Ignore time</b>               | How long the database has been in the ignore state.                                                                                                                                      | All levels      |
| <b>Reset time</b>                | How long the database must stay out of the ignore or isolated state before it returns to normal operations.                                                                              | All levels      |
| <b>Ignore count</b>              | Number of times the database has been in the ignore state: <b>Current</b> and <b>Allowed</b> .                                                                                           | All levels      |
| <b>Restart</b>                   | Graceful restart capability: <b>enabled</b> or <b>disabled</b> .                                                                                                                         | All levels      |
| <b>Restart duration</b>          | Time period for complete reacquisition of OSPF neighbors.                                                                                                                                | All levels      |
| <b>Restart grace period</b>      | Time period for which the neighbors should consider the restarting routing device as part of the topology.                                                                               | All levels      |

Table 354: show ospf overview Output Fields (*continued*)

| Field name                    | Field Description                                                                                                                                    | Level of Output  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Graceful restart helper mode  | (OSPFv2) Standard graceful restart helper capability (based on RFC 3623): <b>enabled</b> or <b>disabled</b> .                                        | All levels       |
| Restart-signaling helper mode | (OSPFv2) Restart signaling-based graceful restart helper capability (based on RFC 4811, RFC 4812, and RFC 4813): <b>enabled</b> or <b>disabled</b> . | All levels       |
| Helper mode                   | (OSPFv3) Graceful restart helper capability: <b>enabled</b> or <b>disabled</b> .                                                                     | All levels       |
| Trace options                 | OSPF-specific trace options.                                                                                                                         | <b>extensive</b> |
| Trace file                    | Name of the file to receive the output of the tracing operation.                                                                                     | <b>extensive</b> |
| Area                          | Area number. Area 0.0.0.0 is the backbone area.                                                                                                      | All levels       |
| Stub type                     | Stub type of area: <b>Normal Stub</b> , <b>Not Stub</b> , or <b>Not so Stubby Stub</b> .                                                             | All levels       |
| Authentication Type           | Type of authentication: <b>None</b> , <b>Password</b> , or <b>MD5</b> .                                                                              | All levels       |
| Area border routers           | Number of area border routers.                                                                                                                       | All levels       |
| Neighbors                     | Number of autonomous system boundary routers.                                                                                                        | All levels       |

## Sample Output

### show ospf overview

```

user@host> show ospf overview
Instance: master
 Router ID: 10.255.245.6
 Route table index: 0
 Configured overload, expires in 118 seconds
 LSA refresh time: 50 minutes
Restart: Enabled
 Restart duration: 20 sec
 Restart grace period: 40 sec
 Helper mode: enabled
Area: 0.0.0.0
 Stub type: Not Stub
 Authentication Type: None
 Area border routers: 0, AS boundary routers: 0
Neighbors
 Up (in full state): 0
Topology: default (ID 0)
 Prefix export count: 0
 Full SPF runs: 1
 SPF delay: 0.200000 sec, SPF holddown: 5 sec, SPF rapid runs: 3

```

**show ospf overview (With Database Protection)**

```

user@host> show ospf overview
Instance: master
Router ID: 10.255.112.218
Route table index: 0
LSA refresh time: 50 minutes
Traffic engineering
Restart: Enabled
 Restart duration: 180 sec
 Restart grace period: 210 sec
 Graceful restart helper mode: Enabled
 Restart-signaling helper mode: Enabled
Database protection state: Normal
Warning threshold: 70 percent
Non self-generated LSAs: Current 582, Warning 700, Allowed 1000
Ignore time: 30, Reset time: 60
Ignore count: Current 0, Allowed 1
Area: 0.0.0.0
 Stub type: Not Stub
 Authentication Type: None
 Area border routers: 0, AS boundary routers: 0
 Neighbors
 Up (in full state): 160
Topology: default (ID 0)
Prefix export count: 0
Full SPF runs: 70
SPF delay: 0.200000 sec, SPF holddown: 5 sec, SPF rapid runs: 3
Backup SPF: Not Needed

```

**show ospf3 overview (With Database Protection)**

```

user@host> show ospf3 overview
Instance: master
Router ID: 10.255.112.128
Route table index: 0
LSA refresh time: 50 minutes
Database protection state: Normal
Warning threshold: 80 percent
Non self-generated LSAs: Current 3, Warning 8, Allowed 10
Ignore time: 30, Reset time: 60
Ignore count: Current 0, Allowed 2
Area: 0.0.0.0
 Stub type: Not Stub
 Area border routers: 0, AS boundary routers: 0
 Neighbors
 Up (in full state): 1
Topology: default (ID 0)
Prefix export count: 0
Full SPF runs: 7
SPF delay: 0.200000 sec, SPF holddown: 5 sec, SPF rapid runs: 3
Backup SPF: Not Needed

```

**show ospf overview extensive**

```

user@host> show ospf overview extensive
Instance: master
Router ID: 1.1.1.103
Route table index: 0
Full SPF runs: 13, SPF delay: 0.200000 sec
LSA refresh time: 50 minutes

```

```
Restart: Disabled
Trace options: lsa
Trace file: /var/log/ospf size 131072 files 10
Area: 0.0.0.0
 Stub type: Not Stub
 Authentication Type: None
 Area border routers: 0, AS boundary routers: 0
 Neighbors
 Up (in full state): 1
```

## show (ospf | ospf3) route

**List of Syntax**    [Syntax on page 4665](#)  
                          [Syntax \(EX Series Switch and QFX Series\) on page 4665](#)

**Syntax**    show (ospf | ospf3) route  
                  <brief | detail | extensive>  
                  <abr | asbr | extern | inter | intra>  
                  <destination>  
                  <instance (default | ipv4-multicast | *instance-name*)>  
                  <logical-system (default | ipv4-multicast | *logical-system-name*)>  
                  <network>  
                  <no-backup-coverage>  
                  <realm (ipv4-multicast | ipv4-unicast | ipv6-multicast)>  
                  <router>  
                  <topology (default | ipv4-multicast | *topology-name*)>  
                  <transit>

**Syntax (EX Series Switch and QFX Series)**    show (ospf | ospf3) route  
                  <brief | detail | extensive>  
                  <abr | asbr | extern | inter | intra>  
                  <destination>  
                  <instance *instance-name*>  
                  <network>  
                  <no-backup-coverage>  
                  <router>  
                  <topology (default | ipv4-multicast | *topology-name*)>  
                  <transit>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                                  Command introduced in Junos OS Release 9.0 for EX Series switches.  
                                  **topology** option introduced in Junos OS Release 9.0.  
                                  **realm** option introduced in Junos OS Release 9.2.  
                                  Command introduced in Junos OS Release 11.3 for the QFX Series.

**Description**    Display the entries in the Open Shortest Path First (OSPF) routing table.

**Options**    **none**—Display standard information about all entries in the OSPF routing table for all routing instances and all topologies.

**destination**—Display routes to the specified IP address (with optional destination prefix length).

**brief | detail | extensive**—(Optional) Display the specified level of output.

**abr**—(Optional) Display routes to area border routers.

**asbr**—(Optional) Display routes to autonomous system border routers.

**extern**—(Optional) Display external routes.

**inter**—(Optional) Display interarea routes.

**intra**—(Optional) Display intra-area routes.

**instance** (**default** | **ipv4-multicast** | *instance-name*)—(Optional) Display entries for the default routing instance, the IPv4 multicast routing instance, or for the specified routing instance.

**logical-system** (**default** | **ipv4-multicast** | *logical-system-name*)—(Optional) Perform this operation on the default logical system, the IPv4 multicast logical system, or on a particular logical system.

**network**—(Optional) Display routes to networks.

**no-backup-coverage**—(Optional) Display routes with no backup coverage.

**realm** (**ipv4-multicast** | **ipv4-unicast** | **ipv6-multicast**)—(OSPFv3 only) (Optional) Display entries in the routing table for the specified OSPFv3 realm, or address family. Use the **realm** option to specify an address family for OSPFv3 other than IPv6 unicast, which is the default.

**router**—(Optional) Display routes to all routers.

**topology** (**default** | **ipv4-multicast** | *topology-name*)—(OSPFv2 only) (Optional) Display routes for the default OSPF topology, IPv4 multicast topology, or for a particular topology.

**transit**—(Optional) (OSPFv3 only) Display OSPFv3 routes to pseudonodes.

**Required Privilege Level**

view

# RIP Feature Guide for QFX10000 Switches

# Overview

- [RIP Overview on page 4677](#)

## RIP Overview

---

RIP is an interior gateway protocol (IGP) that uses a distance-vector algorithm to determine the best route to a destination, using the hop count as the metric.

In a RIP network, each router's forwarding table is distributed among the nodes through the flooding of routing table information. Because topology changes are flooded throughout the network, every node maintains the same list of destinations. Packets are then routed to these destinations based on path-cost calculations done at each node in the network.

**NOTE:** In general, the term *RIP* refers to RIP version 1 and RIP version 2.

This topic contains the following sections:

- [Distance-Vector Routing Protocols on page 4677](#)
- [RIP Protocol Overview on page 4678](#)
- [RIP Packets on page 4679](#)
- [Maximizing Hop Count on page 4680](#)

- [Limitations of Unidirectional Connectivity on page 4681](#)

## Distance-Vector Routing Protocols

Distance-vector routing protocols transmit routing information that includes a distance vector, typically expressed as the number of hops to the destination. This information is flooded out all protocol-enabled interfaces at regular intervals (every 30 seconds in the case of RIP) to create a network map that is stored in each node's local topology database. [Figure 121](#) shows how distance-vector routing works.

**Figure 121: Distance-Vector Protocol**

In Figure 121, Routers A and B have RIP enabled on adjacent interfaces. Router A has known RIP neighbors Routers C, D, and E, which are 1, 2, and 3 hops away, respectively. Router B has known RIP neighbors Routers X, Y, and Z, which are 1, 2, and 3 hops away, respectively. Every 30 seconds, each router floods its entire routing table information out all RIP-enabled interfaces. In this case, flooding exchanges routing table information across the RIP link.

When Router A receives routing information from Router B, it adds 1 to the hop count to determine the new hop count. For example, Router X has a hop count of 1, but when Router A imports the route to X, the new hop count is 2. The imported route also includes information about where the route was learned, so that the original route is imported as a route to Router X through Router B with a hop count of 2.

When multiple routes to the same host are received, RIP uses the distance-vector algorithm to determine which path to import into the forwarding table. The route with the smallest hop count is imported. If there are multiple routes with the same hop count, all are imported into the forwarding table, and traffic is sent along the paths in round-robin fashion.

## RIP Protocol Overview

The RIP IGP uses the Bellman-Ford, or *distance-vector*, algorithm to determine the best route to a destination. RIP uses the hop count as the metric. RIP enables hosts and routers to exchange information for computing routes through an IP-based network. RIP is intended to be used as an IGP in reasonably homogeneous networks of moderate size.

The Junos<sup>®</sup> operating system (Junos OS) supports RIP versions 1 and 2.

**NOTE:** RIP is not supported for multipoint interfaces.

RIP version 1 packets contain the minimal information necessary to route packets through a network. However, this version of RIP does not support authentication or subnetting.

RIP uses User Datagram Protocol (UDP) port 520.

RIP has the following architectural limitations:

- The longest network path cannot exceed 15 hops (assuming that each network, or hop, has a cost of 1).
- RIP depends on counting to infinity to resolve certain unusual situations—When the network consists of several hundred routers, and when a routing loop has formed, the amount of time and network bandwidth required to resolve a next hop might be great.
- RIP uses only a fixed metric to select a route. Other IGPs use additional parameters, such as measured delay, reliability, and load.

## RIP Packets

RIP packets contain the following fields:

- Command—Indicates whether the packet is a request or response message. Request messages seek information for the router's routing table. Response messages are sent periodically and also when a request message is received. Periodic response messages are called *update messages*. Update messages contain the command and version fields and 25 destinations (by default), each of which includes the destination IP address and the metric to reach that destination.

**NOTE:** Beginning with Junos OS Release 11.1, three additional command field types are available to support RIP demand circuits. When you configure an interface for RIP demand circuits, the command field indicates whether the packet is an update request, update response, or update acknowledge message. Neighbor interfaces send updates on demand, not periodically. These command field types are only valid on interfaces configured for RIP demand circuits. For more detailed information, see *RIP Demand Circuits Overview*.

- Version number—Version of RIP that the originating router is running.
- Address family identifier—Address family used by the originating router. The family is always IP.
- Address—IP address included in the packet.
- Metric—Value of the metric advertised for the address.
- Mask—Mask associated with the IP address (RIP version 2 only).
- Next hop—IP address of the next-hop router (RIP version 2 only).

Routing information is exchanged in a RIP network by RIP request and RIP response packets. A router that has just booted can broadcast a RIP request on all RIP-enabled interfaces. Any routers running RIP on those links receive the request and respond by sending a RIP response packet immediately to the router. The response packet contains the routing table information required to build the local copy of the network topology map.

In the absence of RIP request packets, all RIP routers broadcast a RIP response packet every 30 seconds on all RIP-enabled interfaces. The RIP broadcast is the primary way in which topology information is flooded throughout the network.

Once a router learns about a particular destination through RIP, it starts a timer. Every time it receives a new response packet with information about the destination, the router resets the timer to zero. However, if the router receives no updates about a particular destination for 180 seconds, it removes the destination from its RIP routing table.

In addition to the regular transmission of RIP packets every 30 seconds, if a router detects a new neighbor or detects that an interface is unavailable, it generates a triggered update. The new routing information is immediately broadcast out all RIP-enabled interfaces, and the change is reflected in all subsequent RIP response packets.

## Maximizing Hop Count

The successful routing of traffic across a RIP network requires that every node in the network maintain the same view of the topology. Topology information is broadcast between RIP neighbors every 30 seconds. If Router A is many hops away from a new host, Router B, the route to B might take significant time to propagate through the network and be imported into Router A's routing table. If the two routers are 5 hops away from each other, Router A cannot import the route to Router B until 2.5 minutes after Router B is online (30 seconds per hop). For large numbers of hops, the delay becomes prohibitive. To help prevent this delay from growing arbitrarily large, RIP enforces a maximum hop count of 15 hops. Any prefix that is more than 15 hops away is treated as unreachable and assigned a hop count equal to infinity. This maximum hop count is called the *network diameter*.

## Split Horizon and Poison Reverse Efficiency Techniques

Because RIP functions by periodically flooding the entire routing table out to the network, it generates a lot of traffic. The split horizon and poison reverse techniques can help reduce the amount of network traffic originated by RIP hosts and make the transmission of routing information more efficient.

If a router receives a set of route advertisements on a particular interface, RIP determines that those advertisements do not need to be retransmitted out the same interface. This technique, known as *split horizon*, helps limit the amount of RIP routing traffic by eliminating information that other neighbors on that interface have already learned.

[Figure 122](#) shows an example of the split horizon technique.

Figure 122: Split Horizon Example

In [Figure 122](#), Router A advertises routes to Routers C, D, and E to Router B. In this example, Router A can reach Router C in 2 hops. When Router A advertises the route to Router B, Router B imports it as a route to Router C through Router A in 3 hops. If Router B then readvertised this route to Router A, Router A would import it as a route to Router C through Router B in 4 hops. However, the advertisement from Router B to Router A is unnecessary, because Router A can already reach the route in 2 hops. The split horizon technique helps reduce extra traffic by eliminating this type of route advertisement.

Similarly, the poison reverse technique helps to optimize the transmission of routing information and improve the time to reach network convergence. If Router A learns about unreachable routes through one of its interfaces, it advertises those routes as unreachable (hop count of 16) out the same interface. [Figure 123](#) shows an example of the poison reverse technique.

**Figure 123: Poison Reverse Example**

In [Figure 123](#), Router A learns through one of its interfaces that routes to Routers C, D, and E are unreachable. Router A readvertises those routes out the same interface as unreachable. The advertisement informs Router B that Routers C, D, and E are definitely not reachable through Router A.

## Limitations of Unidirectional Connectivity

Because RIP processes routing information based solely on the receipt of routing table updates, it cannot ensure bidirectional connectivity. As [Figure 124](#) shows, RIP networks are limited by their unidirectional connectivity.

**Figure 124: Limitations of Unidirectional Connectivity**

In [Figure 124](#), Routers A and D flood their routing table information to Router B. Because the path to Router E has the fewest hops when routed through Router A, that route is imported into Router B's forwarding table. However, suppose that Router A can transmit traffic but is not receiving traffic from Router B because of an unavailable link or invalid routing policy. If the only route to Router E is through Router A, any traffic destined for Router A is lost, because bidirectional connectivity was never established.

OSPF establishes bidirectional connectivity with a three-way handshake.

## Understanding Basic RIP Routing

---

RIP is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). By default, RIP does not advertise the subnets that are directly connected through the device's interfaces. For traffic to pass through a RIP network, you must create a routing policy to export these routes. Advertising only the direct routes propagates the routes to the immediately adjacent RIP-enabled router only. To propagate all routes through the entire RIP network, you must configure the routing policy to export the routes learned through RIP.

## Example: Configuring a Basic RIP Network

---

This example shows how to configure a basic RIP network.

- [Requirements on page 4685](#)
- [Overview on page 4685](#)
- [Configuration on page 4686](#)
- [Verification on page 4688](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, you configure a basic RIP network, create a RIP group called **rip-group**, and add the directly connected interfaces to the RIP group. Then you configure a routing policy to advertise direct routes using policy statement **advertise-routes-through-rip**.

By default, Junos OS does not advertise RIP routes, not even routes that are learned through RIP. To advertise RIP routes, you must configure and apply an export routing policy that advertises RIP-learned and direct routes.

In Junos OS, you do not need to configure the RIP version. RIP version 2 is used by default.

To use RIP on the device, you must configure RIP on all of the RIP interfaces within the network. [Figure 125](#) shows the topology used in this example.

**Figure 125: Sample RIP Network Topology**

“[CLI Quick Configuration](#)” on [page 4686](#) shows the configuration for all of the devices in [Figure 125](#). The section “[Step-by-Step Procedure](#)” on [page 4687](#) describes the steps on Device R1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter commit from configuration mode.

**Device R1**

```
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.1
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Device R2**

```
set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set interfaces lo0 unit 2 family inet address 192.168.2.2/32
set interfaces lo0 unit 2 family inet address 172.16.2.2/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.2
set protocols rip group rip-group neighbor fe-1/2/1.5
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Device R3**

```

set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a basic RIP network:

1. Configure the network interfaces.

This example shows multiple loopback interface addresses to simulate attached networks.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

```

```

user@R1# set lo0 unit 1 family inet address 172.16.0.1/32
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32

```

2. Create the RIP group and add the interface.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```

[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1

```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```

[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept

```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```

[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@R1# show interfaces
fe-1/2/0 {

```

```
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
 }
}
lo0 {
 unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
 }
}

user@R1# show protocols
rip {
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking the Routing Table on page 4688](#)
- [Looking at the Routes That Device R1 Is Advertising to Device R2 on page 4689](#)
- [Looking at the Routes That Device R1 Is Receiving from Device R2 on page 4689](#)
- [Verifying the RIP-Enabled Interfaces on page 4690](#)
- [Verifying the Exchange of RIP Messages on page 4690](#)
- [Verifying Reachability of All Hosts in the RIP Network on page 4691](#)

---

### Checking the Routing Table

**Purpose** Verify that the routing table is populated with the expected routes..

**Action** From operational mode, enter the **show route protocol rip** command.

```
user@R1> show route protocol rip
inet.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.4/30 *[RIP/100] 00:59:15, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
172.16.2.2/32 *[RIP/100] 02:52:48, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
172.16.3.3/32 *[RIP/100] 00:45:05, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.2.2/32 *[RIP/100] 02:52:48, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.3.3/32 *[RIP/100] 00:45:05, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
224.0.0.9/32 *[RIP/100] 00:45:09, metric 1
 MultiRecv

```

**Meaning** The output shows that the routes have been learned from Device R2 and Device R3.

If you were to delete the **from protocol rip** condition in the routing policy on Device R2, the remote routes from Device R3 would not be learned on Device R1.

### Looking at the Routes That Device R1 Is Advertising to Device R2

**Purpose** Verify that Device R1 is sending the expected routes.

**Action** From operational mode, enter the **show route advertising-protocol rip** command.

```

user@R1> show route advertising-protocol rip 10.0.0.1
inet.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.0.1/32 *[Direct/0] 05:18:26
 > via lo0.1
192.168.1.1/32 *[Direct/0] 05:18:25
 > via lo0.1

```

**Meaning** Device R1 is sending routes to its directly connected networks.

### Looking at the Routes That Device R1 Is Receiving from Device R2

**Purpose** Verify that Device R1 is receiving the expected routes.

**Action** From operational mode, enter the **show route receive-protocol rip** command.

```

user@R1> show route receive-protocol rip 10.0.0.2
inet.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.4/30 *[RIP/100] 02:31:22, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
172.16.2.2/32 *[RIP/100] 04:24:55, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
172.16.3.3/32 *[RIP/100] 02:17:12, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.2.2/32 *[RIP/100] 04:24:55, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.3.3/32 *[RIP/100] 02:17:12, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1

```

**Meaning** Device R1 is receiving from Device R2 all of Device R2's directly connected networks. Device R1 is also receiving from Device R2 all of Device R3's directly connected networks, which Device R2 learned from Device R3 through RIP.

### Verifying the RIP-Enabled Interfaces

**Purpose** Verify that all RIP-enabled Interfaces are available and active.

**Action** From operational mode, enter the **show rip neighbor** command.

```
user@R1> show rip neighbor
```

| Neighbor   | Local State | Source Address | Destination Address | Send Mode | Receive Mode | In Met |
|------------|-------------|----------------|---------------------|-----------|--------------|--------|
| fe-1/2/0.1 | Up          | 10.0.0.1       | 224.0.0.9           | mcast     | both         | 1      |

**Meaning** The output shows that the RIP-enabled interface on Device R1 is operational.

In general for this command, the output shows a list of the RIP neighbors that are configured on the device. Verify the following information:

- Each configured interface is present. Interfaces are listed in alphabetical order.
- Each configured interface is up. The state of the interface is listed in the **Local State** column. A state of **Up** indicates that the link is passing RIP traffic. A state of **Dn** indicates that the link is not passing RIP traffic. In a point-to-point link, this state generally means that either the end point is not configured for RIP or the link is unavailable.

### Verifying the Exchange of RIP Messages

**Purpose** Verify that RIP messages are being sent and received on all RIP-enabled interfaces.

**Action** From operational mode, enter the **show rip statistics** command.

```
user@R1> show rip statistics
RIPv2 info: port 520; holddown 120s.
 rts learned rts held down rqsts dropped resps dropped
 5 0 0 0

fe-1/2/0.1: 5 routes learned; 2 routes advertised; timeout 180s; update interval 30s
```

| Counter                 | Total | Last 5 min | Last minute |
|-------------------------|-------|------------|-------------|
| Updates Sent            | 2669  | 10         | 2           |
| Triggered Updates Sent  | 2     | 0          | 0           |
| Responses Sent          | 0     | 0          | 0           |
| Bad Messages            | 0     | 0          | 0           |
| RIPv1 Updates Received  | 0     | 0          | 0           |
| RIPv1 Bad Route Entries | 0     | 0          | 0           |
| RIPv1 Updates Ignored   | 0     | 0          | 0           |
| RIPv2 Updates Received  | 2675  | 11         | 2           |
| RIPv2 Bad Route Entries | 0     | 0          | 0           |
| RIPv2 Updates Ignored   | 0     | 0          | 0           |
| Authentication Failures | 0     | 0          | 0           |
| RIP Requests Received   | 0     | 0          | 0           |

|                      |   |   |   |
|----------------------|---|---|---|
| RIP Requests Ignored | 0 | 0 | 0 |
| none                 | 0 | 0 | 0 |

**Meaning** The output shows the number of RIP routes learned. It also shows the number of RIP updates sent and received on the RIP-enabled interfaces. Verify the following information:

- The number of RIP routes learned matches the number of expected routes learned. Subnets learned by direct connectivity through an outgoing interface are not listed as RIP routes.
- RIP updates are being sent on each RIP-enabled interface. If no updates are being sent, the routing policy might not be configured to export routes.
- RIP updates are being received on each RIP-enabled interface. If no updates are being received, the routing policy might not be configured to export routes on the host connected to that subnet. The lack of updates might also indicate an authentication error.

### Verifying Reachability of All Hosts in the RIP Network

**Purpose** Use the **traceroute** command on each loopback address in the network to verify that all hosts in the RIP network are reachable from each Juniper Networks device.

**Action** From operational mode, enter the **traceroute** command.

```
user@R1> traceroute 192.168.3.3
traceroute to 192.168.3.3 (192.168.3.3), 30 hops max, 40 byte packets
 1 10.0.0.2 (10.0.0.2) 1.094 ms 1.028 ms 0.957 ms
 2 192.168.3.3 (192.168.3.3) 1.344 ms 2.245 ms 2.125 ms
```

**Meaning** Each numbered row in the output indicates a routing hop in the path to the host. The three-time increments indicate the round-trip time (RTT) between the device and the hop for each traceroute packet.

To ensure that the RIP network is healthy, verify the following information:

- The final hop in the list is the host you want to reach.
- The number of expected hops to the host matches the number of hops in the traceroute output. The appearance of more hops than expected in the output indicates that a network segment is probably unreachable. It might also indicate that the incoming or outgoing metric on one or more hosts has been set unexpectedly.

## Understanding RIP Authentication

---

RIPv2 provides authentication support so that RIP links can require authentication keys (passwords) before they become active. Authentication provides an additional layer of security on the network beyond the other security features. By default, this authentication is disabled.

Authentication keys can be specified in either plain-text or MD5 form. Authentication requires all routers within the RIP network or subnetwork to have the same authentication type and key (password) configured.

This type of authentication is not supported on RIPv1 networks.

## Example: Configuring Route Authentication for RIP

---

This example shows how to configure authentication for a RIP network.

- [Requirements on page 4694](#)
- [Overview on page 4694](#)
- [Configuration on page 4694](#)
- [Verification on page 4697](#)

## Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

You can configure the router to authenticate RIP route queries. By default, authentication is disabled. You can use one of the following authentication methods:

- Simple authentication—Uses a text password that is included in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.
- MD5 authentication—Creates an encoded checksum that is included in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet's MD5 checksum.

This example shows MD5 authentication.

Figure 126 shows the topology used in this example.

**Figure 126: RIP Authentication Network Topology**

"CLI Quick Configuration" on page 4694 shows the configuration for all of the devices in Figure 126. The section "Step-by-Step Procedure" on page 4695 describes the steps on Device R1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device R1**

```

set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.1
set protocols rip authentication-type md5
set protocols rip authentication-key "9ONLRBhreK87dsM8i.5FAAtM8XxNb"
set protocols rip traceoptions file rip-authentication-messages
set protocols rip traceoptions flag auth
set protocols rip traceoptions flag packets

```

```

set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Device R2**

```

set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set interfaces lo0 unit 2 family inet address 192.168.2.2/32

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure RIP authentication:

1. Configure the network interfaces.

This example shows multiple loopback interface addresses to simulate attached networks.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

user@R1# set lo0 unit 1 family inet address 172.16.0.1/32

```

```
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32
```

2. Create the RIP group and add the interface.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```
[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1
```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept
```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip
```

5. Require MD5 authentication for RIP route queries received on an interface.

The passwords must match on neighboring RIP routers. If the password does not match, the packet is rejected. The password can be from 1 through 16 contiguous characters long and can include any ASCII strings.

Do not enter the password as shown here. The password shown here is the encrypted password that is displayed in the configuration after the actual password is already configured.

```
[edit protocols rip]
user@R1# set authentication-type md5
user@R1# set authentication-key "9ONLRBhreK87dsM8i.5FAtm8XxNb"
```

6. Configure tracing operations to track authentication.

```
[edit protocols rip traceoptions]
user@R1# set file rip-authentication-messages
user@R1# set flag auth
user@R1# set flag packets
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R1# show interfaces
fe-1/2/0 {
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
}
lo0 {
```

```

unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
}

user@R1# show protocols
rip {
 traceoptions {
 file rip-authentication-messages;
 flag auth;
 flag packets;
 }
 authentication-type md5;
 authentication-key "9ONLRBhreK87dsM8i.5FAtM8XxNb"; ## SECRET-DATA
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking for Authentication Failures on page 4697](#)
- [Verifying That MD5 Authentication Is Enabled in RIP Update Packets on page 4698](#)

### Checking for Authentication Failures

**Purpose** Verify that there are no authentication failures.

**Action** From operational mode, enter the **show rip statistics** command.

```

user@R1> show rip statistics
RIPv2 info: port 520; holddown 120s.
 rts learned rts held down rqsts dropped resps dropped
 5 0 0 0

fe-1/2/0.1: 5 routes learned; 2 routes advertised; timeout 180s; update interval
30s
Counter Total Last 5 min Last minute

Updates Sent 2669 10 2
Triggered Updates Sent 2 0 0

```

|                         |      |    |   |
|-------------------------|------|----|---|
| Responses Sent          | 0    | 0  | 0 |
| Bad Messages            | 0    | 0  | 0 |
| RIPv1 Updates Received  | 0    | 0  | 0 |
| RIPv1 Bad Route Entries | 0    | 0  | 0 |
| RIPv1 Updates Ignored   | 0    | 0  | 0 |
| RIPv2 Updates Received  | 2675 | 11 | 2 |
| RIPv2 Bad Route Entries | 0    | 0  | 0 |
| RIPv2 Updates Ignored   | 0    | 0  | 0 |
| Authentication Failures | 0    | 0  | 0 |
| RIP Requests Received   | 0    | 0  | 0 |
| RIP Requests Ignored    | 0    | 0  | 0 |
| none                    | 0    | 0  | 0 |

**Meaning** The output shows that there are no authentication failures.

### Verifying That MD5 Authentication Is Enabled in RIP Update Packets

**Purpose** Use tracing operations to verify that MD5 authentication is enabled in RIP updates.

**Action** From operational mode, enter the **show log** command.

```
user@R1> show log rip-authentication-messages | match md5
Feb 15 15:45:13.969462 sending msg 0xb9a8c04, 3 rtes (needs MD5)
Feb 15 15:45:43.229867 sending msg 0xb9a8c04, 3 rtes (needs MD5)
Feb 15 15:46:13.174410 sending msg 0xb9a8c04, 3 rtes (needs MD5)
Feb 15 15:46:42.716566 sending msg 0xb9a8c04, 3 rtes (needs MD5)
Feb 15 15:47:11.425076 sending msg 0xb9a8c04, 3 rtes (needs MD5)
...
```

**Meaning** The **(needs MD5)** output shows that all route updates require MD5 authentication.

## Enabling Authentication with Plain-Text Passwords (CLI Procedure)

To configure authentication that requires a plain-text password to be included in the transmitted packet, enable simple authentication by performing these steps on all RIP devices in the network:

1. Navigate to the top of the configuration hierarchy.
2. Perform the configuration tasks described in [Table 357](#).
3. If you are finished configuring the router, commit the configuration.

**Table 357: Configuring Simple RIP Authentication**

| Task                                                         | CLI Configuration Editor                                                       |
|--------------------------------------------------------------|--------------------------------------------------------------------------------|

## Example: Configuring BFD for RIP

- [Understanding BFD for RIP on page 4701](#)
- [Example: Configuring BFD for RIP on page 4702](#)

### Understanding BFD for RIP

---

The Bidirectional Forwarding Detection (BFD) Protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply after a specified interval. BFD works with a wide variety of network environments and topologies. BFD failure detection times are shorter than RIP detection times, providing faster reaction times to various kinds of failures in the network. Instead of waiting for the routing protocol neighbor timeout, BFD provides rapid detection of link failures. BFD timers are adaptive and can be adjusted to be more or less aggressive. For example, a timer can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the one configured.

BFD enables quick failover between a primary and a secondary routed path. The protocol tests the operational status of the interface multiple times per second. BFD provides for configuration timers and thresholds for failure detection. For example, if the minimum interval is set for 50 milliseconds and the threshold uses the default value of three missed messages, a failure is detected on an interface within 200 milliseconds of the failure.

Intervening devices (for example, an Ethernet LAN switch) hide link-layer failures from routing protocol peers, such as when two routers are connected by way of a LAN switch, where the local interface status remains up even when a physical fault happens on the remote link. Link-layer failure detection times vary, depending on the physical media and the Layer 2 encapsulation. BFD can provide fast failure detection times for all media types, encapsulations, topologies, and routing protocols.

To enable BFD for RIP, both sides of the connection must receive an update message from the peer. By default, RIP does not export any routes. Therefore, you must enable update messages to be sent by configuring an export policy for routes before a BFD session is triggered.

Documentation**

- [Example: Configuring BFD for RIP on page 4702](#)

## Example: Configuring BFD for RIP

---

This example shows how to configure Bidirectional Forwarding Detection (BFD) for a RIP network.

- [Requirements on page 4702](#)
- [Overview on page 4702](#)
- [Configuration on page 4704](#)
- [Verification on page 4706](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

To enable failure detection, include the **bfd-liveness-detection** statement:

```
bfd-liveness-detection {
 detection-time {
 threshold milliseconds;
 }
 minimum-interval milliseconds;
 minimum-receive-interval milliseconds;
 multiplier number;
 no-adaptation;
 transmit-interval {
 threshold milliseconds;
 minimum-interval milliseconds;
 }
 version (1 | automatic);
}
```

Optionally, you can specify the threshold for the adaptation of the detection time by including the **threshold** statement. When the BFD session detection time adapts to a value equal to or greater than the threshold, a single trap and a system log message are sent.

To specify the minimum transmit and receive interval for failure detection, include the **minimum-interval** statement. This value represents the minimum interval at which the local routing device transmits hello packets as well as the minimum interval at which the routing device expects to receive a reply from a neighbor with which it has established a BFD session. You can configure a value in the range from 1 through 255,000 milliseconds. This examples sets a minimum interval of 600 milliseconds.

**NOTE:** BFD is an intensive protocol that consumes system resources. Specifying a minimum interval for BFD of less than 100 ms for Routing Engine-based sessions and 10 ms for distributed BFD sessions can cause undesired BFD flapping.

Depending on your network environment, these additional recommendations might apply:

- For large-scale network deployments with a large number of BFD sessions, specify a minimum interval of 300 ms for Routing Engine-based sessions and 100 ms for distributed BFD sessions.
- For very large-scale network deployments with a large number of BFD sessions, contact Juniper Networks customer support for more information.
- For BFD sessions to remain up during a Routing Engine switchover event when nonstop active routing (NSR) is configured, specify a minimum interval of 2500 ms for Routing Engine-based sessions. For distributed BFD sessions with nonstop active routing configured, the minimum interval recommendations are unchanged and depend only on your network deployment.

You can optionally specify the minimum transmit and receive intervals separately.

To specify only the minimum receive interval for failure detection, include the **minimum-receive-interval** statement. This value represents the minimum interval at which the local routing device expects to receive a reply from a neighbor with which it has established a BFD session. You can configure a value in the range from 1 through 255,000 milliseconds.

To specify only the minimum transmit interval for failure detection, include the **transmit-interval minimum-interval** statement. This value represents the minimum interval at which the local routing device transmits hello packets to the neighbor with which it has established a BFD session. You can configure a value in the range from 1 through 255,000 milliseconds.

To specify the number of hello packets not received by a neighbor that causes the originating interface to be declared down, include the **multiplier** statement. The default is 3, and you can configure a value in the range from 1 through 255.

To specify the threshold for detecting the adaptation of the transmit interval, include the **transmit-interval threshold** statement. The threshold value must be greater than the transmit interval.

To specify the BFD version used for detection, include the **version** statement. The default is to have the version detected automatically.

You can trace BFD operations by including the **traceoptions** statement at the **[edit protocols bfd]** hierarchy level.

In Junos OS Release 9.0 and later, you can configure BFD sessions not to adapt to changing network conditions. To disable BFD adaptation, include the **no-adaptation** statement. We recommend that you not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

Figure 127 shows the topology used in this example.

Figure 127: RIP BFD Network Topology

"CLI Quick Configuration" on page 4704 shows the configuration for all of the devices in Figure 127. The section "Step-by-Step Procedure" on page 4705 describes the steps on Device R1.

## Configuration

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

```

set protocols rip group rip-group neighbor fe-1/2/0.6
set protocols rip group rip-group bfd-liveness-detection minimum-interval 600
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a BFD for a RIP network:

1. Configure the network interfaces.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

```

2. Create the RIP group and add the interface.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```

[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1

```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```

[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept

```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```

[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip

```

5. Enable BFD.

```

[edit protocols rip group rip-group]
user@R1# set bfd-liveness-detection minimum-interval 600

```

6. Configure tracing operations to track BFD messages.

```

[edit protocols bfd traceoptions]
user@R1# set file bfd-trace
user@R1# set flag all

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@R1# show interfaces
fe-1/2/0 {

```

```
unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
}

user@R1# show protocols
bfd {
 traceoptions {
 file bfd-trace;
 flag all;
 }
}
rip {
 group rip-group {
 export advertise-routes-through-rip;
 bfd-liveness-detection {
 minimum-interval 600;
 }
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying That the BFD Sessions Are Up on page 4706](#)
- [Checking the BFD Trace File on page 4707](#)

---

### Verifying That the BFD Sessions Are Up

---

**Purpose** Make sure that the BFD sessions are operating.

**Action** From operational mode, enter the **show bfd session** command.

```
user@R1> show bfd session
```

| Address  | State | Interface  | Detect Time | Transmit Interval | Multiplier |
|----------|-------|------------|-------------|-------------------|------------|
| 10.0.0.2 | Up    | fe-1/2/0.1 | 1.800       | 0.600             | 3          |

1 sessions, 1 clients  
Cumulative transmit rate 1.7 pps, cumulative receive rate 1.7 pps

**Meaning** The output shows that there are no authentication failures.

### Checking the BFD Trace File

**Purpose** Use tracing operations to verify that BFD packets are being exchanged.

**Action** From operational mode, enter the **show log** command.

```
user@R1> show log bfd-trace
Feb 16 10:26:32 PPM Trace: BFD periodic xmit to 10.0.0.2 (IFL 124, rtbl 53,
single-hop port)
Feb 16 10:26:32 Received Downstream TraceMsg (24) len 86:
Feb 16 10:26:32 IfIndex (3) len 4: 0
Feb 16 10:26:32 Protocol (1) len 1: BFD
Feb 16 10:26:32 Data (9) len 61: (hex) 42 46 44 20 70 61 63 6b 65 74 20 66 72
6f 6d 20 31 30 2e
Feb 16 10:26:32 PPM Trace: BFD packet from 10.0.0.1 (IFL 73, rtbl 56, ttl 255)
absorbed
Feb 16 10:26:32 Received Downstream TraceMsg (24) len 60:
Feb 16 10:26:32 IfIndex (3) len 4: 0
Feb 16 10:26:32 Protocol (1) len 1: BFD
Feb 16 10:26:32 Data (9) len 35: (hex) 42 46 44 20 70 65 72 69 6f 64 69 63 20
78 6d 69 74 20 6f
...
```

**Meaning** The output shows the normal functioning of BFD.

## Understanding BFD Authentication for RIP

---

BFD enables rapid detection of communication failures between adjacent systems. By default, authentication for BFD sessions is disabled. However, when running BFD over Network Layer protocols, the risk of service attacks can be significant. We strongly recommend using authentication if you are running BFD over multiple hops or through insecure tunnels. Beginning with Junos OS Release 9.6, Junos OS supports authentication for BFD sessions running over RIP. BFD authentication is only supported in the domestic image and is not available in the export image.

You authenticate BFD sessions by specifying an authentication algorithm and keychain, and then associating that configuration information with a security authentication keychain using the keychain name.

The following sections describe the supported authentication algorithms, security keychains, and the level of authentication that can be configured:

- [BFD Authentication Algorithms on page 4709](#)
- [Security Authentication Keychains on page 4710](#)
- [Strict Versus Loose Authentication on page 4710](#)

## BFD Authentication Algorithms

Junos OS supports the following algorithms for BFD authentication:

- **simple-password**—Plain-text password. One to 16 bytes of plain text are used to authenticate the BFD session. One or more passwords can be configured. This method is the least secure and should be used only when BFD sessions are not subject to packet interception.
- **keyed-md5**—Keyed Message Digest 5 hash algorithm for sessions with transmit and receive intervals greater than 100 ms. To authenticate the BFD session, keyed MD5 uses one or more secret keys (generated by the algorithm) and a sequence number

that is updated periodically. With this method, packets are accepted at the receiving end of the session if one of the keys matches and the sequence number is greater than or equal to the last sequence number received. Although more secure than a simple password, this method is vulnerable to replay attacks. Increasing the rate at which the sequence number is updated can reduce this risk.

- **meticulous-keyed-md5**—Meticulous keyed Message Digest 5 hash algorithm. This method works in the same manner as keyed MD5, but the sequence number is updated with every packet. Although more secure than keyed MD5 and simple passwords, this method might take additional time to authenticate the session.
- **keyed-sha-1**—Keyed Secure Hash Algorithm I for sessions with transmit and receive intervals greater than 100 ms. To authenticate the BFD session, keyed SHA uses one or more secret keys (generated by the algorithm) and a sequence number that is updated periodically. The key is not carried within the packets. With this method, packets are accepted at the receiving end of the session if one of the keys matches and the sequence number is greater than the last sequence number received.
- **meticulous-keyed-sha-1**—Meticulous keyed Secure Hash Algorithm I. This method works in the same manner as keyed SHA, but the sequence number is updated with every packet. Although more secure than keyed SHA and simple passwords, this method might take additional time to authenticate the session.

**NOTE:** Nonstop active routing is not supported with meticulous-keyed-md5 and meticulous-keyed-sha-1 authentication algorithms. BFD sessions using these algorithms might go down after a switchover.

---

## Security Authentication Keychains

The security authentication keychain defines the authentication attributes used for authentication key updates. When the security authentication keychain is configured and associated with a protocol through the keychain name, authentication key updates can occur without interrupting routing and signaling protocols.

The authentication keychain contains one or more keychains. Each keychain contains one or more keys. Each key holds the secret data and the time at which the key becomes valid. The algorithm and keychain must be configured on both ends of the BFD session, and they must match. Any mismatch in configuration prevents the BFD session from being created.

BFD allows multiple clients per session, and each client can have its own keychain and algorithm defined. To avoid confusion, we recommend specifying only one security authentication keychain.

## Strict Versus Loose Authentication

By default, strict authentication is enabled and authentication is checked at both ends of each BFD session. Optionally, to smooth migration from nonauthenticated sessions to authenticated sessions, you can configure *loose checking*. When loose checking is

configured, packets are accepted without authentication being checked at each end of the session. This feature is intended for transitional periods only.

## Example: Configuring BFD Authentication for RIP

This example shows how to configure Bidirectional Forwarding Detection (BFD) authentication for a RIP network.

- [Requirements on page 4711](#)
- [Overview on page 4711](#)
- [Configuration on page 4712](#)
- [Verification on page 4715](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

The devices must be running Junos OS Release 9.6 or later.

### Overview

Only three steps are needed to configure authentication on a BFD session:

1. Specify the BFD authentication algorithm for the RIP protocol.
2. Associate the authentication keychain with the RIP protocol.
3. Configure the related security authentication keychain.

[Figure 128](#) shows the topology used in this example.

**Figure 128: RIP BFD Authentication Network Topology**

"CLI Quick Configuration" on page 4712 shows the configuration for all of the devices in Figure 128. The section "Step-by-Step Procedure" on page 4713 describes the steps on Device R1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**Device R1**

```
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set protocols bfd traceoptions file bfd-trace
set protocols bfd traceoptions flag all
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.1
set protocols rip group rip-group bfd-liveness-detection minimum-interval 600
set protocols rip group rip-group bfd-liveness-detection authentication key-chain bfd-rip
set protocols rip group rip-group bfd-liveness-detection authentication algorithm
 keyed-md5
set protocols rip group rip-group bfd-liveness-detection authentication loose-check
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
set security authentication-key-chains key-chain bfd-rip key 53 secret
 "9d1V2aZGi.fzDiORSeXxDikqmT"
set security authentication-key-chains key-chain bfd-rip key 53 start-time
 "2012-2-16.12:00:00 -0800"
```

**Device R2**

```
set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.2
set protocols rip group rip-group neighbor fe-1/2/1.5
set protocols rip group rip-group bfd-liveness-detection minimum-interval 600
set protocols rip group rip-group bfd-liveness-detection authentication key-chain bfd-rip
set protocols rip group rip-group bfd-liveness-detection authentication algorithm
 keyed-md5
set protocols rip group rip-group bfd-liveness-detection authentication loose-check
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
set security authentication-key-chains key-chain bfd-rip key 53 secret
 "9d1V2aZGi.fzDiORSeXxDikqmT"
set security authentication-key-chains key-chain bfd-rip key 53 start-time
 "2012-2-16.12:00:00 -0800"
```

**Device R3**

```
set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set protocols rip group rip-group bfd-liveness-detection minimum-interval 600
```

```

set protocols rip group rip-group bfd-liveness-detection authentication key-chain bfd-rip

 keyed-md5
set protocols rip group rip-group bfd-liveness-detection authentication loose-check
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
set security authentication-key-chains key-chain bfd-rip key 53 secret
 "9d1V2aZGi.fzDiORSeXxDikqmT"
set security authentication-key-chains key-chain bfd-rip key 53 start-time
 "2012-2-16.12:00:00 -0800"

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a BFD authentication:

1. Configure the network interfaces.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

```

2. Create the RIP group and add the interface.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```

[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1

```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```

[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept

```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```

[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip

```

5. Enable BFD.

```

[edit protocols rip group rip-group]
user@R1# set bfd-liveness-detection minimum-interval 600

```

6. Specify the algorithm (keyed-md5, keyed-sha-1, meticulous-keyed-md5, meticulous-keyed-sha-1, or simple-password) to use.

**NOTE:** Nonstop active routing is not supported with meticulous-keyed-md5 and meticulous-keyed-sha-1 authentication algorithms. BFD sessions using these algorithms might go down after a switchover.

```
[edit protocols rip group rip-group]
user@R1# set bfd-liveness-detection authentication algorithm keyed-md5
```

7. Specify the keychain to be used to associate BFD sessions on RIP with the unique security authentication keychain attributes.

The keychain you specify must match a keychain name configured at the **[edit security authentication key-chains]** hierarchy level.

The algorithm and keychain must be configured on both ends of the BFD session, and they must match. Any mismatch in configuration prevents the BFD session from being created.

```
[edit protocols rip group rip-group]
user@R1# set bfd-liveness-detection authentication key-chain bfd-rip
```

8. (Optional) Specify loose authentication checking if you are transitioning from nonauthenticated sessions to authenticated sessions.

```
[edit protocols rip group rip-group]
user@R1# set bfd-liveness-detection authentication loose-check
```

9. Specify the unique security authentication information for BFD sessions:

- The matching keychain name as specified in Step 7.
- At least one key, a unique integer between 0 and 63. Creating multiple keys allows multiple clients to use the BFD session.
- The secret data used to allow access to the session.
- The time at which the authentication key becomes active, in the format *yyyy-mm-dd.hh:mm:ss*.

```
[edit security authentication-key-chains key-chain bfd-rip]
user@R1# set key 53 secret "9d1V2aZGi.fzDiORSeXxDikqmT"
user@R1# set key 53 start-time "2012-2-16.12:00:00 -0800"
```

10. Configure tracing operations to track BFD authentication.

```
[edit protocols bfd traceoptions]
user@R1# set file bfd-trace
user@R1# set flag all
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show security** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R1# show interfaces
```

```

fe-1/2/0 {
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
}

user@R1# show protocols
bfd {
 traceoptions {
 file bfd-trace;
 flag all;
 }
}
rip {
 group rip-group {
 export advertise-routes-through-rip;
 bfd-liveness-detection {
 minimum-interval 600;
 }
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

user@R1# show security
authentication-key-chains {
 key-chain bfd-rip {
 key 53 {
 secret "9d1V2aZGi.fzDiORSeXxDikqmT"; ## SECRET-DATA
 start-time "2012-2-16.12:00:00 -0800";
 }
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying That the BFD Sessions Are Authenticated on page 4715](#)
- [Viewing Extensive Information About the BFD Authentication on page 4716](#)
- [Checking the BFD Trace File on page 4716](#)

### Verifying That the BFD Sessions Are Authenticated

**Purpose** Make sure that the BFD sessions are authenticated.

**Action** From operational mode, enter the **show bfd session detail** command.

```
user@R1> show bfd session detail
```

| Address  | State | Interface  | Detect Time | Transmit Interval | Multiplier |
|----------|-------|------------|-------------|-------------------|------------|
| 10.0.0.2 | Up    | fe-1/2/0.1 | 1.800       | 0.600             | 3          |

Client RIP, TX interval 0.600, RX interval 0.600, **Authenticate**  
 Session up time 01:39:34  
 Local diagnostic None, remote diagnostic None  
 Remote state Up, version 1  
 Logical system 6, routing table index 53

1 sessions, 1 clients  
 Cumulative transmit rate 1.7 pps, cumulative receive rate 1.7 pps

**Meaning** **Authenticate** is displayed to indicate that BFD authentication is configured.

### Viewing Extensive Information About the BFD Authentication

**Purpose** View the keychain name, the authentication algorithm and mode for each client in the session, and the BFD authentication configuration status.

**Action** From operational mode, enter the **show bfd session extensive** command.

```
user@R1> show bfd session extensive
```

| Address  | State | Interface  | Detect Time | Transmit Interval | Multiplier |
|----------|-------|------------|-------------|-------------------|------------|
| 10.0.0.2 | Up    | fe-1/2/0.1 | 1.800       | 0.600             | 3          |

Client RIP, TX interval 0.600, RX interval 0.600, **Authenticate**  
**keychain bfd-rip, algo keyed-md5, mode loose**  
 Session up time 01:46:29  
 Local diagnostic None, remote diagnostic None  
 Remote state Up, version 1  
 Logical system 6, routing table index 53  
 Min async interval 0.600, min slow interval 1.000  
 Adaptive async TX interval 0.600, RX interval 0.600  
 Local min TX interval 0.600, minimum RX interval 0.600, multiplier 3  
 Remote min TX interval 0.600, min RX interval 0.600, multiplier 3  
 Local discriminator 225, remote discriminator 226  
 Echo mode disabled/inactive  
**Authentication enabled/active, keychain bfd-rip, algo keyed-md5, mode loose**  
 Session ID: 0x300501

1 sessions, 1 clients  
 Cumulative transmit rate 1.7 pps, cumulative receive rate 1.7 pps

**Meaning** The output shows the keychain name, the authentication algorithm and mode for the client in the session, and the BFD authentication configuration status.

### Checking the BFD Trace File

**Purpose** Use tracing operations to verify that BFD packets are being exchanged.

**Action** From operational mode, enter the **show log** command.

```
user@R1> show log bfd-trace
```

```
Feb 16 10:26:32 PPM Trace: BFD periodic xmit to 10.0.0.2 (IFL 124, rtbl 53,
single-hop port)
Feb 16 10:26:32 Received Downstream TraceMsg (24) len 86:
Feb 16 10:26:32 IfIndex (3) len 4: 0

- [Example: Applying Policies to RIP Routes Imported from Neighbors on page 4719](#)

## Understanding RIP Import Policy

---

The default RIP import policy is to accept all received RIP routes that pass a sanity check. To filter routes being imported by the local routing device from its neighbors, include the **import** statement, and list the names of one or more policies to be evaluated. If you specify more than one policy, they are evaluated in order (first to last) and the first matching policy is applied to the route. If no match is found, the local routing device does not import any routes.

## Example: Applying Policies to RIP Routes Imported from Neighbors

---

This example shows how to configure an import policy in a RIP network.

- [Requirements on page 4719](#)
- [Overview on page 4719](#)
- [Configuration on page 4720](#)
- [Verification on page 4723](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, Device R1 has an import policy that accepts the 10/8 and 192.168/16 RIP routes and rejects all other RIP routes. This means that the 172.16/16 RIP routes are excluded from Device R1's routing table.

An export policy is also shown because an export policy is required as part of the minimum configuration for RIP.

Figure 129 shows the topology used in this example.

**Figure 129: RIP Import Policy Network Topology**

"CLI Quick Configuration" on page 4720 shows the configuration for all of the devices in Figure 129. The section "Step-by-Step Procedure" on page 4721 describes the steps on Device R1.

## Configuration

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CLI Quick Configuration</b> | To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the <b>[edit]</b> hierarchy level, and then enter <b>commit</b> from configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

```

set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Device R3**

```

set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a RIP import policy:

1. Configure the network interfaces.

This example shows multiple loopback interface addresses to simulate attached networks.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

user@R1# set lo0 unit 1 family inet address 172.16.0.1/32
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32

```

2. Create the RIP group and add the interface.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled.

You do not need to enable RIP on the loopback interface.

```

[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1

```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```

[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept

```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```

[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip

```

5. Configure the import policy.

```

[edit policy-options policy-statement rip-import]

```

```
user@R1# set term 1 from protocol rip
user@R1# set term 1 from route-filter 10.0.0.0/8 orlonger
user@R1# set term 1 from route-filter 192.168.0.0/16 orlonger
user@R1# set term 1 then accept
user@R1# set term 2 then reject
```

6. Apply the import policy.

```
[edit protocols rip]
user@R1# set import rip-import
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R1# show interfaces
fe-1/2/0 {
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
}
lo0 {
 unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
 }
}

user@R1# show protocols
rip {
 import rip-import;
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}
policy-statement rip-import {
 term 1 {
 from {
 protocol rip;
 route-filter 10.0.0.0/8 orlonger;
 route-filter 192.168.0.0/16 orlonger;
 }
 }
}
```

```

 then accept;
 }
 term 2 {
 then reject;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Looking at the Routes That Device R2 Is Advertising to Device R1 on page 4723](#)
- [Looking at the Routes That Device R1 Is Receiving from Device R2 on page 4723](#)
- [Checking the Routing Table on page 4724](#)
- [Testing the Import Policy on page 4724](#)

### [Looking at the Routes That Device R2 Is Advertising to Device R1](#)

**Purpose** Verify that Device R2 is sending the expected routes.

**Action** From operational mode, enter the **show route advertising-protocol rip 10.0.0.2** command.

```
user@R2> show route advertising-protocol rip 10.0.0.2
```

```
inet.0: 11 destinations, 11 routes (11 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.4/30 *[Direct/0] 2d 01:17:44
 > via fe-1/2/0.5
172.16.2.2/32 *[Direct/0] 2d 04:09:52
 > via lo0.2
172.16.3.3/32 *[RIP/100] 23:40:02, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5
192.168.2.2/32 *[Direct/0] 2d 04:09:52
 > via lo0.2
192.168.3.3/32 *[RIP/100] 23:40:02, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5

```

**Meaning** Device R2 is sending 172.16/16 routes to Device R1.

### [Looking at the Routes That Device R1 Is Receiving from Device R2](#)

**Purpose** Verify that Device R1 is receiving the expected routes.

**Action** From operational mode, enter the **show route receive-protocol rip 10.0.0.2** command.

```
user@R1> show route receive-protocol rip 10.0.0.2
```

```
inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.4/30 *[RIP/100] 01:06:03, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.2.2/32 *[RIP/100] 01:06:03, metric 2, tag 0

```

```
192.168.3.3/32 > to 10.0.0.2 via fe-1/2/0.1
 *[RIP/100] 01:06:03, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
```

**Meaning** The output shows that the 172.16/16 routes are excluded.

---

### Checking the Routing Table

**Purpose** Verify that the routing table is populated with the expected routes.

**Action** From operational mode, enter the **show route protocol rip** command.

```
user@R1> show route protocol rip

inet.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.4/30 *[RIP/100] 00:54:34, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.2.2/32 *[RIP/100] 00:54:34, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
192.168.3.3/32 *[RIP/100] 00:54:34, metric 3, tag 0
 > to 10.0.0.2 via fe-1/2/0.1
224.0.0.9/32 *[RIP/100] 00:49:00, metric 1
 MultiRecv
```

**Meaning** The output shows that the routes have been learned from Device R2 and Device R3.

If you delete or deactivate the import policy, the routing table contains the 172.16/16 routes.

---

### Testing the Import Policy

**Purpose** By using the **test policy** command, monitor the number of rejected prefixes.

**Action** From operational mode, enter the **test policy rip-import 172.16/16** command.

```
user@R1> test policy rip-import 172.16/16
Policy rip-import: 0 prefix accepted, 1 prefix rejected
```

**Meaning** The output shows that the policy rejected one prefix.

### Understanding Traffic Control with Metrics in a RIP Network

To tune a RIP network and control traffic flowing through the network, you increase or decrease the cost of the paths through the network. RIP provides two ways to modify the path cost: an incoming metric and an outgoing metric, which are each set to 1 by default. These metrics are attributes that manually specify the cost of any route advertised through a host. By increasing or decreasing the metrics—and thus the cost—of links throughout the network, you can control packet transmission across the network.

The incoming metric modifies the cost of an individual segment when a route across the segment is imported into the routing table. For example, if you set the incoming metric on the segment to 3, the individual segment cost along the link is changed from 1 to 3. The increased cost affects all route calculations through that link. Other routes that were previously excluded because of a high hop count might now be selected into the router's forwarding table.

The outgoing metric modifies the path cost for all the routes advertised out a particular interface. Unlike the incoming metric, the outgoing metric modifies the routes that other routers are learning and thereby controls the way they send traffic.

If an exported route was learned from a member of the same RIP group, the metric associated with that route is the normal RIP metric. For example, a RIP route with a metric of 5 learned from a neighbor configured with an incoming metric of 2 is advertised with a combined metric of 7 when advertised to neighbors in the same group. However, if this route was learned from a RIP neighbor in a different group or from a different protocol, the route is advertised with the metric value configured in the outgoing metric for that group.

You might want to increase the metric of routes to decrease the likelihood that a particular route is selected and installed in the routing table. This process is sometimes referred to

as *route poisoning*. Some reasons that you might want to poison a route are that the route is relatively expensive to use, or it has relatively low bandwidth.

A route with a higher metric than another route becomes the active route only when the lower-metric route becomes unavailable. In this way, the higher-metric route serves as a backup path.

One way to increase the metric of imported routes is to configure an import policy. Another way is to include the **metric-in** statement in the RIP neighbor configuration. One way to increase the metric of export routes is to configure an export policy. Another way is to include the **metric-out** statement in the RIP neighbor configuration.

## Example: Controlling Traffic in a RIP Network with an Incoming Metric

---

This example shows how to control traffic with an incoming metric.

- [Requirements on page 4726](#)
- [Overview on page 4726](#)
- [Configuration on page 4727](#)
- [Verification on page 4727](#)

### Requirements

Before you begin, define RIP groups, and add interfaces to the groups. Then configure a routing policy to export directly connected routes and routes learned through the RIP routing exchanges. See “[Example: Configuring a Basic RIP Network](#)” on page 4685.

### Overview

In this example, routes to Router D are received by Router A across both of its RIP-enabled interfaces as shown in [Figure 130](#). Because the route through Router B and the route through Router C have the same number of hops, both routes are imported into the forwarding table. However, because the T3 link from Router B to Router D has a higher bandwidth than the T1 link from Router C to Router D, you want traffic to flow from Router A through Router B to Router D.

Figure 130: Controlling Traffic in a RIP Network with the Incoming Metric

To force this flow, you can modify the route metrics as they are imported into Router A's routing table. By setting the incoming metric on the interface from Router A to Router C, you modify the metric on all routes received through that interface. Setting the incoming route metric on Router A changes only the routes in Router A's routing table, and affects only how Router A sends traffic to Router D. Router D's route selection is based on its own routing table, which, by default, includes no adjusted metric values.

In the example, Router C receives a route advertisement from Router D and readvertises the route to Router A. When Router A receives the route, it applies the incoming metric on the interface. Instead of incrementing the metric by 1 (the default), Router A increments it by 3 (the configured incoming metric), giving the route from Router A to Router D through Router C a total path metric of 4. Because the route through Router B has a metric of 2, it becomes the preferred route for all traffic from Router A to Router D.

This example uses a RIP group called **alpha 1** on interface **g3-0/0/0**.

## Configuration

### Step-by-Step Procedure

To control traffic with an incoming metric:

1. Enable RIP on the interface.  

```
[edit protocols rip]
user@host# set group alpha1 neighbor ge-0/0/0
```
2. Set the incoming metric.  

```
[edit protocols rip]
user@host# set metric-in 3
```
3. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify that the configuration is working properly, enter the **show route protocols rip** command.

## Example: Controlling Traffic in a RIP Network with an Outgoing Metric

This example shows how to control traffic with an outgoing metric.

- [Requirements on page 4728](#)
- [Overview on page 4728](#)
- [Configuration on page 4729](#)
- [Verification on page 4729](#)

### Requirements

Before you begin:

- Define RIP groups, and add interfaces to the groups. Then configure a routing policy to export directly connected routes and routes learned through RIP routing exchanges. See [“Example: Configuring a Basic RIP Network” on page 4685](#).
- Control traffic with an incoming metric. See [“Example: Controlling Traffic in a RIP Network with an Incoming Metric” on page 4726](#).

### Overview

In this example, each route from Router A to Router D has two hops as shown in [Figure 131](#). However, because the link from Router A to Router B in the RIP group has a higher bandwidth than the link from Router A to Router C in RIP group Alpha 1, you want traffic from Router D to Router A to flow through Router B. To control the way Router D sends traffic to Router A, you can alter the routes that Router D receives by configuring the outgoing metric on Router A's interfaces in the Alpha 1 RIP group.

**Figure 131: Controlling Traffic in a RIP Network with the Outgoing Metric**

If the outgoing metric for the Alpha 1 RIP group—the A-to-C link—is changed to 3, Router D calculates the total path metric from Router A through Router C as 4. In contrast, the unchanged default total path metric to Router A through Router B in the RIP group is 2. The fact that Router A's interfaces belong to two different RIP groups allows you to configure two different outgoing metrics on its interfaces, because you configure path metrics at the group level.

By configuring the outgoing metric, you control the way Router A sends traffic to Router D. By configuring the outgoing metric on the same router, you control the way Router D sends traffic to Router A.

This example uses an outgoing metric of 3.

## Configuration

### Step-by-Step Procedure

To control traffic with an outgoing metric:

1. Set the outgoing metric.  

```
[edit protocols rip group alpha1]
user@host# set metric-out 3
```
2. If you are done configuring the device, commit the configuration.  

```
[edit]
user@host# commit
```

## Verification

To verify that the configuration is working properly, enter the **show protocols rip** command.

---

## Example: Configuring the Metric Value Added to Imported RIP Routes

This example shows how to change the default metric to be added to incoming routes to control the route selection process.

- [Requirements on page 4729](#)
- [Overview on page 4730](#)
- [Configuration on page 4730](#)
- [Verification on page 4733](#)

## Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

Normally, when multiple routes are available, RIP selects the route with the lowest hop count. Changing the default metric enables you to control the route selection process such that a route with a higher hop count can be preferred over of a route with a lower hop count.

Figure 132 shows the topology used in this example.

**Figure 132: RIP Incoming Metrics Network Topology**

Device R1 has two potential paths to reach 172.16.2.2/32. The default behavior is to send traffic out the 0.1/30 interface facing Device R2. Suppose, though, that the path through Device R3 is less expensive to use or has higher bandwidth links. This example shows how to use the **metric-in** statement to ensure that Device R1 uses the path through Device R3 to reach 172.16.2.2/32. “[CLI Quick Configuration](#)” on page 4730 shows the configuration for all of the devices in Figure 132. The section “[Step-by-Step Procedure](#)” on page 4731 describes the steps on Device R1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device R1**

```

set interfaces fe-1/2/0 unit 1 description to-R2
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces ge-1/2/1 unit 10 description to-R3
set interfaces ge-1/2/1 unit 10 family inet address 10.0.0.10/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32

set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set protocols rip group rip-group neighbor ge-1/2/1.9
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a RIP metrics:

1. Configure the network interfaces.

```

[edit interfaces]
user@R1# set fe-1/2/0 unit 1 description to-R2
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

user@R1# set ge-1/2/1 unit 10 description to-R3
user@R1# set ge-1/2/1 unit 10 family inet address 10.0.0.10/30

user@R1# set lo0 unit 1 family inet address 172.16.0.1/32
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32

```

2. Create the RIP groups and add the interfaces.

To configure RIP in Junos OS, you must configure one or more groups that contain the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

For the interface that is facing Device R2, the **metric-in 4** setting causes this route to be less likely to be chosen as the active route.

```

[edit protocols rip]
user@R1# set group primary neighbor ge-1/2/1.10
user@R1# set group secondary neighbor fe-1/2/0.1 metric-in 4

```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept
```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip]
user@R1# set group primary export advertise-routes-through-rip
user@R1# set group secondary export advertise-routes-through-rip
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R1# show interfaces
fe-1/2/0 {
 unit 1 {
 description to-R2;
 family inet {
 address 10.0.0.1/30;
 }
 }
}
ge-1/2/1 {
 unit 10 {
 description to-R3;
 family inet {
 address 10.0.0.10/30;
 }
 }
}
lo0 {
 unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
 }
}

user@R1# show protocols
rip {
 group primary {
 export advertise-routes-through-rip;
 neighbor ge-1/2/1.10;
 }
 group secondary {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1 {
 metric-in 4;
 }
 }
}
```

```

}
user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying That the Expected Route Is Active on page 4733](#)
- [Removing the metric-in Statement on page 4733](#)

### Verifying That the Expected Route Is Active

**Purpose** Make sure that to reach 172.16.2.2/32, Device R1 uses the path through Device R3.

**Action** From operational mode, enter the **show route 172.16.2.2** command.

```

user@R1> show route 172.16.2.2
inet.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.2.2/32 *[RIP/100] 00:15:46, metric 3, tag 0
 > to 10.0.0.9 via ge-1/2/1.10

```

**Meaning** The **to 10.0.0.9 via ge-1/2/1.10** output shows that Device R1 uses the path through Device R3 to reach 172.16.2.2/32. The metric for this route is 3.

### Removing the metric-in Statement

**Purpose** Delete or deactivate the **metric-in** statement to see what happens to the 172.16.2.2/32 route.

**Action** 1. From configuration mode, deactivate the **metric-in** statement.

```

[edit protocols rip group secondary neighbor fe-1/2/0.1]
user@R1# deactivate metric-in
user@R1# commit

```

2. From operational mode, enter the **show route 172.16.2.2** command.

```

user@R1> show route 172.16.2.2
inet.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.2.2/32 *[RIP/100] 00:00:06, metric 2, tag 0
 > to 10.0.0.2 via fe-1/2/0.1

```

**Meaning** The **to 10.0.0.2 via fe-1/2/0.1** output shows that Device R1 uses the path through Device R2 to reach 172.16.2.2/32. The metric for this route is 2.

## Understanding the Sending and Receiving of RIPv1 and RIPv2 Packets

---

RIP version 1 (RIPv1) and RIP version 2 (RIPv2) can run simultaneously. This might make sense when you are migrating a RIPv1 network to a RIPv2 network. This also allows interoperation with a device that supports RIPv1 but not RIPv2.

By default, when RIP is enabled on an interface, Junos OS receives both RIPv1 and RIPv2 packets and sends only RIPv2 packets. You can configure this behavior by including the [send](#) and [receive](#) statements in the RIP configuration.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

By default, when RIP is enabled on an interface, Junos OS receives both RIPv1 and RIPv2 packets and sends only RIPv2 packets.

Figure 133 shows the topology used in this example.

**Figure 133: Sending and Receiving RIPv1 and RIPv2 Packets Network Topology**

In this example, Device R1 is configured to receive only RIPv2 packets.

“CLI Quick Configuration” on page 4736 shows the configuration for all of the devices in Figure 133. The section “Step-by-Step Procedure” on page 4737 describes the steps on Device R1.

## Configuration

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Device R2</b>               | <pre> set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30 set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30 set interfaces lo0 unit 2 family inet address 192.168.2.2/32 set interfaces lo0 unit 2 family inet address 172.16.2.2/32 set protocols rip group rip-group export advertise-routes-through-rip set protocols rip group rip-group neighbor fe-1/2/0.2 set protocols rip group rip-group neighbor fe-1/2/1.5 set policy-options policy-statement advertise-routes-through-rip term 1 from protocol direct set policy-options policy-statement advertise-routes-through-rip term 1 from protocol rip </pre> |

```
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Device R3**

```
set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure a RIP packet versions that can be received:

1. Configure the network interfaces.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30
```

```
user@R1# set lo0 unit 1 family inet address 172.16.0.1/32
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32
```

2. Create the RIP groups and add the interfaces.

To configure RIP in Junos OS, you must configure one or more groups that contain the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

For the interface that is facing Device R2, the **receive version-2** setting causes this interface to accept only RIPv2 packets.

```
[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1 receive version-2
```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept
```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@R1# show interfaces
fe-1/2/0 {
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
}
lo0 {
 unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
 }
}

user@R1# show protocols
rip {
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1 {
 receive version-2;
 }
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying That the Receive Mode Is Set to RIPv2 Only

**Purpose** Make sure that the interfacing Device R2 is configured to receive only RIPv2 packets, instead of both RIPv1 and RIPv2 packets.

**Action** From operational mode, enter the **show rip neighbor** command.

```
user@R1> show rip neighbor
```

| Neighbor   | Local State | Source Address | Destination Address | Send Mode | Receive Mode | In Met |
|------------|-------------|----------------|---------------------|-----------|--------------|--------|
| fe-1/2/0.1 | Up          | 10.0.0.1       | 224.0.0.9           | mcast     | v2 only      | 1      |

**Meaning** In the output, the **Receive Mode** field displays **v2 only**. The default **Receive Mode** is **both**.

## Example: Redistributing Routes Among RIP Instances

- [Understanding Route Redistribution Among RIP instances on page 4741](#)
- [Example: Redistributing Routes Between Two RIP Instances on page 4742](#)

### Understanding Route Redistribution Among RIP instances

---

You can redistribute routes among RIP processes. Another way to say this is to export RIP routes from one RIP instance to other RIP instances.

In Junos OS, route redistribution among routing instances is accomplished by using routing table groups, also called RIB groups. Routing table groups allow you to import and export routes from a protocol within one routing table into another routing table.

**NOTE:** In contrast, the policy-based import and export functions allow you import and export routes between different protocols within the same routing table.

Consider the following partial example:

```
protocols {
 rip {
 rib-group inet-to-voice;
 }
}
routing-instances {
 voice {
 protocols {
 rip {
 rib-group voice-to-inet;
 }
 }
 }
}
routing-options {
 rib-groups {
 inet-to-voice {
 import-rib [inet.0 voice.inet.0];
 }
 }
}
```

```
 }
 voice-to-inet {
 import-rib [voice.inet.0 inet.0];
 }
}
```

The way to read the **import-rib** statement is as follows. Take the routes from the protocol (RIP, in this case), and import them into the primary (or local) routing table and also into any other routing tables listed after this. The primary routing table is the routing table where the routing table group is being used. That would be either **inet.0** if used in the main routing instance or **voice.inet.0** if used within the routing instance. In the **inet-to-voice** routing table group, **inet.0** is listed first because this routing table group is used in the main routing instance. In the **voice-to-inet** routing table group, **voice.inet.0** is listed first because this routing table group is used in the voice routing instance.

---

## Example: Redistributing Routes Between Two RIP Instances

---

This example shows how to configure a RIP routing instance and control the redistribution of RIP routes between the routing instance and the master instance.

- [Requirements on page 4742](#)
- [Overview on page 4742](#)
- [Configuration on page 4743](#)
- [Verification on page 4746](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

When you create a routing instance called **voice**, Junos OS creates a routing table called **voice.inet.0**. The example shows how to install routes learned through the master RIP instance into the **voice.inet.0** routing table. The example also shows how to install routes learned through the voice routing instance into **inet.0**. This is done by configuring routing table groups. RIP routes are installed into each routing table that belongs to a routing table group.

[Figure 134](#) shows the topology used in this example.

**Figure 134: Redistributing Routes Between RIP Instances Network Topology**

“CLI Quick Configuration” on page 4743 shows the configuration for all of the devices in Figure 134. The section “Step-by-Step Procedure” on page 4744 describes the steps on Device R2.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**Device R1**

```

set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols rip group to-R2 export advertise-routes-through-rip
set protocols rip group to-R2 neighbor fe-1/2/0.1
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Device R2**

```

set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set interfaces lo0 unit 2 family inet address 192.168.2.2/32
set interfaces lo0 unit 2 family inet address 172.16.2.2/32
set protocols rip rib-group inet-to-voice
set protocols rip group to-R3 export advertise-routes-through-rip
set protocols rip group to-R3 neighbor fe-1/2/1.5
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
set routing-instances voice protocols rip group to-R1 export advertise-routes-through-rip
set routing-instances voice interface fe-1/2/0.2
set routing-instances voice protocols rip rib-group voice-to-inet
set routing-instances voice protocols rip group to-R1 neighbor fe-1/2/0.2
set routing-options rib-groups inet-to-voice import-rib inet.0
set routing-options rib-groups inet-to-voice import-rib voice.inet.0
set routing-options rib-groups voice-to-inet import-rib voice.inet.0
set routing-options rib-groups voice-to-inet import-rib inet.0

```

**Device R3**

```
set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group to-R2 export advertise-routes-through-rip
set protocols rip group to-R2 neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To redistribute RIP routes between routing instances:

1. Configure the network interfaces.

```
[edit interfaces]
user@R2# set fe-1/2/0 unit 2 family inet address 10.0.0.2/30

user@R2# set fe-1/2/1 unit 5 family inet address 10.0.0.5/30

user@R2# set lo0 unit 2 family inet address 192.168.2.2/32
user@R2# set lo0 unit 2 family inet address 172.16.2.2/32
```

2. Create the routing instance, and add one or more interfaces to the routing instance.

```
[edit routing-instances voice]
user@R2# set interface fe-1/2/0.2
```

3. Create the RIP groups and add the interfaces.

```
[edit protocols rip group to-R3]
user@R2# set neighbor fe-1/2/1.5

[edit routing-instances voice protocols rip group to-R1]
user@R2# set neighbor fe-1/2/0.2
```

4. Create the routing table groups.

```
[edit routing-options rib-groups]
user@R2# set inet-to-voice import-rib inet.0
user@R2# set inet-to-voice import-rib voice.inet.0

user@R2# set voice-to-inet import-rib voice.inet.0
user@R2# set voice-to-inet import-rib inet.0
```

5. Apply the routing table groups.

```
[edit protocols rip]
user@R2# set rib-group inet-to-voice

[edit routing-instances voice protocols rip]
user@R2# set rib-group voice-to-inet
```

6. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R2# set from protocol direct
user@R2# set from protocol rip
user@R2# set then accept
```

7. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip group to-R3]
user@R2# set export advertise-routes-through-rip
```

```
[edit routing-instances voice protocols rip group to-R1]
user@R2# set export advertise-routes-through-rip
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R2# show interfaces
fe-1/2/0 {
 unit 2 {
 family inet {
 address 10.0.0.2/30;
 }
 }
}
fe-1/2/1 {
 unit 5 {
 family inet {
 address 10.0.0.5/30;
 }
 }
}
lo0 {
 unit 2 {
 family inet {
 address 192.168.2.2/32;
 address 172.16.2.2/32;
 }
 }
}
}

user@R2# show protocols
rip {
 rib-group inet-to-voice;
 group to-R3 {
 export advertise-routes-through-rip;
 neighbor fe-1/2/1.5;
 }
}

user@R2# show policy-options
policy-statement advertise-routes-through-rip {
```

```
term 1 {
 from protocol [direct rip];
 then accept;
}
}

user@R2# show routing-instances
voice {
 interface fe-1/2/0.2;
 protocols {
 rip {
 rib-group voice-to-inet;
 group to-R1 {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.2;
 }
 }
 }
}

user@R2# show routing-options
rib-groups {
 inet-to-voice {
 import-rib [inet.0 voice.inet.0];
 }
 voice-to-inet {
 import-rib [voice.inet.0 inet.0];
 }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Checking the Routing Tables

---

**Purpose** Make sure that the routing tables contain the expected routes.

**Action** From operational mode, enter the **show route protocol rip** command.

```
user@R2> show route protocol rip
inet.0: 9 destinations, 9 routes (9 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

172.16.0.1/32 *[RIP/100] 01:58:14, metric 2, tag 0
 > to 10.0.0.1 via fe-1/2/0.2
172.16.3.3/32 *[RIP/100] 02:06:03, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5
192.168.1.1/32 *[RIP/100] 01:58:14, metric 2, tag 0
 > to 10.0.0.1 via fe-1/2/0.2
192.168.3.3/32 *[RIP/100] 02:06:03, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5
224.0.0.9/32 *[RIP/100] 01:44:13, metric 1
 MultiRecv

voice.inet.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
```

+ = Active Route, - = Last Active, \* = Both

```
172.16.0.1/32 *[RIP/100] 02:06:03, metric 2, tag 0
 > to 10.0.0.1 via fe-1/2/0.2
172.16.3.3/32 *[RIP/100] 01:58:14, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5
192.168.1.1/32 *[RIP/100] 02:06:03, metric 2, tag 0
 > to 10.0.0.1 via fe-1/2/0.2
192.168.3.3/32 *[RIP/100] 01:58:14, metric 2, tag 0
 > to 10.0.0.6 via fe-1/2/0.5
224.0.0.9/32 *[RIP/100] 01:44:13, metric 1
 MultiRecv
```

**Meaning** The output shows that both routing tables contain all of the RIP routes.

## Example: Configuring RIP Timers

- [Understanding RIP Timers on page 4749](#)
- [Example: Configuring RIP Timers on page 4750](#)

### Understanding RIP Timers

---

RIP uses several timers to regulate its operation.

The update interval is the interval at which routes that are learned by RIP are advertised to neighbors. This timer controls the interval between routing updates. The update interval is set to 30 seconds, by default, with a small random amount of time added when the timer is reset. This added time prevents congestion that can occur if all routing devices update their neighbors simultaneously.

To configure the update time interval, include the **update-interval** statement:

```
update-interval seconds;
```

**seconds** can be a value from 10 through 60.

You can set a route timeout interval. If a route is not refreshed after being installed in the routing table by the specified time interval, the route is marked as invalid and is removed from the routing table after the hold-down period expires.

To configure the route timeout for RIP, include the **route-timeout** statement:

```
route-timeout seconds;
```

**seconds** can be a value from 30 through 360. The default value is 180 seconds.

RIP routes expire when either a route timeout limit is met or a route metric reaches infinity, and the route is no longer valid. However, the expired route is retained in the routing table for a specified period so that neighbors can be notified that the route has been dropped. This time period is set by configuring the hold-down timer. Upon expiration of the hold-down timer, the route is removed from the routing table.

To configure the hold-down timer for RIP, include the **holddown** statement:

```
holddown seconds;
```

**seconds** can be a value from 10 through 180. The default value is 120 seconds.

**NOTE:** In Junos OS Release 11.1 and later, a retransmission timer is available for RIP demand circuits.

Generally, we recommend against changing the RIP timers, unless the effects of a change are well understood. The route timeout should be at least three times the update interval. Normally, the default values are best left in effect for standard operations.

## Example: Configuring RIP Timers

This example shows how to configure the RIP update interval and how to monitor the impact of the change.

- [Requirements on page 4750](#)
- [Overview on page 4750](#)
- [Configuration on page 4751](#)
- [Verification on page 4753](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, Device R2 has an update interval of 60 seconds for its neighbor, Device R1, and an update interval of 10 seconds for its neighbor, Device R3.

This example is not necessarily practical, but it is shown for demonstration purposes. Generally, we recommend against changing the RIP timers, unless the effects of a change are well understood. Normally, the default values are best left in effect for standard operations.

An export policy is also shown because an export policy is required as part of the minimum configuration for RIP.

[Figure 135](#) shows the topology used in this example.

Figure 135: RIP Timers Network Topology

"CLI Quick Configuration" on page 4751 shows the configuration for all of the devices in Figure 135. The section "Step-by-Step Procedure" on page 4752 describes the steps on Device R2.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device R1**

```

set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.1
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Device R2**

```

set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set interfaces lo0 unit 2 family inet address 192.168.2.2/32
set interfaces lo0 unit 2 family inet address 172.16.2.2/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.2 update-interval 60
set protocols rip group rip-group neighbor fe-1/2/1.5 update-interval 10
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept

```

**Device R3**

```

set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip

```

```
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the RIP update interval:

1. Configure the network interfaces.

This example shows multiple loopback interface addresses to simulate attached networks.

```
[edit interfaces]
```

```
user@R2# set fe-1/2/0 unit 2 family inet address 10.0.0.2/30
```

```
user@R2# set fe-1/2/1 unit 5 family inet address 10.0.0.5/30
```

```
user@R2# set lo0 unit 2 family inet address 192.168.2.2/32
```

```
user@R2# set lo0 unit 2 family inet address 172.16.2.2/32
```

2. Configure different update intervals for the two RIP neighbors.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```
[edit protocols rip group rip-group]
```

```
user@R2# set neighbor fe-1/2/0.2 update-interval 60
```

```
user@R2# set neighbor fe-1/2/1.5 update-interval 10
```

3. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
```

```
user@R2# set from protocol direct
```

```
user@R2# set from protocol rip
```

```
user@R2# set then accept
```

4. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip group rip-group]
```

```
user@R2# set export advertise-routes-through-rip
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@R2# show interfaces
```

```
fe-1/2/0 {
 unit 2 {
 family inet {
 address 10.0.0.2/30;
 }
 }
}
```

```

fe-1/2/1 {
 unit 5 {
 family inet {
 address 10.0.0.5/30;
 }
 }
}
lo0 {
 unit 2 {
 family inet {
 address 192.168.2.2/32;
 address 172.16.2.2/32;
 }
 }
}

user@R2# show protocols
rip {
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.2 {
 update-interval 60;
 }
 neighbor fe-1/2/1.5 {
 update-interval 10;
 }
 }
}

user@R2# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking the RIP Updates Sent by Device R2 on page 4753](#)
- [Checking the RIP Updates Received by Device R2 on page 4754](#)
- [Checking the RIP Updates Received by Device R3 on page 4755](#)

### Checking the RIP Updates Sent by Device R2

**Purpose** Make sure that the RIP update packets are sent at the expected interval.

**Action** From operational mode, enter the **show rip statistics** command.

```

user@R2> show rip statistics
RIPv2 info: port 520; holddown 120s.
 rts learned rts held down rqsts dropped resps dropped

```

```

4 2 0 0

fe-1/2/0.2: 2 routes learned; 5 routes advertised; timeout 180s; update interval
60s

```

| Counter                 | Total | Last 5 min | Last minute |

| Authentication Failures | 0     | 0          | 0           |
| RIP Requests Received   | 0     | 0          | 0           |
| RIP Requests Ignored    | 0     | 0          | 0           |
| none                    | 0     | 0          | 0           |

```

fe-1/2/1.5: 2 routes learned; 5 routes advertised; timeout 180s; update interval
10s

```

| Counter                 | Total | Last 5 min | Last minute |
|-------------------------|-------|------------|-------------|
| -----                   | ----- | -----      | -----       |
| Updates Sent            | 734   | 32         | 6           |
| Triggered Updates Sent  | 0     | 0          | 0           |
| Responses Sent          | 0     | 0          | 0           |
| Bad Messages            | 0     | 0          | 0           |
| RIPv1 Updates Received  | 0     | 0          | 0           |
| RIPv1 Bad Route Entries | 0     | 0          | 0           |
| RIPv1 Updates Ignored   | 0     | 0          | 0           |
| RIPv2 Updates Received  | 245   | 11         | 2           |
| RIPv2 Bad Route Entries | 0     | 0          | 0           |
| RIPv2 Updates Ignored   | 0     | 0          | 0           |
| Authentication Failures | 0     | 0          | 0           |
| RIP Requests Received   | 0     | 0          | 0           |
| RIP Requests Ignored    | 0     | 0          | 0           |
| none                    | 0     | 0          | 0           |

**Meaning** The **update interval** field shows that the interval is 60 seconds for Neighbor R1 and 10 seconds for Neighbor R3. The **Updates Sent** field shows that Device R2 is sending updates to Device R1 at roughly 1/6 of the rate that it is sending updates to Device R3.

### Checking the RIP Updates Received by Device R2

**Purpose** Make sure that the RIP update packets are sent at the expected interval.

**Action** From operational mode, enter the **show rip statistics** command.

```

user@R1> show rip statistics
RIPv2 info: port 520; holddown 120s.
 rts learned rts held down rqsts dropped resps dropped
 5 0 0 0

```

```

fe-1/2/0.1: 5 routes learned; 2 routes advertised; timeout 180s; update interval
30s

```

| Counter | Total | Last 5 min | Last minute |

## Example: Tracing RIP Protocol Traffic

- [Understanding RIP Trace Operations on page 4757](#)
- [Example: Tracing RIP Protocol Traffic on page 4758](#)

### Understanding RIP Trace Operations

---

You can trace various types of RIP protocol traffic to help debug RIP protocol issues.

To trace RIP protocol traffic, include the **traceoptions** statement at the **[edit protocols rip]** hierarchy level:

```
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
```

You can specify the following RIP protocol-specific trace options using the **flag** statement:

- **auth**—RIP authentication
- **error**—RIP error packets
- **expiration**—RIP route expiration processing
- **holddown**—RIP hold-down processing
- **nsr-synchronization**—Nonstop active routing synchronization events
- **packets**—All RIP packets
- **request**—RIP information packets
- **trigger**—RIP triggered updates
- **update**—RIP update packets

You can optionally specify one or more of the following **flag** modifiers:

- **detail**—Detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

**NOTE:** Use the **detail** flag modifier with caution as this may cause the CPU to become very busy.

Global tracing options are inherited from the configuration set by the **traceoptions** statement at the **[edit routing-options]** hierarchy level. You can override the following global trace options for the RIP protocol using the **traceoptions flag** statement included at the **[edit protocols rip]** hierarchy level:

- **all**—All tracing operations
- **general**—All normal operations and routing table changes (a combination of the normal and route trace operations)
- **normal**—Normal events
- **policy**—Policy processing
- **route**—Routing information
- **state**—State transitions
- **task**—Routing protocol task processing
- **timer**—Routing protocol timer processing

**NOTE:** Use the **trace** flag **all** with caution because this may cause the CPU to become very busy.

## Example: Tracing RIP Protocol Traffic

This example shows how to trace RIP protocol operations.

- [Requirements on page 4758](#)
- [Overview on page 4758](#)
- [Configuration on page 4759](#)
- [Verification on page 4761](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

In this example, Device R1 is set to trace routing information updates.

An export policy is also shown because an export policy is required as part of the minimum configuration for RIP.

Figure 136 shows the topology used in this example.

**Figure 136: RIP Trace Operations Network Topology**

"CLI Quick Configuration" on page 4759 shows the configuration for all of the devices in Figure 136. The section "Step-by-Step Procedure" on page 4760 describes the steps on Device R1.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Device R1

```
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces lo0 unit 1 family inet address 172.16.0.1/32
set interfaces lo0 unit 1 family inet address 192.168.1.1/32
set protocols rip traceoptions file rip-trace-file
set protocols rip traceoptions flag route
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.1
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

#### Device R2

```
set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/2/1 unit 5 family inet address 10.0.0.5/30
set interfaces lo0 unit 2 family inet address 192.168.2.2/32
set interfaces lo0 unit 2 family inet address 172.16.2.2/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.2
set protocols rip group rip-group neighbor fe-1/2/1.5
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

#### Device R3

```
set interfaces fe-1/2/0 unit 6 family inet address 10.0.0.6/30
set interfaces lo0 unit 3 family inet address 192.168.3.3/32
```

```
set interfaces lo0 unit 3 family inet address 172.16.3.3/32
set protocols rip group rip-group export advertise-routes-through-rip
set protocols rip group rip-group neighbor fe-1/2/0.6
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 direct
set policy-options policy-statement advertise-routes-through-rip term 1 from protocol
 rip
set policy-options policy-statement advertise-routes-through-rip term 1 then accept
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the RIP update interval:

1. Configure the network interfaces.

This example shows multiple loopback interface addresses to simulate attached networks.

```
[edit interfaces]
user@R1# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30
```

```
user@R1# set lo0 unit 1 family inet address 172.16.0.1/32
user@R1# set lo0 unit 1 family inet address 192.168.1.1/32
```

2. Configure the RIP group, and add the interface to the group.

To configure RIP in Junos OS, you must configure a group that contains the interfaces on which RIP is enabled. You do not need to enable RIP on the loopback interface.

```
[edit protocols rip group rip-group]
user@R1# set neighbor fe-1/2/0.1
```

3. Configure RIP tracing operations.

```
[edit protocols rip traceoptions]
user@R1# set file rip-trace-file
user@R1# set flag route
```

4. Create the routing policy to advertise both direct and RIP-learned routes.

```
[edit policy-options policy-statement advertise-routes-through-rip term 1]
user@R1# set from protocol direct
user@R1# set from protocol rip
user@R1# set then accept
```

5. Apply the routing policy.

In Junos OS, you can only apply RIP export policies at the group level.

```
[edit protocols rip group rip-group]
user@R1# set export advertise-routes-through-rip
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@R1# show interfaces
fe-1/2/0 {
 unit 1 {
 family inet {
 address 10.0.0.1/30;
 }
 }
}
lo0 {
 unit 1 {
 family inet {
 address 172.16.0.1/32;
 address 192.168.1.1/32;
 }
 }
}

user@R1# show protocols
rip {
 traceoptions {
 file rip-trace-file;
 flag route;
 }
 group rip-group {
 export advertise-routes-through-rip;
 neighbor fe-1/2/0.1;
 }
}

user@R1# show policy-options
policy-statement advertise-routes-through-rip {
 term 1 {
 from protocol [direct rip];
 then accept;
 }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Checking the Log File

**Purpose** Make sure that the RIP route updates are logged in the configured log file.

- Action**
1. Deactivate the extra loopback interface address on Device R3.  

```

[edit interfaces lo0 unit 3 family inet]
user@R3# deactivate address 172.16.3.3/32
user@R3# commit

```
  2. From operational mode on Device R1, enter the **show log rip-trace-file** command with the **| match 172.16.3.3** option.  

```

user@R1> show log rip-trace-file | match 172.16.3.3

```

```
Mar 1 11:39:53.975192 Setting RIPv2 rtbit on route 172.16.3.3/32, tsi =
0xbb69228
Mar 1 11:39:59.847118 172.16.3.3/32: metric-in: 16, change: 3 -> 16; # gw:
1, pkt_upd_src 10.0.0.2, inx: 0, rte_upd_src 10.0.0.2
Mar 1 11:39:59.847568 CHANGE 172.16.3.3/32 nhid 591 gw 10.0.0.2
RIP pref 100/0 metric 3/0 fe-1/2/0.1 <Delete Int>
Mar 1 11:39:59.847629 Best route to 172.16.3.3/32 got deleted. Doing route calculation
on the stored rte-info
```

**Meaning** The output shows that the route to 172.16.3.3/32 was deleted.

| <b>Description</b>              | Configure the type of authentication for RIP route queries received on an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default</b>                  | If you do not include this statement and the <b>authentication-key</b> statement, RIP authentication is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>                  | <b>type</b> —Authentication type: <ul style="list-style-type: none"><li>• <b>md5</b>—Use the MD5 algorithm to create an encoded checksum of the packet. The encoded checksum is included in the transmitted packet. The receiving routing device uses the authentication key to verify the packet, discarding it if the digest does not match. This algorithm provides a more secure authentication scheme.</li><li>• <b>none</b>—Disable authentication. If <b>none</b> is configured, the configured authentication key is ignored.</li><li>• <b>simple</b>—Use a simple password. The password is included in the transmitted packet, which makes this method of authentication relatively insecure. The password can be from 1 through 16 contiguous letters or digits long.</li></ul>                                                                                                                                                                                                                                                                                                                          |
| <b>Required Privilege Level</b> | <b>routing</b> —To view this statement in the configuration.<br><b>routing-control</b> —To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b>         | <p>Configure bidirectional failure detection timers and authentication.</p> <p>The remaining statements are explained separately. See <a href="#">CLI Explorer</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>authentication algorithm</b> <i>algorithm-name</i> —Configure the algorithm used to authenticate the specified BFD session: <b>simple-password</b>, <b>keyed-md5</b>, <b>keyed-sha-1</b>, <b>meticulous-keyed-md5</b>, or <b>meticulous-keyed-sha-1</b>.</p> <p><b>authentication key-chain</b> <i>key-chain-name</i> —Associate a security key with the specified BFD session using the name of the security keychain. The name you specify must</p>                                                                                                                                                                                                                                                                                                                                                                    |

match one of the keychains configured in the **authentication-key-chains key-chain** statement at the **[edit security]** hierarchy level.

**authentication loose-check**—(Optional) Configure loose authentication checking on the BFD session. Use only for transitional periods when authentication may not be configured at both ends of the BFD session.

**detection-time threshold *milliseconds***—Configure a threshold for the adaptation of the BFD session detection time. When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

**minimum-interval *milliseconds***—Configure the minimum interval after which the local routing device transmits a hello packet and then expects to receive a reply from the neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can specify the minimum transmit and receive intervals separately using the **transmit-interval minimum-interval** and **minimum-receive-interval** statements.

**Range:** 1 through 255,000 milliseconds

**minimum-receive-interval *milliseconds***—Configure the minimum interval after which the local routing device expects to receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can configure the minimum receive interval using the **minimum-interval** statement.

**Range:** 1 through 255,000 milliseconds

**multiplier *number***—Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down.

**Range:** 1 through 255

**Default:** 3

**no-adaptation**—Configure BFD sessions not to adapt to changing network conditions. We recommend that you not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

**transmit-interval threshold *milliseconds***—Configure the threshold for the adaptation of the BFD session transmit interval. When the transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent. The interval threshold must be greater than the minimum transmit interval.

**Range:** 0 through 4,294,967,295 ( $2^{32} - 1$ )

**transmit-interval minimum-interval *milliseconds***—Configure a minimum interval after which the local routing device transmits hello packets to a neighbor. Optionally, instead of using this statement, you can configure the minimum transmit interval using the **minimum-interval** statement.

**Range:** 1 through 255,000

**version**—Configure the BFD version to detect: **1** (BFD version 1) or **automatic** (autodetect the BFD version).

**Default:** automatic

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Configure a set of RIP neighbors that share an export policy and metric. The export policy and metric govern what routes to advertise to neighbors in a given group. Each group must contain at least one neighbor. You should create a group for every export policy.

**Options** *group-name*—Name of a group, up to 16 characters long.

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Specify the number of route entries to be included in every RIP update message. To ensure interoperability with other vendors' equipment, use the standard of 25 route entries per message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>                  | <p><i>number</i>—Number of route entries per update message.</p> <p><b>Range:</b> 25 through 255 entries</p> <p><b>Default:</b> 25 entries</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b>              | Specify the metric to add to incoming routes when the routing device advertises into RIP routes that were learned from other protocols. Use this statement to configure the routing device to prefer RIP routes learned through a specific neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Release Information**    Statement introduced before Junos OS Release 7.4.  
                              Statement introduced in Junos OS Release 9.0 for EX Series switches.

**Description**    Configure neighbor-specific RIP parameters, thereby overriding the defaults set for the routing device.

**Options**    *neighbor-name*—Name of an interface over which a routing device communicates to its neighbors.

The remaining statements are explained separately. See [CLI Explorer](#).

| <b>Release Information</b>      | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p>                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | <p>Specify the preference of external routes learned by RIP as compared to those learned from other routing protocols.</p> <p>By default, Junos OS assigns a preference of 100 to routes that originate from RIP. When Junos OS determines a route's preference to become the active route, the software selects the route with the lowest preference and installs this route into the forwarding table.</p>                       |
| <b>Options</b>                  | <p><b>preference</b>—Preference value. A lower value indicates a more preferred route.</p> <p><b>Range:</b> 0 through 4,294,967,295 (<math>2^{32} - 1</math>)</p> <p><b>Default:</b> 100</p>                                                                                                                                                                                                                                       |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                     |

| <b>Description</b>              | Configure the route timeout interval for RIP. If a route is not refreshed after being installed in the routing table by the specified timeout interval, the route is marked as invalid and is removed from the routing table after the hold-down period expires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>         | Set RIP protocol-level tracing options.                                                                                                                                                                                                                                                                                                                                |

**NOTE:** The **traceoptions** statement is not supported on QFabric systems.

**Default** The default RIP protocol-level trace options are inherited from the global **traceoptions** statement.

**Options** **disable**—(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as **all**.

**file *filename***—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place RIP tracing output in the file `/var/log/rip-log`.

**files *number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***, then ***trace-file.1***, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten. If you specify a maximum number of files, you must also specify a maximum file size with the **size** option.

**Range:** 2 through 1000 files

**Default:** 10 files

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements.

### RIP Tracing Options

- auth**—RIP authentication

- **error**—RIP error packets
- **expiration**—RIP route expiration processing
- **holddown**—RIP hold-down processing
- **nsr-synchronization**—Nonstop routing synchronization events
- **packets**—All RIP packets
- **request**—RIP information packets such as request, poll, and poll entry packets
- **trigger**—RIP triggered updates
- **update**—RIP update packets

#### Global Tracing Options

- **all**—All tracing operations
- **general**—A combination of the **normal** and **route** trace operations
- **normal**—All normal operations

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **policy**—Policy operations and actions
- **route**—Routing table changes
- **state**—State transitions
- **task**—Routing protocol task processing
- **timer**—Routing protocol timer processing

***flag-modifier***—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information.
- **receive**—Trace the packets being received.
- **receive-detail**—Provide detailed trace information for packets being received.
- **send**—Trace the packets being transmitted.
- **send-detail**—Provide detailed trace information for packets being transmitted.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then, the oldest trace file is overwritten. If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 128 KB

**world-readable**—(Optional) Allow any user to read the log file.

| <b>Description</b>              | Configure the interval at which routes learned by RIP are sent to neighbors. This timer controls the interval between routing updates. This timer is set to 30 seconds, by default, with a small random amount of time added when the timer is reset. This added time prevents congestion that can happen if all routing devices update their neighbors simultaneously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## CHAPTER 188

# Operational Commands

- `clear rip general-statistics`
- `clear rip statistics`
- `show rip general-statistics`
- `show rip neighbor`
- `show rip statistics`

## clear rip general-statistics

---

| Output Fields                              | <a href="#">Table 360</a> lists the output fields for the <b>show rip neighbor</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                           |

Table 360: show rip neighbor Output Fields

| Field Name                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Neighbor</b>            | Name of the RIP neighbor.<br><br><b>NOTE:</b> Beginning with Junos OS Release 11.1, when you configure demand circuits, the output displays a demand circuit (DC) flag next to neighbor interfaces configured for demand circuits.<br><br>If you configure demand circuits at the <b>[edit protocols rip group group-name neighbor neighbor-name]</b> hierarchy level, the output shows only the neighboring interface that you specifically configured as a demand circuit. If you configure demand circuits at the <b>[edit protocols rip group group-name]</b> hierarchy level, all of the interfaces in the group are configured as demand circuits. Therefore, the output shows all of the interfaces in that group as demand circuits. |
| <b>State</b>               | State of the connection: <b>Up</b> or <b>Dn</b> (Down).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## LDP Introduction

---

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to data link layer-switched paths.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding), or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

## Junos OS LDP Protocol Implementation

---

The Junos OS implementation of LDP supports LDP version 1. The Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. The Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

## LDP Operation

---

You must configure LDP for each interface on which you want LDP to run. LDP creates LSP trees rooted at each egress router for the router ID address that is the subsequent BGP next hop. The ingress point is at every router running LDP. This process provides an inet.3 route to every egress router. If BGP is running, it will attempt to resolve next hops by using the inet.3 table first, which binds most, if not all, of the BGP routes to MPLS tunnel next hops.

Two adjacent routers running LDP become neighbors. If the two routers are connected by more than one interface, they become neighbors on each interface. When LDP routers become neighbors, they establish an LDP session to exchange label information. If per-router labels are in use on both routers, only one LDP session is established between them, even if they are neighbors on multiple interfaces. For this reason, an LDP session is not related to a particular interface.

LDP operates in conjunction with a unicast routing protocol. LDP installs LSPs only when both LDP and the routing protocol are enabled. For this reason, you must enable both LDP and the routing protocol on the same set of interfaces. If this is not done, LSPs might not be established between each egress router and all ingress routers, which might result in loss of BGP-routed traffic.

You can apply policy filters to labels received from and distributed to other routers through LDP. Policy filters provide you with a mechanism to control the establishment of LSPs.

For LDP to run on an interface, MPLS must be enabled on a logical interface on that interface. For more information, see the *Logical Interfaces*.

## Tunneling LDP LSPs in RSVP LSPs

You can tunnel LDP LSPs over RSVP LSPs. The following sections describe how tunneling of LDP LSPs in RSVP LSPs works:

- [Tunneling LDP LSPs in RSVP LSPs Overview on page 4805](#)
- [Label Operations on page 4806](#)

## Tunneling LDP LSPs in RSVP LSPs Overview

If you are using RSVP for traffic engineering, you can run LDP simultaneously to eliminate the distribution of external routes in the core. The LSPs established by LDP are tunneled through the LSPs established by RSVP. LDP effectively treats the traffic-engineered LSPs as single hops.

When you configure the router to run LDP across RSVP-established LSPs, LDP automatically establishes sessions with the router at the other end of the LSP. LDP control packets are routed hop-by-hop, rather than carried through the LSP. This routing allows you to use simplex (one-way) traffic-engineered LSPs. Traffic in the opposite direction flows through LDP-established LSPs that follow unicast routing rather than through traffic-engineered tunnels.

If you configure LDP over RSVP LSPs, you can still configure multiple OSPF areas and IS-IS levels in the traffic engineered core and in the surrounding LDP cloud.

**NOTE:** Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance. This allows splitting of a single routing and MPLS domain into multiple domains so that each domain can be scaled independently. BGP labeled unicast can be used to stitch these domains for service FECs. Each domain uses intra-domain LDP over RSVP LSP for MPLS forwarding.

  - *Configuring a Hierarchy of RSVP LSPs to Tunnel Multiple RSVP LSPs Over a Single RSVP LSP*

## Label Operations

Figure 137 depicts an LDP LSP being tunneled through an RSVP LSP. (For definitions of label operations, see *MPLS Label Overview*.) The shaded inner oval represents the RSVP domain, whereas the outer oval depicts the LDP domain. RSVP establishes an LSP through routers B, C, D, and E, with the sequence of labels L3, L4. LDP establishes an LSP through Routers A, B, E, F, and G, with the sequence of labels L1, L2, L5. LDP views the RSVP LSP between Routers B and E as a single hop.

When the packet arrives at Router A, it enters the LSP established by LDP, and a label (L1) is pushed onto the packet. When the packet arrives at Router B, the label (L1) is swapped with another label (L2). Because the packet is entering the traffic-engineered LSP established by RSVP, a second label (L3) is pushed onto the packet.

This outer label (L3) is swapped with a new label (L4) at the intermediate router (C) within the RSVP LSP tunnel, and when the penultimate router (D) is reached, the top label is popped. Router E swaps the label (L2) with a new label (L5), and the penultimate router for the LDP-established LSP (F) pops the last label.

Figure 137: Swap and Push When LDP LSPs Are Tunneled Through RSVP LSPs

Figure 138 depicts a double push label operation (L1L2). A double push label operation is used when the ingress router (A) for both the LDP LSP and the RSVP LSP tunneled through it is the same device. Note that Router D is the penultimate hop for the LDP-established LSP, so L2 is popped from the packet by Router D.

Figure 138: Double Push When LDP LSPs Are Tunneled Through RSVP LSPs

## LDP Message Types

LDP uses the message types described in the following sections to establish and remove mappings and to report errors. All LDP messages have a common structure that uses a type, length, and value (TLV) encoding scheme.

- [Discovery Messages on page 4807](#)
- [Session Messages on page 4808](#)
- [Advertisement Messages on page 4808](#)
- [Notification Messages on page 4808](#)

## Discovery Messages

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- **Basic discovery**—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- **Extended discovery**—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

## Session Messages

---

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

## Advertisement Messages

---

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

## Notification Messages

---

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

## LDP Session Protection

---

LDP session protection is based on the LDP targeted hello functionality defined in RFC 5036, *LDP Specification*, and is supported by the Junos OS as well as the LDP implementations of most other vendors. It involves sending unicast User Datagram Protocol (UDP) hello packets to a remote neighbor address and receiving similar packets from the neighbor router.

If you configure LDP session protection on a router, the LDP sessions are maintained as follows:

1. An LDP session is established between a router and a remote neighboring router.
2. If all of the direct links between the routers go down, the LDP session remains up so long as there is IP connectivity between the routers based on another connection over the network.
3. When the direct link between the routers is reestablished, the LDP session is not restarted. The routers simply exchange LDP hellos with each other over the direct link.

They can then begin forwarding LDP-signaled MPLS packets using the original LDP session.

By default, LDP targeted hellos are set to the remote neighbor so long as the LDP session is up, even if there are no more link neighbors to that router. You can also specify the duration you would like to maintain the remote neighbor connection in the absence of link neighbors. When the last link neighbor for a session goes down, the Junos OS starts an LDP session protection timer. If this timer expires before any of the link neighbors come back up, the remote neighbor connection is taken down and the LDP session is terminated. If you configure a different value for the timer while it is currently running, the Junos OS updates the timer to the specified value without disrupting the current state of the LDP session.

## LDP Graceful Restart

---

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

You can configure LDP graceful restart in both the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and on a specific routing instance. LDP graceful restart is disabled by default, because at the global level, graceful restart is disabled by default. However, helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default.

The following are some of the behaviors associated with LDP graceful restart:

- Outgoing labels are not maintained in restarts. New outgoing labels are allocated.
- When a router is restarting, no label-map messages are sent to neighbors that support graceful restart until the restarting router has stabilized (label-map messages are immediately sent to neighbors that do not support graceful restart). However, all other messages (keepalive, address-message, notification, and release) are sent as usual. Distributing these other messages prevents the router from distributing incomplete information.

- Helper mode and graceful restart are independent. You can disable graceful restart in the configuration, but still allow the router to cooperate with a neighbor attempting to restart gracefully.

## Minimum LDP Configuration

---

To enable LDP on a single interface, include the **ldp** statement and specify the interface using the **interface** statement. This is the minimum LDP configuration. All other LDP configuration statements are optional.

```
ldp {
 interface interface-name;
}
```

To enable LDP on all interfaces, specify **all** for *interface-name*.

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

## Enabling and Disabling LDP

---

LDP is routing-instance-aware. To enable LDP on a specific interface, include the following statements:

```
ldp {
 interface interface-name;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

To enable LDP on all interfaces, specify **all** for *interface-name*.

If you have configured interface properties on a group of interfaces and want to disable LDP on one of the interfaces, include the **interface** statement with the **disable** option:

```
interface interface-name {
 disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Enabling Strict Targeted Hello Messages for LDP

---

Use strict targeted hello messages to prevent LDP sessions from being established with remote neighbors that have not been specifically configured. If you configure the **strict-targeted-hellos** statement, an LDP peer does not respond to targeted hello messages coming from a source that is not one of its configured remote neighbors. Configured remote neighbors can include:

- Endpoints of RSVP tunnels for which LDP tunneling is configured
- Layer 2 circuit neighbors

If an unconfigured neighbor sends a hello message, the LDP peer ignores the message and logs an error (with the **error** trace flag) indicating the source. For example, if the LDP peer received a targeted hello from the Internet address 10.0.0.1 and no neighbor with this address is specifically configured, the following message is printed to the LDP log file:

```
LDP: Ignoring targeted hello from 10.0.0.1
```

To enable strict targeted hello messages, include the **strict-targeted-hellos** statement:

```
strict-targeted-hellos;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Filtering Inbound LDP Label Bindings

You can filter received LDP label bindings, applying policies to accept or deny bindings advertised by neighboring routers. To configure received-label filtering, include the **import** statement:

```
import [policy-names];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings received from all LDP neighbors. All filtering is done with **from** statements. [Table 362](#) lists the only **from** operators that apply to LDP received-label filtering.

**Table 362: from Operators That Apply to LDP Received-Label Filtering**

| from Operator       | Description                                                                                |
|---------------------|--------------------------------------------------------------------------------------------|
| <b>interface</b>    | Matches on bindings received from a neighbor that is adjacent over the specified interface |
| <b>neighbor</b>     | Matches on bindings received from the specified LDP router ID                              |
| <b>next-hop</b>     | Matches on bindings received from a neighbor advertising the specified interface address   |
| <b>route-filter</b> | Matches on bindings with the specified prefix                                              |

If a binding is filtered, it still appears in the LDP database, but is not considered for installation as part of a label-switched path (LSP).

Generally, applying policies in LDP can be used only to block the establishment of LSPs, not to control their routing. This is because the path that an LSP follows is determined by unicast routing, and not by LDP. However, when there are multiple equal-cost paths to the destination through different neighbors, you can use LDP filtering to exclude some

of the possible next hops from consideration. (Otherwise, LDP chooses one of the possible next hops at random.)

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels; so if multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface. When a router has multiple adjacencies to the same neighbor, take care to ensure that the filter does what is expected. (Generally, using **next-hop** and **interface** is not appropriate in this case.)

If a label has been filtered (meaning that it has been rejected by the policy and is not used to construct an LSP), it is marked as filtered in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.6/32 (Filtered)
Output label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.1/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

## Examples: Filtering Inbound LDP Label Bindings

Accept only /32 prefixes from all neighbors:

```
[edit]
protocols {
 ldp {
 import only-32;
 ...
 }
}
policy-options {
 policy-statement only-32 {
 term first {
 from {
 route-filter 0.0.0.0/0 upto /31;
 }
 then reject;
 }
 then accept;
 }
}
```

Accept 131.108/16 or longer from router ID 10.10.255.2 and accept all prefixes from all other neighbors:

```
[edit]
protocols {
 ldp {
 import nosy-neighbor;
 ...
 }
}
```

```

}
policy-options {
 policy-statement nosy-neighbor {
 term first {
 from {
 neighbor 10.10.255.2;
 route-filter 131.108.0.0/16 orlonger accept;
 route-filter 0.0.0.0/0 orlonger reject;
 }
 }
 then accept;
 }
}

```

## Filtering Outbound LDP Label Bindings

You can configure export policies to filter LDP outbound labels. You can filter outbound label bindings by applying routing policies to block bindings from being advertised to neighboring routers. To configure outbound label filtering, include the **export** statement:

**export** [*policy-name*];

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named export policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings transmitted to all LDP neighbors. The only **from** operator that applies to LDP outbound label filtering is **route-filter**, which matches bindings with the specified prefix. The only **to** operators that apply to outbound label filtering are the operators in [Table 363](#).

**Table 363: to Operators for LDP Outbound-Label Filtering**

| to Operator      | Description                                                                          |
|------------------|--------------------------------------------------------------------------------------|
| <b>interface</b> | Matches on bindings sent to a neighbor that is adjacent over the specified interface |
| <b>neighbor</b>  | Matches on bindings sent to the specified LDP router ID                              |
| <b>next-hop</b>  | Matches on bindings sent to a neighbor advertising the specified interface address   |

If a binding is filtered, the binding is not advertised to the neighboring router, but it can be installed as part of an LSP on the local router. You can apply policies in LDP to block the establishment of LSPs, but not to control their routing. The path an LSP follows is determined by unicast routing, not by LDP.

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels. If multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface.

Do not use the **next-hop** and **interface** operators when a router has multiple adjacencies to the same neighbor.

Filtered labels are marked in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
100007 10.10.255.2/32
3 10.10.255.3/32
Output label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
3 10.10.255.1/32
100001 10.10.255.6/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

## Examples: Filtering Outbound LDP Label Bindings

Block transmission of the route for **10.10.255.6/32** to any neighbors:

```
[edit protocols]
ldp {
 export block-one;
}
policy-options {
 policy-statement block-one {
 term first {
 from {
 route-filter 10.10.255.6/32 exact;
 }
 then reject;
 }
 then accept;
 }
}
```

Send only **131.108/16** or longer to router ID **10.10.255.2**, and send all prefixes to all other routers:

```
[edit protocols]
ldp {
 export limit-lsps;
}
policy-options {
 policy-statement limit-lsps {
 term allow-one {
 from {
 route-filter 131.108.0.0/16 orlonger;
 }
 to {
 neighbor 10.10.255.2;
 }
 then accept;
 }
 term block-the-rest {
```

```

 to {
 neighbor 10.10.255.2;
 }
 then reject;
 }
 then accept;
}
}

```

## Specifying the Transport Address Used by LDP

Routers must first establish a TCP session between each other before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

To configure the LDP transport address, include the `transport-address` statement:

```
transport-address (router-id | interface);
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you specify the **router-id** option, the address of the router identifier is used as the transport address (unless otherwise configured, the router identifier is typically the same as the loopback address). If you specify the **interface** option, the interface address is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. Note that the router identifier is used as the transport address by default.

You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

**Related Documentation**

- [transport-address on page 4882](#)

## Collecting LDP Statistics

LDP traffic statistics show the volume of traffic that has passed through a particular FEC on a router.

When you configure the **traffic-statistics** statement at the **[edit protocols ldp]** hierarchy level, the LDP traffic statistics are gathered periodically and written to a file. You can configure how often statistics are collected (in seconds) by using the **interval** option. The default collection interval is 5 minutes. You must configure an LDP statistics file; otherwise, LDP traffic statistics are not gathered. If the LSP goes down, the LDP statistics are reset.

To collect LDP traffic statistics, include the **traffic-statistics** statement:

```
traffic-statistics {
```

```

file filename <files number> <size size> <world-readable | no-world-readable>;
interval interval;
no-penultimate-hop;
}

```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

This section includes the following topics:

- [LDP Statistics Output on page 4816](#)
- [Disabling LDP Statistics on the Penultimate-Hop Router on page 4816](#)
- [LDP Statistics Limitations on page 4817](#)

## LDP Statistics Output

The following sample output is from an LDP statistics file:

| FEC               | Type    | Packets | Bytes | Shared |
|-------------------|---------|---------|-------|--------|
| 10.255.350.448/32 | Transit | 0       | 0     | No     |
|                   | Ingress | 0       | 0     | No     |
| 10.255.350.450/32 | Transit | 0       | 0     | Yes    |
|                   | Ingress | 0       | 0     | No     |
| 10.255.350.451/32 | Transit | 0       | 0     | No     |
|                   | Ingress | 0       | 0     | No     |
| 220.220.220.1/32  | Transit | 0       | 0     | Yes    |
|                   | Ingress | 0       | 0     | No     |
| 220.220.220.2/32  | Transit | 0       | 0     | Yes    |
|                   | Ingress | 0       | 0     | No     |
| 220.220.220.3/32  | Transit | 0       | 0     | Yes    |
|                   | Ingress | 0       | 0     | No     |

May 28 15:02:05, read 12 statistics in 00:00:00 seconds

The LDP statistics file includes the following columns of data:

- **read**—Number of bytes of data passed by the FEC since its LSP came up.
- **read**—FEC for which LDP traffic statistics are collected.
- **read**—Number of packets passed by the FEC since its LSP came up.
- **read**—This number (which appears next to the date and time) might differ from the actual number of the statistics displayed. Some of the statistics are summarized before being displayed.
- **Shared**—A **Yes** value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
- **Type**—Type of traffic originating from a router, either **Ingress** (originating from this router) or **Transit** (forwarded through this router).

## Disabling LDP Statistics on the Penultimate-Hop Router

Gathering LDP traffic statistics at the penultimate-hop router can consume excessive system resources, on next-hop routes in particular. This problem is exacerbated if you have configured the **deaggregate** statement in addition to the **traffic-statistics** statement.

For routers reaching their limit of next-hop route usage, we recommend configuring the **no-penultimate-hop** option for the **traffic-statistics** statement:

```
traffic-statistics {
 no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can configure the **traffic-statistics** statement, see the statement summary section for this statement.

**NOTE:** When you configure the **no-penultimate-hop** option, no statistics are available for the FECs that are the penultimate hop for this router.

Whenever you include or remove this option from the configuration, the LDP sessions are taken down and then restarted.

The following sample output is from an LDP statistics file showing routers on which the **no-penultimate-hop** option is configured:

| FEC               | Type    | Packets             | Bytes | Shared |
|-------------------|---------|---------------------|-------|--------|
| 10.255.245.218/32 | Transit | 0                   | 0     | No     |
|                   | Ingress | 4                   | 246   | No     |
| 10.255.245.221/32 | Transit | statistics disabled |       |        |
|                   | Ingress | statistics disabled |       |        |
| 13.1.1.0/24       | Transit | statistics disabled |       |        |
|                   | Ingress | statistics disabled |       |        |
| 13.1.3.0/24       | Transit | statistics disabled |       |        |
|                   | Ingress | statistics disabled |       |        |

## LDP Statistics Limitations

The following are issues related to collecting LDP statistics by configuring the **traffic-statistics** statement:

- You cannot clear the LDP statistics.
- If you shorten the specified interval, a new LDP statistics request is issued only if the statistics timer expires later than the new interval.
- A new LDP statistics collection operation cannot start until the previous one has finished. If the interval is short or if the number of LDP statistics is large, the time gap between the two statistics collections might be longer than the interval.

When an LSP goes down, the LDP statistics are reset.

## Tracing LDP Protocol Traffic

The following sections describe how to configure the trace options to examine LDP protocol traffic:

- [Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels on page 4818](#)
- [Tracing LDP Protocol Traffic Within FECs on page 4819](#)
- [Examples: Tracing LDP Protocol Traffic on page 4819](#)

## Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels

To trace LDP protocol traffic, you can specify options in the global **traceoptions** statement at the **[edit routing-options]** hierarchy level, and you can specify LDP-specific options by including the **traceoptions** statement:

```
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`. We recommend that you place LDP-tracing output in the file **ldp-log**.

The following trace flags display the operations associated with the sending and receiving of various LDP messages. Each can carry one or more of the following modifiers:

- **address**—Trace the operation of address and address withdrawal messages.
- **binding**—Trace label-binding operations.
- **error**—Trace error conditions.
- **event**—Trace protocol events.
- **initialization**—Trace the operation of initialization messages.
- **label**—Trace the operation of label request, label map, label withdrawal, and label release messages.
- **notification**—Trace the operation of notification messages.
- **packets**—Trace the operation of address, address withdrawal, initialization, label request, label map, label withdrawal, label release, notification, and periodic messages. This modifier is equivalent to setting the **address**, **initialization**, **label**, **notification**, and **periodic** modifiers.

You can also configure the **filter** flag modifier with the **match-on address** sub-option for the **packets** flag. This allows you to trace based on the source and destination addresses of the packets.

- **path**—Trace label-switched path operations.
- **path**—Trace label-switched path operations.
- **periodic**—Trace the operation of hello and keepalive messages.
- **route**—Trace the operation of route messages.
- **state**—Trace protocol state transitions.

## Tracing LDP Protocol Traffic Within FECs

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers.

You can trace LDP protocol traffic within a specific FEC and filter LDP trace statements based on an FEC. This is useful when you want to trace or troubleshoot LDP protocol traffic associated with an FEC. The following trace flags are available for this purpose: **route**, **path**, and **binding**.

The following example illustrates how you might configure the LDP **traceoptions** statement to filter LDP trace statements based on an FEC:

```
[edit protocols ldp traceoptions]
set flag route filter match-on fec policy "filter-policy-for-ldp-fec";
```

This feature has the following limitations:

- The filtering capability is only available for FECs composed of IP version 4 (IPv4) prefixes.
- Layer 2 circuit FECs cannot be filtered.
- When you configure both route tracing and filtering, MPLS routes are not displayed (they are blocked by the filter).
- Filtering is determined by the policy and the configured value for the **match-on** option. When configuring the policy, be sure that the default behavior is always **reject**.
- The only **match-on** option is **fec**. Consequently, the only type of policy you should include is a route-filter policy.

## Examples: Tracing LDP Protocol Traffic

Trace LDP path messages in detail:

```
[edit]
protocols {
 ldp {
 traceoptions {
 file ldp size 10m files 5;
 flag path;
 }
 }
}
```

Trace all LDP outgoing messages:

```
[edit]
protocols {
 ldp {
 traceoptions {
 file ldp size 10m files 5;
```

```
 flag packets;
 }
}
```

Trace all LDP error conditions:

```
[edit]
protocols {
 ldp {
 traceoptions {
 file ldp size 10m files 5;
 flag error;
 }
 }
}
```

Trace all LDP incoming messages and all label-binding operations:

```
[edit]
protocols {
 ldp {
 traceoptions {
 file ldp size 10m files 5 world-readable;
 flag packets receive;
 flag binding;
 }
 interface all {
 }
 }
}
```

Trace LDP protocol traffic for an FEC associated with the LSP:

```
[edit]
protocols {
 ldp {
 traceoptions {
 flag route filter match-on fec policy filter-policy-for-ldp-fec;
 }
 }
}
```

---

## Example: Configuring LDP Downstream on Demand

This example shows how to configure LDP downstream on demand. LDP is commonly configured using downstream unsolicited advertisement mode, meaning label advertisements for all routes are received from all LDP peers. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between the access and aggregation networks and to reduce the processing requirements for the control plane.

Downstream nodes could potentially receive tens of thousands of label bindings from upstream aggregation nodes. Instead of learning and storing all label bindings for all possible loopback addresses within the entire MPLS network, the downstream aggregation node can be configured using LDP downstream on demand to only request the label

bindings for the FECs corresponding to the loopback addresses of those egress nodes on which it has services configured.

- [Requirements on page 4821](#)
- [Overview on page 4821](#)
- [Configuration on page 4821](#)
- [Verification on page 4824](#)

## Requirements

This example uses the following hardware and software components:

- M Series router
- Junos OS 12.2

## Overview

You can enable LDP downstream on demand label advertisement for an LDP session by including the **downstream-on-demand** statement at the **[edit protocols ldp session]** hierarchy level. If you have configured downstream on demand, the Juniper Networks router advertises the downstream on demand request to its peer routers. For a downstream on demand session to be established between two routers, both have to advertise downstream on demand mode during LDP session establishment. If one router advertises downstream unsolicited mode and the other advertises downstream on demand, downstream unsolicited mode is used.

## Configuration

### Configuring LDP Downstream on Demand

#### Step-by-Step Procedure

To configure a LDP downstream on demand policy and then configure that policy and enable LDP downstream on demand on the LDP session:

1. Configure the downstream on demand policy (DOD-Request-Loopbacks in this example).

This policy causes the router to forward label request messages only to the FECs that are matched by the DOD-Request-Loopbacks policy.

```
[edit policy-options]
user@host# set prefix-list Request-Loopbacks 10.1.1.1/32
user@host# set prefix-list Request-Loopbacks 10.1.1.2/32
user@host# set prefix-list Request-Loopbacks 10.1.1.3/32
user@host# set prefix-list Request-Loopbacks 10.1.1.4/32
user@host# set policy-statement DOD-Request-Loopbacks term 1 from prefix-list
Request-Loopbacks
user@host# set policy-statement DOD-Request-Loopbacks term 1 then accept
```

2. Specify the DOD-Request-Loopbacks policy using the **dod-request-policy** statement at the **[edit protocols ldp]** hierarchy level.

The policy specified with the **dod-request-policy** statement is used to identify the prefixes to send label request messages. This policy is similar to an egress policy

or an import policy. When processing routes from the inet.0 routing table, the Junos OS software checks for routes matching the **DOD-Request-Loopbacks** policy (in this example). If the route matches the policy and the LDP session is negotiated with DOD advertisement mode, label request messages are sent to the corresponding downstream LDP session.

```
[edit protocols ldp]
user@host# set dod-request-policy DOD-Request-Loopbacks
```

3. Include the **downstream-on-demand** statement in the configuration for the LDP session to enable downstream on demand distribution mode.

```
[edit protocols ldp]
user@host# set session 1.1.1.1 downstream-on-demand
```

---

### Distributing LDP Downstream on Demand Routes into Labeled BGP

---

#### Step-by-Step Procedure

To distribute LDP downstream on demand routes into labeled BGP, use a BGP export policy.

1. Configure the LDP route policy (**redistribute\_ldp** in this example).

```
[edit policy-options]
user@host# set policy-statement redistribute_ldp term 1 from protocol ldp
user@host# set policy-statement redistribute_ldp term 1 from tag 1000
user@host# set policy-statement redistribute_ldp term 1 then accept
```

2. Include the LDP route policy, **redistribute\_ldp** in the BGP configuration (as a part of the BGP group configuration **ebgp-to-abr** in this example).

BGP forwards the LDP routes based on the **redistribute\_ldp** policy to the remote PE router

```
[edit protocols bgp]
user@host# set group ebgp-to-abr type external
user@host# set group ebgp-to-abr local-address 192.168.0.1
user@host# set group ebgp-to-abr peer-as 65319
user@host# set group ebgp-to-abr local-as 65320
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet unicast
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet labeled-unicast
rib inet.3
user@host# set group ebgp-to-abr neighbor 192.168.6.1 export redistribute_ldp
```

#### Step-by-Step Procedure

To restrict label propagation to other routers configured in downstream unsolicited mode (instead of downstream on demand), configure the following policies:

1. Configure the **dod-routes** policy to accept routes from LDP.

```
user@host# set policy-options policy-statement dod-routes term 1 from protocol ldp
user@host# set policy-options policy-statement dod-routes term 1 from tag 1145307136
user@host# set policy-options policy-statement dod-routes term 1 then accept
```

2. Configure the **do-not-propagate-du-sessions** policy to not forward routes to neighbors 1.1.1.1, 2.2.2.2, and 3.3.3.3.

```

user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 1.1.1.1
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 2.2.2.2
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 to neighbor 3.3.3.3
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 then reject

```

3. Configure the **filter-dod-on-du-sessions** policy to prevent the routes examined by the **dod-routes** policy from being forwarded to the neighboring routers defined in the **do-not-propagate-du-sessions** policy.

```

user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 from policy dod-routes
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 to policy do-not-propagate-du-sessions

```

4. Specify the **filter-dod-routes-on-du-session** policy as the export policy for BGP group **ebgp-to-abr**.

```

[edit protocols bgp]
user@host# set group ebgp-to-abr neighbor 192.168.6.2 export
filter-dod-routes-on-du-sessions

```

**Results** From configuration mode, confirm your configuration by entering the **show policy-options** and **show protocols ldp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@host#
show policy-options
prefix-list Request-Loopbacks {
 10.1.1.1/32;
 10.1.1.2/32;
 10.1.1.3/32;
 10.1.1.4/32;
}
policy-statement DOD-Request-Loopbacks {
 term 1 {
 from {
 prefix-list Request-Loopbacks;
 }
 then accept;
 }
}
policy-statement redistribute_ldp {
 term 1 {
 from {
 protocol ldp;
 tag 1000;
 }
 then accept;
 }
}

user@host#
show protocols ldp

```

```

 }
 }
 }
 }
 export redistribute_ldp;
}
```

## Verification

### Verifying Label Advertisement Mode

---

**Purpose** Confirm that the configuration is working properly.

Use the **show ldp session** command to verify the status of the label advertisement mode for the LDP session.

**Action** Issue the `show ldp session` and `show ldp session detail` commands:

- The following command output for the `show ldp session` command indicates that the **Adv. Mode** (label advertisement mode) is **DOD** (meaning the LDP downstream on demand session is operational):

```
user@host> show ldp session
 Address State Connection Hold time Adv. Mode
 1.1.1.2 Operational Open 22 DOD
```

- The following command output for the `show ldp session detail` command indicates that the **Local Label Advertisement mode** is **Downstream unsolicited**, the default value (meaning downstream on demand is not configured on the local session). Conversely, the **Remote Label Advertisement mode** and the **Negotiated Label Advertisement mode** both indicate that **Downstream on demand** is configured on the remote session

```
user@host> show ldp session detail
Address: 1.1.1.2, State: Operational, Connection: Open, Hold time: 24
Session ID: 1.1.1.1:0--1.1.1.2:0
Next keepalive in 4 seconds
Passive, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
Neighbor types: configured-tunneled
Keepalive interval: 10, Connect retry interval: 1
Local address: 1.1.1.1, Remote address: 1.1.1.2
Up for 17:54:52
Capabilities advertised: none
Capabilities received: none
Protection: disabled
Local - Restart: disabled, Helper mode: enabled,
Remote - Restart: disabled, Helper mode: enabled
Local maximum neighbor reconnect time: 120000 msec
Local maximum neighbor recovery time: 240000 msec
Local Label Advertisement mode: Downstream unsolicited
Remote Label Advertisement mode: Downstream on demand
Negotiated Label Advertisement mode: Downstream on demand
Nonstop routing state: Not in sync
Next-hop addresses received:
 1.1.1.2
```

## Configuring the LDP Timer for Hello Messages

LDP hello messages enable LDP nodes to discover one another and to detect the failure of a neighbor or the link to the neighbor. Hello messages are sent periodically on all interfaces where LDP is enabled.

There are two types of LDP hello messages:

- Link hello messages—Sent through the LDP interface as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Targeted hello messages—Sent as UDP packets addressed to the LDP discovery port at a specific address. Targeted hello messages are used to support LDP sessions between routers that are not directly connected. A targeted router determines whether to respond or ignore a targeted hello message. A targeted router that chooses to

respond does so by periodically sending targeted hello messages back to the initiating router.

By default, LDP sends hello messages every 5 seconds for link hello messages and every 15 seconds for targeted hello messages. You can configure the LDP timer to alter how often both types of hello messages are sent. However, you cannot configure a time for the LDP timer that is greater than the LDP hold time. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down” on page 4826](#).

### Configuring the LDP Timer for Link Hello Messages

To modify how often LDP sends link hello messages, specify a new link hello message interval for the LDP timer using the **hello-interval** statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

### Configuring the LDP Timer for Targeted Hello Messages

To modify how often LDP sends targeted hello messages, specify a new targeted hello message interval for the LDP timer by configuring the **hello-interval** statement as an option for the **targeted-hello** statement:

```
targeted-hello {
 hello-interval seconds;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

## Configuring the Delay Before LDP Neighbors Are Considered Down

---

The hold time determines how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. The values sent by each neighbor do not have to match.

The hold time should normally be at least three times the hello interval. The default is 15 seconds for link hello messages and 45 seconds for targeted hello messages. However, it is possible to configure an LDP hold time that is close to the value for the hello interval.

**NOTE:** By configuring an LDP hold time close to the hello interval (less than three times the hello interval), LDP neighbor failures might be detected more quickly. However, this also increases the possibility that the router might declare an LDP neighbor down that is still functioning normally. For more information, see [“Configuring the LDP Timer for Hello Messages” on page 4825](#).

The LDP hold time is also negotiated automatically between LDP peers. When two LDP peers advertise different LDP hold times to one another, the smaller value is used. If an

LDP peer router advertises a shorter hold time than the value you have configured, the peer router's advertised hold time is used. This negotiation can affect the LDP keepalive interval as well.

If the local LDP hold time is not shortened during LDP peer negotiation, the user-configured keepalive interval is left unchanged. However, if the local hold time is reduced during peer negotiation, the keepalive interval is recalculated. If the LDP hold time has been reduced during peer negotiation, the keepalive interval is reduced to one-third of the new hold time value. For example, if the new hold-time value is 45 seconds, the keepalive interval is set to 15 seconds.

This automated keepalive interval calculation can cause different keepalive intervals to be configured on each peer router. This enables the routers to be flexible in how often they send keepalive messages, because the LDP peer negotiation ensures they are sent more frequently than the LDP hold time.

When you reconfigure the hold-time interval, changes do not take effect until after the session is reset. The hold time is negotiated when the LDP peering session is initiated and cannot be renegotiated as long as the session is up (required by RFC 5036, *LDP Specification*). To manually force the LDP session to reset, issue the **clear ldp session** command.

## Configuring the LDP Hold Time for Link Hello Messages

To modify how long an LDP node should wait for a link hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement:

```
hold-time seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the LDP Hold Time for Targeted Hello Messages

To modify how long an LDP node should wait for a targeted hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement as an option for the **targeted-hello** statement:

```
targeted-hello {
 hold-time seconds;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

## Configuring the Interval for LDP Keepalive Messages

---

The keepalive interval determines how often a message is sent over the session to ensure that the keepalive timeout is not exceeded. If no other LDP traffic is sent over the session in this much time, a keepalive message is sent. The default is 10 seconds. The minimum value is 1 second.

The value configured for the keepalive interval can be altered during LDP session negotiation if the value configured for the LDP hold time on the peer router is lower than the value configured locally. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down” on page 4826](#).

To modify the keepalive interval, include the **keepalive-interval** statement:

```
keepalive-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring the LDP Keepalive Timeout

After an LDP session is established, messages must be exchanged periodically to ensure that the session is still working. The keepalive timeout defines the amount of time that the neighbor LDP node waits before deciding that the session has failed. This value is usually set to at least three times the keepalive interval. The default is 30 seconds.

To modify the keepalive interval, include the **keepalive-timeout** statement:

```
keepalive-timeout seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The value configured for the **keepalive-timeout** statement is displayed as the hold time when you issue the **show ldp session detail** command.

---

## Configuring LDP Route Preferences

When several protocols calculate routes to the same destination, route preferences are used to select which route is installed in the forwarding table. The route with the lowest preference value is selected. The preference value can be a number in the range 0 through 255. By default, LDP routes have a preference value of 9.

To modify the route preferences, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring LDP Graceful Restart

When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

By default, graceful restart helper mode is enabled, but graceful restart is disabled. Thus, the default behavior of a router is to assist neighboring routers attempting a graceful restart, but not to attempt a graceful restart itself.

To configure LDP graceful restart, see the following sections:

- [Enabling Graceful Restart on page 4829](#)
- [Disabling LDP Graceful Restart or Helper Mode on page 4829](#)
- [Configuring Reconnect Time on page 4830](#)
- [Configuring Recovery Time and Maximum Recovery Time on page 4830](#)

## Enabling Graceful Restart

To enable LDP graceful restart, you also need to enable graceful restart on the router.

To enable graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library for Routing Devices*.

By default, LDP graceful restart is enabled when you enable graceful restart at both the LDP protocol level and on all the routing instances. However, you can disable both LDP graceful restart and LDP graceful restart helper mode.

## Disabling LDP Graceful Restart or Helper Mode

To disable LDP graceful restart and recovery, include the **disable** statement:

```
ldp {
 graceful-restart {
 disable;
 }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can disable helper mode at the LDP protocols level only. You cannot disable helper mode for a specific routing instance. To disable LDP helper mode, include the **helper-disable** statement:

```
ldp {
 graceful-restart {
 helper-disable;
 }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The following LDP graceful restart configurations are possible:

- LDP graceful restart and helper mode are both enabled.
- LDP graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully but can help a restarting neighbor.
- LDP graceful restart and helper mode are both disabled. The router does not use LDP graceful restart or the graceful restart type, length, and value (TLV) sent in the initialization message. The router behaves as a router that cannot support LDP graceful restart.

A configuration error is issued if you attempt to enable graceful restart and disable helper mode.

## Configuring Reconnect Time

After the LDP connection between neighbors fails, neighbors wait a certain amount of time for the gracefully restarting router to resume sending LDP messages. After the wait period, the LDP session can be reestablished. You can configure the wait period in seconds. This value is included in the fault tolerant session TLV sent in LDP initialization messages when LDP graceful restart is enabled.

Suppose that Router A and Router B are LDP neighbors. Router A is the restarting Router. The reconnect time is the time that Router A tells Router B to wait after Router B detects that Router A restarted.

To configure the reconnect time, include the **reconnect-time** statement:

```
graceful-restart {
 reconnect-time seconds;
}
```

You can set the reconnect time to a value in the range from 30 through 300 seconds. By default, it is 60 seconds.

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Configuring Recovery Time and Maximum Recovery Time

The recovery time is the amount of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This period is also typically the amount of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

To prevent a neighboring router from being adversely affected if it receives a false value for the recovery time from the restarting router, you can configure the maximum recovery time on the neighboring router. A neighboring router maintains its state for the shorter of the two times. For example, Router A is performing an LDP graceful restart. It has sent a recovery time of 900 seconds to neighboring Router B. However, Router B has its maximum recovery time configured at 400 seconds. Router B will only wait for 400 seconds before it purges its LDP information from Router A.

To configure recovery time, include the **recovery-time** statement and the **maximum-neighbor-recovery-time** statement:

```

graceful-restart {
 maximum-neighbor-recovery-time seconds;
 recovery-time seconds;
}

```

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Configuring the Prefixes Advertised into LDP from the Routing Table

You can control the set of prefixes that are advertised into LDP and cause the router to be the egress router for those prefixes. By default, only the loopback address is advertised into LDP. To configure the set of prefixes from the routing table to be advertised into LDP, include the **egress-policy** statement:

```
egress-policy policy-name;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** If you configure an egress policy for LDP that does not include the loopback address, it is no longer advertised in LDP. To continue to advertise the loopback address, you need to explicitly configure it as a part of the LDP egress policy.

The named policy (configured at the **[edit policy-options]** or **[edit logical-systems logical-system-name policy-options]** hierarchy level) is applied to all routes in the routing table. Those routes that match the policy are advertised into LDP. You can control the set of neighbors to which those prefixes are advertised by using the **export** statement. Only **from** operators are considered; you can use any valid **from** operator. For more information, see the *Junos OS Routing Protocols Library for Routing Devices*.

### Example: Configuring the Prefixes Advertised into LDP

Advertise all connected routes into LDP:

```

[edit protocols]
ldp {
 egress-policy connected-only;
}
policy-options {
 policy-statement connected-only {
 from {
 protocol direct;
 }
 then accept;
 }
}

```

## Configuring LDP LSP Traceroute

---

You can trace the route followed by an LDP-signaled LSP. LDP LSP traceroute is based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*. This feature allows you to periodically trace all paths in a FEC. The FEC topology information is stored in a database accessible from the CLI.

A topology change does not automatically trigger a trace of an LDP LSP. However, you can manually initiate a traceroute. If the traceroute request is for an FEC that is currently in the database, the contents of the database are updated with the results.

The periodic traceroute feature applies to all FECs specified by the **oam** statement configured at the **[edit protocols ldp]** hierarchy level. To configure periodic LDP LSP traceroute, include the **periodic-traceroute** statement:

```
periodic-traceroute {
 disable;
 exp exp-value;
 fanout fanout-value;
 frequency minutes;
 paths number-of-paths;
 retries retry-attempts;
 source address;
 ttl ttl-value;
 wait seconds;
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ldp oam]**
- **[edit protocols ldp oam fec *address*]**

You can configure the **periodic-traceroute** statement by itself or with any of the following options:

- **exp**—Specify the class of service to use when sending probes.
- **fanout**—Specify the maximum number of next hops to search per node.
- **frequency**—Specify the interval between traceroute attempts.
- **paths**—Specify the maximum number of paths to search.
- **retries**—Specify the number of attempts to send a probe to a specific node before giving up.
- **source**—Specify the IPv4 source address to use when sending probes.
- **ttl**—Specify the maximum time-to-live value. Nodes that are beyond this value are not traced.
- **wait**—Specify the wait interval before resending a probe packet.

---

## Configuring Miscellaneous LDP Properties

---

The following sections describe how to configure a number of miscellaneous LDP properties:

- [Configuring LDP to Use the IGP Route Metric on page 4833](#)
- [Preventing Addition of Ingress Routes to the inet.0 Routing Table on page 4833](#)
- [Multiple-Instance LDP and Carrier-of-Carriers VPNs on page 4834](#)
- [Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router on page 4834](#)
- [Enabling LDP over RSVP-Established LSPs on page 4834](#)
- [Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks on page 4835](#)
- [Configuring the TCP MD5 Signature for LDP Sessions on page 4835](#)
- [Configuring LDP Session Protection on page 4836](#)
- [Disabling SNMP Traps for LDP on page 4837](#)
- [Configuring LDP Synchronization with the IGP on LDP Links on page 4837](#)
- [Configuring LDP Synchronization with the IGP on the Router on page 4838](#)
- [Configuring the Label Withdrawal Timer on page 4838](#)
- [Ignoring the LDP Subnet Check on page 4838](#)

### Configuring LDP to Use the IGP Route Metric

Use the **track-igp-metric** statement if you want the interior gateway protocol (IGP) route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1).

To use the IGP route metric, include the **track-igp-metric** statement:

```
track-igp-metric;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

### Preventing Addition of Ingress Routes to the inet.0 Routing Table

By configuring the **no-forwarding** statement, you can prevent ingress routes from being added to the inet.0 routing table instead of the inet.3 routing table even if you enabled the **traffic-engineering bgp-igp** statement at the **[edit protocols mpls]** or the **[edit logical-systems *logical-system-name* protocols mpls]** hierarchy level. By default, the **no-forwarding** statement is disabled.

To omit ingress routes from the inet.0 routing table, include the **no-forwarding** statement:

```
no-forwarding;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Multiple-Instance LDP and Carrier-of-Carriers VPNs

By configuring multiple LDP routing instances, you can use LDP to advertise labels in a carrier-of-carriers VPN from a service provider provider edge (PE) router to a customer carrier customer edge (CE) router. This is especially useful when the carrier customer is a basic Internet service provider (ISP) and wants to restrict full Internet routes to its PE routers. By using LDP instead of BGP, the carrier customer shields its other internal routers from the Internet. Multiple-instance LDP is also useful when a carrier customer wants to provide Layer 2 or Layer 3 VPN services to its customers.

For an example of how to configure multiple LDP routing instances for carrier-of-carriers VPNs, see the *Multiple Instances for Label Distribution Protocol Feature Guide*.

## Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router

The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

To configure ultimate-hop popping, include the **explicit-null** statement:

```
explicit-null;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

For more information about labels, see *MPLS Label Overview* and *MPLS Label Allocation*.

## Enabling LDP over RSVP-Established LSPs

You can run LDP over LSPs established by RSVP, effectively tunneling the LDP-established LSP through the one established by RSVP. To do so, enable LDP on the lo0.0 interface (see “[Enabling and Disabling LDP](#)” on page 4810). You must also configure the LSPs over which you want LDP to operate by including the **ldp-tunneling** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit]
protocols {
 mpls {
 label-switched-path lsp-name {
 from source;
 to destination;
 ldp-tunneling;
 }
 }
}
```

```
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**Related  
Documentation**

- [Tunneling LDP LSPs in RSVP LSPs Overview on page 4805](#)

## Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This might require that you manually configure the RSVP metric when deploying LDP tunneling over RSVP LSPs in heterogeneous networks.

When a Juniper Networks router is linked to another vendor's router through an RSVP tunnel, and LDP tunneling is also enabled, by default the Juniper Networks router might not use the RSVP tunnel to route traffic to the LDP destinations downstream of the other vendor's egress router if the RSVP path has a metric of 1 larger than the physical OSPF path.

To ensure that LDP tunneling functions properly in heterogeneous networks, you can configure OSPF to ignore the RSVP LSP metric by including the **ignore-lsp-metrics** statement:

```
ignore-lsp-metrics;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ospf traffic-engineering shortcuts]**
- **[edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]**

To enable LDP over RSVP LSPs, you also still need to complete the procedure in Section [“Enabling LDP over RSVP-Established LSPs” on page 4834](#).

## Configuring the TCP MD5 Signature for LDP Sessions

You can configure an MD5 signature for an LDP TCP connection to protect against the introduction of spoofed TCP segments into LDP session connection streams.

A router using the MD5 signature option is configured with a password for each peer for which authentication is required. The password is stored encrypted.

LDP hello adjacencies can still be created even when peering interfaces are configured with different security signatures. However, the TCP session cannot be authenticated and is never established.

To configure an MD5 signature for an LDP TCP connection, include the **session** and **authentication-key** statement:

```
session address {
 authentication-key md5-authentication-key;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary section for the **session** statement.

Use the **session** statement to configure the address for the remote end of the LDP session.

The **md5-authentication-key** (password) can be up to 69 characters long. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks.

You can also configure an authentication key update mechanism for the LDP routing protocol. This mechanism allows you to update authentication keys without interrupting associated routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).

To configure the authentication key update mechanism, include the **key-chain** statement at the **[edit security authentication-key-chains]** hierarchy level, and specify the **key** option to create a keychain consisting of several authentication keys.

```
[edit security authentication-key-chains]
key-chain key-chain-name {
 key key {
 secret secret-data;
 start-time yyyy-mm-dd.hh:mm:ss;
 }
}
```

To configure the authentication key update mechanism for the LDP routing protocol, include the **authentication-key-chain** statement at the **[edit protocols ldp]** hierarchy level to associate the protocol with the **[edit security authentication-key-chains]** authentication keys.

```
[edit protocols ldp]
group group-name {
 neighbor address {
 authentication-key-chain key-chain-name;
 }
}
```

For more information about the authentication key update feature, see *Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols*.

## Configuring LDP Session Protection

An LDP session is normally created between a pair of routers that are connected by one or more links. The routers form one hello adjacency for every link that connects them and associate all the adjacencies with the corresponding LDP session. When the last hello adjacency for an LDP session goes away, the LDP session is terminated. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished.

You can configure the Junos OS to leave the LDP session between two routers up even if there are no hello adjacencies on the links connecting the two routers by configuring the **session-protection** statement. You can optionally specify a time in seconds using the **timeout** option. The session remains up for the duration specified as long as the routers maintain IP network connectivity.

```
session-protection {
```

```

 timeout seconds;
}

```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Disabling SNMP Traps for LDP

Whenever an LDP LSP makes a transition from up to down, or down to up, the router sends an SNMP trap. However, it is possible to disable the LDP SNMP traps on a router, logical system, or routing instance.

For information about the LDP SNMP traps and the proprietary LDP MIB, see the *SNMP MIBs and Traps Reference* and *Interpreting the Enterprise-Specific LDP MIB*.

To disable SNMP traps for LDP, specify the **trap disable** option for the **log-updown** statement:

```

log-updown {
 trap disable;
}

```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on LDP Links

LDP is a protocol for distributing labels in non-traffic-engineered applications. Labels are distributed along the best path determined by the IGP. If synchronization between LDP and the IGP is not maintained, the LSP goes down. When LDP is not fully operational on a given link (a session is not established and labels are not exchanged), the IGP advertises the link with the maximum cost metric. The link is not preferred but remains in the network topology.

LDP synchronization is supported only on active point-to-point interfaces and LAN interfaces configured as point-to-point under the IGP. LDP synchronization is not supported during graceful restart.

To advertise the maximum cost metric until LDP is operational for synchronization, include the **ldp-synchronization** statement:

```

ldp-synchronization {
 disable;
 hold-time seconds;
}

```

To disable synchronization, include the **disable** statement. To configure the time period to advertise the maximum cost metric for a link that is not fully operational, include the **hold-time** statement.

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on the Router

You can configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

To configure the time the LDP waits before informing the IGP that the LDP neighbor and session are operational, include the **igp-synchronization** statement and specify a time in seconds for the **holddown-interval** option:

```
igp-synchronization holddown-interval seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring the Label Withdrawal Timer

The label withdrawal timer delays sending a label withdrawal message for a FEC to a neighbor. When an IGP link to a neighbor fails, the label associated with the FEC has to be withdrawn from all the upstream routers if the neighbor is the next hop for the FEC. After the IGP converges and a label is received from a new next hop, the label is readvertised to all the upstream routers. This is the typical network behavior. By delaying label withdrawal by a small amount of time (for example, until the IGP converges and the router receives a new label for the FEC from the downstream next hop), the label withdrawal and sending a label mapping soon could be avoided. The **label-withdrawal-delay** statement allows you to configure this delay time. By default, the delay is 60 seconds.

If the router receives the new label before the timer runs out, the label withdrawal timer is canceled. However, if the timer runs out, the label for the FEC is withdrawn from all of the upstream routers.

By default, LDP waits for 60 seconds before withdrawing labels to avoid resignaling LSPs multiple times while the IGP is reconverging. To configure the label withdrawal delay time in seconds, include the **label-withdrawal-delay** statement:

```
label-withdrawal-delay seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Ignoring the LDP Subnet Check

In Junos OS Release 8.4 and later releases, an LDP source address subnet check is performed during the neighbor establishment procedure. The source address in the LDP link hello packet is matched against the interface address. This causes an interoperability issue with some other vendors' equipment.

To disable the subnet check, include the **allow-subnet-mismatch** statement:

```
allow-subnet-mismatch;
```

This statement can be included at the following hierarchy levels:

- [edit protocols ldp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols ldp **interface** *interface-name*]

**Release Information** Statement introduced in Junos OS Release 7.6.  
 Statement introduced for BGP in Junos OS Release 8.0.  
 Statement introduced in Junos OS Release 9.0 for EX Series switches.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.  
 Statement introduced for BMP in Junos OS Release 13.2X51-D15 for the QFX Series.  
 Statement introduced for BMP in Junos OS Release 13.3.  
 Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Configure an authentication algorithm type.

**NOTE:** Keep the following points in mind when you configure the authentication algorithm in an IPsec proposal:

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, an error occurs and the tunnel is not established in this scenario. For example, if one end of the tunnel contains router 1 configured with the authentication algorithm as hmac-sha-256-128 and the other end of the tunnel contains router 2 configured with the authentication algorithm as hmac-md5-96, the VPN tunnel is not established.

- When both ends of an IPsec VPN tunnel contain the same IKE proposal but different IPsec proposals, and when one end of the tunnel contains two IPsec proposals to check whether a less secure algorithm is selected or not, an error occurs and the tunnel is not established. For example, if you configure two authentication algorithms for an IPsec proposal as `hmac-sha-256-128` and `hmac-md5-96` on one end of the tunnel, router 1, and if you configure the algorithm for an IPsec proposal as `hmac-md5-96` on the other end of the tunnel, router 2, the tunnel is not established and the number of proposals mismatch.
  - When you configure two IPsec proposals at both ends of a tunnel, such as the `authentication-algorithm hmac-sha-256-128` and `authentication-algorithm hmac-md5-96` statements at the `[edit services ipsec-vpn ipsec proposal proposal-name]` hierarchy level on one of the tunnel, router 1 (with the algorithms in two successive statements to specify the order), and the `authentication-algorithm hmac-md5-96` and `authentication-algorithm hmac-sha-256-128` statements at the `[edit services ipsec-vpn ipsec proposal proposal-name]` hierarchy level on one of the tunnel, router 2 (with the algorithms in two successive statements to specify the order, which is the reverse order of router 1), the tunnel is established in this combination as expected because the number of proposals is the same on both ends and they contain the same set of algorithms. However, the authentication algorithm selected is `hmac-md5-96` and not the stronger algorithm of `hmac-sha-256-128`. This method of selection of the algorithm occurs because the first matching proposal is selected. Also, for a default proposal, regardless of whether the router supports the Advanced Encryption Standard (AES) encryption algorithm, the `3des-cbc` algorithm is chosen and not the `aes-cfb` algorithm, which is because of the first algorithm in the default proposal being selected. In the sample scenario described here, on router 2, if you reverse the order of the algorithm configuration in the proposal so that it is the same order as the one specified on router 1, `hmac-sha-256-128` is selected as the authentication method.
  - You must be aware of the order of proposals in an IPsec policy at the time of configuration if you want the matching of proposals to happen in a certain order of preference, such as the strongest algorithm to be considered first when a match is made when both policies from the two peers have a proposal.
-

**Options** *algorithm*—Specify one of the following types of authentication algorithms:

- **aes-128-cmac-96**—Cipher-based message authentication code (AES128, 96 bits).
- **hmac-sha-1-96**—Hash-based message authentication code (SHA1, 96 bits).
- **md5**—Message digest 5.

**Default:** hmac-sha-1-96

**NOTE:** The default is not displayed in the output of the `show bgp bmp` command unless a key or key-chain is also configured.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

The use of the <b>deaggregate</b> statement in LDP is a standard practice that we recommend for LDP deployments.                                                                                            |
| <b>Default</b>                  | Deaggregation is disabled on the router.                                                                                                                                                                                                                                            |
| <b>Options</b>                  | <b>deaggregate</b> —Deaggregate FECs.<br><b>no-deaggregate</b> —Aggregate FECs.                                                                                                                                                                                                     |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Enable LDP downstream on demand on the LDP session. LDP is widely deployed in downstream unsolicited advertisement mode. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between access and aggregation networks to minimize the workload for the access node (AN) control plane and to avoid the storage of tens of thousands of label bindings from upstream aggregation nodes. |

                          [edit protocols ldp oam]

**Release Information**    Statement introduced in Junos OS Release 8.5.  
                              Statement introduced in Junos OS Release 12.2 for EX Series switches.  
                              Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**    Allows you to configure BFD for a specific LDP forwarding equivalence class (FEC).

**Options**    *fec-address*—Specify the FEC address.  
  
              The other statements are explained separately.

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration.

## graceful-restart (Protocols LDP)

|                            |                                                                                                                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <pre>graceful-restart {   disable;   helper-disable;   maximum-neighbor-recovery-time <i>value</i>;   reconnect-time <i>seconds</i>;   recovery-time <i>value</i>; }</pre>                                                                                                            |
| <b>Hierarchy Level</b>     | <pre>[edit logical-systems <i>logical-system-name</i> protocols ldp], [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols ldp], [edit protocols ldp], [edit routing-instances <i>routing-instance-name</i> protocols ldp]</pre> |
| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.</p>                                                                                                                                                  |
| <b>Description</b>         | Configure LDP graceful restart on the LDP master protocol instance or for a specific routing instance.                                                                                                                                                                                |

**NOTE:** When you alter the graceful restart configuration at either the [edit routing-options graceful-restart] or [edit protocols ldp graceful-restart] hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Specify how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that each LDP node tells its neighbors how long to wait. You can specify times for both link hello messages and targeted hello messages depending on the hierarchy level at which you configure the <b>hold-time</b> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>         | Specify LDP protocol-level trace options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>             | The default LDP protocol-level trace options are inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>ldp-log</b>. We recommend that you place LDP tracing output in the file <b>ldp-log</b>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 2 files</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <ul style="list-style-type: none"> <li>• <b>address</b>—Operation of address and address withdrawal messages</li> <li>• <b>binding</b>—Label-binding operations</li> <li>• <b>error</b>—Error conditions</li> <li>• <b>event</b>—Protocol events</li> </ul> |

- **initialization**—Operation of initialization messages
- **label**—Operation of label request, label map, label withdrawal, and label release messages
- **notification**—Operation of notification messages
- **nsr-synchronization**—Nonstop active routing synchronization events
- **p2mp-nsr-synchronization**—Point-to-multipoint nonstop active routing synchronization events
- **packets**—Equivalent to setting **address**, **initialization**, **label**, **notification**, and **periodic** flags (see also the **filter** flag modifier)
- **path**—Label-switched path operations
- **periodic**—Operation of hello and keepalive messages
- **route**—Operation of route messages
- **state**—Protocol state transitions

**flag-modifier**—(Optional) Modifier for the tracing flag. You can specify one or more of these modifiers:

- **detail**—Provide detailed trace information.
- **disable**—Disable this trace flag.
- **filter**—Filter to apply to this flag. The **filter** flag modifier can be applied only to the **route**, **path**, and **binding** flags. This flag modifier has the following options:
  - **match-on**—Match on argument specified. The **match-on** option has the following suboptions:
    - **address**—Filter based on the source and destination addresses of packets. Available for the **packets** flag option only.
    - **fec**—Filter based on the FEC associated with the traced object.
  - **policy *policy-name***—Specify the filter policy.
- **receive**—Packets being received.
- **send**—Packets being transmitted.

**no-world-readable**—(Optional) Prevent all users from reading the log file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

**world-readable**—(Optional) Enable any user to read the log file.

**Required Privilege Level** routing and trace—To view this statement in the configuration.  
routing-control and trace-control—To add this statement to the configuration.

| Description         | LDP traffic statistics display the amount of traffic passed through a router for a particular FEC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Options             | <p><b>file <i>filename</i></b>—Name of the file to receive the output of the LDP statistics operation.<br/>Enclose the name within quotation marks. All files are placed in the directory <code>/var/log</code>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of LDP statistics files. When a statistics file named <b><i>ldp-stat</i></b> reaches its maximum size, it is renamed <b><i>ldp-stat.0</i></b>, then <b><i>ldp-stat.1</i></b>, and so on, until the maximum number of LDP statistics files is reached. Then the oldest file is overwritten.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 2 files</p> <p>If you specify a maximum number of files, you also must include the <b>size</b> statement to specify the maximum file size.</p> <p><b>interval <i>seconds</i></b>—(Optional) Specify the interval at which the statistics are polled and written to the file.</p> <p><b>Default:</b> 300 seconds (5 minutes)</p> <p><b>no-penultimate-hop</b>—(Optional) Do not collect traffic statistics on the penultimate hop router.</p> <p><b>no-world-readable</b>—(Optional) Prevent all users from reading the log file.</p> <p><b>size <i>size</i></b>—(Optional) Maximum size of each statistics file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a statistics file named <b><i>ldp-stat</i></b> reaches this size, it is renamed <b><i>ldp-stat.0</i></b>. When <b><i>ldp-stat</i></b> again reaches this size, <b><i>ldp-stat.0</i></b> is renamed <b><i>ldp-stat.1</i></b> and <b><i>ldp-stat</i></b> is renamed <b><i>ldp-stat.0</i></b>. This renaming scheme continues until the maximum number of statistics files is reached. Then the oldest statistics file is overwritten.</p> <p><b>Syntax:</b> <b><i>xk</i></b> to specify KB, <b><i>xm</i></b> to specify MB, or <b><i>xg</i></b> to specify GB</p> <p><b>Range:</b> 10 KB through the maximum file size supported on your system</p> |

**Default:** 1 MB

If you specify a maximum file size, you also must also include the **files** statement to specify the maximum number of files.

**world-readable**—(Optional) Enable log file access for all users.

| <b>Description</b>              | Enables you to configure the IP address used to specify the TCP session for the LDP session. Routers must first establish a TCP session between one another before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>                  | <b>router-id</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <b>interface</b> —The first IP address on the interface is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. You cannot specify the <b>interface</b> option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the <b>router-id</b> option.<br><br><b>router-id</b> —The router identifier is used as the transport address. Unless otherwise configured, the router identifier is the loopback address. |
| <b>Required Privilege Level</b> | <b>interface</b> —To view this statement in the configuration.<br><b>interface-control</b> —To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Monitoring Commands for LDP

---

- [clear ldp neighbor](#)
- [clear ldp session](#)
- [clear ldp statistics](#)
- [ping mpls ldp](#)

- `show ldp database`
- `show ldp fec-filters`
- `show ldp interface`
- `show ldp neighbor`
- `show ldp path`
- `show ldp route`
- `show ldp session`
- `show ldp statistics`
- `show ldp traffic-statistics`
- `traceroute mpls ldp`

## clear ldp neighbor

### Sample Output

#### clear ldp statistics

```
user@host> clear ldp statistics
```

## ping mpls ldp

**Syntax**    ping mpls ldp *fec*  
                  <count *count*>  
                  <destination *address*>  
                  <detail>  
                  <exp *forwarding-class*>  
                  <instance *routing-instance-name*>  
                  <logical-system (all | *logical-system-name*)>  
                  <p2mp root-addr *ip-address* lsp-id *identifier*>  
                  <size *bytes*>  
                  <source *source-address*>  
                  <sweep>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                  Command introduced in Junos OS Release 9.0 for EX Series switches.  
                  **size** and **sweep** options introduced in Junos OS Release 9.6.  
                  **instance** option introduced in Junos OS Release 10.0.  
                  **p2mp**, **root-address**, and **lsp-id** options introduced in Junos OS Release 11.2.  
                  Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**    Check the operability of MPLS LDP-signaled label-switched path (LSP) connections.  
                  Type Ctrl+c to interrupt a **ping mpls** command.

**Options**    **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**fec**—Ping an LDP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

**instance** *routing-instance-name*—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**p2mp root-addr** *ip-address* **lsp-id** *identifier*—(Optional) Ping the end points of a point-to-multipoint LSP. Enter the IP address of the point-to-multipoint LSP root and the ID number of the point-to-multipoint LSP.

**size** *bytes*—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller

than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

You can configure the ping interval for the **ping mpls ldp** command by specifying a new time in seconds using the **lsp-ping-interval** statement at the **[edit protocols ldp oam]** hierarchy level. For more information, see the *MPLS Applications Feature Guide for Routing Devices*.

In asymmetric MTU scenarios, the echo response may be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls ldp fec count on page 4888](#)  
[ping mpls ldp p2mp root-addr lsp-id on page 4888](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately.

## Sample Output

### ping mpls ldp fec count

```
user@host> ping mpls ldp 10.255.245.222 count 10
!!!xxx...x--- lsping statistics ---10 packets transmitted, 3 packets received,
70% packet loss 4 packets received with error status, not counted as received.
```

### ping mpls ldp p2mp root-addr lsp-id

```
user@host> ping mpls ldp p2mp root-addr 10.1.1.1/32 lsp-id 1 count 1
Request for seq 1, to interface 71, no label stack.

[show ldp database summary on page 4898](#)

**Output Fields** Table 364 describes the output fields for the **show ldp database** command. Output fields are listed in the approximate order in which they appear.

**Table 364: show ldp database Output Fields**

| Field Name                   | Field Description                                                                | Level of Output |
|------------------------------|----------------------------------------------------------------------------------|-----------------|
| <b>Input label database</b>  | Label received from the other router.                                            | All levels      |
| <b>Output label database</b> | Label advertised to the other router.                                            | All levels      |
| <i>session-identifier</i>    | Session identifier, which includes the local and remote label space identifiers. | All levels      |
| <b>Labels received</b>       | Number of labels received from the other router.                                 | All levels      |
| <b>Labels advertised</b>     | Number of labels advertised to the other router.                                 | All levels.     |
| <b>Label</b>                 | Label binding to a route prefix.                                                 | All levels      |

Table 364: show ldp database Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>Prefix</b>                          | <p>Route prefix.</p> <p>It can be one of the following values:</p> <ul style="list-style-type: none"> <li>• IP prefix.</li> <li>• Point-to-multipoint root address, multicast source address, and multicast group address when multipoint LDP (M-LDP) inband signaling is configured.</li> <li>• Layer 2 encapsulation type.</li> </ul> <p>Layer 2 encapsulation types are displayed in the format <b>L2CKT control word status encapsulation-type vc-number</b>, for example, <b>L2CKT CtlfWord FRAME RELAY VC 2</b></p> <ul style="list-style-type: none"> <li>• <b>control-word-status</b>—Displays whether the use of the control word has been negotiated for this virtual circuit: <ul style="list-style-type: none"> <li>• <b>NoCtrlWord</b></li> <li>• <b>CtrlWord</b></li> </ul> </li> <li>• <b>encapsulation-type</b>—Encapsulation type: <ul style="list-style-type: none"> <li>• <b>FRAME RELAY</b></li> <li>• <b>ATM AAL5</b></li> <li>• <b>ATM CELL</b></li> <li>• <b>VLAN</b></li> <li>• <b>ETHERNET</b></li> <li>• <b>CISCO_HDLC</b></li> <li>• <b>PPP</b></li> </ul> </li> <li>• <b>VC number</b>—Virtual circuit number. It can have any numeric value.</li> <li>• <b>(Stale)</b>—When you display the LDP database for the neighbor of a restarting router, the bindings learned from the restarting neighbor are displayed as (Stale). Stale bindings are deleted if they are not refreshed within the recovery time.</li> </ul> | All levels       |
| <b>MTU</b>                             | MTU of the Layer 2 circuit. MTU is displayed for all encapsulation types except ATM cell encapsulations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <b>detail</b>    |

| Field Name   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Level of Output |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>State</b> | State of the label binding: <ul style="list-style-type: none"> <li><b>Active</b>—Label binding has been installed and distributed appropriately. A label binding is almost always in this state.</li> <li><b>New</b>—New label that has not yet been distributed. <ul style="list-style-type: none"> <li><b>MapRcv</b>—Waiting to receive a label mapping message.</li> <li><b>MapSend</b>—Waiting to send a label mapping message.</li> <li><b>RelRcv</b>—Waiting to receive a label release message.</li> <li><b>RelRsnd</b>—Waiting to receive a label release message before resending label mapping message.</li> <li><b>RelSend</b>—Waiting to send a label release message.</li> <li><b>ReqSend</b>—Waiting to send a label request message.</li> <li><b>W/dSend</b>—Waiting to send a label withdrawal message.</li> </ul> </li> </ul> | <b>detail</b>   |
| <b>Age</b>   | Time elapsed since the binding was created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <b>detail</b>   |

## Sample Output

### show ldp database (master)

```

user@host> show ldp database extensive
Input label database, 10.255.107.232:0--10.255.107.236:0
 Label Prefix
 299840 10.255.107.232/32
 State: Active
 Age: 9:35
 Entropy Label Capability: No
 3 10.255.107.236/32
 State: Active
 Age: 9:35
 Entropy Label Capability: No
 299776 L2CKT CtrlWord VLAN VC 100
 MTU: 1500 Requested VLAN ID: 600 Flow Label T Bit: 1 Flow Label R
 Bit: 1
 State: Active
 Age: 9:35
 Entropy Label Capability: No
 VCCV Control Channel types:
 PWE3 control word
 MPLS router alert label
 MPLS PW label with TTL=1
 VCCV Control Verification types:
 LSP ping
 BFD with PW-ACH-encapsulation for Fault Detection
 BFD with IP/UDP-encapsulation for Fault Detection

Output label database, 10.255.107.232:0--10.255.107.236:0
 Label Prefix
 3 10.255.107.232/32
 State: Active
 Age: 9:35
 Entropy Label Capability: No
 299776 10.255.107.236/32

```

State: Active  
Age: 9:35  
Entropy Label Capability: No

| <b>Output Fields</b>            | Table 366 describes the output fields for the <b>show ldp interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 366: show ldp interface Output Fields

| Field Name            | Field Description                                                                                                                                                              | Level of Output                   |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| <b>Interface</b>      | Interface name.                                                                                                                                                                | All levels                        |
| <b>Label space ID</b> | Label space identifier that the router is advertising on the interface.                                                                                                        | All levels                        |
| <b>Nbr count</b>      | Number of neighbors on the interface.                                                                                                                                          | All levels                        |
| <b>Next hello</b>     | How long until the next hello packet is sent on this interface, in seconds.                                                                                                    | All levels                        |
| <b>Hello interval</b> | One-third of the negotiated hold time (in seconds). If the user-configured value for the hello interval is smaller than the computed value, the user-configured value is used. | <b>detail</b><br><b>extensive</b> |
| <b>Hold time</b>      | Configured hold time, in seconds.                                                                                                                                              | <b>detail</b><br><b>extensive</b> |

Table 366: show ldp interface Output Fields (*continued*)

| Field Name           | Field Description                                                                 | Level of Output |
|----------------------|-----------------------------------------------------------------------------------|-----------------|
| Transport address    | Address to which the neighbor wants the local route to establish the LDP session. | extensive       |
| Local hello interval | Locally configured hello interval.                                                | extensive       |

## Sample Output

### show ldp interface extensive

```
user@host> show ldp interface extensive
Interface Label space ID Nbr count Next hello
fe-0/0/3.0 10.255.245.6:0 2 0
Hello interval: 1, Hold time: 15, Transport address: 10.255.245.6
Local hello interval: 2, Index: 69
```

## show ldp neighbor

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 367: show ldp neighbor Output Fields**

| Field Name            | Field Description                                  | Level of Output |
|-----------------------|----------------------------------------------------|-----------------|
| <b>Address</b>        | IP address of the neighbor.                        | All levels      |
| <b>Interface</b>      | Interface over which the neighbor was discovered.  | All levels      |
| <b>Label space ID</b> | Label space identifier advertised by the neighbor. | All levels      |

Table 367: show ldp neighbor Output Fields (*continued*)

| Field Name             | Field Description                                                                                           | Level of Output  |
|------------------------|-------------------------------------------------------------------------------------------------------------|------------------|
| Hold time              | Remaining hold time before the neighbor expires, in seconds.                                                | All levels       |
| Transport address      | Address to which the neighbor wants the local route to establish the LDP session.                           | detail           |
| Configuration sequence | Counter that increments whenever the neighbor changes its configuration.                                    | detail           |
| Up for                 | Length of time the LDP neighbor has been in operation.                                                      | detail extensive |
| Reference count        | Reference count for the LDP neighbor.                                                                       | extensive        |
| Hold time              | Displays the neighbor's hold time. The hold time is the proposed hold times for the local and peer routers. | extensive        |
| Proposed local/peer    | Hold time value proposed by the local router and the peer router.                                           | extensive        |

## Sample Output

### show ldp neighbor extensive

```

user@host> show ldp neighbor extensive
Address Interface Label space ID Hold Time
192.168.37.23 so-1/0/0.0 10.255.245.5:0 44
Transport address: 10.255.245.5, Configuration sequence: 6
Up for 00:03:37
Reference count: 1
Hold time: 45, Proposed local/peer: 15/45

```

### show ldp neighbor auto-targeted extensive

```

user@host> show ldp neighbor auto-targeted extensive
Address Interface Label space ID Hold time
10.255.107.236 lo0.0 10.255.107.236:0 41
Transport address: 10.255.107.236, Configuration sequence: 14
Up for 00:10:53
Reference count: 2
Hold time: 45, Proposed local/peer: 45/45
Hello interval: 15
Hello flags: targeted
Neighbor types: Auto-targeted

```

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 368: show ldp path Output Fields**

| Field Name                    | Field Description                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Output Session (label)</b> | Session ID and labels that this system has sent using LDP. These correspond to MPLS packets received.        |
| <b>Input Session (label)</b>  | Session ID and labels that this system has received using LDP. These correspond to MPLS packets transmitted. |
| <b>route</b>                  | MPLS route.                                                                                                  |
| <b>Attached route</b>         | Route corresponding to the LSP.                                                                              |
| <b>Ingress route</b>          | The router acts as the ingress for the LSP.                                                                  |
| <b>Reference count</b>        | Reference count for the LDP neighbor.                                                                        |

Table 368: show ldp path Output Fields (*continued*)

| Field Name    | Field Description                                                               |
|---------------|---------------------------------------------------------------------------------|
| Transit route | Names of the forwarding equivalence class (FEC) filters on the transit routers. |
| Global label  | MPLS label that is used globally.                                               |

## Sample Output

### show ldp path extensive

```
user@host> show ldp path extensive
Output Session (label) Input Session (label)
10.255.14.220:0(3) ()
 Attached route: 10.255.14.221/32
 Reference count: 3, Global label: 3

| <b>Output Fields</b>            | <a href="#">Table 369</a> describes the output fields for the <b>show ldp route</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 369: show ldp route Output Fields**

| Field Name                     | Field Description                                         |
|--------------------------------|-----------------------------------------------------------|
| <b>Destination</b>             | Destination prefix.                                       |
| <b>Next-hop intf/lsp/table</b> | Interface that is the next hop to the destination prefix. |
| <b>Next-hop address</b>        | IP address of the next hop.                               |
| <b>Session ID</b>              | LDP session ID.                                           |

Table 369: show ldp route Output Fields (*continued*)

| Field Name              | Field Description                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route flags             | Information about the route. For example, the <b>Ingress TTL propagate</b> flag indicates that the time-to-live (TTL) value is being propagated with the route. |
| Bound to outgoing label | The route has been bound to LSPs with the label being distributed for that LSP.                                                                                 |
| Topology entry          | The topology that the route is bound to.                                                                                                                        |
| Ingress route status    | Status of the ingress route. For example, it could be <b>Active</b> or <b>Inactive</b> .                                                                        |
| Last modified           | The length of time since the ingress route status last changed.                                                                                                 |

| <b>Active</b>                 | Whether the local router is playing the active role in the session and during session establishment.                                                                                                                  | <b>detail extensive</b> |
| <b>Passive</b>                | Whether the local router is playing the passive role in the session and during session establishment.                                                                                                                 | <b>detail extensive</b> |
| <b>Maximum PDU</b>            | Maximum protocol data unit (PDU) size (packet size) for the session.                                                                                                                                                  | <b>detail extensive</b> |
| <b>Hold time</b>              | Time remaining until the session will be closed, in seconds. This value corresponds to the one configured using the <b>keepalive-timeout</b> statement configured at the <b>[edit protocols ldp]</b> hierarchy level. | <b>detail extensive</b> |
| <b>Neighbor count</b>         | Number of neighbors that are contributing to the session.                                                                                                                                                             | <b>detail extensive</b> |
| <b>Neighbor types</b>         | Category of LDP session: <b>discovered</b> or <b>auto-targeted</b> .                                                                                                                                                  | any                     |
| <b>Keepalive interval</b>     | Keepalive interval, in seconds.                                                                                                                                                                                       | <b>detail extensive</b> |
| <b>Connect retry interval</b> | TCP connection retry interval, in seconds.                                                                                                                                                                            | <b>detail extensive</b> |
| <b>Local address</b>          | Local transport address.                                                                                                                                                                                              | <b>detail extensive</b> |
| <b>Remote address</b>         | Remote transport address.                                                                                                                                                                                             | <b>detail extensive</b> |
| <b>Up for</b>                 | Time that this session has been up.                                                                                                                                                                                   | <b>detail extensive</b> |
| <b>Last down</b>              | Time since the session last went down.                                                                                                                                                                                | <b>detail extensive</b> |

| Field Name            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Event type</b>     | <p>LDP events and errors:</p> <ul style="list-style-type: none"> <li>• <b>Sessions opened</b>—Number of LDP sessions that have been opened.</li> <li>• <b>Sessions closed</b>—Number of LDP sessions that have been closed.</li> <li>• <b>Topology changes</b>—Number of changes to the known LDP topology.</li> <li>• <b>No interface</b>—Number of missing interface address messages. When a new LDP session is initialized and before sending label lapping or label request messages, the LSR advertises its interface addresses with one or more address messages.</li> <li>• <b>No session</b>—Number of missing session messages. Session messages are used to establish, maintain, and terminate sessions between LDP peers.</li> <li>• <b>No adjacency</b>—The exchange of hello adjacency messages results in the creation of an adjacency. The LDP identifier, together with the sender's LDP identifier in the PDU header, enables the receiver to match the initialization message with one of its hello adjacencies. If there is no matching hello adjacency, the LSR sends a session the initialization message is rejected.</li> <li>• <b>Unknown version</b>—The LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment.</li> <li>• <b>Malformed PDU</b>—An LDP PDU received on a TCP connection for an LDP session is malformed if the LDP identifier in the PDU header is unknown to the receiver, or if it is known but is not the LDP identifier associated by the receiver with the LDP peer for this LDP session.<br/> An LDP PDU is considered to be malformed if the LDP protocol version is not supported by the receiver, or it is supported but is not the version negotiated for the session during session establishment.<br/> An LDP PDU is considered malformed if the PDU length field is too small (less than 14) or too large (greater than maximum PDU length).</li> <li>• <b>Malformed message</b>—Malformed LDP messages that are part of the LDP discovery mechanism are handled by silently discarding them.<br/> An LDP message is malformed if the message type is unknown. If the message type is less than 0x8000 (high order bit = 0), it is an error signaled by the unknown message type status code.<br/> An LDP message is considered to be malformed if the message length is too large, meaning that the message extends beyond the end of the containing LDP PDU.<br/> The LDP message is considered to be malformed if the message length is too small, meaning that it is smaller than the smallest possible value component.<br/> The LDP message is considered to be malformed if the message is missing one or more mandatory parameters.</li> <li>• <b>Unknown message type</b>—If the message type is less than 0x8000 (high order bit = 0) or greater than or equal to 0x8000 (high order bit = 1) it is considered to be an unknown message.</li> <li>• <b>Inappropriate message</b>—The message is not of the type that the receiver expects to receive.</li> <li>• <b>Malformed TLV</b>—The TLV Length is too large or the receiver cannot decode the TLV value. This can indicate an issue in either the sending or receiving LSR.</li> <li>• <b>Bad TLV value</b>—The TLV Length is too large.</li> <li>• <b>Missing TLV</b>—The TLV is missing one or more mandatory parameters.</li> <li>• <b>PDU too large</b>—The PDF is greater than the maximum PDU length. Section "Initialization Message" in RFC 5036 describes how the maximum PDU length for a session is determined.</li> </ul> |
| <b>Total</b>          | Total number of each event or error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>FEC</b>          | Forwarding equivalence class (FEC) for which LDP traffic statistics are collected.<br><br>For P2MP LSPs, FEC appears as a combination of root address and the LSP ID ( <b>root_addr:lsp_id</b> ).<br><br>For M-LDP P2MP LSPs, FEC appears as a combination of root address multicast source address, and multicast group address ( <b>root_addr:lsp_id/grp,src</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Type</b>         | Type of traffic originating from a router, either <b>Ingress</b> (originating from this router) or <b>Transit</b> (forwarded through this router).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Packets</b>      | Number of packets passed by the FEC since its LSP came up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Bytes</b>        | Number of bytes of data passed by the FEC since its LSP came up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Shared</b>       | Whether a label is shared by prefixes: <b>Yes</b> or <b>No</b> . A <b>Yes</b> value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Nextthop</b>     | The next hop address for P2MP LSPs. (This is the downstream LDP Session ID.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Label</b>        | For multipoint LDP with multicast-only fast reroute (MoFRR), the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop.<br><br>Multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label. |
| <b>Backup route</b> | For multipoint LDP with MoFRR, the route that is used if the primary route becomes unavailable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## traceroute mpls ldp

---

**Syntax** `traceroute mpls <ldp> fec`  
`<destination>`  
`<detail>`  
`<exp>`  
`<fanout>`  
`<logical-system>`  
`<no-resolve>`  
`<paths>`  
`<retries>`  
`<routing-instance>`  
`<source>`  
`<ttl>`  
`<update>`  
`<wait>`

**Release Information** Command introduced in Junos OS Release 8.4.  
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Trace route to a remote host for an MPLS label-switched path signaled by the LDP. Use **traceroute mpls ldp** as a debugging tool to locate MPLS label-switched path forwarding issues in a network. (Currently supported for IPv4 packets only.)

**Options** *fec*—Specify the IP address and optional prefix of the forwarding equivalence class (FEC).  
*destination*—(Optional) Specify the destination address to use when sending probes.  
*detail*—(Optional) Display detailed output.  
*exp*—(Optional) Specify the class-of-service to use when sending probes. The range of values is 0 through 7. The default value is 7.  
*fanout*—(Optional) Specify the maximum number of nexthops to search per node. The range of values is 1 through 16. The default value is 16.  
*logical-system*—(Optional) Specify the name of the logical system for the traceroute attempt.  
*no-resolve*—(Optional) Specify not to resolve the hostname that corresponds to the IP address.  
*paths*—(Optional) Specify the number of paths to search. The range of values is 1 through 255. The default value is 16.  
*retries*—(Optional) Specify the number of times to resend probe. values. The range of values is 1 through 9. The default value is 3.  
*routing-instance routing-instance-name*—(Optional) Specify the name of the routing instance for the traceroute attempt.  
*source source-address*—(Optional) Specify the source address of the outgoing traceroute packets.

**ttl value**—(Optional) Specify the maximum time-to-live value to include in the traceroute request, in seconds. The range of values is **1** through **125** and the default value is **64**.

**update**—(Optional) Update database contents with traceroute results.

**wait seconds**—(Optional) Specify the number of seconds to wait before resending a probe. The range of values is **5** through **15** and the default value is **10** seconds.

**Required Privilege Level**

network

**List of Sample Output**

[traceroute mpls ldp on page 4926](#)  
[traceroute mpls ldp detail on page 4926](#)

**Output Fields**

[Table 373](#) describes the output fields for the **traceroute mpls ldp fec** command and the **traceroute mpls ldp fec detail** commands. Output fields are listed in the approximate order in which they appear.

**Table 373: traceroute mpls ldp Output Fields**

| Field Name    | Field Description                                                                                                        | Level of Output |
|---------------|--------------------------------------------------------------------------------------------------------------------------|-----------------|
| Probe options | Probe options specified in the <b>traceroute mpls ldp fec</b> command.                                                   | all levels      |
| ttl           | Time to live value of the labeled packet.                                                                                | none specified  |
| Label         | Outgoing label used for forwarding the packet along the label-switched paths.                                            | none specified  |
| Protocol      | Signaling protocol used. For this command, it is LDP.                                                                    | none specified  |
| Address       | Address of the next hop.                                                                                                 | none specified  |
| Previous Hop  | Address of the previous hop. Previous hop address of the first hop is <b>null</b> .                                      | none specified  |
| Probe status  | Forwarding status from the first hop to the last-hop label-switching router (egress point in the label-switched paths).  | none specified  |
| Hop           | Address of the hops in the label-switched path from the first hop to the last hop. Depth indicates the level of the hop. | <b>detail</b>   |
| Parent        | Address of the previous hop. Parent value for the first hop is <b>null</b> .                                             | <b>detail</b>   |
| Return Code   | Return code for reporting the result of processing the echo request by the receiver.                                     | <b>detail</b>   |
| Response time | Time for the echo request to reach the receiver.                                                                         | <b>detail</b>   |

Table 373: traceroute mpls ldp Output Fields (*continued*)

| Field Name     | Field Description                                                                                                | Level of Output |
|----------------|------------------------------------------------------------------------------------------------------------------|-----------------|
| Multipath type | Labels or addresses used by the specified multipath type. If multipaths are not used, the value is <b>none</b> . | <b>detail</b>   |
| Label Stack    | Label stack used to forward the packet.                                                                          | <b>detail</b>   |

## Sample Output

### traceroute mpls ldp

## **MPLS Overview For QFX Series and EX4600 Switches**

---

Multiprotocol Label Switching (MPLS) is a protocol that uses labels to route packets instead of using IP addresses. In a traditional network, each switch performs an IP routing lookup, determines a next-hop based on its routing table, and then forwards a packet to that next-hop. With MPLS, only the first device does a routing lookup, and, instead of finding the next-hop, finds the ultimate destination along with a path to that destination. The path of an MPLS packet is called a label-switched path (LSP).

MPLS applies one or more labels to a packet so it can follow the LSP to the destination. Each switch pops off its label and sends the packet to the next switch label in the sequence.

The Junos OS includes everything you need to configure MPLS. You do not need to install any additional programs or protocols. MPLS is supported on switches with a subset of the commands supported on routers. The Junos MPLS-configured switches can interact with each other and with Junos MPLS-configured routers.

MPLS has the following advantages over conventional packet forwarding:

- Packets arriving on different ports can be assigned different labels.
- A packet arriving at a particular provider edge (PE) switch can be assigned a label that is different from that of the same packet entering the network at a different PE switch. As a result, forwarding decisions that depend on the ingress PE switch can be easily made.
- Sometimes it is desirable to force a packet to follow a particular route that is explicitly chosen at or before the time the packet enters the network, rather than letting it follow the route chosen by the normal dynamic routing algorithm as the packet travels through the network. In MPLS, a label can be used to represent the route so that the packet need not carry the identity of the explicit route.

This topic describes:

- [Why Use MPLS? on page 4931](#)
- [Why Not Use MPLS? on page 4931](#)
- [How Do I Configure MPLS? on page 4931](#)
- [What Does the MPLS Protocol Do? on page 4932](#)
- [How Does MPLS Interface to Other Protocols? on page 4933](#)
- [If I Have Used Cisco MPLS, What Do I Need to Know? on page 4933](#)

## Why Use MPLS?

MPLS reduces the use of the forwarding table by using labels instead of the forwarding table. The size of forwarding tables on a switch are limited by silicon and using exact matching for forwarding to destination devices is cheaper than buying more sophisticated hardware. In addition, MPLS allows you to control where and how traffic is routed on your network – this is called traffic engineering.

Some reasons to use MPLS instead of another switching solution are:

- MPLS can connect different technologies that would not otherwise be compatible---service providers have this compatibility issue when connecting clients with different autonomous systems in their networks. In addition, MPLS has a feature called Fast Reroute that provides alternate backups for paths – this prevents network degradation in case of a switch failure.
- Other IP-based encapsulations such as Generic Route Encapsulation (GRE) or Virtual Extensible Local Area Networks (VXLAN) support only two levels of hierarchy, one for the transport tunnel and one piece of metadata. Using virtual servers means that you need multiple hierarchy levels. For example, one label is needed for top-of-rack (ToR), one label for the egress port that identifies the server, and one for the virtual server.

## Why Not Use MPLS?

There are no protocols to auto-discover MPLS enabled nodes. MPLS protocol just exchanges label values for an LSP. They do not create the LSPs.

You must build the MPLS mesh, switch by switch. We recommend using scripts for this repetitive process.

MPLS hides suboptimal topologies from BGP where multiple exits may exist for the same route.

Large LSPs are limited by the circuits they traverse. You can work around this by creating multiple, parallel LSPs.

## How Do I Configure MPLS?

There are three types of switches you must set up for MPLS:

- Label Edge Router/Switch (LER) or ingress node to the MPLS network. This switch encapsulates the packets.
- Label Switching Routers/Switches (LSR). One or more switches that transfer MPLS packets in the MPLS network.
- Egress router/switch is the final MPLS device that removes the last label before packets leave the MPLS network.

Service providers (SP) use the term provider router (P) for a backbone router/switch doing label switching only. The customer-facing router at the SP is called a provider edge router (PE). Each customer needs a customer edge router (CE) to communicate with

the PE. Customer facing routers typically can terminate IP addresses, L3VPNs, L2VPNs/pseudowires, and VPLS before packets are transferred to the CE.

### Configure the MPLS LER (Ingress) Switch and the Egress Switch

---

To configure MPLS, you must first create one or more named paths on the ingress and egress routers. For each path, you can specify some or all transit routers in the path, or you can leave it empty. See *Configuring the Ingress Router for MPLS-Signaled LSPs* and *Configuring the Intermediate and Egress Routers for MPLS-Signaled LSPs*, *Configuring the Ingress and Egress Router Addresses for LSPs*, and *Configuring the Connection Between Ingress and Egress Routers*.

### Configure LSRs for MPLS

---

Configure one or more MPLS LSRs by following these steps:

1. Configure interfaces on each switch to transmit and receive MPLS packets using the usual interface command with MPLS appended. For example:

```
[edit interfaces ge-0/0/0 unit 0] family mpls;
```

2. Add those same interfaces under [edit protocols mpls]. For example:

```
[edit protocols mpls]
 interface ge-0/0/0;
```

3. Configure the interfaces on each switch to handle MPLS labels with a protocol. For example, for LDP:

```
[edit protocols ldp]
 Interface ge-0/0/0.0;
```

To watch a demo of these configurations, see  
<https://www.youtube.com/watch?v=xegWBCUJ4tE>.

## What Does the MPLS Protocol Do?

Multiprotocol Label Switching (MPLS) is an Internet Engineering Task Force (IETF)-specified framework that provides for the designation, routing, forwarding and switching of traffic flows through the network. In addition, MPLS:

- Specifies mechanisms to manage traffic flows of various granularities, such as flows between different hardware, machines, or even flows between different applications.
- Remains independent of the layer-2 and layer-3 protocols.
- Provides a means to map IP addresses to simple, fixed-length labels used by different packet-forwarding and packet-switching technologies.
- Interfaces to existing routing protocols, such as Resource ReSerVation Protocol (RSVP) and Open Shortest PathFirst (OSPF).
- Supports IP, ATM, and Frame Relay layer-2 protocols.
- Uses these additional technologies:

- FRR: MPLS Fast Reroute improves convergence during a failure by mapping out alternate LSPs in advance.
- Link Protection/ Next-hop backup: A bypass LSP is created for every possible link failure.
- Node Protection/ Next-hop backup: A bypass LSP is created for every possible switch (node) failure.
- VPLS: Creates Ethernet multipoint switching service over MPLS and emulates functions of an L2 switch.
- L3VPN: IP-based VPN customers get individual virtual routing domains.

## How Does MPLS Interface to Other Protocols?

Some of the protocols that work with MPLS are:

- RSVP-TE: Resource Reservation Protocol - Traffic Engineering reserves bandwidth for LSPs.
- LDP: Label Distribution Protocol is the defacto protocol used for distribution of MPLS packets and is usually configured to tunnel inside RSVP-TE.
- IGP: Interior Gateway Protocol is a routing protocol. Edge routers (PE-routers) run BGP between themselves to exchange external (customer) prefixes. Edge and core (P) routers run IGP (usually OSPF or IS-IS) to find optimum path toward BGP next hops. P- and PE-routers use LDP to exchange labels for known IP prefixes (including BGP next hops). LDP indirectly builds end-to-end LSPs across the network core.
- BGP: Border Gateway Protocol (BGP) is allows policy-based routing to take place, using TCP as its transport protocol on port 179 to establish connections. The Junos OS routing protocol software includes BGP version 4. You do not configure BGP---configuring interfaces with MPLS and LDP/RSVP establishes the labels and the ability to transmit packets. BGP automatically determines the routes packets take.
- OSPF and ISIS: These protocols are used for routing between the MPLS PE and CE. Open Shortest Path First (OSPF) is perhaps the most widely used interior gateway protocol (IGP) in large enterprise networks. IS-IS, another link-state dynamic routing protocol, is more common in large service provider networks. Assuming you're running L3VPN to your customers, on the SP edge between the PE and the CE you can run any protocol that your platform supports as a VRF aware instance.

## If I Have Used Cisco MPLS, What Do I Need to Know?

Cisco Networks and Juniper Networks use different MPLS terminology.

| What Cisco Calls:    | Juniper Calls: |
|----------------------|----------------|
| affinities           | admin-groups   |
| autoroute announce   | TE shortcuts   |
| forwarding adjacency | LSP-advertise  |

| What Cisco Calls:       | Juniper Calls:  |
|-------------------------|-----------------|
| tunnel                  | LSP             |
| make-before-break       | adaptive        |
| application-window      | adjust-interval |
| shared risk link groups | fate-sharing    |

## MPLS Feature Support on QFX Series and EX4600 Switches

Multiprotocol Label Switching (MPLS) is a set of procedures for augmenting network layer packets with label stacks, thereby turning them into labeled packets. Service providers frequently use MPLS. Simply put, where traditional networks' routers each perform an IP lookup to determine the next hop, an MPLS network's first device does a routing lookup for the final destination instead of the next hop. A label is then applied to the packet—this is called packet switching. The final destination device removes the label.

A number of Juniper Networks switches are capable of running a subset of MPLS and can therefore communicate, not only with each other, but with Juniper Networks routers running MPLS. This topic describes the major MPLS features that are supported on QFX Series switches and on one EX Series switch, the EX4600. Be sure to check for any exceptions to this support in "[MPLS Limitations on QFX Series and EX4600 Switches](#)" on page 4943.

**NOTE:** EX4600 switches use the same chipset as QFX5100 switches—this is why that EX Series switch is discussed here along with QFX Series switches. Other EX Series switches also support MPLS but with a different feature set.

This topic describes:

- [MPLS Commands Supported by QFX Series and EX4600 Switches on page 4935](#)
- [MPLS Features Supported by QFX Series and EX4600 Switches on page 4935](#)

## MPLS Commands Supported by QFX Series and EX4600 Switches

QFX Series and EX4600 switches support a subset of MPLS features. The command-line interface (CLI) for switches displays all MPLS related configuration statements, even those that are not supported. However, configuring those unsupported statements on a switch has no effect on the operation of the switch. See the following topics for the list of all MPLS related configuration statements:

- “[[edit protocols mpls](#)] Hierarchy Level” on [page 5019](#) for the list of supported configuration statements at the [[edit protocols mpls](#)] hierarchy level
- “[[edit protocols rsvp](#)] Hierarchy Level” on [page 5302](#) for the list of supported configuration statements at the [[edit protocols rsvp](#)] hierarchy level

## MPLS Features Supported by QFX Series and EX4600 Switches

This section lists the major MPLS features supported on QFX Series and EX4600 switches and the Junos OS release in which they were introduced. [Table 374](#) lists the features for the QFX10000 Series switches. [Table 375](#) lists the features for the QFX3500, QFX5100, and QFX5200 switches. [Table 376](#) lists the features for the EX4600 switches.

**Table 374: QFX10000 Switch MPLS Features with Junos OS Release Support**

| Feature                                                                          | QFX10002      | QFX10008      |

**Table 376: EX4600 Switch MPLS Features with Junos OS Release Support**

| Feature                                                                          | EX4600                                 |
|----------------------------------------------------------------------------------|----------------------------------------|
| QFX standalone switch as an MPLS provider edge (PE) switch or provider switch    | 14.1X53-D15 but not 15.1X53-D10X53-D10 |
| Route reflector for BGP labeled routes                                           | 14.1X53-D15 but not 15.1X53-D10        |
| Label edge router (LER)                                                          | 14.1X53-D15 but not 15.1X53-D10        |
| Label switch router (LSR)                                                        | 14.1X53-D15 but not 15.1X53-D10        |
| Border Gateway Protocol (BGP) labeled unicast                                    | 14.1X53-D15 but not 15.1X53-D10        |
| Carrier-over-carrier and inter-provider BGP L3 VPN                               | not supported                          |
| Class of Service (CoS or QoS) for MPLS traffic                                   | 14.1X53-D15 but not 15.1X53-D10        |
| Fast Reroute (FRR), one-to-one local protection and many-to-one local protection | not supported                          |
| Ethernet-over-MPLS pseudowires based on LDP                                      | 14.1X53-D15 but not 15.1X53-D10        |
| FRR using detours and secondary LSP                                              | not supported                          |
| Firewall filters                                                                 | 14.1X53-D15 but not 15.1X53-D10        |

Table 376: EX4600 Switch MPLS Features with Junos OS Release Support (*continued*)

| Feature                                                                                                                                                                     | EX4600                          |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| Graceful restart for Open Shortest Path First (OSPF) for Resource Reservation Protocol (RSVP)                                                                               | 13.2X51-D25                     |
| IPv6 tunneling for over an MPLS-based IPv4 network (6PE)                                                                                                                    | 14.1X53-D15 but not 15.1X53-D10 |
| Layer 3 VPN 6PE                                                                                                                                                             |                                 |
| Intermediate System to Intermediate System (ISIS) routing protocol as an interior gateway protocol (IGP) for MPLS. IS-IS interior gateway protocol traffic engineering (TE) | 14.1X53-D15 but not 15.1X53-D10 |
| L2 circuit (draft Martini/L2Circuit)                                                                                                                                        | 14.1X53-D15 but not 15.1X53-D10 |
| Layer 3 VPNs IPv4                                                                                                                                                           | 14.1X53-D15 but not 15.1X53-D10 |
| Label Distribution Protocol (LDP) based signaling over RSVP                                                                                                                 | 14.1X53-D15 but not 15.1X53-D10 |
| IP-over-MPLS label-switched paths (LSPs) both static and dynamic links                                                                                                      | 14.1X53-D15 but not 15.1X53-D10 |
| MTU signaling in RSVP                                                                                                                                                       | 14.1X53-D15 but not 15.1X53-D10 |
| Object access method (OAM) including MPLS ping, traceroute and BFD                                                                                                          | 14.1X53-D15 but not 15.1X53-D10 |
| MPLS over integrated bridging and routing (IRB) interfaces                                                                                                                  | not supported                   |
| Open Shortest Path First traffic engineering (OSPF TE)                                                                                                                      | 14.1X53-D15 but not 15.1X53-D10 |
| OSPFv2 as an interior gateway protocol                                                                                                                                      | 13.2X51-D25                     |
| Per VRF label support                                                                                                                                                       | 14.1X53-D15 but not 15.1X53-D10 |
| Ethernet-over-MPLS pseudowires based on LDP                                                                                                                                 | 14.1X53-D15 but not 15.1X53-D10 |
| Pseudowire-over-aggregated Ethernet interfaces (core-facing interface)                                                                                                      | 14.1X53-D15 but not 15.1X53-D10 |
| Pseudowire, static and dynamic                                                                                                                                              | 14.1X53-D15 but not 15.1X53-D10 |
| Resource Reservation Protocol (RSVP)                                                                                                                                        | 14.1X53-D15 but not 15.1X53-D10 |

Table 376: EX4600 Switch MPLS Features with Junos OS Release Support (*continued*)

| Feature                                                                                                 | EX4600                          |
|---------------------------------------------------------------------------------------------------------|---------------------------------|
| RSVP bandwidth and auto-bandwidth                                                                       | 14.1X53-D15 but not 15.1X53-D10 |
| RSVP fast reroute including link-protection, node-link-protection, FRR using detours, and secondary LSP | not supported                   |
| RSVP Traffic engineering (used to establish LSPs) with IS-IS and OSPF extensions                        | 14.1X53-D15 but not 15.1X53-D10 |
| SNMP MIB support                                                                                        | 14.1X53-D15 but not 15.1X53-D10 |
| Static and dynamic LSPs                                                                                 | 14.1X53-D15 but not 15.1X53-D10 |
| Virtual private wire service (VPWS)                                                                     | not supported                   |
| Traffic Engineering (TE)                                                                                | 14.1X53-D15 but not 15.1X53-D10 |
| TE auto-bandwidth and RSVP bandwidth                                                                    | 14.1X53-D15 but not 15.1X53-D10 |

## MPLS Limitations on QFX Series and EX4600 Switches

MPLS is fully implemented on routers, while switches support a subset of the MPLS features. The limitations of each switch are listed in a separate section here, even though many of the limitations are duplicates that apply to more than one switch.

- [MPLS Limitations on QFX3500 Switches on page 4943](#)
- [MPLS Limitations on QFX5100 and EX4600 Switches on page 4944](#)
- [MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric on page 4945](#)
- [MPLS Limitations on QFX10000 Switches on page 4946](#)

### MPLS Limitations on QFX3500 Switches

- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Fast reroute is supported, however the **include-all** and **include-any** options for fast reroute are not supported. For more information, see [“Fast Reroute Overview” on page 4967](#).

- MPLS-based circuit cross-connects (CCC) is not supported—only circuit-based pseudowires are supported.
- MTU signaling in RSVP and discovery is supported in Control Plane. However, this cannot be enforced in data plane.
- With L2 circuit-based pseudowires, if multiple equal-cost RSVP LSP's are available to reach a Layer 2 Circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.

## MPLS Limitations on QFX5100 and EX4600 Switches

- On a QFX5100 switch, you can observe traffic drop after changing your configuration to enable VLAN tagged for MPLS packets. As a result of packet capture, a QFX5100 switch can swap the wrong VLAN ID for MPLS packets.
- Even though both QFX5100 and EX4600 Switches use the same chipset, MPLS support differs. EX4600 switches support only basic MPLS functionality while QFX5100 switches support some of the more advanced features. See [“MPLS Feature Support on QFX Series and EX4600 Switches” on page 4934](#) for details.
- If you configure the BGP labeled unicast address family (using the **labeled-unicast** statement at the **[edit protocols bgp family inet]** hierarchy level) on a QFX switch or on an EX4600 switch deployed as a route reflector for BGP labeled routes, path selection will occur at the route reflector, and a single best path will be advertised. This will result in loss of BGP multipath information.
- Fast reroute is supported, however the **include-all** and **include-any** options for fast reroute are not supported. For more information, see [“Fast Reroute Overview” on page 4967](#).
- MPLS-based circuit cross-connects (CCC) is not supported—only circuit-based pseudowires are supported.
- MTU signaling in RSVP and discovery is supported in the control plane. However, this cannot be enforced in data plane.
- With L2 circuit-based pseudowires, if multiple equal-cost RSVP LSP's are available to reach a Layer 2 Circuit neighbor, one LSP is randomly used for forwarding. Use this feature to specify LSPs for specific L2circuit traffic to load-share the traffic in the MPLS core.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.

- ECMP for MPLS is not supported on a QFX5100 switch.
- These are hardware limitations for both EX4600 MPLS and QFX5100 MPLS switches:
  - Push of a maximum of 3 labels is supported in MPLS edge switch if label swap is not done.
  - Push of a maximum of 2 labels is supported in MPLS edge switch if label swap is done.
  - Pop at line rate is supported for a maximum of 2 labels.
  - Global label space is supported but interface-specific label space is not supported.
  - ECMP based on incoming labels at LSR is not supported.
  - QFX switches with Broadcom chips do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes QFX3500, QFX3600, QFX5100, and QFX5200 switches.
  - On QFX5100, the MPLS MTU command can cause unexpected behavior—this is due to SDK chipset limitations on this platform.
- These LDP features are not supported on both QFX5100 switches:
  - LDP multipoint
  - LDP link protection
  - LDP bidirectional forwarding detection (BFD)
  - LDP operation administration and management (OAM)
  - LDP multicast-only fast reroute (MoFRR)
  - LDP equal-cost multipath (ECMP)
- On QFX5100, IRB/L3-sub interfaces are not supported on the NNI port in L2circuit configuration. Because of this, a QFX5100 is unable to ping the neighbor IP of either a direct or local interface.

## MPLS Limitations on QFX5100 Virtual Chassis and Virtual Chassis Fabric

The following MPLS features are not supported by QFX5100 VC and QFX5100 VCF:

- Next-hop LSP Details in section 2.2.6.1
- BFD including BFD triggered FRR
- L2VPN based on BGP (VPWS / draft Kompella)
- VPLS
- Extended-vlan-ccc
- Pseudo-wire protection using Ethernet OAM
- Local switching of pseudo-wire

- Pseudowire fault detection based on VCCV
- QFX switches with Broadcom chips do not support separate next hops for the same label with different S bits (S-0 and S-1). This includes QFX3500, QFX3600, QFX5100, and QFX5200 switches.

## MPLS Limitations on QFX10000 Switches

- Carrier-of-carriers and inter-provider VPNs are not needed on QFX10000 Series switches.
- Configuring an MPLS firewall filter on a switch that is deployed as an egress provider edge (PE) switch has no effect.
- Configuring the **revert-timer** statement at the **[edit protocols mpls]** hierarchy level has no effect.
- These LDP features are not supported on QFX10000 switches:
  - LDP multipoint
  - LDP link protection
  - LDP bidirectional forwarding detection (BFD)
  - LDP operation administration and management (OAM)
  - LDP multicast-only fast reroute (MoFRR)
- On QFX10008, IRB/L3-sub interfaces are not supported on the NNI port in L2circuit configuration. Because of this, a QFX10008 is unable to ping the neighbor IP of either a direct or local interface.

## Understanding MPLS Components for QFX Series and EX4600 Switches

MPLS devices include a number of components. While some components are required for all MPLS applications, others might not be, depending on the specific application.

This topic includes:

- [Provider Edge Switches on page 4946](#)
- [Provider Switch on page 4948](#)
- [Components Required for All Switches in the MPLS Network on page 4948](#)

### Provider Edge Switches

To implement MPLS on a network, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch. In addition, you must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets.

The ingress PE switch (the entry point to the MPLS tunnel) receives a packet, analyzes it, and pushes an MPLS label onto it. This label places the packet in a forwarding equivalence class (FEC) and determines its handling and destination through the MPLS tunnel. The egress PE switch (the exit point from the MPLS tunnel) pops the MPLS label off the outgoing packet.

Within an MPLS tunnel, the network traffic is bidirectional. Therefore, each PE switch can be configured to be both an ingress switch and an egress switch, depending on the direction of the traffic.

The following MPLS components are configured on the PE switches but not on the provider switches:

- [MPLS Protocol and Label-Switched Paths on page 4947](#)
- [IP Over MPLS for Customer Edge Interfaces on page 4947](#)
- [BGP Layer 3 VPN Configuration on page 4947](#)
- [Routing Instances for Layer 3 VPN on page 4947](#)
- [Routing Instances for Layer 2 VPN and Layer 3 VPN on page 4948](#)
- [Ethernet Encapsulation for Layer 2 VPN on page 4948](#)

---

### MPLS Protocol and Label-Switched Paths

Each PE switch must be configured to support the MPLS protocol. You must also configure label-switched paths (LSPs) at the `[edit protocols mpls]` hierarchy level.

---

### IP Over MPLS for Customer Edge Interfaces

You can configure the customer edge interfaces of the PE switches for IP over MPLS using a Layer 3 interface and a static route from the ingress PE switch to the egress PE switch. See “[Configuring MPLS on Provider Edge Switches](#)” on page 4981.

---

### BGP Layer 3 VPN Configuration

If you are implementing a Layer 3 virtual private network (VPN), you must configure the BGP routing protocol on the PE switches.

---

### Routing Instances for Layer 3 VPN

If you are implementing a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series and EX4600 devices support VPN routing and forwarding (VRF) routing instances for Layer 3 VPNs.

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

### Routing Instances for Layer 2 VPN and Layer 3 VPN

---

If you are implementing a Layer 2 VPN or a Layer 3 VPN, you must configure a routing instance. A routing instance is a collection of routing tables, interfaces, and routing protocol parameters. The set of interfaces belongs to the routing tables, and the routing protocol parameters control the information in the routing tables.

QFX Series devices support the following types of routing instances:

- Layer 2 VPN—To support a Layer 2 VPN
- VPN routing and forwarding (VRF)—To support a Layer 3 VPN

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name **my-instance**, its corresponding IP unicast table will be **my-instance.inet.0**. All routes for **my-instance** are installed in **my-instance.inet.0**.

### Ethernet Encapsulation for Layer 2 VPN

---

If you are implementing a Layer 2 VPN, you must also configure the physical layer encapsulation type on the customer edge interface and within the routing instance.

## Provider Switch

You must configure one or more provider switches as transit switches within the network to support the forwarding of MPLS packets. You can add provider switches without changing the configuration of the PE switches.

A provider switch does not analyze packets. It refers to an MPLS label forwarding table and swaps one label for another. The new label determines the next hop along the MPLS tunnel. A provider switch cannot perform push or pop operations.

## Components Required for All Switches in the MPLS Network

The following MPLS components are configured on both the PE switches and the provider switches:

- [Interior Gateway Protocol on page 4948](#)
- [Traffic Engineering on page 4949](#)
- [MPLS Protocol on page 4949](#)
- [RSVP on page 4949](#)
- [Family mpls on page 4950](#)

### Interior Gateway Protocol

---

MPLS works in coordination with OSPF as the interior gateway protocol (IGP). Therefore, you must configure OSPF as the IGP on the loopback interface and CE-facing interfaces of both the PE switches and the provider switches.

The CE-facing interfaces can be either Gigabit Ethernet or 10-Gigabit Ethernet interfaces, and they can be configured as either individual interfaces or as aggregated Ethernet interfaces.

**NOTE:** The CE-facing interfaces cannot be configured with VLAN tagging or a VLAN ID. When you configure them to belong to family `mpls`, they are removed from the default VLAN if they were members of that VLAN. They operate as an exclusive tunnel for MPLS traffic.

---

## Traffic Engineering

Traffic engineering maps traffic flows onto an existing physical topology and provides the ability to move traffic flow away from the shortest path selected by the IGP and to a potentially less congested physical path across a network.

Traffic engineering enables the selection of specific end-to-end paths to send given types of traffic through your network. You must configure OSPF traffic engineering on the PE switches and the provider switches.

---

## MPLS Protocol

You must enable the MPLS protocol on all switches that participate in the MPLS network and apply it to the core interfaces of both the PE and provider switches. You do not need to apply it to the loopback interface because the MPLS protocol uses the framework established by the RSVP signaling protocol to create LSPs. On the PE switches, the configuration of the MPLS protocol must also include the definition of an LSP.

---

## RSVP

RSVP is a signaling protocol that allocates and distributes labels throughout an MPLS network. RSVP sets up unidirectional paths between the ingress PE switch and the egress PE switch. RSVP makes the LSPs dynamic; it can detect topology changes and outages and establish new LSPs to allow traffic to move around a failure.

You must enable RSVP and apply it to the loopback interface and the core interface of both the PE and provider switches. The path message contains the configured information about the resources required for the LSP to be established.

When the egress PE switch receives the path message, it sends a reservation message back to the ingress PE switch. This reservation message is passed along from switch to switch along the same path as the original path message. Once the ingress PE switch receives this reservation message, an RSVP path is established.

The established LSP stays active as long as the RSVP session remains active. RSVP continues activity through the transmissions and responses to RSVP path and reservation messages. If the messages stop for three minutes, the RSVP session terminates and the LSP is lost.

RSVP runs as a separate software process in Junos OS and is not in the packet-forwarding path.

## Family mpls

---

You must configure the core interfaces used for MPLS traffic to belong to **family mpls**.

**NOTE:** You can enable **family mpls** on either individual interfaces or on aggregated Ethernet interfaces. You cannot enable it on tagged VLAN interfaces.

## Understanding MPLS Label Operations

---

In the traditional packet-forwarding paradigm, as a packet travels from one switch to the next, an independent forwarding decision is made at each hop. The IP network header is analyzed and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is made only once, when a packet enters the MPLS tunnel (that is, the path used for MPLS traffic).

When an IP packet enters a label-switched path (LSP), the ingress provider edge (PE) switch examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label. The packet is then forwarded to the next provider switch in the LSP. This switch and all subsequent switches in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next switch in the path. When the packet reaches the egress PE switch, the label is removed, and the packet again becomes a native IP packet and is forwarded based on its IP routing information.

This topic describes:

- [MPLS Label-Switched Paths and MPLS Labels on page 4951](#)
- [Reserved Labels on page 4952](#)
- [MPLS Label Operations on page 4952](#)
- [Penultimate-Hop Popping and Ultimate-Hop Popping on page 4954](#)

### MPLS Label-Switched Paths and MPLS Labels

When a packet enters the MPLS network, it is assigned to an LSP. Each LSP is identified by a label, which is a short (20-bit), fixed-length value at the front of the MPLS label (32 bits). Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. Because no additional parsing or lookup is done on the encapsulated packet, MPLS supports the transmission of any other protocols within the packet payload.

[Figure 139](#) shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

Figure 139: Label Encoding

## Reserved Labels

Labels range from 0 through 1,048,575. Labels 0 through 999,999 are for internal use.

Some of the reserved labels (in the range 0 through 15) have well-defined meanings.

The following reserved labels are used by QFX Series and EX4600 devices:

- 0, IPv4 Explicit Null label—This value is valid only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 3, Implicit Null label—This label is used in the signaling protocol (RSVP) only to request label popping by the downstream switch. It never actually appears in the encapsulation. Labels with a value of 3 must not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.

## MPLS Label Operations

QFX Series and EX4600 devices support the following MPLS label operations:

- Push
- Pop
- Swap

**NOTE:** There is a limit with regard to the number of labels that QFX and EX4600 devices can affix (push operations) to the label stack or remove (pop operations) from the label stack.

- For Push operations—As many as three labels are supported.
- For Pop operations—As many as three labels are supported.

The push operation affixes a new label to the top of the IP packet. For IPv4 packets, the new label is the first label. The time to live (TTL) field value in the packet header is derived from the IP packet header. The push operation cannot be applied to a packet that already has an MPLS label.

The pop operation removes a label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet.

The swap operation removes an existing MPLS label from an IP packet and replaces it with a new MPLS label, based on the following:

- Incoming interface
- Label
- Label forwarding table

Figure 140 shows an IP packet without a label arriving on the customer edge interface (ge-0/0/1) of the ingress PE switch. The ingress PE switch examines the packet and identifies that packet's destination as the egress PE switch. The ingress PE switch applies label 100 to the packet and sends the MPLS packet to its outgoing MPLS core interface (ge-0/0/5). The MPLS packet is transmitted on the MPLS tunnel through the provider switch, where it arrives at interface ge-0/0/5 with label 100. The provider switch swaps label 100 with label 200 and forwards the MPLS packet through its core interface (ge-0/0/7) to the next hop on the tunnel, which is the egress PE switch. The egress PE switch receives the MPLS packet through its core interface (ge-0/0/7), removes the MPLS label, and sends the IP packet out of its customer edge interface (ge-0/0/1) to a destination that is beyond the tunnel.

**Figure 140: MPLS Label Swapping**

Figure 140 shows the path of a packet as it passes in one direction from the ingress PE switch to the egress PE switch. However, the MPLS configuration also allows traffic to travel in the reverse direction. Thus, each PE switch operates as both an ingress switch and an egress switch.

## Penultimate-Hop Popping and Ultimate-Hop Popping

The switches enable penultimate-hop popping (PHP) by default with IP over MPLS configurations. With PHP, the penultimate provider switch is responsible for popping the MPLS label and forwarding the traffic to the egress PE switch. The egress PE switch then performs an IP route lookup and forwards the traffic. This reduces the processing load on the egress PE switch, because it is not responsible for popping the MPLS label.

- The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop switch removes the label and sends the packet to the egress PE switch.
- If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised and the egress PE switch of the LSP removes the label.

## Understanding BGP

---

BGP is an exterior gateway protocol (EGP) that is used to exchange routing information among routers in different autonomous systems (ASs). BGP routing information includes the complete route to each destination. BGP uses the routing information to maintain a database of network reachability information, which it exchanges with other BGP systems. BGP uses the network reachability information to construct a graph of AS connectivity, which enables BGP to remove routing loops and enforce policy decisions at the AS level.

Multiprotocol BGP (MBGP) extensions enable BGP to support IP version 6 (IPv6). MBGP defines the attributes `MP_REACH_NLRI` and `MP_UNREACH_NLRI`, which are used to carry IPv6 reachability information. Network layer reachability information (NLRI) update messages carry IPv6 address prefixes of feasible routes.

BGP allows for policy-based routing. You can use routing policies to choose among multiple paths to a destination and to control the redistribution of routing information.

BGP uses TCP as its transport protocol, using port 179 for establishing connections. Running over a reliable transport protocol eliminates the need for BGP to implement update fragmentation, retransmission, acknowledgment, and sequencing.

The Junos OS routing protocol software supports BGP version 4. This version of BGP adds support for Classless Interdomain Routing (CIDR), which eliminates the concept of network classes. Instead of assuming which bits of an address represent the network by looking at the first octet, CIDR allows you to explicitly specify the number of bits in the network address, thus providing a means to decrease the size of the routing tables. BGP version 4 also supports aggregation of routes, including the aggregation of AS paths.

This section discusses the following topics:

- [Autonomous Systems on page 4955](#)
- [AS Paths and Attributes on page 4955](#)
- [External and Internal BGP on page 4956](#)
- [Multiple Instances of BGP on page 4956](#)

### Autonomous Systems

An *autonomous system* (AS) is a set of routers that are under a single technical administration and normally use a single interior gateway protocol and a common set of metrics to propagate routing information within the set of routers. To other ASs, an AS appears to have a single, coherent interior routing plan and presents a consistent picture of what destinations are reachable through it.

### AS Paths and Attributes

The routing information that BGP systems exchange includes the complete route to each destination, as well as additional information about the route. The route to each destination is called the *AS path*, and the additional route information is included in *path attributes*. BGP uses the AS path and the path attributes to completely determine the network topology. Once BGP understands the topology, it can detect and eliminate

routing loops and select among groups of routes to enforce administrative preferences and routing policy decisions.

## External and Internal BGP

BGP supports two types of exchanges of routing information: exchanges among different ASs and exchanges within a single AS. When used among ASs, BGP is called *external BGP* (EBGP) and BGP sessions perform *inter-AS routing*. When used within an AS, BGP is called *internal BGP* (IBGP) and BGP sessions perform *intra-AS routing*. Figure 56 illustrates ASs, IBGP, and EBGP.

Figure 141: ASs, EBGP, and IBGP

A BGP system shares network reachability information with adjacent BGP systems, which are referred to as *neighbors* or *peers*.

BGP systems are arranged into *groups*. In an IBGP group, all peers in the group—called *internal peers*—are in the same AS. Internal peers can be anywhere in the local AS and do not have to be directly connected to one another. Internal groups use routes from an IGP to resolve forwarding addresses. They also propagate external routes among all other internal routers running IBGP, computing the next hop by taking the BGP next hop received with the route and resolving it using information from one of the interior gateway protocols.

In an EBGP group, the peers in the group—called *external peers*—are in different ASs and normally share a subnet. In an external group, the next hop is computed with respect to the interface that is shared between the external peer and the local router.

## Multiple Instances of BGP

You can configure multiple instances of BGP at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

Multiple instances of BGP are primarily used for Layer 3 VPN support.

IGP peers and external BGP (EBGP) peers (both nonmultihop and multihop) are all supported for routing instances. BGP peering is established over one of the interfaces configured under the **routing-instances** hierarchy.

**NOTE:** When a BGP neighbor sends BGP messages to the local routing device, the incoming interface on which these messages are received must be configured in the same routing instance that the BGP neighbor configuration exists in. This is true for neighbors that are a single hop away or multiple hops away.

Routes learned from the BGP peer are added to the **instance-name.inet.0** table by default. You can configure import and export policies to control the flow of information into and out of the instance routing table.

For Layer 3 VPN support, configure BGP on the provider edge (PE) router to receive routes from the customer edge (CE) router and to send the instances' routes to the CE router if necessary. You can use multiple instances of BGP to maintain separate per-site forwarding tables for keeping VPN traffic separate on the PE router.

You can configure import and export policies that allow the service provider to control and rate-limit traffic to and from the customer.

You can configure an EBGP multihop session for a VRF routing instance. Also, you can set up the EBGP peer between the PE and CE routers by using the loopback address of the CE router instead of the interface addresses.

**Related  
Documentation**

- [BGP Routes Overview on page 3596](#)
- [BGP Messages Overview on page 3597](#)

## IPv6 Layer 3 VPNs

The interfaces between the PE and CE routers of a Layer 3 VPN can be configured to carry IP version 6 (IPv6) traffic. IP allows numerous nodes on different networks to interoperate seamlessly. IPv4 is currently used in intranets and private networks, as well as the Internet. IPv6 is the successor to IPv4, and is based for the most part on IPv4.

In the Juniper Networks implementation of IPv6, the service provider implements an MPLS-enabled IPv4 backbone to provide VPN service for IPv6 customers. The PE routers have both IPv4 and IPv6 capabilities. They maintain IPv6 VPN routing and forwarding (VRF) tables for their IPv6 sites and encapsulate IPv6 traffic in MPLS frames that are then sent into the MPLS core network.

IPv6 for Layer 3 VPNs is supported for BGP and for static routes.

IPv6 over Layer 3 VPNs is described in RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*.

For more information about IPv6, see the *Junos OS Routing Protocols Library for Routing Devices*.

## Ethernet Pseudowire Overview

---

An Ethernet pseudowire is used to carry Ethernet or 802.3 Protocol Data Units (PDUs) over an MPLS network enabling service providers to offer emulated Ethernet services over existing MPLS networks. Ethernet or 802.3 PDUs are encapsulated within the pseudowire to provide a point-to-point Ethernet service. For the point-to-point Ethernet service, the following fault management features are supported:

- The IEEE 802.3ah standard for Operation, Administration, and Management (OAM). You can configure IEEE 802.3ah OAM link-fault management on Ethernet point-to-point direct links or links across Ethernet repeaters.

Ethernet OAM link-fault management can be used for physical link-level fault detection and management. It uses a new, optional sublayer in the data link layer of the OSI model. Ethernet OAM can be implemented on any full-duplex point-to-point or emulated point-to-point Ethernet link. A system-wide implementation is not required; OAM can be deployed on particular interfaces of a router. Transmitted Ethernet OAM messages or OAM PDUs are of standard length, untagged Ethernet frames within the normal frame length limits in the range 64–1518 bytes.

- Ethernet connectivity fault management (CFM) to monitor the physical link between two routers.
  - Connection protection using the continuity check protocol for fault monitoring . The continuity check protocol is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
  - Path protection using the linktrace protocol for path discovery and fault verification . Similar to IP traceroute, the linktrace protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.

## Understanding CoS MPLS EXP Classifiers and Rewrite Rules

You can use class of service (CoS) within MPLS networks to prioritize certain types of traffic during periods of congestion by applying packet classifiers and rewrite rules to the MPLS traffic. MPLS classifiers are global and apply to all interfaces configured as **family mpls** interfaces.

When a packet enters a customer-edge interface on the ingress provider edge (PE) switch, the switch associates the packet with a particular CoS servicing level before placing the packet onto the label-switched path (LSP). The switches within the LSP utilize the CoS value set at the ingress PE switch to determine the CoS service level. The CoS value embedded in the classifier is translated and encoded in the MPLS header by means of the experimental (EXP) bits.

EXP classifiers map incoming MPLS packets to a forwarding class and a loss priority, and assign MPLS packets to output queues based on the forwarding class mapping. EXP classifiers are behavior aggregate (BA) classifiers.

EXP rewrite rules change (rewrite) the CoS value of the EXP bits in outgoing packets on the egress queues of the switch so that the new (rewritten) value matches the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

**NOTE:** On QFX5200, QFX5100, QFX3500, QF3600, and EX4600 switches, and on QFabric systems, there is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global EXP classifier applies to all MPLS traffic on interfaces configured as **family mpls**.

On QFX10000 switches, there is a no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure EXP classifiers and apply them to logical interfaces configured as **family mpls**. (You cannot apply classifiers to physical interfaces.). You can configure up to 64 EXP classifiers.

There is no default EXP rewrite rule. If you want to rewrite the EXP bit value at the egress interface, you must configure EXP rewrite rules and apply them to logical interfaces.

EXP classifiers and rewrite rules are applied only to interfaces that are configured as **family mpls** (for example, set interfaces **xe-0/0/35 unit 0 family mpls.**)

This topic includes:

- [EXP Classifiers on page 4960](#)
- [EXP Rewrite Rules on page 4961](#)
- [Schedulers on page 4962](#)

## EXP Classifiers

On QFX5200, QFX5100, EX4600, QFX3500, and QFX3600 switches, and on QFabric systems, unlike DSCP and IEEE 802.1p BA classifiers, EXP classifiers are global to the switch and apply to all switch interfaces that are configured as **family mpls**. On QFX10000 switches, you apply EXP classifiers to individual logical interfaces, and different interfaces can use different EXP classifiers.

When you configure and apply an EXP classifier, MPLS traffic on all **family mpls** interfaces uses the EXP classifier, even on interfaces that also have a fixed classifier. If an interface has both an EXP classifier and a fixed classifier, the EXP classifier is applied to MPLS traffic and the fixed classifier is applied to all other traffic.

Also unlike DSCP and IEEE 802.1p BA classifiers, there is no default EXP classifier. If you want to classify MPLS traffic based on the EXP bits, you must explicitly configure an EXP classifier and apply it to the switch interfaces. Each EXP classifier has eight entries that correspond to the eight EXP CoS values (0 through 7, which correspond to CoS bits 000 through 111).

You can configure up to 64 EXP classifiers.

However, on QFX5200, QFX5100, EX4600, and legacy CLI switches, the switch uses only one MPLS EXP classifier as a global classifier on all interfaces. After you configure an MPLS EXP classifier, you can configure that classifier as the global EXP classifier by including the EXP classifier in the **[edit class-of-service system-defaults classifiers exp]** hierarchy level. All switch interfaces configured as **family mpls** use the global EXP classifier to classify MPLS traffic.

On these switches, only one EXP classifier can be configured as the global EXP classifier at any time. If you want to change the global EXP classifier, delete the global EXP classifier configuration (use the **user@switch# delete class-of-service system-defaults classifiers exp** configuration statement), then configure the new global EXP classifier.

QFX10000 switches do not support global EXP classifiers. You can configure one EXP classifier and apply it to multiple logical interfaces, or configure multiple EXP classifiers and apply different EXP classifiers to different logical interfaces.

If an EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. (Switches that have a default EXP classifier use the default classifier.) If no EXP classifier and no fixed classifier are applied to the interface, MPLS traffic is treated as best-effort traffic using the 802.1 default untrusted classifier. DSCP classifiers are not applied to MPLS traffic.

On QFX5200, QFX5100, EX4600, and legacy CLI switches, because the EXP classifier is global, you cannot configure some ports to use a fixed IEEE 802.1p classifier for MPLS traffic on some interfaces and the global EXP classifier for MPLS traffic on other interfaces. When you configure a global EXP classifier, all MPLS traffic on all interfaces uses the EXP classifier.

**NOTE:** The switch uses only the outermost label of incoming EXP packets for classification.

**NOTE:** MPLS packets with 802.1Q tags are not supported.

## EXP Rewrite Rules

As MPLS packets enter or exit a network, edge switches might be required to alter the class-of-service (CoS) settings of the packets. EXP rewrite rules set the value of the EXP CoS bits within the header of the outgoing MPLS packet on **family mpls** interfaces. Each rewrite rule reads the current forwarding class and loss priority associated with the packet, locates the chosen CoS value from a table, and writes that CoS value into the packet header, replacing the old CoS value. EXP rewrite rules apply only to MPLS traffic.

EXP rewrite rules apply only to logical interfaces. You cannot apply EXP rewrite rules to physical interfaces.

There are no default EXP rewrite rules. If you want to rewrite the EXP value in MPLS packets, you must configure EXP rewrite rules and apply them to logical interfaces. If no rewrite rules are applied, all MPLS labels that are pushed have a value of zero (0). The EXP value remains unchanged on MPLS labels that are swapped.

You can configure up to 64 EXP rewrite rules, but you can only apply 16 EXP rewrite rules at any time on the switch. On a given logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

You can apply an EXP rewrite rule to an interface that has a DSCP, DSCP IPv6, or IEEE 802.1p rewrite rule. Only MPLS traffic uses the EXP rewrite rule. MPLS traffic does not use DSCP or DSCP IPv6 rewrite rules.

If the switch is performing penultimate hop popping (PHP), EXP rewrite rules do not take effect. If both an EXP classifier and an EXP rewrite rule are configured on the switch, then the EXP value from the last popped label is copied into the inner label. If either an EXP classifier or an EXP rewrite rule (but not both) is configured on the switch, then the inner label EXP value is sent unchanged.

**NOTE:** On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

## Schedulers

The schedulers for using CoS with MPLS are the same as for the other CoS configurations on the switch. Default schedulers are provided only for the best-effort, fcoe, no-loss, and network-control default forwarding classes. If you configure a custom forwarding class for MPLS traffic, you need to configure a scheduler to support that forwarding class and provide bandwidth to that forwarding class.

## Understanding Ethernet-over-MPLS (L2 Circuit)

Ethernet-over-MPLS allows sending Layer 2 (L2) Ethernet frames transparently over MPLS. Ethernet-over-MPLS uses a tunneling mechanism for Ethernet traffic through an MPLS-enabled Layer 3 core. It encapsulates Ethernet protocol data units (PDUs) inside MPLS packets and forwards the packets, using label stacking, across the MPLS network. This technology has applications in service provider, enterprise and data center environments. For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network.

**NOTE:** A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a dedicated LSP.

- 
- [Ethernet-over-MPLS in Data Centers on page 4962](#)

## Ethernet-over-MPLS in Data Centers

For disaster recovery purposes, data centers are hosted in multiple sites that are geographically distant and interconnected using a WAN network. These data centers require L2 connectivity between them for the following reasons:

- To replicate the storage over Fiber Channel IP (FCIP). FCIP works only on the same broadcast domain.
- To run a dynamic routing protocol between the sites.
- To support High Availability clusters that interconnect the nodes hosted in the various data centers.

## Understanding Using MPLS-Based Layer 3 VPNs on Switches

---

On the QFX Series switches and on EX4600 switches, you can use MPLS-based Layer 3 virtual private networks (VPNs) to securely connect geographically diverse sites across an MPLS network. MPLS services can be used to connect various sites to a backbone network and to ensure better performance for low-latency applications such as voice over IP (VoIP) and other business-critical functions.

A VPN uses a public telecommunications infrastructure, such as the Internet, to provide remote offices or individual users with secure access to their organization's network. VPNs are designed to provide the same level of performance and security as privately owned or leased networks but without the attendant costs.

This topic describes:

- [MPLS-Based Layer 3 VPNs on page 4963](#)

### MPLS-Based Layer 3 VPNs

In Junos OS, Layer 3 VPNs are based on RFC 4364, *BGP/MPLS IP Virtual Private Networks*. RFC 4364 defines a mechanism by which service providers can use their IP backbones to provide VPN services to their customers. A Layer 3 VPN is a set of sites that share common routing information and whose connectivity is controlled by a collection of policies. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

Customer networks, because they are private, can use either public or private addresses, as defined in RFC 1918, *Address Allocation for Private Internets*. When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the same private addresses used by other network users. BGP/MPLS VPNs solve this problem by adding a VPN identifier prefix to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and on the public Internet. In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. Two different VPNs can use overlapping addresses. Each route within a VPN is assigned an MPLS label (for example, MPLS-ARCH, MPLS-BGP, or MPLS-ENCAPS). When BGP distributes a VPN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the service provider's backbone, it is encapsulated along with the MPLS label that corresponds to the route within the customer's VPN that is the best match based on the packet's destination address. This MPLS packet is further encapsulated with another MPLS label or with an IP, so that it gets tunneled across the backbone to the egress provider edge (PE) switch. Thus, the backbone core switches do not need to know the VPN routes.

QFX5100 switches also support interprovider VPNs, and carrier-of-carriers VPNs. For more information, see ["Interprovider and Carrier-of-Carriers VPNs" on page 4966](#)

## Carrier-of-Carriers VPNs

The customer of a VPN service provider might be a service provider for the end customer. The following are the two main types of carrier-of-carriers VPNs (as described in RFC 4364):

- “Internet Service Provider as the Customer” on page 4966—The VPN customer is an ISP that uses the VPN service provider’s network to connect its geographically disparate regional networks. The customer does not have to configure MPLS within its regional networks.
- “VPN Service Provider as the Customer” on page 4966—The VPN customer is itself a VPN service provider offering VPN service to its customers. The carrier-of-carriers VPN service customer relies on the backbone VPN service provider for inter-site connectivity. The customer VPN service provider is required to run MPLS within its regional networks.

Figure 142 illustrates the network architecture used for a carrier-of-carriers VPN service.

Figure 142: Carrier-of-Carriers VPN Architecture

This topic covers the following:

- [Internet Service Provider as the Customer on page 4966](#)
- [VPN Service Provider as the Customer on page 4966](#)

## Internet Service Provider as the Customer

In this type of carrier-of-carriers VPN configuration, ISP A configures its network to provide Internet service to ISP B. ISP B provides the connection to the customer wanting Internet service, but the actual Internet service is provided by ISP A.

This type of carrier-of-carriers VPN configuration has the following characteristics:

- The carrier-of-carriers VPN service customer (ISP B) does not need to configure MPLS on its network.
- The carrier-of-carriers VPN service provider (ISP A) must configure MPLS on its network.
- MPLS must also be configured on the CE routers and PE routers connected together in the carrier-of-carriers VPN service customer's and carrier-of-carriers VPN service provider's networks.

## VPN Service Provider as the Customer

A VPN service provider can have customers that are themselves VPN service providers. In this type of configuration, also called a hierarchical or recursive VPN, the customer VPN service provider's VPN-IPv4 routes are considered external routes, and the backbone VPN service provider does not import them into its VRF table. The backbone VPN service provider imports only the customer VPN service provider's internal routes into its VRF table.

The similarities and differences between interprovider and carrier-of-carriers VPNs are shown in [Table 377](#).

**Table 377: Comparison of Interprovider and Carrier-of-Carriers VPNs**

| Feature                                | ISP Customer      | VPN Service Provider Customer                         |
|----------------------------------------|-------------------|-------------------------------------------------------|
| Customer edge device                   | AS border router  | PE router                                             |
| IBGP sessions                          | Carry IPv4 routes | Carry external VPN-IPv4 routes with associated labels |
| Forwarding within the customer network | MPLS is optional  | MPLS is required                                      |

## Interprovider and Carrier-of-Carriers VPNs

All interprovider and carrier-of-carriers VPNs share the following characteristics:

- Each interprovider or carrier-of-carriers VPN customer must distinguish between internal and external customer routes.

- Internal customer routes must be maintained by the VPN service provider in its PE routers.
- External customer routes are carried only by the customer's routing platforms, not by the VPN service provider's routing platforms.

The key difference between interprovider and carrier-of-carriers VPNs is whether the customer sites belong to the same AS or to separate ASs:

- *Understanding Interprovider VPNs*—The customer sites belong to different ASs. You need to configure EBGp to exchange the customer's external routes.
- [“Understanding Carrier-of-Carriers VPNs” on page 4965](#)—The customer sites belong to the same AS. You need to configure IBGP to exchange the customer's external routes.

In general, each service provider in a VPN hierarchy is required to maintain its own internal routes in its P routers, and the internal routes of its customers in its PE routers. By recursively applying this rule, it is possible to create a hierarchy of VPNs.

The following are definitions of the types of PE routers specific to interprovider and carrier-of-carriers VPNs:

- The AS border router is located at the AS border and handles traffic leaving and entering the AS.
- The end PE router is the PE router in the customer VPN; it is connected to the CE router at the end customer's site.

## Fast Reroute Overview

Fast reroute provides redundancy for an LSP path. When you enable fast reroute, detours are precomputed and preestablished along the LSP. In case of a network failure on the current LSP path, traffic is quickly routed to one of the detours. [Figure 143](#) illustrates an LSP from Router A to Router F, showing the established detours. Each detour is established by an upstream node to avoid the link toward the immediate downstream node and the immediate downstream node itself. Each detour might traverse through one or more label-switched routers (or switches) that are not shown in the figure.

Fast reroute protects traffic against any single point of failure between the ingress and egress routers (or switches). If there are multiple failures along an LSP, fast reroute itself might fail. Also, fast reroute does not protect against failure of the ingress or egress routers.

**Figure 143: Detours Established for an LSP Using Fast Reroute**

If a node detects that a downstream link has failed (using a link-layer-specific liveness detection mechanism) or that a downstream node has failed (for example, using the RSVP neighbor hello protocol), the node quickly switches the traffic to the detour and, at the same time, signals the ingress router about the link or node failure. [Figure 144](#) illustrates the detour taken when the link between Router B and Router C fails.

**Figure 144: Detour After the Link from Router B to Router C Fails**

If the network topology is not rich enough (there are not enough routers with sufficient links to other routers), some of the detours might not succeed. For example, the detour from Router A to Router C in [Figure 143](#) cannot traverse link A-B and Router B. If such a path is not possible, the detour does not occur.

Note that after the node switches traffic to the detour, it might switch the traffic again to a newly calculated detour soon after. This is because the initial detour route might not be the best route. To make rerouting as fast as possible, the node switches traffic onto the initial detour without first verifying that the detour is valid. Once the switch is made, the node recomputes the detour. If the node determines that the initial detour is still valid, traffic continues to flow over this detour. If the node determines that the initial detour is no longer valid, it again switches the traffic to a newly computed detour.

**NOTE:** If you issue `show` commands after the node has switched traffic to the initial detour, the node might indicate that the traffic is still flowing over the original LSP. This situation is temporary and should correct itself quickly.

The time required for a fast-rerouting detour to take effect depends on two independent time intervals:

- Amount of time to detect that there is a link or node failure—This interval depends greatly on the link layer in use and the nature of the failure. For example, failure detection on an SONET/SDH link typically is much faster than on a Gigabit Ethernet link, and both are much faster than detection of a router failure.

- Amount of time required to splice the traffic onto the detour—This operation is performed by the Packet Forwarding Engine, which requires little time to splice traffic onto the detour. The time needed can vary depending on the number of LSPs being switched to detours.

Fast reroute is a short-term patch to reduce packet loss. Because detour computation might not reserve adequate bandwidth, the detours might introduce congestion on the alternate links. The ingress router is the only router that is fully aware of LSP policy constraints and, therefore, is the only router able to come up with adequate long-term alternate paths.

Detours are created by use of RSVP and, like all RSVP sessions, they require extra state and overhead in the network. For this reason, each node establishes at most one detour for each LSP that has fast reroute enabled. Creating more than one detour for each LSP increases the overhead, but serves no practical purpose.

To reduce network overhead further, each detour attempts to merge back into the LSP as soon as possible after the failed node or link. If you can consider an LSP that travels through  $n$  router nodes, it is possible to create  $n - 1$  detours. For instance, in [Figure 145](#), the detour tries to merge back into the LSP at Router D instead of at Router E or Router F. Merging back into the LSP makes the detour scalability problem more manageable. If topology limitations prevent the detour from quickly merging back into the LSP, detours merge with other detours automatically.

Figure 145: Detours Merging into Other Detours

## Graceful Restart and MPLS-Related Protocols

This section contains the following topics:

- [LDP on page 4970](#)
- [RSVP on page 4970](#)
- [CCC and TCC on page 4970](#)

## LDP

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

The reconnect time is configured in Junos OS as 60 seconds and is not user-configurable. The reconnect time is how long the helper router waits for the restarting router to establish a connection. If the connection is not established within the reconnect interval, graceful restart for the LDP session is terminated. The maximum reconnect time is 120 seconds and is not user-configurable. The maximum reconnect time is the maximum value that a helper router accepts from its restarting neighbor.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, so it can continue to forward traffic.

You can configure LDP graceful restart both in the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and for a specific routing instance only.

## RSVP

RSVP graceful restart enables a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

## CCC and TCC

CCC and TCC graceful restart enables Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the provider edge (PE) routers and provider (P) routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

## Types of LSPs

There are three types of LSPs:

- **Static LSPs**—For static paths, you must manually assign labels on all routers involved (ingress, transit, and egress). No signaling protocol is needed. This procedure is similar to configuring static routes on individual routers. Like static routes, there is no error reporting, liveliness detection, or statistics reporting.
- **LDP-signaled LSPs**—See [“LDP Introduction” on page 4804](#).
- **RSVP-signaled LSPs**—For signaled paths, RSVP is used to set up the path and dynamically assign labels. (RSVP signaling messages are used to set up signaled paths.) You configure only the ingress router. The transit and egress routers accept signaling information from the ingress router, and they set up and maintain the LSP cooperatively. Any errors encountered while establishing an LSP are reported to the ingress router for diagnostics. For signaled LSPs to work, a version of RSVP that supports tunnel extensions must be enabled on all routers.

There are two types of RSVP-signaled LSPs:

- **Explicit-path LSPs**—All intermediate hops of the LSP are manually configured. The intermediate hops can be strict, loose, or any combination of the two. Explicit path LSPs provide you with complete control over how the path is set up. They are similar to static LSPs but require much less configuration.
- **Constrained-path LSPs**—The intermediate hops of the LSP are automatically computed by the software. The computation takes into account information provided by the topology information from the IS-IS or OSPF link-state routing protocol, the current network resource utilization determined by RSVP, and the resource requirements and constraints of the LSP. For signaled constrained-path LSPs to work, either the IS-IS or OSPF protocol and the IS-IS or OSPF traffic engineering extensions must be enabled on all routers.

## Configuring CoS Bits for an MPLS Network

---

When traffic enters a labeled-switch path (LSP) tunnel, the CoS bits in the MPLS header are set in one of two ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. The *Class of Service Feature Guide for Routing Devices* explains the IP CoS values, and summarizes how the CoS bits are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.

To set a fixed CoS value on all packets entering the LSP:

1. Specify a class of service value for the LSP:

**NOTE:** The CoS value set using the `class-of-service` statement at the `[edit protocols mpls]` hierarchy level supersedes the CoS value set at the `[edit class-of-service]` hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

```
[edit protocols mpls]
user@switch# set class-of-service cos-value
```

## Configuring Ethernet over MPLS (L2 Circuit)

---

To implement Ethernet over MPLS, you must configure a Layer 2 circuit on the provider edge (PE) switches. No special configuration is required on the customer edge (CE) switches. The provider switches require MPLS and LDP to be configured on the interfaces that will be receiving and transmitting MPLS packets.

**NOTE:** A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple Layer 2 circuits can be transported over a single label-switched path (LSP) tunnel between two PE switches. In contrast, each CCC requires a dedicated LSP.

This topic describes how to configure the PE switches to support Ethernet over MPLS. You must configure interfaces and protocols on both the local PE (PE1) and the remote PE (PE2) switches. The interface configuration varies depending upon whether the Layer 2 circuit is port-based or VLAN-based.

Figure 146 shows an example of a Layer 2 circuit configuration.

Figure 146: Ethernet over MPLS Layer 2 Circuit

**NOTE:** This topic refers to the local PE switch as PE1 and the remote PE switch as PE2. It also uses interface names rather than variables to help clarify the connections between the switches. The loopback addresses of the switches are configured as follows:

- PE1: 1.1.1.1
- PE2: 4.4.4.4

- [Configuring the Local PE Switch for Port-Based Layer 2 Circuit \(Pseudo-wire\) on page 4973](#)
- [Configuring the Remote PE Switch for Port-Based Layer 2 Circuit \(Pseudo-wire\) on page 4974](#)
- [Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit on page 4975](#)
- [Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit on page 4975](#)

### Configuring the Local PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

**CAUTION:** Configure MPLS networks with an MTU (maximum transmission unit) that is at least 12 bytes larger than the largest frame size that will be transported by the LSPs. If the size of an encapsulated packet on the ingress LSR exceeds the LSP MTU, that packet is dropped. If an egress LSR receives a packet on a VC LSP with a length (after the label stack and sequencing control word have been popped) that exceeds the MTU of the destination layer 2 interface, that packet is also dropped.

To configure the local PE switch (PE1) for a port-based layer 2 circuit (pseudo-wire):

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

**NOTE:** On QFX Series switches, the L2 circuit CE facing interface does not support Aggregated Ethernet (AE) interfaces.

2. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch# set l2circuit neighbor 4.4.4.4 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch# set mpls label-switched-path PE1-to-PE2 to 4.4.4.4
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set rsdp interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

## Configuring the Remote PE Switch for Port-Based Layer 2 Circuit (Pseudo-wire)

To configure the remote PE switch (PE2) for a port-based layer 2 circuit:

1. Configure an access CE-facing interface for Ethernet encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation ethernet-ccc
```

**NOTE:** On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
user@switch# set l2circuit neighbor 1.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

3. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
user@switch# set mpls label-switched-path PE2-to-PE1 to 1.1.1.1
```

4. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set rsdp interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

## Configuring the Local PE Switch for VLAN-Based Layer 2 Circuit

To configure the local PE switch (PE1) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

**NOTE:** On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE1 to PE2:

```
[edit protocols]
user@switch# set l2circuit neighbor 4.4.4.4 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE1 to PE2:

```
[edit protocols]
user@switch# set mpls label-switched-path PE1-to-PE2 to 4.4.4.4
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
user@switch# set mpls interface xe-0/0/7
user@switch# set rsvp interface xe-0/0/7
user@switch# set ldp interface lo0.0
```

## Configuring the Remote PE Switch for VLAN-Based Layer 2 Circuit

To configure the remote PE switch (PE2) for a VLAN-based layer 2 circuit:

1. Configure an access CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
user@switch# set xe-0/0/6 encapsulation vlan-ccc
```

**NOTE:** On QFX Series switches, the L2 circuit CE facing interface does not support AE interfaces.

2. Configure the logical unit of the CE-facing interface for VLAN encapsulation:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/6 unit 0 encapsulation vlan-ccc
```

3. Configure the logical unit of the CE-facing interface to belong to family ccc:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/6 unit 0 family ccc
```

4. Configure the same interface for VLAN tagging:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/6 vlan-tagging
```

5. Configure the VLAN ID of the interface:

```
[edit interfaces]
```

```
user@switch# set xe-0/0/6 unit 0 vlan-id 600
```

6. Configure the Layer 2 circuit from PE2 to PE1:

```
[edit protocols]
```

```
user@switch# set l2circuit neighbor 1.1.1.1 interface xe-0/0/6 virtual-circuit-id 1
```

7. Configure the label switched path from PE2 to PE1:

```
[edit protocols]
```

```
user@switch# set mpls label-switched-path PE2-to-PE1 to 1.1.1.1
```

8. Configure the protocols on the core and loopback interfaces:

```
[edit protocols]
```

```
user@switch# set mpls interface xe-0/0/7
```

```
user@switch# set rsdp interface xe-0/0/7
```

```
user@switch# set ldp interface lo0.0
```

## Configuring a Global MPLS EXP Classifier

EXP packet classification associates incoming packets with a particular MPLS CoS servicing level. EXP behavior aggregate (BA) classifiers examine the MPLS EXP value in the packet header to determine the CoS settings applied to the packet. EXP BA classifiers allow you to set the forwarding class and loss priority of an MPLS packet based on the incoming CoS value.

You can configure up to 64 EXP classifiers, however, the switch uses only one MPLS EXP classifier as a global classifier, which is applied only on interfaces configured as **family mpls**. All **family mpls** switch interfaces use the global EXP classifier to classify MPLS traffic.

There is no default EXP classifier. If you want to classify incoming MPLS packets using the EXP bits, you must configure a global EXP classifier. The global classifier applies to all MPLS traffic on all **family mpls** interfaces.

If a global EXP classifier is configured, MPLS traffic on **family mpls** interfaces uses the EXP classifier. If a global EXP classifier is not configured, then if a fixed classifier is applied to the interface, the MPLS traffic uses the fixed classifier. If no EXP classifier and no fixed classifier is applied to the interface, MPLS traffic is treated as best-effort traffic. DSCP classifiers are not applied to MPLS traffic.

To configure an MPLS EXP classifier using the CLI:

1. Create an EXP classifier and associate it with a forwarding class, a loss priority, and a code point:

```
[edit class-of-service classifiers]
user@switch# set (dscp | ieee-802.1 | exp) classifier-name forwarding-class
forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

2. Apply the EXP classifier to the switch interfaces:

```
[edit class-of-service]
user@switch# set system-defaults classifiers exp classifier-name
```

## Configuring MPLS Firewall Filters and Policers

You can configure firewall filters to filter MPLS traffic. To use an MPLS firewall filter, you must first configure the filter and then apply it to an interface you have configured for forwarding MPLS traffic. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached.

**NOTE:** You can configure ingress MPLS firewall filters only. Egress MPLS firewall filters are not supported. You cannot apply MPLS firewall filters to loopback interfaces.

When you configure an MPLS firewall filter, you define filtering criteria (terms, with match conditions) for the packets and an action (action, or action modifier) for the switch to take if the packets match the filtering criteria.

- [Table 378](#) describes the match conditions you can configure for MPLS firewall filters at the `[edit firewall family mpls filter filter-name term term-name from]` hierarchy level.

**NOTE:** If a packet has multiple MPLS labels, the filter applies the match conditions to only the bottom label in the label stack.

**Table 378: Supported Match Conditions for MPLS Firewall Filters**

| Match Condition     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>exp number</i>   | <p>Experimental (EXP) bit number or range of bit numbers in the MPLS header of a packet.</p> <p>For <i>number</i>, you can specify one or more values from 0 through 7 in binary, decimal or hexadecimal format, as given below:</p> <ul style="list-style-type: none"> <li>• A single EXP bit—for example, <b>exp 3</b></li> <li>• Several EXP bits—for example, <b>exp 0,4</b></li> <li>• A range of EXP bits—for example, <b>exp [0-5]</b></li> </ul> |
| <i>label number</i> | <p>MPLS label value or range of label values in the MPLS header of a packet.</p> <p>For <i>number</i>, you can specify one or more values from 0 through 1048575 in decimal or hexadecimal format, as given below:</p> <ul style="list-style-type: none"> <li>• A single label—for example, <b>label 3</b></li> <li>• Several labels—for example, <b>label 0,4</b></li> <li>• A range of labels—for example, <b>label [0-5]</b></li> </ul>               |

- [Table 379](#) describes the actions you can configure for MPLS firewall filters at the `[edit firewall family mpls filter filter-name term term-name then]` hierarchy level.

**Table 379: Supported Actions for MPLS Firewall Filters**

| Action                    | Description                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>accept</i>             | Accept a packet                                                                                                                                                                                                                                                            |
| <i>count counter-name</i> | <p>Count the number of packets that pass this filter or term.</p> <p><b>NOTE:</b> We recommend that you configure a counter for each term in a firewall filter, so that you can monitor the number of packets that match the conditions specified in each filter term.</p> |

Table 379: Supported Actions for MPLS Firewall Filters (*continued*)

| Action                     | Description                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>discard</b>             | Discard a packet silently without sending an Internet Control Message Protocol (ICMP) message                |
| <b>policer</b>             | Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer.   |
| <b>three-color-policer</b> | Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a three-color policer. |

- [Configuring an MPLS Firewall Filter on page 4979](#)
- [Applying an MPLS Firewall Filter to an MPLS Interface on page 4979](#)
- [Configuring Policers for LSPs on page 4980](#)

## Configuring an MPLS Firewall Filter

To configure an MPLS firewall filter:

1. Configure the filter name, term name, and at least one match condition—for example, match on MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls]
user@switch# set filter ingress-exp-filter term term-one from exp 0,4
```

2. In each firewall filter term, specify the actions to take if the packet matches all the conditions in that term—for example, count MPLS packets with EXP bits set to either 0 or 4:

```
[edit firewall family mpls filter ingress-exp-filter term term-one then]
user@switch# set count counter0
user@switch# set accept
```

## Applying an MPLS Firewall Filter to an MPLS Interface

To apply the MPLS firewall filter to an interface you have configured for forwarding MPLS traffic (using the **family mpls** statement at the **[edit interfaces *interface-name* unit *unit-number*]** hierarchy level):

**NOTE:** You can apply firewall filters only to filter MPLS packets that enter an interface.

1. Apply the firewall filter to an MPLS interface—for example, apply the firewall filter to interface xe-0/0/5:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls filter input ingress-exp-filter
```

2. Review your configuration and issue the **commit** command:

```
[edit interfaces]
```

```
user@switch# commit
commit complete
```

## Configuring Policers for LSPs

Starting with Junos OS 13.2X51-D15, you can send traffic matched by an MPLS filter to a two-color policer or three-color policer. MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.

## Configuring MPLS to Gather Statistics

You can configure MPLS so that it periodically gathers traffic statistics about all MPLS sessions, including transit sessions, by configuring the **statistics** statement. You must configure the **statistics** statement if you want to collect MPLS traffic statistics using SNMP polling of MPLS Management Information Bases (MIBs).

To enable or disable MPLS statistics collection, include the **statistics** statement:

```
statistics {
```

```

auto-bandwidth;
file filename <files number> <size size> <world-readable | no-world-readable>;
interval seconds;
no-transit-statistics;
transit-statistics-polling;
}

```

You can configure these statements at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The default interval is 300 seconds.

If you configure the **file** option, the statistics are placed in a file, with one entry per LSP. During the specified interval, the following information is recorded in this file:

- The number of packets, number of bytes, packets per second, and bytes per second transmitted by each LSP. Feature parity for the display of packet and byte statistics for sub-LSPs of a point-to-multipoint LSP on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.
- The percent of bandwidth transmitted over a given LSP in relation to the bandwidth percentage configured for that LSP. If no bandwidth is configured for an LSP, 0 percent is recorded in the percentage column.

At the end of each periodic report, a summary shows the current time, total number of sessions, number of sessions read, number of sessions ignored, and read errors, if any. Ignored sessions are typically those not in the up state or those with a reserved (0 through 15) incoming label (typically the egress point of an LSP). The reason for a read error appears on the same line as the entry for the LSP on which the error occurred. Gathering statistics is an unreliable process; occasional read errors might affect their accuracy. Sample output follows:

|                                                               |           |              |          |           |     |
|---------------------------------------------------------------|-----------|--------------|----------|-----------|-----|
| lsp6                                                          | 0 pkt     | 0 Byte       | 0 pps    | 0 Bps     | 0   |
| lsp5                                                          | 0 pkt     | 0 Byte       | 0 pps    | 0 Bps     | 0   |
| lsp6.1                                                        | 34845 pkt | 2926980 Byte | 1049 pps | 88179 Bps | 132 |
| lsp5.1                                                        | 0 pkt     | 0 Byte       | 0 pps    | 0 Bps     | 0   |
| lsp4                                                          | 0 pkt     | 0 Byte       | 0 pps    | 0 Bps     | 0   |
| Dec 7 17:28:38 Total 6 sessions: 5 success, 0 fail, 1 ignored |           |              |          |           |     |

## Configuring MPLS on Provider Edge Switches

To implement MPLS, you must configure two provider edge (PE) switches—an ingress PE switch and an egress PE switch—and at least one provider switch. You can configure

the customer edge (CE) interfaces on the PE switches of the MPLS network using IP over MPLS.

This topic describes how to configure an ingress PE switch and an egress PE switch using IP over MPLS:

1. [Configuring the Ingress PE Switch on page 4982](#)
2. [Configuring the Egress PE Switch on page 4983](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.10.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
```

3. Configure OSPF traffic engineering:

```
[edit protocols ospf]
user@switch# set traffic-engineering
```

4. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure MPLS traffic engineering.

```
[edit protocols mpls]
user@switch# set traffic-engineering
```

6. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

7. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
```

- ```

user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls

```
8. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```

[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 121.100.10.1/16

```
 9. Configure this Layer 3 customer edge interface for the routing protocol:

```

[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3.0

```
 10. Configure an LSP on the ingress PE switch (192.168.10.1) to send IP packets over MPLS to the egress PE switch (192.168.12.1):

```

[edit protocols mpls]
user@switch# set label-switched-path lsp_1 to 192.168.12.1

```
 11. Disable constrained-path LSP computation for this LSP:

```

[edit protocols mpls]
user@switch# set label-switched-path lsp_1 no-cspf

```
 12. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```

[edit routing-options]
user@switch# set static route 2.2.2.0/24 next-hop 192.168.10.1
user@switch# set static route 2.2.2.0/24 resolve

```

Configuring the Egress PE Switch

To configure the egress PE switch:

1. Configure an IP address for the loopback interface and the core interfaces:

```

[edit interfaces]
user@switch# set lo0 unit 0 family inet address 192.168.12.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.20.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.21.1/24

```

NOTE: You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure OSPF on the loopback interface and the core interfaces:

NOTE: You can use the switch address as an alternative to the loopback interface.

- ```

[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0

```
3. Configure RSVP on the loopback interface and the core interfaces:
 

```

[edit protocols rsvp]
user@switch# set rsvp interface lo0.0
user@switch# set rsvp interface xe-0/0/5.0

```

```
user@switch# set rsvp interface xe-0/0/6.0
```

4. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
```

6. Configure a customer edge interface as a Layer 3 routed interface, specifying an IP address:

```
[edit interfaces]
user@switch# set xe-0/0/3 unit 0 family inet address 2.2.2.1/16
```

7. Configure this Layer 3 customer edge interface for the routing protocol:

```
[edit]
user@switch# set protocols ospf area 0.0.0 interface xe-0/0/3
```

8. Configure an LSP on the egress PE switch (192.168.12.1) to send IP packets over MPLS to the ingress PE switch (192.168.10.1):

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 to 192.168.10.1
```

9. Disable constrained-path LSP computation for this LSP:

```
[edit protocols mpls]
user@switch# set label-switched-path lsp_2 no-cspf
```

10. Configure a static route from the ingress PE switch to the egress PE switch, thereby indicating to the routing protocol that the packets will be forwarded over the MPLS LSP that has been set up to that destination:

```
[edit routing-options]
user@switch# set static route 121.121.121.0/24 next-hop 192.168.12.1
user@switch# set static route 121.121.121.0/24 resolve
```

## Configuring MPLS on Provider Switches

To implement MPLS, you must configure at least one provider switch as a transit switch for the MPLS packets.

MPLS requires the configuration of an interior gateway protocol (OSPF) and a signaling protocol (RSVP) on the core interfaces and the loopback interface of all the switches. This procedure includes the configuration of OSPF on the provider switch.

To configure the provider switch, complete the following tasks:

1. Configure OSPF on the loopback and core interfaces:

**NOTE:** You can use the switch address as an alternative to the loopback interface.

```
[edit protocols ospf]
user@switch# set area 0.0.0.0 interface lo0.0
user@switch# set area 0.0.0.0 interface xe-0/0/5.0
user@switch# set area 0.0.0.0 interface xe-0/0/6.0
user@switch# set area 0.0.0.0 interface ae0
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure MPLS on the core interfaces:

```
[edit protocols mpls]
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

3. Configure RSVP on the loopback interface and the core interfaces:

```
[edit protocols rsvp]
user@switch# set interface lo0.0
user@switch# set interface xe-0/0/5.0
user@switch# set interface xe-0/0/6.0
user@switch# set interface ae0
```

4. Configure an IP address for the loopback interface and the core interfaces:

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 127.1.1.1/32
user@switch# set xe-0/0/5 unit 0 family inet address 10.1.5.1/24
user@switch# set xe-0/0/6 unit 0 family inet address 10.1.6.1/24
user@switch# set ae0 unit 0 family inet address 10.1.9.2/24
```

5. Configure **family mpls** on the logical units of the core interfaces, thereby identifying the interfaces that will be used for forwarding MPLS packets:

```
[edit interfaces]
user@switch# set xe-0/0/5 unit 0 family mpls
user@switch# set xe-0/0/6 unit 0 family mpls
user@switch# set ae0 unit 0 family mpls
```

**NOTE:** You can configure **family mpls** on either individual interfaces or aggregated Ethernet interfaces. You cannot configure it on tagged VLAN interfaces.

## Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure the device to collect statistics related to automatic bandwidth allocation by completing the following steps:

1. To collect statistics related to automatic bandwidth allocation, configure the **auto-bandwidth** option for the **statistics** statement at the **[edit protocols mpls]** hierarchy level. These settings apply to all LSPs configured on the router on which you have also configured the **auto-bandwidth** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level.

```
statistics {
 auto-bandwidth;
 file filename <files number> <size size> <world-readable | no-world-readable>;
 interval seconds;
 no-transit-statistics;
 transit-statistics-polling;
}
```
2. Specify the ***filename*** for the files used to store the MPLS trace operation output using the **file** option. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.
3. Specify the maximum number of trace files using the **files *number*** option. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***, then ***trace-file.1***, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.
4. Specify the interval for calculating the average bandwidth usage by configuring a time in seconds using the **interval** option. You can also set the adjustment interval on a specific LSP by configuring the **interval** option at the **[edit protocols mpls label-switch-path *label-switched-path-name* statistics]** hierarchy level.

**NOTE:** To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (interval statement at the [edit protocols mpls statistics] hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (adjust-interval statement at the [edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth] hierarchy level).

- To trace automatic bandwidth allocation, include the **autobw-state flag** for the MPLS **traceoptions** statement at the [edit protocols mpls] hierarchy level.

The following configuration enables the MPLS traceoptions for automatic bandwidth allocation. The trace records are stored in a file called **auto-band-trace** (the filename is user configurable):

```
[edit protocols mpls]
traceoptions {
 file auto-band-trace size 10k files 10 world-readable;
 flag autobw-state;
}
```

- Using the **show log** command, you can display the automatic bandwidth allocation statistics file generated when you configure the *auto-bandwidth* statement. The following shows sample log file output taken from an MPLS statistics file named **auto-band-stats** on a router configured with an LSP named **E-D**. The log file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. Before **Oct 30 17:14:57**, the router triggered an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:16:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```
user@host> show log auto-band-stats

```

7. Issue the `show mpls lsp autobandwidth` command to display current information about automatic bandwidth allocation. The following shows sample output from the `show mpls lsp autobandwidth` command taken at about the same time as the log file shown previously:

```

user@host> show mpls lsp autobandwidth
Lspname Last Requested Reserved Highwater AdjustTime LastAdjust
BW BW BW mark Left (sec)
E-D 300bps 812.005bps 812bps 1.56801kbps 294 sec Wed Oct 30 17:15:26 2013

```

8. Issue the `file show` command to display the MPLS trace file. You need to specify the file location and file name (the file is located in `/var/log/`). The following shows sample trace file output is taken from an MPLS trace file named `auto-band-trace.0.gz` on a router configured with an LSP named `E-D`. The trace file shows that LSP `E-D` is operating over its reserved bandwidth limit initially. At `Oct 30 17:15:26`, the router triggers an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By `Oct 30 17:15:57`, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

## Configuring Static Label Switched Paths for MPLS

Configuring static label-switched paths (LSPs) for MPLS is similar to configuring static routes on individual switches. As with static routes, there is no error reporting, liveliness detection, or statistics reporting.

To configure static LSPs, configure the ingress PE switch and each provider switch along the path up to and including the egress PE switch.

For the ingress PE switch, configure which packets to tag (based on the packet's destination IP address), configure the next switch in the LSP, and the tag to apply to the packet. Manually assigned labels can have values from 0 through 1,048,575.

For the transit switches in the path, configure the next switch in the path and the tag to apply to the packet. Manually assigned labels can have values from 1,000,000 through 1,048,575.

The egress PE switch removes the label and forwards the packet to the IP destination. However, if the previous switch removed the label, the egress switch examines the packet's IP header and forwards the packet toward its IP destination.

Before you configure a static LSP, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches” on page 4981](#).

**NOTE:** Do not configure LSPs at the [edit protocols mpls label-switched-path] hierarchy level on the PE switches.

- Configure one or more provider switches. See [“Configuring MPLS on Provider Switches” on page 4985](#).

This topic describes how to configure an ingress PE switch, one or more provider switches, and an egress PE switch for static LSP:

1. [Configuring the Ingress PE Switch on page 4990](#)
2. [Configuring the Provider and the Egress PE Switch on page 4991](#)

## Configuring the Ingress PE Switch

To configure the ingress PE switch:

1. Configure an IP address for every core interface:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family inet address address
```

**NOTE:** You cannot use routed VLAN interfaces (RVIs) or Layer 3 subinterfaces as core interfaces.

2. Configure the name associated with the static LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name
```

3. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress next-hop address-of-next-hop
```

4. Specify the address of the egress switch for the LSP:

```
[edit protocols mpls]
user@switch# set static-label-switched-path lsp-name ingress to address-of-egress-switch
```

5. Configure the new label that you want to add to the top of the label stack:

```
[edit protocols mpls]
```

```
user@switch# set static-label-switched-path lsp-name ingress push out-label
```

## Configuring the Provider and the Egress PE Switch

To configure a static LSP for MPLS on the provider and egress PE switch:

1. Configure a transit static LSP:

```
[edit protocols mpls]
```

```
user@switch# set static-label-switched-path lsp-name transit incoming-label
```

2. Configure the next hop switch for the LSP:

```
[edit protocols mpls]
```

```
user@switch# set static-label-switched-path lsp-name transit incoming-label next-hop
address-of-next-hop
```

3. Only for provider switches, remove the label at the top of the label stack and replace it with the specified label:

```
[edit protocols mpls]
```

```
user@switch# set static-label-switched-path lsp-name transit incoming-label swap out-label
```

4. Only for the egress PE switch, remove the label at the top of the label stack:

**NOTE:** If there is another label in the stack, that label becomes the label at the top of the label stack. Otherwise, the packet is forwarded as a native protocol packet (typically, as an IP packet).

```
[edit protocols mpls]
```

```
user@switch# set static-label-switched-path lsp-name transit incoming-label pop
```

## Configuring Rewrite Rules for MPLS EXP Classifiers

You configure EXP rewrite rules to alter CoS values in outgoing MPLS packets on the outbound **family mpls** interfaces of a switch to match the policies of a targeted peer. Policy matching allows the downstream routing platform or switch in a neighboring network to classify each packet into the appropriate service group.

To configure an EXP CoS rewrite rule, create the rule by giving it a name and associating it with a forwarding class, loss priority, and code point. This creates a rewrite table. After the rewrite rule is created, enable it on a logical **family mpls** interface. EXP rewrite rules can only be enabled on logical **family mpls** interfaces, not on physical interfaces or on interfaces of other family types. You can also apply an existing EXP rewrite rule on a logical interface.

**NOTE:** There are no default rewrite rules.

You can configure up to 64 EXP rewrite rules, but you can only use 16 EXP rewrite rules at any time on the switch. On a given **family mpls** logical interface, all pushed MPLS labels have the same EXP rewrite rule applied to them. You can apply different EXP rewrite rules to different logical interfaces on the same physical interface.

**NOTE:** On each physical interface, either all forwarding classes that are being used on the interface must have rewrite rules configured, or no forwarding classes that are being used on the interface can have rewrite rules configured. On any physical port, do not mix forwarding classes with rewrite rules and forwarding classes without rewrite rules.

**NOTE:** To replace an existing rewrite rule on the interface with a new rewrite rule of the same type, first explicitly remove the existing rewrite rule and then apply the new rule.

To create an EXP rewrite rule for MPLS traffic and enable it on a logical interface:

1. Create an EXP rewrite rule:

```
user@switch# set class-of-service rewrite-rules exp rewrite-rule-name forwarding-class forwarding-class-name loss-priority level code-points [aliases] [bit-patterns]
```

For example, to configure an EXP rewrite rule named **exp-rr-1** for a forwarding class named **mpls-1** with a loss priority of **low** that rewrites the EXP code point value to **001**:

```
user@switch# set class-of-service rewrite-rules exp exp-rr-1 forwarding-class mpls-1 loss-priority low code-points 001
```

2. Apply the rewrite rule to a logical interface:

```
user@switch # set class-of-service interfaces interface-name unit logical-unit rewrite-rules exp rewrite-rule-name
```

For example, to apply a rewrite rule named **exp-rr-1** to logical interface **xe-0/0/10.0**:

```
user@switch# set class-of-service interfaces xe-0/0/10 unit 0 rewrite-rules exp exp-rr-1
```

**NOTE:** In this example, all forwarding classes assigned to port **xe-0/0/10** must have rewrite rules. Do not mix forwarding classes that have rewrite rules with forwarding classes that do not have rewrite rules on the same interface.

## Example: Configuring MPLS-Based Layer 3 VPNs

You can implement an MPLS-based Layer 3 virtual private network (VPN) on QFX switches to interconnect sites for customers who want the service provider to handle all the Layer 3 routing functions. To support an MPLS-based Layer 3 VPN, you need to add components of the Layer 3 VPN to the configuration of the two provider edge (PE) switches. You do not need to change the configuration of the provider switches.

This example shows how to configure an MPLS-based Layer 3 VPN spanning two corporate sites:

- [Requirements on page 4994](#)
- [Overview and Topology on page 4994](#)
- [Configuring the Local PE Switch on page 4996](#)
- [Configuring the Remote PE Switch on page 4999](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.3 or later for the QFX Series
- Three QFX switches

Before you configure the Layer 3 VPN components, you must configure the basic components for an MPLS network:

- Configure two PE switches. See [“Configuring MPLS on Provider Edge Switches” on page 4981](#).
- Configure one or more provider switches. See [“Configuring MPLS on Provider Switches” on page 4985](#).

## Overview and Topology

Layer 3 VPNs allow customers to leverage the service provider’s technical expertise to ensure efficient site-to-site routing. The customer’s customer edge (CE) switch uses a routing protocol such as BGP or OSPF to communicate with the service provider’s provider edge (PE) switch to carry IP prefixes across the network. MPLS-based Layer 3 VPNs use only IP over MPLS; other protocol packets are not supported. This example includes two PE switches, PE1 and PE2.

In the basic MPLS configuration of the PE switches using IP over MPLS, the PE switches were configured to use OSPF as the routing protocol between the MPLS switches and RSVP as the signaling protocol. Traffic engineering was enabled. A label-switched path (LSP) was configured.

The following components must be added to the PE switches for an MPLS-based Layer 3 VPN:

- BGP group with **family inet-vpn unicast**
- Routing instance with instance type **vrf**

[Figure 147](#) illustrates the topology of this MPLS-based Layer 3 VPN.

**Figure 147: MPLS-Based Layer 3 VPN**

[Table 380](#) shows the settings of the customer edge interface on the local CE switch.

Table 380: Local CE Switch in the MPLS-Based Layer 3 VPN Topology

| Property                 | Settings                                                                      | Description                         |

## Configuring the Local PE Switch

**CLI Quick Configuration** To quickly configure the Layer 3 VPN components on the local PE switch, copy the following commands and paste them into the switch terminal window of PE1:

```
[edit]
set protocols bgp local-address 21.21.21.21 family inet-vpn unicast
```

```

set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 22.22.22.22
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-0/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label
set routing-options router-id 21.21.21.21
set routing-options autonomous-system 10

```

### Step-by-Step Procedure

To configure the Layer 3 VPN components on the local PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying family `inet-vpn unicast`:  

```
[edit protocols bgp]
user@switchPE1# set local-address 21.21.21.21 family inet-vpn unicast
```
2. Configure the BGP group, specifying the group name and type:  

```
[edit protocols bgp]
user@switchPE1# set group PE1-PE2 type internal
```
3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:  

```
[edit protocols bgp]
user@switchPE1# set neighbor 22.22.22.22
```
4. Configure the routing instance, specifying the routing-instance name and using `vrf` as the instance type:  

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 instance-type vrf
```
5. Configure a description for this routing instance:  

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```
6. Configure the routing instance to use a route distinguisher:  

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 route-distinguisher 21:21
```

**NOTE:** Each routing instance that you configure on a PE switch must have a unique route distinguisher associated with it. VPN routing instances require a route distinguisher to allow BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

7. Configure the VPN routing and forwarding (VRF) target of the routing instance:  

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-target target:21:21
```

**NOTE:** You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the *Junos OS VPNs Library for Routing Devices*.

8. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header:

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 vrf-table-label
```

9. Configure the router ID and autonomous system (AS):

**NOTE:** We recommend that you explicitly configure the router identifier under the [edit routing-options] hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

```
[edit routing-options]
user@switchPE1# set router-id 21.21.21.21 autonomous-system 10
```

**Results** Display the results of the configuration:

```
user@switchPE1> show configuration
```

```

```

## Configuring the Remote PE Switch

**CLI Quick Configuration** To quickly configure the Layer 3 VPN components on the remote PE switch, copy the following commands and paste them into the switch terminal window of PE2:

```

[edit]
set protocols bgp local-address 22.22.22.22 family inet-vpn unicast
set protocols bgp group PE1-PE2 type internal
set protocols bgp neighbor 21.21.21.21
set routing-instances L3VPN-1 instance-type vrf
set routing-instances L3VPN-1 description "BETWEEN PE1 AND PE2"
set routing-instances L3VPN-1 interface ge-11/0/14.0
set routing-instances L3VPN-1 route-distinguisher 21:21
set routing-instances L3VPN-1 vrf-target target:21:21
set routing-instances L3VPN-1 vrf-table-label;
set routing-options router-id 22.22.22.22
set routing-options autonomous-system 10

```

**Step-by-Step  
Procedure**

To configure Layer 3 VPN components on the remote PE switch:

1. Configure BGP, specifying the loopback address as the local address and specifying **family inet-vpn unicast**:  

```
[edit protocols bgp]
user@switchPE2# set local-address 22.22.22.22 family inet-vpn unicast
```
2. Configure the BGP group, specifying the group name and type:  

```
[edit protocols bgp]
user@switchPE2# set group PE1-PE2 type internal
```
3. Configure the BGP neighbor, specifying the loopback address of the remote PE switch as the neighbor's address:  

```
[edit protocols bgp]
user@switchPE2# set neighbor 21.21.21.21
```
4. Configure the routing instance, specifying the routing-instance name and using **vrf** as the instance type:  

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 instance-type vrf
```
5. Configure a description for this routing instance:  

```
[edit routing-instances]
user@switchPE1# set L3VPN-1 description "BETWEEN PE1 AND PE2"
```
6. Configure the routing instance to apply to the customer edge interface:  

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 interface ge-0/0/14.0
```
7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:  

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 route-distinguisher 21:21
```
8. Configure the VPN routing and forwarding (VRF) target of the routing instance:  

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-target target:21:21
```
9. Configure this routing instance with **vrf-table-label**, which maps the inner label of a packet to a specific VPN routing and forwarding (VRF) table and allows the examination of the encapsulated IP header.  

```
[edit routing-instances]
user@switchPE2# set L3VPN-1 vrf-table-label
```
10. Configure the router ID and autonomous system (AS):  

```
[edit routing-options]
user@switchPE2# set router-id 22.22.22.22 autonomous-system 10
```

**Results** Display the results of the configuration:

```
user@switchPE2> show configuration

interfaces {

## Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

---

This example shows how to configure Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

- [Requirements on page 5002](#)
- [Overview on page 5002](#)
- [Configuration on page 5005](#)
- [Verification on page 5010](#)

### Requirements

No special configuration beyond device initialization is required before you configure this example.

### Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at <http://www.ietf.org/>.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In [Figure 148](#), PE1 and PE2 are dual-stack BGP routers or switches, meaning they have both IPv4 and IPv6 stacks. The PE devices link the IPv6 networks through the customer edge (CE) routers or switches to the IPv4 core network. The CE devices and the PE devices connect through a link layer that can carry IPv6 traffic. The PE devices use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 148: IPv6 Networks Linked by MPLS IPv4 Tunnels

The two PE devices are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE devices can learn the IPv6 routes from the CE devices connected to them using MP-BGP or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE device and CE device could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGp, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE devices always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE device is not a Juniper Networks routing or switching platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE devices to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The

penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 device in [Figure 148](#) receives an IPv6 packet from the CE1 device, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 device, then no labels need to be pushed and the packet is simply sent to the CE2 device. If the destination matches a prefix that was learned from the PE2 device, then the PE1 router pushes two labels onto the packet and sends it to the Provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router-facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

**NOTE:** BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the **labeled-unicast** statement at the `[edit protocols bgp family inet]` hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.

---

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

Device PE1
set interfaces xe-0/0/5 unit 2 family inet6 address ::10.1.1.2/126
set interfaces xe-0/0/5 unit 2 family mpls
set interfaces xe-0/0/6 unit 5 family inet address 10.1.1.5/30
set interfaces xe-0/0/6 unit 5 family inet6
set interfaces xe-0/0/6 unit 5 family mpls
set interfaces lo0 unit 2 family inet address 1.1.1.2/32
set protocols mpls ipv6-tunneling
set protocols mpls interface xe-0/0/5.2
set protocols mpls interface xe-0/0/6.5
set protocols bgp group toCE1 type external
set protocols bgp group toCE1 local-address ::10.1.1.2
set protocols bgp group toCE1 family inet6 unicast
set protocols bgp group toCE1 export send-bgp6
set protocols bgp group toCE1 peer-as 1

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set xe-0/0/5 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set xe-0/0/5 unit 2 family mpls

user@PE1# set xe-0/0/6 unit 5 family inet address 10.1.1.5/30
user@PE1# set xe-0/0/6 unit 5 family inet6
user@PE1# set xe-0/0/6 unit 5 family mpls

user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32

```

2. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface xe-0/0/5.2
user@PE1# set interface xe-0/0/6.5

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1

user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6

```

```
user@PE1# set group toPE2 neighbor 1.1.1.4
```

4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface xe-0/0/6.5
user@PE1# set interface lo0.2 passive
```

5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set rsvp interface xe-0/0/6.5
```

6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self
```

```
user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept
```

```
user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```

7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
xe-0/0/5 {
 unit 2 {
 family inet6 {
 address ::10.1.1.2/126;
 }
 family mpls;
 }
}
xe-0/0/6 {
 unit 5 {
 family inet {
 address 10.1.1.5/30;
 }
 family inet6;
 family mpls;
 }
}
lo0 {
```

```
unit 2 {
 family inet {
 address 1.1.1.2/32;
 }
}

user@R1# show policy-options
policy-statement next-hop-self {
 then {
 next-hop self;
 }
}
policy-statement send-bgp6 {
 from {
 family inet6;
 protocol bgp;
 }
 then accept;
}
policy-statement send-v6 {
 from {
 family inet6;
 protocol [bgp direct];
 }
 then accept;
}

user@R1# show protocols
mpls {
 ipv6-tunneling;
 interface xe-0/0/5.2;
 interface xe-0/0/6.5;
}
bgp {
 group toCE1 {
 type external;
 local-address ::10.1.1.2;
 family inet6 {
 unicast;
 }
 export send-bgp6;
 peer-as 1;
 neighbor ::10.1.1.1;
 }
 group toPE2 {
 type internal;
 local-address 1.1.1.2;
 family inet6 {
 labeled-unicast {
 explicit-null;
 }
 }
 export [next-hop-self send-v6];
 neighbor 1.1.1.4;
 }
}
```

```
ospf {
 area 0.0.0.0 {
 interface xe-0/0/6.5;
 interface lo0.2 {
 passive;
 }
 }
}
rsvp {
 interface xe-0/0/6.5;
}

user@R1# show routing-options
router-id 1.1.1.2;
autonomous-system 2;
```

If you are done configuring the device, enter **commit** from configuration mode. Configure the other devices in the topology, as shown in “[CLI Quick Configuration](#)” on [page 5005](#).

## Verification

Confirm that the configuration is working properly.

### Verifying That the CE Devices Have Connectivity

**Purpose** Make sure that the tunnel is operating.

**Action** From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms

user@CE3> ping ::10.1.1.1
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

**Meaning** The IPv6 CE devices can communicate over the core IPv4 network.

**Related  
Documentation**

## Verifying That MPLS Is Working Correctly

To verify that MPLS is working correctly, perform the following tasks:

1. [Verifying the Physical Layer on the Switches on page 5011](#)
2. [Verifying the Routing Protocol on page 5011](#)

3. [Verifying the Core Interfaces Being Used for the MPLS Traffic on page 5011](#)
4. [Verifying RSVP on page 5012](#)

## Verifying the Physical Layer on the Switches

**Purpose** Verify that the interfaces are up. Perform this verification task on each of the switches.

**Action** user@switch> **show interfaces xe-\* terse**

| Interface  | Admin | Link | Proto        | Local       | Remote |
|------------|-------|------|--------------|-------------|--------|
| xe-0/0/0   | up    | up   |              |             |        |
| xe-0/0/0.0 | up    | up   |              |             |        |
| xe-0/0/1.0 | up    | up   |              |             |        |
| xe-0/0/2.0 | up    | up   |              |             |        |
| xe-0/0/3.0 | up    | up   | inet         | 2.2.2.1/16  |        |
| xe-0/0/4.0 | up    | up   |              |             |        |
| xe-0/0/5.0 | up    | up   | inet<br>mpls | 10.1.5.1/24 |        |
| xe-0/0/6.0 | up    | up   | inet<br>mpls | 10.1.6.1/24 |        |

**Meaning** The **show interfaces terse** command displays status information about the 10-Gigabit Ethernet interfaces on the switch. This output verifies that the interfaces are **up**. The output for the protocol family (Proto column) of the core interfaces (xe-0/0/5.0 and xe-0/0/6.0), shows that these interfaces are configured as both **inet** and **mpls**. The **Local** column for the core interfaces shows the IP address configured for these interfaces.

## Verifying the Routing Protocol

**Purpose** Verify the state of the configured routing protocol. You should perform this verification task on each of the switches. The state should be **Full**. If you have configured OSPF as the routing protocol, use the **show ospf neighbor** command to verify that the routing protocol is communicating with the switch neighbors.

**Action** user@switch> **show ospf neighbor**

| Address   | Interface | State | ID          | Pri | Dead |
|-----------|-----------|-------|-------------|-----|------|
| 127.1.1.1 | xe-0/0/5  | Full  | 10.10.10.10 | 128 | 39   |

**Meaning** The **show ospf neighbor** command displays the status of the routing protocol that has been configured on this switch. The output shows that the state is **Full**, meaning that the routing protocol is operating correctly—that is, hello packets are being exchanged between directly connected neighbors. For additional information on checking and monitoring routing protocols, see the [Junos OS Routing Protocols and Policies Command Reference](#).

## Verifying the Core Interfaces Being Used for the MPLS Traffic

**Purpose** Verify that the state of the MPLS interface is **Up**. You should perform this verification task on each of the switches.

**Action** user@switch> **show mpls interface**

| Interface | State | Administrative groups |
|-----------|-------|-----------------------|
| ge-0/0/5  | Up    | <none>                |
| ge-0/0/6  | Up    | <none>                |

**Meaning** The **show mpls interface** command displays the status of the core interfaces that have been configured to belong to **family mpls**. This output shows that the interface configured to belong to **family mpls** is up.

## Verifying RSVP

**Purpose** Verify the state of the RSVP session. You should perform this verification task on each of the switches.

user@switch> **show rsvp session**

```
Ingress RSVP: 1 sessions
To From State Rt Style Labelin Labelout LSPname
127.1.1.3 127.1.1.1 Up 0 1 FF - 300064 lsp_to_pe2_ge1
Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions
To From State Rt Style Labelin Labelout LSPname
127.1.1.1 127.1.1.3 Up 0 1 FF 299968 - lsp_to_pe1_ge1
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** This output confirms that the RSVP sessions are up.

## MPLS Configuration Guidelines

---

When configuring MPLS on QFX Series devices or on EX4600, note that the number of IP prefixes supported depends on the specific platform being used. See the scale specifications in the data sheet of your device for additional information.

- We recommend the following:
  - If your ingress provider edge (PE) switch needs to support more than 8000 external IP prefixes, use a larger capacity device as an ingress PE switch.
  - If you use a switch as a route reflector for BGP labeled routes, use it as a dedicated route reflector (that is, the switch must not participate in managing data traffic).

- If you use a switch as a PE switch or as a route reflector for BGP labeled routes, configure routing policies on the PE switch and the route reflector to filter external IP routes from the routing table.

The configuration example for a routing policy named `fib_policy` (at the `[edit policy-options` and `[edit routing-options` hierarchy levels) to filter BGP labeled routes from the `inet.0` routing table is given below:

```
user@switch# show policy-options
policy-statement fib_policy {
 from {
 protocol bgp;
 rib inet.0;
 }
 then reject;
}

user@switch# show routing-options
forwarding-table {
 export fib_policy;
}
```

- Packet fragmentation using the `allow-fragmentation` statement at the `[edit protocols mpls path-mtu]` hierarchy level is not supported on QFX Series devices or on the EX4600 switch. Therefore, you must ensure that the maximum transmission unit (MTU) values configured on every MPLS interface is sufficient to handle MPLS packets. The packets whose size exceeds the MTU value of an interface will be dropped.

## MPLS Stitching For Virtual Machine Connection

By using MPLS, the stitching feature of Junos OS provides connectivity between virtual machines that reside either on opposite sides of data center routers or in different data centers. An external controller, programmed in the data-plane, assigns MPLS labels to both virtual machines and servers. Then, the signaled MPLS labels are used between the data center routers, generating static link switched paths (LSPs), resolved over BGP labeled unicast, RSVP or LDP, to provide the routes dictated by the labels.

- [Q&A on page 5016](#)

## When Would I Use Stitching?

There are several ways to connect virtual machines. One option when you have virtual machines on opposite sides of a router (or different data centers) is to use MPLS stitching. A typical topology for using MPLS stitching is shown in Figure 149.

**Figure 149: Virtual Machines on Either Side of Routers**

ERROR: Unresolved graphic fileref="" not found in  
 "/cmsxml/default/main/supplemental/STAGING/images/".

The above topology consists of the following MPLS layers: VMs | Servers | ToRs | Router  
 ..... Router | ToRs | Servers | VMs

**NOTE:** The label on the left is the top of the label stack.

## How Does MPLS Stitching Work?

With stitching, the MPLS static allocation of labels demultiplexes incoming traffic onto any device/entity in the next layer in the direction of traffic flow. Essentially, there is a label hierarchy that picks up labels for the correct top-of-rack switch, server, and virtual machine that receives traffic. Static label assignments are done between the top-of-rack switches and the virtual machines.

For example, imagine that traffic is sent from VM1 to VM3 in Figure 149. When traffic exits Server1, its label stack is L1 | L2 | L3 where:

- L1 represents the egress top-of-rack switch ToR1.
- L2 represents the physical server, Server2, towards which the egress-side ToR will forward the traffic.
- L3: represents the virtual machine on Server2 to which the Server2 should deliver the traffic.

When traffic arrives at ToR1, it needs to be sent to ToR2. Since ToR1 and ToR2 are not directly connected, traffic must flow from ToR1 to ToR2 using label-switching starting on the outermost (top) label. Stitching has been added to static-LSP functionality to SWAP L1 to a L-BGP label that ToR2 advertises to ToR1. The label stack now must contain another label at the top to enable forwarding of the labeled packets between ToR1 and ToR2. An L-Top label is added if L-BGP is resolved over RSVP/LDP. If static LSP is resolved over L-BGP, then the top label is swapped with the L-BGP label and there is no L-Top label. When the traffic exits ToR1, the stack is: L-top | L-BGP | L2 | L3.

Traffic from ToR1 to ToR2 is then label switched over any signaled LSP.

When traffic arrives at ToR2, the top label is removed with PHP (popped) and the label stack becomes L-BGP | L2 | L3. Since L-BGP is a implicit null label, ToR2 pops the static LSP label L2 that corresponds to the egress server and then forward the packet to the egress server using the static-LSP configuration on ToR2, which corresponds to a single-hop implicit-NULL LSP.

The outgoing stack becomes L3 and the next-hop is the egress server Server2.

When traffic arrives at the egress server Server2, Server2 pops L3 and delivers the packet to VM3.

## How Do I Configure Stitching?

The new keyword **stitch** for LSPs under the command *transit* has been added to resolve the remote next-hop. The **show mpls static-lsp** command has been extended to show the LSP state as 'InProgress' whenever the LSP is waiting for protocol next-hop resolution by resolver.

## Which Switches Support Stitching?

QFX5100, QFX3500 and EX4600 support the static LSP stitching feature.

## Q&A

Q: Is link and node protection for the next-hop provided by MPLS stitching?

A: link and node protection for the next-hop of transit LSP stitched to L-BGP LSP are not needed. That is provided by L-BGP LSP.

Q: Does stitching work with real L-BGP labels?

A: No, stitching does not work when the L-BGP label is a real label.

### [edit protocols mpls] Hierarchy Level

This topic lists the supported configuration statements at the **[edit protocols mpls]** hierarchy level on the QFX Series and on the EX4600 switch. For more information about these statements, see the *Junos OS MPLS Applications Library for Routing Devices*.

**NOTE:** Both the command-line interface (CLI) on QFX Series devices and the CLI on the EX4600 switch display MPLS configuration statements that are not supported. However, configuring unsupported statements on these devices is ignored and has no effect on the operation of the device.

| <b>Description</b>              | Enable an LSP to monitor the status of its destination PE router. You can configure multiple backup PE router groups using the same router's address. Backup PE router groups provide ingress PE router redundancy when point-to-multipoint LSPs are configured for multicast distribution. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. This statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to the destination address. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | Configure the bandwidth model for differentiated services. Note that you cannot configure both bandwidth models at the same time.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>                  | <p><b>extended-mam</b>—The extended maximum allocation model (MAM) is a bandwidth model based on MAM.</p> <p><b>mam</b>—The MAM is defined in RFC 4125, <i>Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering</i>.</p> <p><b>rdm</b>—The Russian dolls bandwidth allocation model (RDM) is defined in RFC 4127, <i>Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering</i>. RDM makes efficient use of bandwidth by allowing the class types to share bandwidth.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                              |
| <b>Description</b>              | Specify that the label-switched path be a passive LSP associated with a bidirectional LSP when it is signaled at the ingress router. This passive LSP enables the MPLS application to utilize the reverse LSP. You cannot configure this statement at the same time as the <b>corouted-bidirectional</b> statement. |
| <b>Default</b>                  | This statement is disabled by default.                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | <p>Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.</p> <p>When specified, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. When not specified and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.</p>                                                                                                                                                                  |

| <b>Description</b>              | <p>Specify the maximum number of routers that an LSP can traverse. This limit can be applied to any of the following:</p> <ul style="list-style-type: none"> <li>• LSPs—The configured hop limit includes the ingress and egress routers. You can specify a hop limit for an LSP and for both primary and secondary paths.</li> <li>• Fast reroute detour—Specify the number of additional routers a fast reroute detour can traverse relative to the protected LSP. For example, if an LSP traverses 4 routers, any detour for the LSP can be no more than 10 router hops, including the ingress and egress routers.</li> <li>• Link protection bypass—Specify the maximum number of routers that a link protection bypass can traverse.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>                  | <p><b><i>number</i></b>—Maximum number of hops.</p> <p><b>Range:</b> 2 through 255 (for an LSP or for a link protection bypass); 0 through 255 (for fast reroute)</p> <p><b>Default:</b> 255 (for an LSP or for a link protection bypass); 6 (for fast reroute)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 14.1X53-D30 for QFX Series switches.                                                                                                                                                                      |
| <b>Description</b>              | Allow IPv6 routes to be resolved over an MPLS network by converting LDP and RSVP routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                     |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.1.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | Enable link protection on the specified static LSP. Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.                                                                                                                                                                                                                                   |
| <b>Default</b>                  | Link protection is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | <p>Disable constrained-path LSP computation.</p> <p>An explicit-path LSP is completely configured through operator action. Once configured, it is initiated only along the explicitly specified path.</p> <p>A constrained-path LSP relies on an ingress router to compute the complete path. The ingress router takes into account the following information during the computation:</p> <ul style="list-style-type: none"><li>• Interior gateway protocol (IGP) topology database</li><li>• Link utilization information from extensions in the IGP link-state database</li><li>• Administrative group information from extensions in the IGP link-state database</li><li>• LSP requirements, including bandwidth, hop count, and administrative group</li></ul> <p>Constrained-path LSPs can generally avoid link failures and congested links. They also permit recomputation (therefore, a new path) during topology changes or unsuccessful setup.</p> |
| <b>Default</b>                  | Constrained-path LSP computation enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b>              | Disable normal time-to-live (TTL) decrementing, which decrements the TTL field in the IP header by 1. This statement decrements the IP TTL by 1 before encapsulating the IP packet within an MPLS packet. When the penultimate router pops off the top label, it does not use the standard write-back procedure of writing the MPLS TTL into the IP TTL field. Therefore, the IP packet is decremented by 1. The ultimate router then decrements the packet by one more for a total cloud appearance of 2, thus hiding the network topology.                                                                                                                      |
| <b>Default</b>                  | Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b>              | <p>Disable normal time-to-live (TTL) decrementing. You configure this statement once per router, and it affects all RSVP-signaled or LDP-signaled LSPs. When this router acts as an ingress router for an LSP, it pushes an MPLS header with a TTL value of 255, regardless of the IP packet TTL. When the router acts as the penultimate router, it pops the MPLS header without writing the MPLS TTL into the IP packet.</p> <p>When you add the <b>no-propagate-ttl</b> statement to the configuration or delete it from the configuration, the effect takes place immediately. There is no need to clear existing RSVP LSPs or LDP sessions.</p> |
| <b>Default</b>                  | Normal TTL decrementing enabled; the TTL field value is decremented by 1 as the packet passes through each label-switched router in the LSP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Hierarchy Level</b>          | [edit logical-systems <i>logical-system-name</i> protocols mpls],<br>[edit protocols mpls]                                                                                                                                                                                                                 |
| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                  |
| <b>Description</b>              | If enabled, the LSP reoptimization is based solely on the IGP metric. The reoptimization process ignores the available bandwidth ratio calculations, the least-fill 10 percent congestion improvement rule, and the hop-counts rule. This statement makes reoptimization more aggressive than the default. |
| <b>Default</b>                  | Aggressive optimization is disabled.                                                                                                                                                                                                                                                                       |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                        |

| <b>Hierarchy Level</b>          | [edit logical-systems <i>logical-system-name</i> protocols mpls],<br>[edit logical-systems <i>logical-system-name</i> protocols mpls label-switch-path <i>lsp-name</i> ],<br>[edit protocols mpls],<br>[edit protocols mpls label-switch-path <i>lsp-name</i> ]                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>              | Allows you to specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The specified delay helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths. This delay timer starts when the timer specified by the <b>optimize-switchover-dealy</b> statement has elapsed. |
| <b>Options</b>                  | <b><i>seconds</i></b> —Configure the time in seconds to wait before tearing down the old paths that were in use prior to the last LSP optimization.<br><b>Default:</b> 60 seconds<br><b>Range:</b> 0 through 65,535 seconds                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | <p>Enable periodic reoptimization of an LSP that is already set up. If topology changes occur, an existing path might become suboptimal, and a subsequent recomputation might be able to determine a better path. This feature is useful only on LSPs for which constrained-path computation is enabled; that is, for which the <b>no-cspf</b> statement is not configured. Also, you only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers).</p> <p>To avoid extensive resource consumption that might result because of frequent path recomputations, or to avoid destabilizing the network as a result of constantly changing LSPs, we recommend that you either leave the timer value sufficiently large or disable the timer value.</p> |
| <b>Default</b>                  | The optimize timer is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>              | <p>Create a named path and optionally specify the sequence of explicit routers that form the path.</p> <p>You must include this statement when configuring explicit LSPs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <p><b>address</b>—IP address of each transit router in the LSP. You must specify the address or hostname of each transit router, although you do not need to list each transit router if its type is <b>loose</b>. As an option, you can include the ingress and egress routers in the path. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path until reaching the egress router (optional) or the router immediately before the egress router.</p> <p><b>Default:</b> If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.</p> <p><b>hostname</b>—See <b>address</b>.</p> <p><b>Default:</b> If you do not specify any routers explicitly, no routing limitations are imposed on the LSP.</p> <p><b>loose</b>—(Optional) Indicate that the next address in the <b>path</b> statement is a loose link. This means that the LSP can traverse through other routers before reaching this router.</p> <p><b>Default:</b> <b>strict</b></p> <p><b>path-name</b>—Name that identifies the sequence of nodes that form an LSP. The name can contain up to 32 characters and can include letters, digits, periods, and hyphens. To include other characters or use a longer name, enclose the name in quotation marks. The name must be unique within the ingress router.</p> <p><b>strict</b>—(Optional) Indicate that the LSP must go to the next address specified in the <b>path</b> statement without traversing other nodes. This is the default.</p> |

| <b>Description</b>         | <p>Define a routing policy, including subroutine policies.</p> <p>A <i>term</i> is a named structure in which match conditions and actions are defined. Routing policies are made up of one or more terms. Each routing policy term is identified by a term name. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in double quotation marks.</p> <p>Each term contains a set of match conditions and a set of actions:</p>                                                                                                                                                                                                                                                                                                                                                                                |

- Match conditions are criteria that a route must match before the actions can be applied. If a route matches all criteria, one or more actions are applied to the route.
- Actions specify whether to accept or reject the route, control how a series of policies are evaluated, and manipulate the characteristics associated with a route.

Generally, a router compares a route against the match conditions of each term in a routing policy, starting with the first and moving through the terms in the order in which they are defined, until a match is made and an explicitly configured or default action of **accept** or **reject** is taken. If none of the terms in the policy match the route, the router compares the route against the next policy, and so on, until either an action is taken or the default policy is evaluated.

If none of the match conditions of each term evaluates to true, the final action is executed. The final action is defined in an unnamed term. Additionally, you can define a default action (either **accept** or **reject**) that overrides any action intrinsic to the protocol.

The order of match conditions in a term is not relevant, because a route must match all match conditions in a term for an action to be taken.

To list the routing policies under the **[edit policy-options]** hierarchy level by **policy-statement *policy-name*** in alphabetical order, enter the **show policy-options** configuration command.

**Options** **actions**—(Optional) One or more actions to take if the conditions match. The actions are described in *Configuring Flow Control Actions*.

**family** **family-name**—(Optional) Specify an address family protocol. Specify **inet** for IPv4. Specify **inet6** for 128-bit IPv6, and to enable interpretation of IPv6 router filter addresses. For IS-IS traffic, specify **iso**. For IPv4 multicast VPN traffic, specify **inet-mvpn**. For IPv6 multicast VPN traffic, specify **inet6-mvpn**. For multicast-distribution-tree (MDT) IPv4 traffic, specify **inet-mdt**. For BGP route target VPN traffic, specify **route-target**. For traffic engineering, specify **traffic-engineering**.

**NOTE:** When family is not specified, the routing device or routing instance uses the address family or families carried by BGP. If multiprotocol BGP (MP-BGP) is enabled, the policy defaults to the protocol family or families carried in the network layer reachability information (NLRI) as configured in the **family** statement for BGP. If MP-BGP is not enabled, the policy uses the default BGP address family unicast IPv4.

**from**—(Optional) Match a route based on its source address.

**match-conditions**—(Optional in **from** statement; required in **to** statement) One or more conditions to use to make a match. The qualifiers are described in *Routing Policy Match Conditions*.

**policy subroutine-policy-name**—Use another policy as a match condition within this policy. The name identifying the subroutine policy can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policy names cannot take the form **\_\_.\*-internal\_\_**, as this form is reserved. For information about how to configure subroutines, see *Understanding Policy Subroutines in Routing Policy Match Conditions*.

**no-entropy-label-capability**—(Optional) Disable the entropy label capability advertisement at egress or transit routes specified in the policy.

**policy subroutine-policy-name**—Use another policy as a match condition within this policy. The name identifying the subroutine policy can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" "). Policy names cannot take the form **\_\_.\*-internal\_\_**, as this form is reserved. For information about how to configure subroutines, see *Understanding Policy Subroutines in Routing Policy Match Conditions*.

**policy-name**—Name that identifies the policy. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (" ").

**prefix-list prefix-list-name**—Name of a list of IPv4 or IPv6 prefixes.

**prefix-list-filter prefix-list-name**—Name of a prefix list to evaluate using qualifiers; **match-type** is the type of match (see *Configuring Prefix List Filters*), and **actions** is the action to take if the prefixes match.

**protocol** *protocol-name*—Name of the protocol used to control traffic engineering database import at the originating point.

**route-filter** *destination-prefix match-type <actions>*—(Optional) List of routes on which to perform an immediate match; *destination-prefix* is the IPv4 or IPv6 route prefix to match, *match-type* is the type of match (see *Configuring Route Lists*), and *actions* is the action to take if the *destination-prefix* matches.

**source-address-filter** *source-prefix match-type <actions>*—(Optional) Unicast source addresses in multiprotocol BGP (MBGP) and Multicast Source Discovery Protocol (MSDP) environments on which to perform an immediate match. *source-prefix* is the IPv4 or IPv6 route prefix to match, *match-type* is the type of match (see *Configuring Route Lists*), and *actions* is the action to take if the *source-prefix* matches.

**term** *term-name*—Name that identifies the term. The term name must be unique in the policy. It can contain letters, numbers, and hyphens (-) and can be up to 64 characters long. To include spaces in the name, enclose the entire name in quotation marks (" "). A policy statement can include multiple terms. We recommend that you name all terms. However, you do have the option to include an unnamed term which must be the final term in the policy. To configure an unnamed term, omit the **term** statement when defining match conditions and actions.

**to**—(Optional) Match a route based on its destination address or the protocols into which the route is being advertised.

**then**—(Optional) Actions to take on matching routes. The actions are described in *Configuring Flow Control Actions* and *Configuring Actions That Manipulate Route Characteristics*.

| <b>Description</b>              | <p>Preference for the route.</p> <p>You can optionally configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs, by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for LSPs is lower (more preferred) than all learned routes except direct interface routes.</p>                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <p><b><i>preference</i></b>—Preference to assign to the route. | <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | Specify whether an LSP should actively record the routes in the path. Recording routes requires that all transit routers support the RSVP Record Route object. Recording routes can be useful for diagnostics and loop detection.                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>                  | Record routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>BFD behavior modified in Junos OS Release 9.0.<br>Statement introduced in Junos OS Release 12.3X50 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>              | <p>Specify the amount of time (in seconds) that an LSP must wait before traffic reverts to a primary path. If during this time the primary path experiences any connectivity problem or stability problem, the timer is restarted.</p> <p>If you have configured BFD on the LSP, the Junos OS waits until the BFD session is restored before starting the revert timer counter.</p> <p>If you have configured a value of 0 seconds for the <b>revert-timer</b> statement and traffic is switched to the secondary path, the traffic remains on that path indefinitely. It is never switched back to the primary path unless you intervene.</p> |
| <b>Options</b>                  | <p><b>seconds</b>—Time in seconds.</p> <p><b>Range:</b> 0 through 65,535 seconds</p> <p><b>Default:</b> 60 seconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | <p>Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations. The more time you configure, the more time a source node (ingress of an RSVP LSP) can have to learn about the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes.</p> <p>Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the database and the network.</p> |

| Description              | <p>Specify one or more secondary paths to use for the LSP. You can configure more than one secondary path. All secondary paths are equal, and the first one that is available is chosen.</p> <p>You can specify secondary paths even if you have not specified any primary paths.</p> <p>Optionally, you can specify preference, CoS, and bandwidth values for the secondary path, which override any equivalent values that you configure for the LSP (at the [edit mpls label-switched-path] hierarchy level).</p>                                                                                                                                                                                      |
| Options                  | <p><b><i>path-name</i></b>—Name of a path that you created with the <b>path</b> statement.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b>              | <p>Enable the smart optimization timer. When you enable the smart optimization timer on a router, the Junos OS operates on the assumption that the original LSP path is preferable to any alternate or secondary path. When you enable the smart optimization timer and an LSP fails and its traffic is switched to an alternate path, the smart optimization timer starts and waits 3 minutes (this time is configurable). After 3 minutes have passed, the LSP is switched back to the original path. If the original path fails again and the LSP is switched to an alternate path again, the router waits 1 hour before attempting to switch the LSP back to its original path.</p> <p>If you want to disable the smart optimizer, you can set it to zero. The <b>smart-optimize-timer</b> value in seconds indicates the time before which the LSP is switched back to its primary path in case the primary path becomes available. Otherwise, the time to wait is controlled by the <b>optimize-timer</b>, which is usually set to a high value. Some ISPs have the <b>optimize-timer</b> set to once a day. Sometimes after the smart optimizer causes the LSP to be placed back on its primary path, the primary path goes down again within 60 minutes. When this happens, the <b>smart-optimize-timer</b> is disabled automatically, and the <b>optimize-timer</b> (regular path optimization) goes into effect. This is to protect against a flapping link being used.</p> |
| <b>Default</b>                  | The smart optimization timer is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Options</b>                  | <p><b>seconds</b>—(Optional) Specify the number of seconds to wait before switching an LSP back to its original path. If you do not specify the number of seconds, the default value is used.</p> <p><b>Range:</b> 0 through 65,535 seconds</p> <p><b>Default:</b> 180 seconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Release Information**    Statement introduced in Junos OS Release 10.1.  
                              Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**        Configure a static LSP.

**Options**            *lsp-name*—Name of the path.

                      The remaining statements are explained separately.

| <b>Description</b>         | Enable MPLS statistics collection and reporting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—(Optional) Name of the file to receive the output. We recommend that you place MPLS tracing output in the file mpls-stat in the /var/log directory.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <i>file</i> reaches its maximum size, it is renamed <i>file.0</i>, then <i>file.1</i>, and so on, until the maximum number of files is reached. Then, the oldest file is overwritten.</p> <p><b>Range:</b> 2 or more</p> <p><b>Default:</b> 2 files</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option.</p> <p><b>interval <i>seconds</i></b>—Interval at which to periodically collect statistics.</p> <p><b>Range:</b> 1 through 65,535</p> <p><b>Default:</b> 300 seconds</p> <p><b>no-world-readable</b>—(Optional) Prevent users from reading the log file.</p> <p><b>size <i>size</i></b>—(Optional) Maximum size of each file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a file named <i>file</i> reaches this size, it is renamed <i>file.0</i>. When the <i>file</i> again reaches its maximum size, <i>file.0</i> is renamed <i>file.1</i> and <i>file</i> is renamed <i>file.0</i>. This renaming scheme continues until the maximum number of files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum file size, you also must specify a maximum number of files with the <b>files</b> option.</p> <p><b>world-readable</b>—(Optional) Enable users to read the log file.</p> <p><b>Syntax:</b> Syntax: <b>xk</b> to specify KB, <b>xm</b> to specify MB, or <b>xg</b> to specify GB</p> <p><b>Range:</b> 10 KB through the maximum file size supported on your system</p> |

**Default:** 1 MB

**traffic-class-statistics**—(Optional) Create counters that maintain data traffic statistics per traffic class at the ingress of all types of LSPs and egress of ultimate hop popping (UHP) point-to-point LSPs. These counters are not created by default and are required to be configured to perform traffic-class-scoped loss measurement.

**transit-statistics-polling**—(Optional) Enable the polling and display of MPLS statistics for LSPs transiting the router. By default, RSVP does not periodically poll for transit LSP statistics. You cannot configure this statement and the **no-transit-statistics** statement at the same time.

The remaining statements are explained separately.

**Required Privilege Level** routing and trace—To view this statement in the configuration.  
routing-control and trace-control—To add this statement to the configuration.

| <b>Description</b>              | Select whether MPLS performs traffic engineering on BGP destinations only or on both BGP and IGP destinations. Affects only LSPs originating from this routing device, not transit or egress LSPs.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Default</b>                  | bgp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <p><b>bgp</b>—On BGP destinations only. Ingress routes are installed in the inet.3 routing table.</p> <p><b>bgp-igp</b>—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 routing table. If IGP shortcuts are enabled, the shortcut routes are automatically installed in the inet.0 routing table.</p> <p><b>bgp-igp-both-ribs</b>—On both BGP and IGP destinations. Ingress routes are installed in the inet.0 and inet.3 routing tables. This option is used to support VPNs.</p> <p><b>mpls-forwarding</b>—On both BGP and IGP destinations. Use ingress routes for forwarding only, not for routing.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b>         | Configure MPLS tracing options at the protocol level or for a label-switched path.<br><br>To specify more than one tracing operation, include multiple <b>flag</b> statements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>             | The default MPLS protocol-level tracing options are inherited from the routing protocols <b>traceoptions</b> statement included at the [edit routing-options] hierarchy level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Options</b>             | <p><b>filename</b>—Name of the file to receive the output of the tracing operation. All files are placed in the directory <b>/var/log</b>. We recommend that you place MPLS tracing output in the file <b>mpls-log</b>.</p> <p><b>files number</b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p><b>Range:</b> 2 through 1000</p> <p><b>Default:</b> 2 files</p> <p>If you specify a maximum number of files, you must also include the <b>size</b> statement to specify the maximum file size.</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements.</p> <p><b>MPLS Tracing Flags</b></p> <ul style="list-style-type: none"><li>• <b>all</b>—Trace all operations</li><li>• <b>autobw-state</b>—Automatic bandwidth events.</li><li>• <b>connection</b>—All circuit cross-connect (CCC) activity</li><li>• <b>connection-detail</b>—Detailed CCC activity</li></ul> |

- **cspf**—CSPF computations
- **cspf-link**—Links visited during CSPF computations
- **cspf-node**—Nodes visited during CSPF computations
- **error**—MPLS error packets
- **graceful-restart**—Trace MPLS graceful restart events
- **lsp-history**—Trace LSP history events
- **lsping**—Trace lsping packets and return codes
- **nsr-synchronization**—Trace NSR synchronization events
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail
- **state**—All LSP state transitions
- **static**—Trace static label-switched path
- **ted-export**—Trace leaking of entries from **lsdist.0** table into the traffic engineering database
- **ted-import**—Trace leaking traffic engineering database entries into the **lsdist.0** table
- **timer**—Timer usage

**no-world-readable**—(Optional) Allow only certain users to read the log file.

**size** *size*—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches this size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

If you specify a maximum file size, you must also include the **files** statement to specify the maximum number of files.

**world-readable**—(Optional) Allow any user to read the log file.

## Monitoring Commands for MPLS

- `clear mpls lsp`
- `monitor label-switched-path`
- `ping mpls bgp`
- `ping mpls l2circuit`
- `ping mpls l3vpn`
- `ping mpls lsp-end-point`
- `request mpls lsp adjust-autobandwidth`
- `show security keychain`
- `show link-management`
- `show link-management peer`
- `show link-management routing`
- `show link-management statistics`

- `show link-management te-link`
- `show mpls call-admission-control`
- `show mpls cspf`
- `show mpls diffserv-te`
- `show route forwarding-table`
- `show mpls interface`
- `show link-management statistics`
- `show link-management te-link`
- `show mpls call-admission-control`
- `show mpls cspf`
- `show mpls diffserv-te`
- `show route forwarding-table`
- `show mpls interface`
- `show mpls lsp`
- `show mpls lsp autobandwidth`
- `show mpls path`
- `show route table`
- `show route forwarding-table`
- `show mpls static-lsp`
- `show ted database`
- `show ted link`
- `show ted protocol`

## clear mpls lsp

**List of Syntax**    [Syntax on page 5107](#)  
                          [Syntax \(EX and QFX Series Switches\) on page 5107](#)

**Syntax**    clear mpls lsp  
                  <autobandwidth>  
                  <logical-system (all | *logical-system-name*)>  
                  <name *name*>  
                  <optimize | optimize-aggressive>  
                  <path *regular-expression*>  
                  <statistics>

**Syntax (EX and QFX Series Switches)**    clear mpls lsp  
                  <autobandwidth>  
                  <name *name*>  
                  <optimize | optimize-aggressive>  
                  <path *regular-expression*>  
                  <statistics>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                                  Command introduced in Junos OS Release 9.5 for EX Series switches.  
                                  Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

**Description**    Release the routes and states associated with MPLS label-switched paths (LSPs), and start new LSPs.

**CAUTION:** This command disconnects existing Resource Reservation Protocol (RSVP) sessions on the ingress routing device. If there is a time lag between the old path being torn down and the new path being set up, this command might impact traffic traveling along the LSPs.

**Options**    **none**—Reset and restart all LSPs that originated from this routing device; that is, all LSPs for which this routing device is the ingress routing device. Depending on the number of LSPs involved, it might take a while to restart all the LSPs.

**autobandwidth**—(Optional) Clear LSP autobandwidth counters.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**name *name***—(Optional) Reset and restart the specified LSP or group of LSPs. You can include wildcard characters in the interface name, as described in the *Junos Network Interfaces Configuration Guide*.

**optimize | optimize-aggressive**—(Optional) Run nonpreemptive optimization or aggressive optimization computation now.

**path *regular-expression***—(Optional) Clear the specific LSP path matching the specified regular expression.

**statistics**—(Optional) Clear LSP statistics. You cannot clear the MPLS LSP statistics using a regular expression (**name** and **path** options) on transit routers.

**Required Privilege Level**

clear

**List of Sample Output** [clear mpls lsp on page 5108](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request.

## Sample Output

### clear mpls lsp

```
user@host> clear mpls lsp
```

## monitor label-switched-path

**Syntax** `monitor label-switched-path lsp-name`  
`<logical-system (logical-system-name)>`

**Release Information** Command introduced before Junos OS Release 7.4.  
 Logical system support introduced in Junos OS Release 9.4.  
 Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.

**Description** Display the real-time status of the specified RSVP label-switched path (LSP). You can also use this command to monitor LSPs configured within logical systems.

**Options** `logical-system ( logical-system-name )`—(Optional) Perform this operation on all logical systems or on a particular logical system.

*lsp-name*—Name of the LSP.

**Additional Information** You can track the amount of traffic traversing an RSVP LSP and observe its essential parameters, such as uptime, ingress and egress addresses, labels, routes, and ports. Values are typically sampled every second. The display also allows you to scroll to other currently running LSPs. You cannot use this command to display information about static LSPs or LDP-signaled LSPs.

The output of this command shows how much each field has changed since you started the command or since you cleared the counters by using the `c` key. To control the output of the **monitor label-switched-path** command while it is running, use the keys listed in [Table 385](#). The keys are not case-sensitive.

**Table 385: Output Control Keys for the monitor label-switched-path Command**

| Key      | Action                                                                                                                            |
|----------|-----------------------------------------------------------------------------------------------------------------------------------|
| c        | Clears the screen and refreshes the display for this LSP.                                                                         |
| f        | Freezes the display, preventing new information from being displayed.                                                             |
| l        | Monitors a different LSP. After you type l, you can type the new LSP name.                                                        |
| n        | Displays information about the next LSP (whose name is alphabetically higher than the current LSP name) configured on the router. |
| p        | Goes to the previous LSP (whose name is alphabetically lower than the current LSP name) configured on the router.                 |
| q or Esc | Quits the command and returns to the command prompt.                                                                              |
| t        | Thaws, or restarts, the data display for this LSP.                                                                                |

## ping mpls bgp

---

**Syntax**    ping mpls bgp fec  
             <bottom-label-ttl>  
             <count *count*>  
             <destination *address*>  
             <detail>  
             <exp *forwarding-class*>  
             <instance *routing-instance-name*>  
             <logical-system (all | *logical-system-name*)>  
             <size *bytes*>  
             <source *source-address*>  
             <sweep>

**Release Information**    Command introduced in Junos OS Release 11.1.

**Description**    Check the operability of MPLS BGP-signaled label-switched path (LSP) connections. Press Ctrl+c to interrupt a **ping mpls bgp** command.

**NOTE:** The **ping mpls bgp fec** command only supports single paths.

---

**Options**    **bottom-label-ttl**—(Optional) Time-to-live (TTL) value for the bottom label in the label stack. The range of values is 1 through 255. The default value is **255**.

**count *count***—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination *address***—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp *forwarding-class***—(Optional) Value of the forwarding class for the MPLS ping packets.

**fec**—Ping a BGP-signaled LSP using the forwarding equivalence class (FEC) prefix and length.

**instance *routing-instance-name***—(Optional) Allows you to ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on the specified logical system.

**size *bytes***—(Optional) Size of the LSP ping request packet (88 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 89, 90, 91, or 92, the router or switch uses a size value of 92 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 88-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only BGP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

**Required Privilege Level** network

**List of Sample Output** [ping mpls bgp fec count on page 5113](#)

**Output Fields** When you enter this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code. Packets with error codes are not counted in the received packets count. They are accounted for separately. To display the error codes, use the **detail** option (for example, **ping mpls bgp 10.255.245.222 detail**).

## Sample Output

### ping mpls bgp fec count

```
user@host> ping mpls bgp 10.255.245.222 count 10
!!!xxx...x--- 1sping statistics ---10 packets transmitted, 3 packets received,
70% packet loss 4 packets received with error status, not counted as received.
```

## ping mpls l2circuit

---

**Syntax** ping mpls l2circuit (interface *interface-name* | virtual-circuit *virtual-circuit-id* neighbor *address*)  
<count *count*>  
<destination *address*>  
<detail>  
<exp *forwarding-class*>  
<logical-system (all | *logical-system-name*)>  
reply-mode (application-level-control-channel | ip-udp | no-reply)  
<size *bytes*>  
<source *source-address*>  
<sweep>  
<v1>

**Release Information** Command introduced before Junos OS Release 7.4.  
Command introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 12.3X50 for the QFX Series.  
The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
The **reply-mode** option and its suboptions are introduced in Junos OS Release 10.4R1.

**Description** Check the operability of the MPLS Layer 2 circuit connections. Type Ctrl+c to interrupt a ping mpls l2circuit command.

**Options** **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through **1,000,000**. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**interface** *interface-name*—Ping an interface configured for the Layer 2 circuit on the egress provider edge (PE) router.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**reply-mode**—(Optional) Reply mode for the ping request. This option has the following suboptions:

**application-level-control-channel**—Reply using an application level control channel.

**ip-udp**—Reply using an IPv4 or IPv6 UDP packet.

**no-reply**—Do not reply to the ping request.

**NOTE:** The **reply-mode** option and its suboptions **application-level-control-channel**, **ip-udp**, and **no-reply** are also available in Junos OS Release 10.2R4 and 10.3R2.

**size bytes**—(Optional) Size of the label-switched path (LSP) ping request packet (96 through 65468 bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

**source source-address**—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**vt**—(Optional) Use the type 9 Layer 2 circuit type, length, and value (TLV).

**virtual-circuit virtual-circuit-id neighbor address**—Ping the virtual circuit identifier on the egress PE router or switch and the specified neighbor, testing the integrity of the Layer 2 circuit between the ingress and egress PE routers or switches.

**Additional Information** You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

Request for seq 1, to interface 68, labels <100048, 100128>, packet size 100

Reply for seq 1, return code: Egress-ok time: 0.539 ms
```

### ping mpls l2circuit interface <interface-name> reply-mode

```
user@host> ping mpls l2circuit interface lt-1/2/0.21 reply-mode application-level-control-channel
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

## ping mpls l3vpn

**Syntax** ping mpls l3vpn prefix *prefix-name*  
 <*l3vpn-name*>  
 <bottom-label-ttl>  
 <count *count*>  
 <destination *address*>  
 <detail>  
 <exp *forwarding-class*>  
 <logical-system (all | *logical-system-name*)>  
 <size *bytes*>  
 <source *source-address*>  
 <sweep>

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.0 for EX Series switches.  
 The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
 Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description** Check the operability of a MPLS Layer 3 virtual private network (VPN) connection. Type Ctrl+c to interrupt a **ping mpls l3vpn** command.

**Options** **bottom-label-ttl**—(Optional) Display the time-to-live value for the bottom label in the label stack.

**count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through **1,000,000**. The default value is **5**.

**destination** *address*—(Optional) Specify an address other than the default (**127.0.0.1/32**) for the ping echo requests. The address can be anything within the **127/8** subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**l3vpn-name**—(Optional) Layer 3 VPN name.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**prefix** *prefix-name*—Ping to test whether a prefix is present in a provider edge (PE) router's or switch's VPN routing and forwarding (VRF) table, by means of a Layer 3 VPN destination prefix. This option does not test the connection between a PE router or switch and a customer edge (CE) router or switch.

**size** *bytes*—(Optional) Size of the label-switched path (LSP) ping request packet (**96** through **65468** bytes). Packets are 4-byte aligned. For example, If you enter a size of 97, 98, 99, or 100, the router or switch uses a size value of 100 bytes. If you enter a packet size that is smaller than the minimum size, an error message is displayed reminding you of the 96-byte minimum.

**source *source-address***—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (**lo.0**).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router or switch (the router or switch receiving the MPLS echo packets) to ping a Layer 2 circuit.

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

If the Layer 3 VPN traffic transits a route reflector within the network, the **ping mpls l3vpn** command does not work.

**Required Privilege Level** network

## ping mpls lsp-end-point

---

**Syntax**    ping mpls lsp-end-point *prefix-name*  
             <count *count*>  
             <destination *address*>  
             <detail>  
             <exp *forwarding-class*>  
             <instance *routing-instance-name*>  
             <logical-system (all | *logical-system-name*)>  
             <size *bytes*>  
             <source *source-address*>  
             <sweep>

**Release Information**    Command introduced before Junos OS Release 7.4.  
                             Command introduced in Junos OS Release 9.0 for EX Series switches.  
                             The **size** and **sweep** options were introduced in Junos OS Release 9.6.  
                             The **instance** option was introduced in Junos OS Release 10.0.  
                             Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**    Check the operability of MPLS label-switched path (LSP) endpoint connections. Type Ctrl+c to interrupt a **ping mpls** command.

**Options**    **count** *count*—(Optional) Number of ping requests to send. If **count** is not specified, five ping requests are sent. The range of values is 1 through 1,000,000. The default value is 5.

**destination** *address*—(Optional) Specify an address other than the default (127.0.0.1/32) for the ping echo requests. The address can be anything within the 127/8 subnet.

**detail**—(Optional) Display detailed information about the echo requests sent and received.

**exp** *forwarding-class*—(Optional) Value of the forwarding class for the MPLS ping packets.

**instance** *routing-instance-name*—(Optional) Ping a combination of the routing instance and forwarding equivalence class (FEC) associated with an LSP connection.

**logical-system** (all | *logical-system-name*)—(Optional) Perform this operation on all logical systems or on the specified logical system.

**prefix-name**—LDP forwarding equivalence class (FEC) prefix or RSVP LSP endpoint address.

**size** *bytes*—(Optional) Size of the LSP ping request packet. If the endpoint is LDP-based, the minimum size of the packet is 88 bytes. If the endpoint is RSVP-based, the minimum size of the packet is 100 bytes. The maximum size in either case is 65468 bytes.

**source** *source-address*—(Optional) IP address of the outgoing interface. This address is sent in the IP source address field of the ping request. If this option is not specified, the default address is usually the loopback interface (lo.0).

**sweep**—(Optional) Automatically determine the size of the maximum transmission unit (MTU).

**Additional Information** If the LSP changes, the label and interface information displayed when you issued the **ping** command continues to be used. You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router or switch to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

In asymmetric MTU scenarios, the echo response might be dropped. For example, if the MTU from System A to System B is 1000 bytes, the MTU from System B to System A is 500 bytes, and the ping request packet size is 1000 bytes, the echo response is dropped because the PAD TLV is included in the echo response, making it too large.

| <b>Release Information</b>                 | Command introduced before Junos OS Release 7.4.<br>Command introduced in Junos OS Release 9.5 for EX Series switches.<br>Command introduced in Junos OS Release 13.2X51-D15 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>                         | <p>Manually trigger a bandwidth allocation adjustment for active label-switched paths (LSPs).</p> <p>Without running this command, the bandwidth adjustment is recomputed at a configurable interval. The default interval is 5 minutes. If you do not want to wait for the periodic adjustment (for example, during a software demonstration), this command is useful.</p> <p>During bandwidth allocation adjustment, the LSP stays up to enable the bandwidth to be changed without dropping any traffic. This functionality is often referred to as <i>make-before-break</i>.</p> |
| <b>Options</b>                             | <p><b>none</b>—Manually trigger a bandwidth allocation adjustment for all active LSP paths.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>name <i>lsp-name</i></b>—(Optional) Manually trigger a bandwidth allocation adjustment on the specified LSP only.</p>                                                                                                                                                                                              |
| <b>Additional Information</b>              | <p>For this command to work properly, the following conditions must exist:</p> <ul style="list-style-type: none"><li>• Automatic bandwidth allocation must be enabled on the LSP. The parameters for adjustment interval and maximum average bandwidth are not reset after you issue the <b>request mpls lsp adjust-autobandwidth</b> command.</li><li>• The difference between the adjusted bandwidth and the current LSP path bandwidth must be greater than the threshold limit.</li></ul>                                                                                        |
| <b>Required Privilege Level</b>            | clear, maintenance                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Output Fields</b>            | Table 388 describes the output fields for the <b>show link-management</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                   |

**Table 388: show link-management Output Fields**

| Field Name        | Field Description                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------|
| Peer Name         | Name of the peer.                                                                                                 |
| System identifier | Internal identifier for the peer. The range of values is 0 through 64,000.                                        |
| State             | State of the peer: <b>Up</b> or <b>Down</b> .                                                                     |
| Control address   | Address to which a control channel is established.                                                                |
| CC local ID       | Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296.     |
| CC remote ID      | Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296.    |
| State             | State of the control channel: <b>Up</b> or <b>Down</b> .                                                          |
| TxSeqNum          | Sequence number of the hello message being sent to the peer. The range of values is 1 through 4,294,967,295.      |
| RcvSeqNum         | Sequence number of the last hello message received from the peer. The range of values is 0 through 4,294,967,295. |

Table 388: show link-management Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Flags</b>               | Code that provides information about the control channel. Currently supports only code value <b>R</b> , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts. |
| <b>TE links</b>            | Traffic-engineered links that are managed by their peer.                                                                                                                                                                                                                    |
| <b>TE link name</b>        | Name of the traffic-engineered link.                                                                                                                                                                                                                                        |
| <b>State</b>               | State of the traffic-engineered link: <b>Up</b> , <b>Down</b> , or <b>Init</b> .                                                                                                                                                                                            |
| <b>Local identifier</b>    | Identifier of the local side of the link.                                                                                                                                                                                                                                   |
| <b>Remote identifier</b>   | Identifier of the remote side of the link.                                                                                                                                                                                                                                  |
| <b>Local address</b>       | Address of the local side of the link.                                                                                                                                                                                                                                      |
| <b>Remote address</b>      | Address of the remote side of the link.                                                                                                                                                                                                                                     |
| <b>Encoding</b>            | Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include <b>SDH/SONET</b> , <b>Ethernet</b> , <b>Packet</b> , and <b>PDH</b> .                                                                               |
| <b>Switching</b>           | Type of switching that can be performed on the traffic-engineered link. Supported values are <b>PSC-1</b> and <b>Packet</b> .                                                                                                                                               |
| <b>Minimum bandwidth</b>   | Smallest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link (in bps).                                                                         |
| <b>Maximum bandwidth</b>   | Largest single allocation of bandwidth possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).                                                                                              |
| <b>Total bandwidth</b>     | Sum of the bandwidth, in bits per second (bps) and megabits per second (Mbps), of all interfaces that are members of the link.                                                                                                                                              |
| <b>Available bandwidth</b> | Sum of the bandwidths of all interfaces that are members of the link and that are not yet allocated (in bps).                                                                                                                                                               |
| <b>Name</b>                | Name of the interface.                                                                                                                                                                                                                                                      |
| <b>State</b>               | State of the interface: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                                          |
| <b>Local ID</b>            | Identifier of the local side of the interface.                                                                                                                                                                                                                              |
| <b>Remote ID</b>           | Identifier of the remote side of the interface.                                                                                                                                                                                                                             |
| <b>Bandwidth</b>           | Bandwidth, in bps or Mbps, of the member interface.                                                                                                                                                                                                                         |
| <b>Used</b>                | Whether the resource is allocated to an LSP: <b>Yes</b> or <b>No</b> .                                                                                                                                                                                                      |

| <b>Output Fields</b>            | Table 389 describes the output fields for the <b>show link-management peer</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                         |

**Table 389: show link-management peer Output Fields**

| Field Name                 | Field Description                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Peer Name</b>           | Name of the peer.                                                                                                                                                                                          |
| <b>System identifier</b>   | Internal identifier for the peer. The range of values is 0 through 64,000.                                                                                                                                 |
| <b>State</b>               | State of the peer: <b>Up</b> or <b>Down</b> .                                                                                                                                                              |
| <b>Control address</b>     | Address to which a control channel is established.                                                                                                                                                         |
| <b>Hello interval</b>      | How often the routing device sends Link Management Protocol (LMP) hello packets.                                                                                                                           |
| <b>Hello dead interval</b> | How long LMP waits before declaring the control channel to be dead. This is an interval during which the routing device receives no LMP hello packets from the neighbor on a control that is active or up. |
| <b>CC local ID</b>         | Identifier assigned to the control channel by the local peer. The range of values is 1 through 4,294,967,296.                                                                                              |
| <b>CC remote ID</b>        | Identifier assigned to the control channel by the remote peer. The range of values is 1 through 4,294,967,296.                                                                                             |

Table 389: show link-management peer Output Fields (*continued*)

| Field Name       | Field Description                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>     | State of the control channel: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                                    |
| <b>TxSeqNum</b>  | Sequence number of the hello message being sent to the peer. The range of values is <b>1</b> through <b>4,294,967,295</b> .                                                                                                                                                 |
| <b>RcvSeqNum</b> | Sequence number of the last hello message received from the peer. The range of values is <b>0</b> through <b>4,294,967,295</b> .                                                                                                                                            |
| <b>Flags</b>     | Code that provides information about the control channel. Currently supports only code value <b>R</b> , which indicates that the control channel is restarting after a failure in the control plane, as when the Link Management Protocol (LMP) process starts or restarts. |
| <b>TE links</b>  | Traffic-engineered links that are managed by their peer.                                                                                                                                                                                                                    |

## Sample Output

### show link-management peer

```

user@host> show link-management peer
Peer name: sonet, System identifier: 41448
State: Up, Control address: 70.70.70.70
Hello interval: 10000, Hello dead interval: 30000
 CC local ID CC remote ID State TxSeqNum RcvSeqNum Flags
 3265 0 ConfSnd 1 0 R
TE links:
to-sonet

```

## show link-management routing

| <b>Output Fields</b>            | Table 390 describes the output fields for the <b>show link-management routing</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                   |

**Table 390: show link-management routing Output Fields**

| Field Name        | Field Description                                                          |
|-------------------|----------------------------------------------------------------------------|
| Peer Name         | Name of the peer.                                                          |
| System identifier | Internal identifier for the peer. The range of values is 0 through 64,000. |
| State             | State of the peer: Up or Down.                                             |
| Control address   | Address to which a control channel is established.                         |
| Control channel   | Interface over which control packets are sent.                             |

Table 390: show link-management routing Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>               | State of the control channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>TE link name</b>        | Traffic-engineered link name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>State</b>               | State of the traffic-engineered link: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Local identifier</b>    | Identifier of the local side of the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Remote identifier</b>   | Identifier of the remote side of the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Local address</b>       | Address of the local side of the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Remote address</b>      | Address of the remote side of the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Encoding</b>            | Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include <b>SDH/SONET</b> , <b>Ethernet</b> , and <b>Packet</b> .                                                                                                                                                                                                                                                                                                                                                   |
| <b>Minimum bandwidth</b>   | Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link.                                                                                                                                                                                                                                                                                |
| <b>Maximum bandwidth</b>   | Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link (in bps).                                                                                                                                                                                                                                                                                                                                    |
| <b>Total bandwidth</b>     | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Available bandwidth</b> | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Resource</b>            | Forwarding adjacency LSP information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Type</b>                | Type of resource. The type is always a forwarding adjacency LSP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>State</b>               | State of the LSP: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>System Identifier</b>   | Internal identifier for the peer. The range of values is <b>0</b> through <b>64,000</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Total bandwidth</b>     | Bandwidth resource, in bps or Mbps, on the TE-link learned from the routing process.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Traffic parameters</b>  | <ul style="list-style-type: none"> <li>• <b>Encoding</b>—Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include <b>SDH/SONET</b>, <b>Ethernet</b>, and <b>Packet</b>.</li> <li>• <b>Switching</b>—Type of switching that can be performed on the traffic-engineered link: <b>PSC-1</b> and <b>Packet</b>.</li> <li>• <b>Granularity</b>—Layer 2 data for switching Layer 2 LSPs for this resource. Not supported. This value is always <b>unknown</b>.</li> </ul> |

## Sample Output

Output fields are listed in the approximate order in which they appear.                                                                                                                             |

**Table 391: show link-management statistics Output Fields**

| Field Name                | Field Description                                                                                                                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Received packets          | Number of received packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.     |
| Received bad packets      | Number of received bad packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed. |
| Small packets             | Number of packets that are too small.                                                                                                                                                                 |
| Wrong protocol version    | Number of packets specifying the wrong LMP version.                                                                                                                                                   |
| Messages for unknown peer | Number of packets destined for an unknown peer.                                                                                                                                                       |
| Messages for bad state    | Number of packets indicating a state that does not match the recipient.                                                                                                                               |
| Stale acknowledgments     | Number of <b>configAck</b> and <b>LinkSummaryAck</b> packets received that have a stale message ID.                                                                                                   |

Table 391: show link-management statistics Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Stale negative acknowledgments</b> | Number of <b>configNack</b> and <b>LinkSummaryNack</b> packets received that have a stale message ID.                                                                                                                                                                                          |
| <b>Sent packets</b>                   | Number of sent packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.                                                                                                  |
| <b>Retransmitted packets</b>          | Number of retransmitted packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.                                                                                         |
| <b>Dropped packets</b>                | Number of packets sent, by message type, that have been dropped by the receiver after the LMP retransmission interval has been exceeded. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed. |

## Sample Output

### show link-management statistics

```

user@host> show link-management statistics peer pro4-a
Statistics for peer pro4-a
 Received packets
 Config: 1
 Hello: 2572
 Small packets: 0
 Wrong protocol version: 0
 Messages for unknown peer: 0
 Messages for bad state: 0
 Stale acknowledgments: 0
 Stale negative acknowledgments: 0
 Sent packets
 Config: 2
 ConfigAck: 1
 Hello: 2572
 Retransmitted packets
 Config: 1

```

| Field Name                 | Field Description                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Switching</b>           | Type of switching that can be performed on the traffic-engineered link. Supported values are <b>PSC-1</b> and <b>Packet</b> .                                                                                                                       |
| <b>Minimum bandwidth</b>   | Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link. |
| <b>Maximum bandwidth</b>   | Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link.                                                              |
| <b>Total bandwidth</b>     | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link (in bps).                                                                                                                                                      |
| <b>Available Bandwidth</b> | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.                                                                                                                                |
| <b>Name</b>                | Name of the interface.                                                                                                                                                                                                                              |
| <b>State</b>               | State of the interface: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                  |
| <b>Local ID</b>            | Identifier of the local side of the interface.                                                                                                                                                                                                      |
| <b>Remote ID</b>           | Identifier of the remote side of the interface.                                                                                                                                                                                                     |
| <b>Bandwidth</b>           | Bandwidth, in bps or Mbps, of the member interface.                                                                                                                                                                                                 |
| <b>Used</b>                | Whether the resource is allocated to an LSP: <b>Yes</b> or <b>No</b> .                                                                                                                                                                              |
| <b>LSP-name</b>            | LSP name.                                                                                                                                                                                                                                           |

## Sample Output

### show link-management te-link

```

user@host> show link-management te-link
TE link name: FA-bd, State: Up
 Local identifier: 4144, Remote identifier: 0, Local address: 2.2.2.1,
 Remote address: 2.2.2.2, Encoding: Ethernet, Switching: Packet,
 Minimum bandwidth: 0bps, Maximum bandwidth: 0bps, Total bandwidth: 0bps,
 Available bandwidth: 0bps
 Name State Local ID Remote ID Bandwidth Used LSP-name
 falsp-bd Dn 43077 0 0bps No
TE link name: FA-be, State: Up
 Local identifier: 4145, Remote identifier: 0, Local address: 1.1.1.1,
 Remote address: 1.1.1.2, Encoding: Ethernet, Switching: Packet,
 Minimum bandwidth: 0bps, Maximum bandwidth: 10Mbps, Total bandwidth: 10Mbps,
 Available bandwidth: 8Mbps
 Name State Local ID Remote ID Bandwidth Used LSP-name
 falsp-be Up 43076 0 10Mbps Yes e2elasp-bf

| <b>Description</b>                 | Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) call admission control (CAC) information.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>                     | <p><b>none</b>—Display CAC information for all LSPs.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Display MPLS LSP CAC information for the specified instance. If <i>instance-name</i> is omitted, MPLS LSP CAC information for the master instance is displayed.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b><i>lsp-name</i></b>—(Optional) Display CAC information for the specified LSP only.</p> |
| <b>Additional Information</b>      | The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by any Layer 2 connection at that class type.                                                                                                                                                                                                                                                                                                                                        |
| <b>Required Privilege Level</b>    | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                                                                                            |

**Table 393: show mpls call-admission-control Output Fields**

| Field Name                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Available bandwidth</b> | Current available bandwidth on each LSP path. Depending on whether the LSP is an E-LSP or a regular LSP, either per-class bandwidth or a single bandwidth value (corresponding to best-effort bandwidth at <b>ct0</b> ) is displayed. The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by some Layer 2 connections at that class type. |

Table 393: show mpls call-admission-control Output Fields (*continued*)

| Field Name         | Field Description                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------|
| Layer2 connections | Different Layer 2 connections that had some bandwidth requirement and were admitted into an LSP path. |
| LSP name           | LSP pathname.                                                                                         |
| Neighbor address   | Neighbor address from which CAC and bandwidth booking are configured for Layer 2 circuits.            |
| Circuit            | Interface name and circuit information.                                                               |
| Primary            | LSP's primary standby path.                                                                           |
| Standby            | LSP's secondary standby path.                                                                         |
| VC bandwidth       | Bandwidth constraints associated with a Layer 2 circuit route.                                        |

## Sample Output

### show mpls call-admission-control

```

user@host# show mpls call-admission-control

LSP name: pro1-be
*Primary
 Available bandwidth: 0bps

LSP name: pro1-be-1
*Primary
 Available bandwidth: 60kbps

LSP name: pro1-be-gold
*Primary
 Available bandwidth: <ct0 50kbps> <ct1 20kbps> <ct2 30kbps> <ct3 0bps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.0(vc 5)
 VC bandwidth: <ct0 50kbps> <ct1 40kbps> <ct2 40kbps>

LSP name: pro1-be-gold-2
*Primary
 Available bandwidth: <ct0 0bps> <ct1 40kbps> <ct2 40kbps> <ct3 0bps>

LSP name: pro1-be-silver
*Primary prim1
 Available bandwidth: <ct0 10kbps> <ct1 20kbps> <ct2 0bps> <ct3 40kbps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.1(vc 3)
 VC bandwidth: <ct0 20kbps> <ct1 20kbps>
 Standby sec1
 Available bandwidth: <ct0 10kbps> <ct1 10kbps> <ct2 20kbps> <ct3 0bps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.1(vc 3)
 VC bandwidth: <ct0 20kbps> <ct1 20kbps>

```

## show mpls cspf

**List of Syntax** [Syntax on page 5142](#)  
[Syntax \(EX Series Switches\) on page 5142](#)

**Syntax** show mpls cspf  
 <instance *instance-name*>  
 <logical-system (all | *logical-system-name*)>

**Syntax (EX Series Switches)** show mpls cspf

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.5 for EX Series switches.  
*instance instance-name* option added in Junos OS Release 15.1.

**Description** Display Multiprotocol Label Switching (MPLS) Constrained Shortest Path First (CSPF) statistics.

**Options** none—Display MPLS CSFP statistics.

*instance instance-name*—(Optional) Display MPLS CSPF information for the specified instance. If *instance-name* is omitted, MPLS CSPF information for the master instance is displayed.

*logical-system (all | logical-system-name)*—(Optional) Perform this operation on all logical systems or on a particular logical system.

**Required Privilege Level** view

**List of Sample Output** [show mpls cspf on page 5143](#)

**Output Fields** [Table 394](#) describes the output fields for the **show mpls cspf** command. Output fields are listed in the approximate order in which they appear.

**Table 394: show mpls cspf Output Fields**

| Field Name   | Field Description                                     |
|--------------|-------------------------------------------------------|
| Queue length | Number of LSPs queued for automatic path computation. |
| current      | Current queue length.                                 |
| maximum      | Maximum queue length (high-water mark).               |
| dequeued     | Number of aborted computation attempts.               |
| Paths        | Counters for label-switched path computations.        |
| total        | Sum of the next four fields.                          |

Table 394: show mpls cspf Output Fields (*continued*)

| Field Name          | Field Description                                                                          |
|---------------------|--------------------------------------------------------------------------------------------|
| <b>successful</b>   | Number of path computations that were successfully completed.                              |
| <b>no route</b>     | Number of path computations that failed because the destination is unreachable.            |
| <b>Sys Error</b>    | Number of path computations that failed because of lack of memory.                         |
| <b>CSPFs</b>        | Total number of CSPF computations. A single path might require multiple CSPF computations. |
| <b>Time</b>         | Time, in seconds, required to perform the label-switched path computation.                 |
| <b>Total</b>        | Total amount of time consumed by the CSPF path computation algorithm.                      |
| <b>CSPFs</b>        | Total number of CSPF computations.                                                         |
| <b>Avg per CSPF</b> | Average amount of time required for each CSPF computation.                                 |
| <b>% of rpd</b>     | Percentage of routing process CPU used in the CSPF computation.                            |

## Sample Output

### show mpls cspf

```

user@host> show mpls cspf
CSPF statistics
Queue length current maximum dequeued
 0 0 0
Paths total successful no route sys error CSPFs
 0 0 0 0 0
Time (secs) total CSPFs avg per CSPF % of rpd
 0.000000 0.000000 0.000000 0.0000

```

| <b>Description</b>              | Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Output Fields** Table 306 lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used instead of the **extensive** keyword.

**Table 396: show route forwarding-table Output Fields**

| Field Name                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Level of Output                  |

| <b>Nexthop</b>                 | IP address of the next hop to the destination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <b>detail</b> , <b>extensive</b> |

Table 396: show route forwarding-table Output Fields (*continued*)

| Field Name                        | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Level of Output               |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>Next hop type (Type)</b>       | <p>Next-hop type. When the <b>detail</b> keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> <li>• <b>broadcast (bcst)</b>—Broadcast.</li> <li>• <b>deny</b>—Deny.</li> <li>• <b>hold</b>—Next hop is waiting to be resolved into a unicast or multicast type.</li> <li>• <b>indexed (idxd)</b>—Indexed next hop.</li> <li>• <b>indirect (indr)</b>—Indirect next hop.</li> <li>• <b>local (locl)</b>—Local address on an interface.</li> <li>• <b>routed multicast (mcr)</b>—Regular multicast next hop</li> <li>• <b>multicast (mcst)</b>—Wire multicast next hop (limited to the LAN).</li> <li>• <b>multicast discard (mdsc)</b>—Multicast discard.</li> <li>• <b>multicast group (mgrp)</b> —Multicast group member.</li> <li>• <b>receive (rcv)</b>—Receive.</li> <li>• <b>reject (rjct)</b>—Discard. An ICMP unreachable message was sent.</li> <li>• <b>resolve (rslv)</b>—Resolving the next hop.</li> <li>• <b>unicast (ucst)</b>—Unicast.</li> <li>• <b>unilist (ulst)</b>—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.</li> </ul> | <b>detail, extensive</b>      |
| <b>Index</b>                      | Software index of the next hop that is used to route the traffic for a given prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>detail, extensive none</b> |
| <b>Route interface-index</b>      | Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>              |
| <b>Reference (NhRef)</b>          | Number of routes that refer to this next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>none detail, extensive</b> |
| <b>Next-hop interface (Netif)</b> | Interface used to reach the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | <b>none detail, extensive</b> |
| <b>Alternate forward nh index</b> | Index number of the alternate next hop interface. Seen with <b>multicast</b> option only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>extensive</b>              |
| <b>Next-hop L3 Interface</b>      | The next hop layer 3 interface. This option can be expressed as a VLAN name and is only seen with the <b>multicast</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>              |
| <b>Next-hop L2 Interfaces</b>     | The next hop layer 2 interfaces. Seen with <b>multicast</b> option only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>extensive</b>              |

| <b>Administrative groups</b> | Administratively assigned colors of the link.          |

Table 397: show mpls interface Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum labels                        | Maximum number of MPLS labels upon which MPLS can operate on a logical interface. This is configured using the <b>maximum-labels</b> statement at the [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] or the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] hierarchy levels.                                                                                                                                                                                                            |
| Static protection revert time         | Time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path. This is configured using the <b>protection-revert-time</b> statement at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels.                                                                                                                                                                                                                    |
| Always mark connection protection tlv | Enabled or Disabled: Enabled indicates that the <b>always-mark-connection-protection-tlv</b> statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. When this statement is configured, it marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, the <b>switch-away-lsps</b> statement must be configured. |
| Switch away lsps                      | Enabled or Disabled: Enabled indicates that the <b>switch-away-lsps</b> statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. This enables you to switch an LSP away from a network node using a bypass LSP. This feature can be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.                |

## Sample Output

### show mpls interface

```
user@host> show mpls interface
```

```
Interface: ge-0/2/1.57
State: Up
Administrative group: <none>
Maximum labels: 5
Static protection revert time: 5 seconds
Always mark connection protection tlv: Disabled
Switch away lsps : Disabled
```

Output fields are listed in the approximate order in which they appear.                                                                                                                             |

**Table 398: show link-management statistics Output Fields**

| Field Name                       | Field Description                                                                                                                                                                                     |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Received packets</b>          | Number of received packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.     |
| <b>Received bad packets</b>      | Number of received bad packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed. |
| <b>Small packets</b>             | Number of packets that are too small.                                                                                                                                                                 |
| <b>Wrong protocol version</b>    | Number of packets specifying the wrong LMP version.                                                                                                                                                   |
| <b>Messages for unknown peer</b> | Number of packets destined for an unknown peer.                                                                                                                                                       |
| <b>Messages for bad state</b>    | Number of packets indicating a state that does not match the recipient.                                                                                                                               |
| <b>Stale acknowledgments</b>     | Number of <b>configAck</b> and <b>LinkSummaryAck</b> packets received that have a stale message ID.                                                                                                   |

Table 398: show link-management statistics Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Stale negative acknowledgments</b> | Number of <b>configNack</b> and <b>LinkSummaryNack</b> packets received that have a stale message ID.                                                                                                                                                                                          |
| <b>Sent packets</b>                   | Number of sent packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.                                                                                                  |
| <b>Retransmitted packets</b>          | Number of retransmitted packets by message type. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed.                                                                                         |
| <b>Dropped packets</b>                | Number of packets sent, by message type, that have been dropped by the receiver after the LMP retransmission interval has been exceeded. If the count for a message type is zero, that message type is not displayed. If the count for all message types is zero, this field is not displayed. |

## Sample Output

### show link-management statistics

```

user@host> show link-management statistics peer pro4-a
Statistics for peer pro4-a
 Received packets
 Config: 1
 Hello: 2572
 Small packets: 0
 Wrong protocol version: 0
 Messages for unknown peer: 0
 Messages for bad state: 0
 Stale acknowledgments: 0
 Stale negative acknowledgments: 0
 Sent packets
 Config: 2
 ConfigAck: 1
 Hello: 2572
 Retransmitted packets
 Config: 1

```

Table 399: show link-management te-link Output Fields

| Field Name        | Field Description                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TE link name      | Traffic-engineered link name.                                                                                                                                                                 |
| State             | State of the traffic-engineered link: <b>Up</b> or <b>Down</b> .                                                                                                                              |
| Local identifier  | Identifier of the local side of the link.                                                                                                                                                     |
| Remote identifier | Identifier of the remote side of the link.                                                                                                                                                    |
| Local address     | Address of the local side of the link.                                                                                                                                                        |
| Remote address    | Address of the remote side of the link.                                                                                                                                                       |
| Encoding          | Physical layer media type determined by the interfaces contained in the traffic-engineered link. Typical values include <b>SDH/SONET</b> , <b>Ethernet</b> , <b>Packet</b> , and <b>PDH</b> . |

Table 399: show link-management te-link Output Fields (*continued*)

| Field Name                 | Field Description                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Switching</b>           | Type of switching that can be performed on the traffic-engineered link. Supported values are <b>PSC-1</b> and <b>Packet</b> .                                                                                                                       |
| <b>Minimum bandwidth</b>   | Smallest single allocation of bandwidth, in bits per second (bps) or megabits per second (Mbps), possible on the traffic-engineered link. This number is equal to the smallest bandwidth interface that is a member of the traffic-engineered link. |
| <b>Maximum bandwidth</b>   | Largest single allocation of bandwidth, in bps or Mbps, possible on the traffic-engineered link. This number is equal to the largest bandwidth interface that is a member of the link.                                                              |
| <b>Total bandwidth</b>     | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link (in bps).                                                                                                                                                      |
| <b>Available Bandwidth</b> | Sum of the bandwidth, in bps or Mbps, of all interfaces that are members of the link and that are not yet allocated.                                                                                                                                |
| <b>Name</b>                | Name of the interface.                                                                                                                                                                                                                              |
| <b>State</b>               | State of the interface: <b>Up</b> or <b>Down</b> .                                                                                                                                                                                                  |
| <b>Local ID</b>            | Identifier of the local side of the interface.                                                                                                                                                                                                      |
| <b>Remote ID</b>           | Identifier of the remote side of the interface.                                                                                                                                                                                                     |
| <b>Bandwidth</b>           | Bandwidth, in bps or Mbps, of the member interface.                                                                                                                                                                                                 |
| <b>Used</b>                | Whether the resource is allocated to an LSP: <b>Yes</b> or <b>No</b> .                                                                                                                                                                              |
| <b>LSP-name</b>            | LSP name.                                                                                                                                                                                                                                           |

## Sample Output

### show link-management te-link

```

user@host> show link-management te-link
TE link name: FA-bd, State: Up

| <b>Description</b>                 | Display Multiprotocol Label Switching (MPLS) label-switched path (LSP) call admission control (CAC) information.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>                     | <p><b>none</b>—Display CAC information for all LSPs.</p> <p><b>instance <i>instance-name</i></b>—(Optional) Display MPLS LSP CAC information for the specified instance. If <b>instance-name</b> is omitted, MPLS LSP CAC information for the master instance is displayed.</p> <p><b>logical-system (all   <i>logical-system-name</i>)</b>—(Optional) Perform this operation on all logical systems or on a particular logical system.</p> <p><b>lsp-name</b>—(Optional) Display CAC information for the specified LSP only.</p> |
| <b>Additional Information</b>      | The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by any Layer 2 connection at that class type.                                                                                                                                                                                                                                                                                                                                 |
| <b>Required Privilege Level</b>    | view                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Output Fields</b>               | <p><a href="#">Table 393</a> describes the output fields for the <b>show mpls call-admission-control</b> command. Output fields are listed in the approximate order in which they appear.</p>                                                                                                                                                                                                                                                                                                                                     |

**Table 400: show mpls call-admission-control Output Fields**

| Field Name                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Available bandwidth</b> | Current available bandwidth on each LSP path. Depending on whether the LSP is an E-LSP or a regular LSP, either per-class bandwidth or a single bandwidth value (corresponding to best-effort bandwidth at <b>ct0</b> ) is displayed. The available bandwidth on an LSP path at a particular class type is the total path bandwidth at that class type minus the total bandwidth reserved by some Layer 2 connections at that class type. |

Table 400: show mpls call-admission-control Output Fields (*continued*)

| Field Name         | Field Description                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------|
| Layer2 connections | Different Layer 2 connections that had some bandwidth requirement and were admitted into an LSP path. |
| LSP name           | LSP pathname.                                                                                         |
| Neighbor address   | Neighbor address from which CAC and bandwidth booking are configured for Layer 2 circuits.            |
| Circuit            | Interface name and circuit information.                                                               |
| Primary            | LSP's primary standby path.                                                                           |
| Standby            | LSP's secondary standby path.                                                                         |
| VC bandwidth       | Bandwidth constraints associated with a Layer 2 circuit route.                                        |

## Sample Output

### show mpls call-admission-control

```

user@host# show mpls call-admission-control

LSP name: pro1-be
*Primary
 Available bandwidth: 0bps

LSP name: pro1-be-1
*Primary
 Available bandwidth: 60kbps

LSP name: pro1-be-gold
*Primary
 Available bandwidth: <ct0 50kbps> <ct1 20kbps> <ct2 30kbps> <ct3 0bps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.0(vc 5)
 VC bandwidth: <ct0 50kbps> <ct1 40kbps> <ct2 40kbps>

LSP name: pro1-be-gold-2
*Primary
 Available bandwidth: <ct0 0bps> <ct1 40kbps> <ct2 40kbps> <ct3 0bps>

LSP name: pro1-be-silver
*Primary prim1
 Available bandwidth: <ct0 10kbps> <ct1 20kbps> <ct2 0bps> <ct3 40kbps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.1(vc 3)
 VC bandwidth: <ct0 20kbps> <ct1 20kbps>
 Standby sec1
 Available bandwidth: <ct0 10kbps> <ct1 10kbps> <ct2 20kbps> <ct3 0bps>
 Layer2 connections:
 Neighbor address: 10.255.245.215, Circuit: so-0/3/0.1(vc 3)
 VC bandwidth: <ct0 20kbps> <ct1 20kbps>

```

## show mpls cspf

**List of Syntax** [Syntax on page 5162](#)  
[Syntax \(EX Series Switches\) on page 5162](#)

**Syntax** `show mpls cspf`  
`<instance instance-name>`  
`<logical-system (all | logical-system-name)>`

**Syntax (EX Series Switches)** `show mpls cspf`

**Release Information** Command introduced before Junos OS Release 7.4.  
 Command introduced in Junos OS Release 9.5 for EX Series switches.  
**instance *instance-name*** option added in Junos OS Release 15.1.

**Description** Display Multiprotocol Label Switching (MPLS) Constrained Shortest Path First (CSPF) statistics.

**Options** `none`—Display MPLS CSFP statistics.

**instance *instance-name***—(Optional) Display MPLS CSPF information for the specified instance. If *instance-name* is omitted, MPLS CSPF information for the master instance is displayed.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

**Required Privilege Level** view

**List of Sample Output** [show mpls cspf on page 5163](#)

**Output Fields** [Table 394](#) describes the output fields for the **show mpls cspf** command. Output fields are listed in the approximate order in which they appear.

**Table 401: show mpls cspf Output Fields**

| Field Name          | Field Description                                     |
|---------------------|-------------------------------------------------------|
| <b>Queue length</b> | Number of LSPs queued for automatic path computation. |
| <b>current</b>      | Current queue length.                                 |
| <b>maximum</b>      | Maximum queue length (high-water mark).               |
| <b>dequeued</b>     | Number of aborted computation attempts.               |
| <b>Paths</b>        | Counters for label-switched path computations.        |
| <b>total</b>        | Sum of the next four fields.                          |

Table 401: show mpls cspf Output Fields (*continued*)

| Field Name          | Field Description                                                                          |
|---------------------|--------------------------------------------------------------------------------------------|
| <b>successful</b>   | Number of path computations that were successfully completed.                              |
| <b>no route</b>     | Number of path computations that failed because the destination is unreachable.            |
| <b>Sys Error</b>    | Number of path computations that failed because of lack of memory.                         |
| <b>CSPFs</b>        | Total number of CSPF computations. A single path might require multiple CSPF computations. |
| <b>Time</b>         | Time, in seconds, required to perform the label-switched path computation.                 |
| <b>Total</b>        | Total amount of time consumed by the CSPF path computation algorithm.                      |
| <b>CSPFs</b>        | Total number of CSPF computations.                                                         |
| <b>Avg per CSPF</b> | Average amount of time required for each CSPF computation.                                 |
| <b>% of rpd</b>     | Percentage of routing process CPU used in the CSPF computation.                            |

## Sample Output

### show mpls cspf

```

user@host> show mpls cspf
CSPF statistics
Queue length current maximum dequeued
 0 0 0
Paths total successful no route sys error CSPFs
 0 0 0 0 0
Time (secs) total CSPFs avg per CSPF % of rpd
 0.000000 0.000000 0.000000 0.0000

```

## show mpls diffserv-te

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | Display the Routing Engine's forwarding table, including the network-layer prefixes and their next hops. This command is used to help verify that the routing protocol process has relayed the correction information to the forwarding table. The Routing Engine constructs and maintains one or more routing tables. From the routing tables, the Routing Engine derives a table of active routes, called the forwarding table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Output Fields** Table 306 lists the output fields for the **show route forwarding-table** command. Output fields are listed in the approximate order in which they appear. Field names might be abbreviated (as shown in parentheses) when no level of output is specified or when the **detail** keyword is used instead of the **extensive** keyword.

**Table 403: show route forwarding-table Output Fields**

| Field Name                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Level of Output                  |

| <b>Routing table</b>           | Name of the routing table (for example, <b>inet</b> , <b>inet6</b> , <b>mpls</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | All levels                       |
| <b>Address family</b>          | Address family (for example, <b>IP</b> , <b>IPv6</b> , <b>ISO</b> , <b>MPLS</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | All levels                       |
| <b>Destination</b>             | Destination of the route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>detail</b> , <b>extensive</b> |
| <b>Route Type (Type)</b>       | How the route was placed into the forwarding table. When the <b>detail</b> keyword is used, the route type might be abbreviated (as shown in parentheses): <ul style="list-style-type: none"> <li>• <b>cloned (clon)</b>—(TCP or multicast only) Cloned route.</li> <li>• <b>destination (dest)</b>—Remote addresses directly reachable through an interface.</li> <li>• <b>destination down (iddn)</b>—Destination route for which the interface is unreachable.</li> <li>• <b>interface cloned (ifcl)</b>—Cloned route for which the interface is unreachable.</li> <li>• <b>route down (ifdn)</b>—Interface route for which the interface is unreachable.</li> <li>• <b>ignore (ignr)</b>—Ignore this route.</li> <li>• <b>interface (intf)</b>—Installed as a result of configuring an interface.</li> <li>• <b>permanent (perm)</b>—Routes installed by the kernel when the routing table is initialized.</li> <li>• <b>user</b>—Routes installed by the routing protocol process or as a result of the configuration.</li> </ul> | All levels                       |
| <b>Route reference (RtRef)</b> | Number of routes to reference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b> , <b>extensive</b> |
| <b>Flags</b>                   | Route type flags: <ul style="list-style-type: none"> <li>• <b>none</b>—No flags are enabled.</li> <li>• <b>accounting</b>—Route has accounting enabled.</li> <li>• <b>cached</b>—Cache route.</li> <li>• <b>incoming-iface interface-number</b>—Check against incoming interface.</li> <li>• <b>prefix load balance</b>—Load balancing is enabled for this prefix.</li> <li>• <b>sent to PFE</b>—Route has been sent to the Packet Forwarding Engine.</li> <li>• <b>static</b>—Static route.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>extensive</b>                 |
| <b>Nexthop</b>                 | IP address of the next hop to the destination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b> , <b>extensive</b> |

Table 403: show route forwarding-table Output Fields (*continued*)

| Field Name                        | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Level of Output               |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>Next hop type (Type)</b>       | <p>Next-hop type. When the <b>detail</b> keyword is used, the next-hop type might be abbreviated (as indicated in parentheses):</p> <ul style="list-style-type: none"> <li>• <b>broadcast (bcst)</b>—Broadcast.</li> <li>• <b>deny</b>—Deny.</li> <li>• <b>hold</b>—Next hop is waiting to be resolved into a unicast or multicast type.</li> <li>• <b>indexed (idxd)</b>—Indexed next hop.</li> <li>• <b>indirect (indr)</b>—Indirect next hop.</li> <li>• <b>local (locl)</b>—Local address on an interface.</li> <li>• <b>routed multicast (mcr)</b>—Regular multicast next hop</li> <li>• <b>multicast (mcst)</b>—Wire multicast next hop (limited to the LAN).</li> <li>• <b>multicast discard (mdsc)</b>—Multicast discard.</li> <li>• <b>multicast group (mgrp)</b> —Multicast group member.</li> <li>• <b>receive (rcv)</b>—Receive.</li> <li>• <b>reject (rjct)</b>—Discard. An ICMP unreachable message was sent.</li> <li>• <b>resolve (rslv)</b>—Resolving the next hop.</li> <li>• <b>unicast (ucst)</b>—Unicast.</li> <li>• <b>unilist (ulst)</b>—List of unicast next hops. A packet sent to this next hop goes to any next hop in the list.</li> </ul> | <b>detail, extensive</b>      |
| <b>Index</b>                      | Software index of the next hop that is used to route the traffic for a given prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>detail, extensive none</b> |
| <b>Route interface-index</b>      | Logical interface index from which the route is learned. For example, for interface routes, this is the logical interface index of the route itself. For static routes, this field is zero. For routes learned through routing protocols, this is the logical interface index from which the route is learned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>              |
| <b>Reference (NhRef)</b>          | Number of routes that refer to this next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>none detail, extensive</b> |
| <b>Next-hop interface (Netif)</b> | Interface used to reach the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | <b>none detail, extensive</b> |
| <b>Alternate forward nh index</b> | Index number of the alternate next hop interface. Seen with <b>multicast</b> option only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>extensive</b>              |
| <b>Next-hop L3 Interface</b>      | The next hop layer 3 interface. This option can be expressed as a VLAN name and is only seen with the <b>multicast</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>extensive</b>              |

|------------------------------|--------------------------------------------------------|
| <b>Interface</b>             | Name of the interface.                                 |
| <b>State</b>                 | State of the interface: <b>Up</b> or <b>Dn</b> (down). |
| <b>Administrative groups</b> | Administratively assigned colors of the link.          |

Table 404: show mpls interface Output Fields (*continued*)

| Field Name                            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum labels                        | Maximum number of MPLS labels upon which MPLS can operate on a logical interface. This is configured using the <b>maximum-labels</b> statement at the [edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] or the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family mpls] hierarchy levels.                                                                                                                                                                                                            |
| Static protection revert time         | Time (in seconds) that a static LSP must wait before traffic reverts from the bypass path to the original path. This is configured using the <b>protection-revert-time</b> statement at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels.                                                                                                                                                                                                                    |
| Always mark connection protection tlv | Enabled or Disabled: Enabled indicates that the <b>always-mark-connection-protection-tlv</b> statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. When this statement is configured, it marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality. To switch traffic to the bypass LSP, the <b>switch-away-lsps</b> statement must be configured. |
| Switch away lsps                      | Enabled or Disabled: Enabled indicates that the <b>switch-away-lsps</b> statement is configured at the [edit logical-systems <i>logical-system-name</i> protocols mpls interface <i>interface-name</i> static] or the [edit protocols mpls interface <i>interface-name</i> static] hierarchy levels. This enables you to switch an LSP away from a network node using a bypass LSP. This feature can be used in maintenance of active networks when a network device needs to be replaced without interrupting traffic passing through the network. The LSPs can be either static or dynamic.                |

## Sample Output

### show mpls interface

```
user@host> show mpls interface
```

```
Interface: ge-0/2/1.57
State: Up
Administrative group: <none>
Maximum labels: 5
Static protection revert time: 5 seconds
Always mark connection protection tlv: Disabled
Switch away lsps : Disabled
```

## show mpls lsp

**Release Information**    Command introduced before Junos OS Release 7.4.  
                              **defaults** option added in Junos OS Release 8.5.  
                              Command introduced in Junos OS Release 9.5 for EX Series switches.  
                              Statement introduced in Junos OS Release 12.3X50 for the QFX Series.

**Description**    Display information about configured and active dynamic Multiprotocol Label Switching (MPLS) label-switched paths (LSPs).

**Options**    **none**—Display standard information about all configured and active dynamic MPLS LSPs.

**brief | detail | extensive | terse**—(Optional) Display the specified level of output. The extensive option displays the same information as the detail option, but covers the most recent 50 events.

**autobandwidth**—(Optional) Display automatic bandwidth information. This option is explained separately (see [show mpls lsp autobandwidth](#)).

**bidirectional | unidirectional**—(Optional) Display bidirectional or unidirectional LSP information, respectively.

**bypass**—(Optional) Display LSPs used for protecting other LSPs.

**count-active-routes**—(Optional) Display active routes for LSPs.

**defaults**—(Optional) Display the MPLS LSP default settings.

**descriptions**—(Optional) Display the MPLS label-switched path (LSP) descriptions. To view this information, you must configure the description statement at the **[edit protocol mpls lsp]** hierarchy level. Only LSPs with a description are displayed. This command is only valid for the ingress routing device, because the description is not propagated in RSVP messages.

**down | up**—(Optional) Display only LSPs that are inactive or active, respectively.

**externally-controlled**—(Optional) Display the LSPs that are under the control of an external Path Computation Element (PCE).

**externally-provisioned**—(Optional) Display the LSPs that are generated dynamically and provisioned by an external Path Computation Element (PCE).

**instance *instance-name***—(Optional) Display MPLS LSP information for the specified instance. If *instance-name* is omitted, MPLS LSP information is displayed for the master instance.

**logical-system (all | *logical-system-name*)**—(Optional) Perform this operation on all logical systems or on a particular logical system.

***lsp-type***—(Optional) Display information about a particular LSP type:

- **bypass**—Sessions for bypass LSPs.
- **egress**—Sessions that terminate on this routing device.
- **ingress**—Sessions that originate from this routing device.
- **transit**—Sessions that pass through this routing device.

**name *name***—(Optional) Display information about the specified LSP or group of LSPs.

**p2mp**—(Optional) Display information about point-to-multipoint LSPs.

**statistics**—(Optional) (Ingress and transit routers only) Display accounting information about LSPs. Statistics are not available for LSPs on the egress routing device, because the penultimate routing device in the LSP sets the label to 0. Also, as the packet arrives at the egress routing device, the hardware removes its MPLS header and the packet reverts to being an IPv4 packet. Therefore, it is counted as an IPv4 packet, not an MPLS packet.

**NOTE:** If a bypass LSP is configured for the primary static LSP, display cumulative statistics of packets traversing through the protected LSP and bypass LSP when traffic is re-optimized when the protected LSP link is restored. (Bypass LSPs are not supported on QFX Series switches.)

When used with the **bypass** option (**show mpls lsp bypass statistics**), display statistics for the traffic that flows only through the bypass LSP.

**transit**—(Optional) Display LSPs transiting this routing device.

**Output Fields**

[Table 405](#) describes the output fields for the **show mpls lsp** command. Output fields are listed in the approximate order in which they appear.

**Table 405: show mpls lsp Output Fields**

| Field Name         | Field Description                                                                                                                                                                                        | Level of Output |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Ingress LSP</b> | Information about LSPs on the ingress routing device. Each session has one line of output.                                                                                                               | All levels      |
| <b>Egress LSP</b>  | Information about the LSPs on the egress routing device. MPLS learns this information by querying RSVP, which holds all the transit and egress session information. Each session has one line of output. | All levels      |
| <b>Transit LSP</b> | Number of LSPs on the transit routing devices and the state of these paths. MPLS learns this information by querying RSVP, which holds all the transit and egress session information.                   | All levels      |

Table 405: show mpls lsp Output Fields (*continued*)

| Field Name                  | Field Description                                                                                                                                                                                                                                                                     | Level of Output         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>P2MP name</b>            | Name of the point-to-multipoint LSP. Dynamically generated P2MP LSPs used for VPLS flooding use dynamically generated P2MP LSP names. The name uses the format <i>identifier:vpls:router-id:routing-instance-name</i> . The <i>identifier</i> is automatically generated by Junos OS. | All levels              |
| <b>P2MP branch count</b>    | Number of destination LSPs the point-to-multipoint LSP is transmitting to.                                                                                                                                                                                                            | All levels              |
| <b>P</b>                    | An asterisk (*) under this heading indicates that the LSP is a primary path.                                                                                                                                                                                                          | All levels              |
| <b>address</b>              | ( <b>detail</b> and <b>extensive</b> ) Destination (egress routing device) of the LSP.                                                                                                                                                                                                | <b>detail extensive</b> |
| <b>To</b>                   | Destination (egress routing device) of the session.                                                                                                                                                                                                                                   | <b>brief</b>            |
| <b>From</b>                 | Source (ingress routing device) of the session.                                                                                                                                                                                                                                       | <b>brief detail</b>     |
| <b>State</b>                | State of the LSP handled by this RSVP session: <b>Up</b> , <b>Dn</b> (down), or <b>Restart</b> .                                                                                                                                                                                      | <b>brief detail</b>     |
| <b>Active Route</b>         | Number of active routes (prefixes) installed in the forwarding table. For ingress LSPs, the forwarding table is the primary IPv4 table ( <b>inet.0</b> ). For transit and egress RSVP sessions, the forwarding table is the primary MPLS table ( <b>mpls.0</b> ).                     | <b>detail extensive</b> |
| <b>Rt</b>                   | Number of active routes (prefixes) installed in the routing table. For ingress RSVP sessions, the routing table is the primary IPv4 table ( <b>inet.0</b> ). For transit and egress RSVP sessions, the routing table is the primary MPLS table ( <b>mpls.0</b> ).                     | <b>brief</b>            |
| <b>P</b>                    | Path. An asterisk (*) underneath this column indicates that the LSP is a primary path.                                                                                                                                                                                                | <b>brief</b>            |
| <b>ActivePath</b>           | (Ingress LSP) Name of the active path: <b>Primary</b> or <b>Secondary</b> .                                                                                                                                                                                                           | <b>detail extensive</b> |
| <b>LSPname</b>              | Name of the LSP.                                                                                                                                                                                                                                                                      | <b>brief detail</b>     |
| <b>Statistics</b>           | Displays the number of packets and the number of bytes transmitted over the LSP. These counters are reset to zero whenever the LSP path is optimized (for example, during an automatic bandwidth allocation).                                                                         | <b>extensive</b>        |
| <b>Aggregate statistics</b> | Displays the number of packets and the number of bytes transmitted over the LSP. These counters continue to iterate even if the LSP path is optimized. You can reset these counters to zero using the <b>clear mpls lsp statistics</b> command.                                       | <b>extensive</b>        |
| <b>Packets</b>              | Displays the number of packets transmitted over the LSP.                                                                                                                                                                                                                              | <b>brief extensive</b>  |
| <b>Bytes</b>                | Displays the number of bytes transmitted over the LSP.                                                                                                                                                                                                                                | <b>brief extensive</b>  |
| <b>DiffServInfo</b>         | Type of LSP: multiclass LSP ( <b>multiclass diffServ-TE LSP</b> ) or Differentiated-Services-aware traffic engineering LSP ( <b>diffServ-TE LSP</b> ).                                                                                                                                | <b>detail</b>           |

Table 405: show mpls lsp Output Fields (*continued*)

| Field Name                          | Field Description                                                                                                                                                                                                                                                                                                             | Level of Output         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>LSPtype</b>                      | Type of LSP: <ul style="list-style-type: none"> <li>• <b>Static configured</b>—Static</li> <li>• <b>Dynamic configured</b>—Dynamic</li> <li>• <b>Externally controlled</b>—External path computing entity</li> </ul> Also indicates if the LSP is a <b>Penultimate hop popping</b> LSP or an <b>Ultimate hop popping</b> LSP. | <b>detail extensive</b> |
| <b>Bypass</b>                       | (Bypass LSP) Destination address (egress routing device) for the bypass LSP.                                                                                                                                                                                                                                                  | All levels              |
| <b>LSPpath</b>                      | Indicates whether the RSVP session is for the primary or secondary LSP path. <b>LSPpath</b> can be either <b>primary</b> or <b>secondary</b> and can be displayed on the ingress, egress, and transit routing devices.                                                                                                        | <b>detail</b>           |
| <b>Bidir</b>                        | (GMPLS) The LSP allows data to travel in both directions between GMPLS devices.                                                                                                                                                                                                                                               | All levels              |
| <b>Bidirectional</b>                | (GMPLS) The LSP allows data to travel both ways between GMPLS devices.                                                                                                                                                                                                                                                        | All levels              |
| <b>FastReroute desired</b>          | Fast reroute has been requested by the ingress routing device.                                                                                                                                                                                                                                                                | <b>detail</b>           |
| <b>Link protection desired</b>      | <b>detail</b>                                                                                                                                                                                                                                                                                                                 |                         |
| <b>Node/Link protection desired</b> | Link protection has been requested by the ingress routing device.                                                                                                                                                                                                                                                             | <b>detail</b>           |
| <b>LoadBalance</b>                  | (Ingress LSP) CSPF load-balancing rule that was configured to select the LSP's path among equal-cost paths: <b>Most-fill</b> , <b>Least-fill</b> , or <b>Random</b> .                                                                                                                                                         | <b>detail extensive</b> |
| <b>Signal type</b>                  | Signal type for GMPLS LSPs. The signal type determines the peak data rate for the LSP: <b>DS0</b> , <b>DS3</b> , <b>STS-1</b> , <b>STM-1</b> , or <b>STM-4</b> .                                                                                                                                                              | All levels              |
| <b>Encoding type</b>                | LSP encoding type: <b>Packet</b> , <b>Ethernet</b> , <b>PDH</b> , <b>SDH/SONET</b> , <b>Lambda</b> , or <b>Fiber</b> .                                                                                                                                                                                                        | All levels              |
| <b>Switching type</b>               | Type of switching on the links needed for the LSP: <b>Fiber</b> , <b>Lambda</b> , <b>Packet</b> , <b>TDM</b> , or <b>PSC-1</b> .                                                                                                                                                                                              | All levels              |
| <b>GPID</b>                         | Generalized Payload Identifier (identifier of the payload carried by an LSP): <b>HDLC</b> , <b>Ethernet</b> , <b>IPv4</b> , <b>PPP</b> , or <b>Unknown</b> .                                                                                                                                                                  | All levels              |
| <b>Protection</b>                   | Configured protection capability desired for the LSP: <b>Extra</b> , <b>Enhanced</b> , <b>none</b> , <b>One plus one</b> , <b>One to one</b> , or <b>Shared</b> .                                                                                                                                                             | All levels              |
| <b>Upstream label in</b>            | (Bidirectional LSPs) Incoming label for reverse direction traffic for this LSP.                                                                                                                                                                                                                                               | All levels              |
| <b>Upstream label out</b>           | (Bidirectional LSPs) Outgoing label for reverse direction traffic for this LSP.                                                                                                                                                                                                                                               | All levels              |

Table 405: show mpls lsp Output Fields (*continued*)

| Field Name                                          | Field Description                                                                                                                                                                       | Level of Output  |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>Suggested label received</b>                     | (Bidirectional LSPs) Label the upstream node suggests to use in the Resv message that is sent.                                                                                          | All levels       |
| <b>Suggested label sent</b>                         | (Bidirectional LSPs) Label the downstream node suggests to use in the Resv message that is returned.                                                                                    | All levels       |
| <b>Autobandwidth</b>                                | (Ingress LSP) The LSP is performing autobandwidth allocation.                                                                                                                           | detail extensive |
| <b>MinBW</b>                                        | (Ingress LSP) Configured minimum value of the LSP, in bps.                                                                                                                              | detail extensive |
| <b>MaxBW</b>                                        | (Ingress LSP) Configured maximum value of the LSP, in bps.                                                                                                                              | detail extensive |
| <b>AdjustTimer</b>                                  | (Ingress LSP) Configured value of the bandwidth adjustment timer, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.                  | detail extensive |
| <b>Adjustment Threshold</b>                         | (Ingress LSP) Configured value for the <b>adjust-threshold</b> statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization. | detail extensive |
| <b>Time for Next Adjustment</b>                     | (Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.                                                                                            | detail extensive |
| <b>Time of Last Adjustment</b>                      | (Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.                                                                                                | detail extensive |
| <b>MaxAvgBW util</b>                                | (Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps.                                                                                                | detail extensive |
| <b>Overflow limit</b>                               | (Ingress LSP) Configured value of the threshold overflow limit.                                                                                                                         | detail extensive |
| <b>Overflow sample count</b>                        | (Ingress LSP) Current value for the overflow sample count.                                                                                                                              | detail extensive |
| <b>Bandwidth Adjustment in <i>nnn</i> second(s)</b> | (Ingress LSP) Current value of the bandwidth adjustment timer, indicating the amount of time remaining until the bandwidth adjustment will take place, in seconds.                      | detail extensive |
| <b>Underflow limit</b>                              | (Ingress LSP) Configured value of the threshold underflow limit.                                                                                                                        | detail extensive |
| <b>Underflow sample count</b>                       | (Ingress LSP) Current value for the underflow sample count.                                                                                                                             | detail extensive |
| <b>Underflow Max AvgBW</b>                          | (Ingress LSP) The highest sample bandwidth among the underflow samples recorded currently. This is the signaling bandwidth if an adjustment occurs because of an underflow.             | detail extensive |

Table 405: show mpls lsp Output Fields (*continued*)

| Field Name                                              | Field Description                                                                                                                                                                                                                                                                                                                           | Level of Output  |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>Active path indicator</b>                            | (Ingress LSP) A value of * indicates that the path is active. The absence of * indicates that the path is not active. In the following example, "long" is the active path.<br><br>*Primary long<br>Standby short                                                                                                                            | detail extensive |
| <b>Primary</b>                                          | (Ingress LSP) Name of the primary path.                                                                                                                                                                                                                                                                                                     | detail extensive |
| <b>Secondary</b>                                        | (Ingress LSP) Name of the secondary path.                                                                                                                                                                                                                                                                                                   | detail extensive |
| <b>Standby</b>                                          | (Ingress LSP) Name of the path in standby mode.                                                                                                                                                                                                                                                                                             | detail extensive |
| <b>State</b>                                            | (Ingress LSP) State of the path: <b>Up</b> or <b>Dn</b> (down).                                                                                                                                                                                                                                                                             | detail extensive |
| <b>COS</b>                                              | (Ingress LSP) Class-of-service value.                                                                                                                                                                                                                                                                                                       | detail extensive |
| <b>Bandwidth per class</b>                              | (Ingress LSP) Active bandwidth for the LSP path for each MPLS class type, in bps.                                                                                                                                                                                                                                                           | detail extensive |
| <b>Priorities</b>                                       | (Ingress LSP) Configured value of the setup priority and the hold priority respectively (the setup priority is displayed first), where 0 is the highest priority and 7 is the lowest priority. If you have not explicitly configured these values, the default values are displayed (7 for the setup priority and 0 for the hold priority). | detail extensive |
| <b>OptimizeTimer</b>                                    | (Ingress LSP) Configured value of the optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.                                                                                                                                                                                                   | detail extensive |
| <b>SmartOptimizeTimer</b>                               | (Ingress LSP) Configured value of the smart optimize timer, indicating the total amount of time allowed before path reoptimization, in seconds.                                                                                                                                                                                             | detail extensive |
| <b>Reoptimization in xxx seconds</b>                    | (Ingress LSP) Current value of the optimize timer, indicating the amount of time remaining until the path will be reoptimized, in seconds.                                                                                                                                                                                                  | detail extensive |
| <b>Computed ERO (S [L] denotes strict [loose] hops)</b> | (Ingress LSP) Computed explicit route. A series of hops, each with an address followed by a hop indicator. The value of the hop indicator can be strict (S) or loose (L).                                                                                                                                                                   | detail extensive |
| <b>CSPF metric</b>                                      | (Ingress LSP) Constrained Shortest Path First metric for this path.                                                                                                                                                                                                                                                                         | detail extensive |

Table 405: show mpls lsp Output Fields (*continued*)

| Field Name          | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Level of Output               |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>Received RRO</b> | <p>(Ingress LSP) Received record route. A series of hops, each with an address followed by a flag. (In most cases, the received record route is the same as the computed explicit route. If <b>Received RRO</b> is different from <b>Computed ERO</b>, there is a topology change in the network, and the route is taking a detour.) The following flags identify the protection capability and status of the downstream node:</p> <ul style="list-style-type: none"> <li>• <b>0x01</b>—Local protection available. The link downstream from this node is protected by a local repair mechanism. This flag can be set only if the Local protection flag was set in the <b>SESSION_ATTRIBUTE</b> object of the corresponding Path message.</li> <li>• <b>0x02</b>—Local protection in use. A local repair mechanism is in use to maintain this tunnel (usually because of an outage of the link it was routed over previously).</li> <li>• <b>0x03</b>—Combination of <b>0x01</b> and <b>0x02</b>.</li> <li>• <b>0x04</b>—Bandwidth protection. The downstream routing device has a backup path providing the same bandwidth guarantee as the protected LSP for the protected section.</li> <li>• <b>0x08</b>—Node protection. The downstream routing device has a backup path providing protection against link and node failure on the corresponding path section. If the downstream routing device can set up only a link-protection backup path, the <b>Local protection available</b> bit is set but the <b>Node protection</b> bit is cleared.</li> <li>• <b>0x09</b>—Detour is established. Combination of <b>0x01</b> and <b>0x08</b>.</li> <li>• <b>0x10</b>—Preemption pending. The preempting node sets this flag if a pending preemption is in progress for the traffic engine LSP. This flag indicates to the ingress legacy edge router (LER) of this LSP that it should be rerouted.</li> <li>• <b>0x20</b>—Node ID. Indicates that the address specified in the RRO's IPv4 or IPv6 sub-object is a node ID address, which refers to the router address or router ID. Nodes must use the same address consistently.</li> <li>• <b>0xb</b>—Detour is in use. Combination of <b>0x01</b>, <b>0x02</b>, and <b>0x08</b>.</li> </ul> | <b>detail extensive</b>       |
| <b>Index number</b> | (Ingress LSP) Log entry number of each LSP path event. The numbers are in chronological descending order, with a maximum of 50 index numbers displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <b>extensive</b>              |

| <b>Time left</b>               | Number of seconds remaining in the lifetime of the reservation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>detail</b>       |
| <b>Since</b>                   | Date and time when the RSVP session was initiated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>       |
| <b>Tspec</b>                   | Sender's traffic specification, which describes the sender's traffic parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <b>detail</b>       |
| <b>Port number</b>             | Protocol ID and sender or receiver port used in this RSVP session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>       |
| <b>PATH rcvfrom</b>            | Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this router, and number of packets received from the upstream neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>detail</b>       |
| <b>PATH sentto</b>             | Address of the next-hop (downstream) routing device or client, interface used to reach this neighbor, and number of packets sent to the downstream routing device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <b>detail</b>       |
| <b>RESV rcvfrom</b>            | Address of the previous-hop (upstream) routing device or client, interface the neighbor used to reach this routing device, and number of packets received from the upstream neighbor. The output in this field, which is consistent with that in the <b>PATH rcvfrom</b> field, indicates that the RSVP negotiation is complete.                                                                                                                                                                                                                                                                                                                                                                                                        | <b>detail</b>       |
| <b>Record route</b>            | Recorded route for the session, taken from the record route object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <b>detail</b>       |
| <b>Soft preempt</b>            | Number of soft preemptions that occurred on a path and when the last soft preemption occurred. Only successful soft preemptions are counted (those that actually resulted in a new path being used).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <b>detail</b>       |
| <b>Soft preemption pending</b> | Path is in the process of being soft preempted. This display is removed once the ingress router has calculated a new path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <b>detail</b>       |
| <b>MPLS-TE LSP Defaults</b>    | Default settings for MPLS traffic engineered LSPs: <ul style="list-style-type: none"> <li>• <b>LSP Holding Priority</b>—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully.</li> <li>• <b>LSP Setup Priority</b>—Determines whether a new LSP that preempts an existing LSP can be established.</li> <li>• <b>Hop Limit</b>—Specifies the maximum number of routers the LSP can traverse (including the ingress and egress).</li> <li>• <b>Bandwidth</b>—Specifies the bandwidth in bits per second for the LSP.</li> <li>• <b>LSP Retry Timer</b>—Length of time in seconds that the ingress router waits between attempts to establish the primary path.</li> </ul> | <b>defaults</b>     |

The XML tag name of the **bandwidth** tag under the **auto-bandwidth** tag has been updated to **maximum-average-bandwidth**. You can see the new tag when you issue the **show mpls lsp extensive** command with the **| display xml** pipe option. If you have any scripts that use the **bandwidth** tag, ensure that they are updated to **maximum-average-bandwidth**.

## Sample Output

### show mpls lsp defaults

```
user@host> show mpls lsp defaults
MPLS-TE LSP Defaults
 LSP Holding Priority 0
 LSP Setup Priority 7
 Hop Limit 255
 Bandwidth 0
 LSP Retry Timer 30 seconds
```

### show mpls lsp descriptions

```
user@host> show mpls lsp descriptions

| <b>Output Fields</b>            | Table 406 describes the output fields for the <b>show mpls lsp autobandwidth</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                         |

Table 406: show mpls lsp autobandwidth Output Fields

| Field Name                   | Field Description                                                                        | Level of Output         |
|------------------------------|------------------------------------------------------------------------------------------|-------------------------|
| <b>To</b>                    | Destination (egress routing device) of the session.                                      | All Levels              |
| <b>From</b>                  | Source (ingress routing device) of the session.                                          | All Levels              |
| <b>LSPname</b>               | Name of the LSP.                                                                         | All Levels              |
| <b>Min BW</b>                | (Ingress LSP) Configured minimum value of the LSP, in bps.                               | <b>detail extensive</b> |
| <b>Max BW</b>                | (Ingress LSP) Configured maximum value of the LSP, in bps.                               | <b>detail extensive</b> |
| <b>Max AvgBW util</b>        | (Ingress LSP) Current value of the actual maximum average bandwidth utilization, in bps. | <b>detail extensive</b> |
| <b>Overflow limit</b>        | (Ingress LSP) Configured value of the threshold overflow limit.                          | <b>detail extensive</b> |
| <b>Overflow sample count</b> | (Ingress LSP) Current value for the overflow sample count.                               | <b>detail extensive</b> |
| <b>Underflow limit</b>       | (Ingress LSP) Configured value of the threshold underflow limit.                         | <b>detail extensive</b> |

Table 406: show mpls lsp autobandwidth Output Fields (*continued*)

| Field Name                      | Field Description                                                                                                                                                                | Level of Output         |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <b>Underflow sample count</b>   | (Ingress LSP) Current value for the underflow sample count.                                                                                                                      | <b>detail extensive</b> |
| <b>Adjustment Timer</b>         | (Ingress LSP) Configured value for the adjust-timer statement, indicating the total amount of time allowed before bandwidth adjustment will take place, in seconds.              | <b>detail extensive</b> |
| <b>Adjustment Threshold</b>     | (Ingress LSP) Configured value for the adjust-threshold statement. Specifies how sensitive the automatic bandwidth adjustment for an LSP is to changes in bandwidth utilization. | <b>detail extensive</b> |
| <b>Time for Next Adjustment</b> | (Ingress LSP) Time in seconds until the next automatic bandwidth adjustment sample is taken.                                                                                     | <b>detail extensive</b> |
| <b>Time of Last Adjustment</b>  | (Ingress LSP) Date and time since the last automatic bandwidth adjustment was completed.                                                                                         | <b>detail extensive</b> |
| <b>Last BW</b>                  | Previous active bandwidth of the LSP.                                                                                                                                            | <b>detail extensive</b> |
| <b>Last Requested BW</b>        | Bandwidth requested in the previous automatic bandwidth adjustment.                                                                                                              | <b>detail extensive</b> |
| <b>Last Signaled BW</b>         | Bandwidth signaled in the previous automatic bandwidth adjustment.                                                                                                               | <b>detail extensive</b> |
| <b>Highest Watermark BW</b>     | Maximum bandwidth used by the LSP.                                                                                                                                               | <b>detail extensive</b> |
| <b>Total AutoBw Adjustments</b> | Total number of attempts to adjust automatic bandwidth including failed and successful adjustments.                                                                              | <b>detail extensive</b> |
| <b>Successful Adjustments</b>   | Number of successful automatic bandwidth adjustments.                                                                                                                            | <b>detail extensive</b> |
